A Theory of Spherical Diagrams

Giovanni Viglietta*

Abstract

We introduce the axiomatic theory of Spherical Occlusion Diagrams as a tool to study certain combinatorial properties of polyhedra in $\mathbb{R}^3$, which are of central interest in the context Art Gallery problems for polyhedra and other visibility-related problems in discrete and computational geometry.

1 Introduction

Geometric intuition. Consider a set of polygons $\mathcal{P}$ in $\mathbb{R}^3$ and a point $p \in \mathbb{R}^3$ such that no vertex of any polygon in $\mathcal{P}$ is visible to $p$. Such is, for example, the set of six rectangles in Figure 1 (left) with respect to the point $p$ located at the center of the arrangement.

Let $S$ be a sphere centered at $p$ that does not intersect any of the polygons in $\mathcal{P}$, and let $S_\mathcal{P}$ be the set of projections onto $S$ of the portions of edges of polygons in $\mathcal{P}$ that are visible to $p$ (i.e., where polygons occlude projection rays). We call $S_\mathcal{P}$ a Spherical Occlusion Diagram. Figure 1 (right) shows an example of such a projection.

In this work we set out to study the combinatorial structure of Spherical Occlusion Diagrams.

Applications. Spherical Occlusion Diagrams naturally arise in visibility-related problems for arrangements of polygons in $\mathbb{R}^3$, and especially for polyhedra.

An example is found in Figure 1, where an upper bound is given on the number of edge guards that solve the Art Gallery problem in a general polyhedron. That is, given an arrangement of $\mathcal{P}$, the problem is to find a (small) set of edges that collectively see the whole interior of $\mathcal{P}$ (an edge $e$ sees a point $p$ if and only if there is a point $x \in e$ such that the line segment $xp$ does not properly cross the boundary of $\mathcal{P}$).

The idea of Figure 1 is to preliminarily select a (small) set of edges $E$ that cover all vertices of $\mathcal{P}$. Note that $E$ may be insufficient to guard the interior of $\mathcal{P}$, as some of its points may be invisible to all vertices (cf. Figure 1 (center)). Thus, an additional (small) set of edges $E'$ is selected, which collectively see all internal points of $\mathcal{P}$ that do not see any vertices. Clearly, $E \cup E'$ is a set of edges that see all the internal points of $\mathcal{P}$.

The selection of the edges $E'$ is carried out in Figure 1 by means of an ad-hoc analysis of some properties of points that do not see any vertices of $\mathcal{P}$. Spherical Occlusion Diagrams offer a systematic and general tool to reason about points in a polyhedron that do not see any vertices.

Spherical Occlusion Diagrams have also been employed successfully to prove that a point that does not see any vertex of a polyhedron must see at least 8 of its edges, and that the bound is tight (this result will appear in an upcoming paper by the author, C. D. Tóth, and J. Urrutia).

2 Axiomatic Theory

Toward an axiomatization. The construction outlined in Section 1 produces a sphere $S$ with some arcs on it, collectively denoted as $S_\mathcal{P}$. For each arc $a \in S_\mathcal{P}$, let $e_a$ be the edge of a polygon in $\mathcal{P}$ whose orthographic projection on $S$ (partly occluded by other polygons) is $a$. Since $e_a$ is a line segment, then $a$ must be an arc of great circle. The fact that each vertex of a polygon in $\mathcal{P}$ is occluded by some other polygon translates into the fact that each endpoint of each arc in $S_\mathcal{P}$ must lie in the interior of another arc of $S_\mathcal{P}$. Also, since $e_a$ is an edge of a polygon $P \in \mathcal{P}$, all arcs of $S_\mathcal{P}$ that end the interior of $e_a$ must reach it from the same side (as these correspond to edges of polygons partially obstructed by $P$).

Axioms. In the following, $S$ will be the unit sphere immersed in $\mathbb{R}^3$, and we will abstract from a specific set of polygons $\mathcal{P}$ and a point $p$.

It will be useful to give the following definition.

Definition 1. Let $a$ and $b$ be two non-collinear arcs of great circle on a sphere. If an endpoint $p$ of $a$ lies in the relative interior of $b$, we say that $a$ hits $b$ at $p$ (or feeds into $b$ at $p$) and $b$ blocks $a$ at $p$.

We are now ready to formulate an abstract theory of Spherical Occlusion Diagrams.

Definition 2. A Spherical Occlusion Diagram, or simply Diagram, is a finite non-empty collection $\mathcal{D}$ of arcs of great circle on the unit sphere in $\mathbb{R}^3$, satisfying the following axioms:

A1. If two arcs $a, b \in \mathcal{D}$ have a non-empty intersection, then $a$ hits $b$ or $b$ hits $a$.

A2. Each arc in $\mathcal{D}$ is blocked by an arc in $\mathcal{D}$ at each endpoint.

A3. All arcs in $\mathcal{D}$ that hit the same arc of $\mathcal{D}$ reach it from the same side.
Figure 1: Construction of a Spherical Occlusion Diagram (right) from an arrangement of six rectangles (left) or a polyhedron where the central point sees no vertices (center).

Figure 2: Example of a Diagram with 18 arcs.

Figure 2 shows a Diagram with 18 arcs.

It is easy to prove that the Diagrams constructed in Section 1 indeed provide a model for our theory.

**Proposition 1.** The set $S_P$ constructed in Section 1 (rescaled in such a way that $S$ is the unit sphere) satisfies the axioms of Spherical Occlusion Diagrams, provided that $p$ is in general position with respect to $P$, i.e., no ray emanating from $p$ intersects more than two edges of polygons in $P$.

Whether the converse of Proposition 1 is true is a fundamental problem that is left open.

**Conjecture 2.** For every Spherical Occlusion Diagram $D$ as in Definition 2, there exists a set of polygons $P$ and a sphere $S$ such that $D = S_P$.

It can be proved that Conjecture 2 is equivalent to its stronger version where $P$ is a polyhedron of genus zero. Indeed, a set of polygons $P$ that gives rise to a Diagram $D$ with respect to a point $p$ can easily be extended by a mesh of additional polygons whose edges are either shared with $P$ or concealed from $p$ by polygons in $P$. The resulting polyhedron gives rise to the same Diagram $D$.

3 Elementary Properties

We will prove some basic properties of Diagrams.

**Proposition 3.** Every arc in a Diagram is strictly shorter than a great semicircle.

**Proof.** Referring to Figure 3, assume that an arc $a$ (in red) is at least as long as a great semicircle. Then, taking an endpoint $p$ of $a$ as the North pole and $a$ itself as the prime meridian, consider an arc $b_0$ that blocks $a$ at $p$ (which exists by Axiom 2). $b_0$ has exactly one endpoint in the Eastern hemisphere; let $b_1$ be an arc that blocks $b_0$ at this endpoint. We can construct a sequence $(b_0, b_1, b_2, \ldots)$ of arcs, each of which hits the next at a point of smaller (or equal) latitude, until one of them hits $a$ from the East. Symmetrically, we can construct a similar sequence of arcs starting from the endpoint of $b_0$ that lies in the Western hemisphere. The last arc of this sequence hits $a$ from the West, contradicting Axiom 3.

Next can now prove a stronger form of Axiom 2:

**Proposition 4.** Every arc in a Diagram hits exactly two distinct arcs: one at each endpoint.
Proof. Assume for a contradiction that an endpoint \( p \) of an arc \( a \) lies in the interior of two arcs \( b \) and \( c \). Then \( b \) and \( c \) intersect at \( p \). By Axiom 1, without loss of generality, \( b \) hits \( c \) at \( p \), and therefore \( b \) and \( a \) share an endpoint, which contradicts Axiom 1. Thus, \( a \) hits at most one arc at each endpoint; by Axiom 2, it hits exactly one. Moreover, \( a \) cannot hit the same arc \( b \) at both endpoints \( p \) and \( p' \); or else \( p \) and \( p' \) would be antipodal points, and \( b \) would be longer than a great semicircle, contradicting Proposition 3. Thus, \( a \) hits exactly two distinct arcs.

**Proposition 5.** No two arcs in a Diagram feed into each other.

Proof. Two arcs feeding into each other must be longer than a great semicircle, as Figure 4 shows. This contradicts Proposition 3.

**Corollary 7.** In a Diagram, no tile contains two antipodal points in its topological closure. Moreover, the relative interior of any great semicircle on the unit sphere intersects some arc of the Diagram.

**Proposition 8.** Every Diagram is connected.

Proof. Let a Diagram \( D \) have two connected components \( D_1 \) and \( D_2 \). Note that \( D_1 \) and \( D_2 \) individually satisfy all axioms, and therefore both are Diagrams. Hence, \( D_2 \) is contained in a tile \( F \) determined by \( D_1 \), as shown in Figure 6. Take two points \( p \) and \( q \) close to the boundary of \( F \) such that the arc of great circle connecting \( p \) and \( q \) (in orange) intersects \( D_2 \). Observe that there exists a chain of arcs of great circle (in green) that connects \( p \) and \( q \) without intersecting \( D_1 \) nor \( D_2 \). Hence \( p \) and \( q \) are in the same tile determined by \( D \). However, since the arc \( pq \) intersects \( D \), the tile cannot be convex, contradicting Proposition 6.
Proposition 9. A Diagram with \( n \) arcs partitions the unit sphere into \( n + 2 \) tiles.

Proof. Every endpoint of an arc of a Diagram divides the arc it hits into two sub-arcs. The set of these sub-arcs induces a spherical drawing of a planar graph with \( 2n \) vertices and \( 3n \) edges. Each face of this drawing coincides with a tile of the Diagram. By Euler’s formula, the number of faces is \( f = 3n - 2n + 2 = n + 2 \).

4 Swirls

In this section we study an important pattern frequently occurring in Diagrams.

Definition 4. A swirl in a Diagram is a cycle of arcs, each of which feeds into the next going clockwise or counterclockwise. The spherically convex region enclosed by a swirl is called the swirl’s eye.

Figure 2 shows a Diagram with six clockwise swirls and six counterclockwise swirls. Note that the eye of a swirl does not necessarily coincide with a single tile: in general, it is a union of tiles, as it may have internal arcs.

Definition 5. The swirl graph of a Diagram \( D \) is the undirected multigraph on the set of swirls of \( D \) having an edge between two swirls for every arc in \( D \) shared by the two swirls.

Figure 7: A Diagram and its swirl graph

In Figure 4 the eyes of clockwise swirls are colored green; the eyes of counterclockwise swirls are colored red. Note that the swirl graph is simple and bipartite; this is true in general:

Theorem 10. The swirl graph of any Diagram is a simple planar bipartite graph with non-empty partite sets.

Proof. The swirl graph is spherical, hence planar. It is bipartite, where the partite sets correspond to clockwise and counterclockwise swirls, respectively. Indeed, if the same arc is shared by two concordant swirls (say, clockwise), then it is hit by arcs on both sides, violating Axiom 3.

Figure 8 shows how to find a clockwise swirl in any Diagram: start from any arc, and follow it in any direction until it hits another arc. Turn clockwise and follow this arc until it hits another arc, and so on. The sequence of arcs encountered is eventually periodic, and the period identifies a clockwise swirl. A counterclockwise swirl is found in a similar way.

To prove that the swirl graph is simple, assume for a contradiction that the swirl \( S_1 \) shares two arcs \( a \) and \( b \) with the same swirl \( S_2 \). Then, the eye of \( S_2 \) must be entirely contained in the spherical lune determined by \( a \) and \( b \), as shown in Figure 9. Since the eye of \( S_2 \) is bounded by \( a \), it must lie in the region \( A \). However, the eye of \( S_2 \) is also bounded by \( b \), and thus it must lie in the region \( B \). This is a contradiction, since \( A \) and \( B \) are disjoint.

Lemma 11. In any Diagram, every hemisphere entirely contains the eye of at least one swirl.

Proof. Let \( D \) be a Diagram, and let \( H \) be a hemisphere. By Corollary 7 there is an arc \( a_0 \in D \) with an endpoint
Figure 10: Proof of Lemma 11

$p_0$ in $H$, as shown in Figure 10. Turn clockwise at $p_0$ and follow the Diagram as in the proof of Theorem 10. If the walk remains in $H$, it eventually traces out the eye of a clockwise swirl fully contained in $H$.

Otherwise, the walk encounters an arc $a_i \in D$ whose clockwise endpoint $p_i$ is outside of $H$. By Proposition 3, the other endpoint $p'_i$ of $a_i$ must be in $H$. In this case, the walk reaches $p'_i$ instead of $p_i$. Continuing in this fashion, always turning clockwise at each new arc unless it leads outside of $H$, the walk either traces out the eye of a clockwise swirl in $H$, or it encloses a region $A \subseteq H$. In the latter case, any walk that starts from the boundary of $A$ and follows the Diagram counterclockwise eventually traces out the eye of a counterclockwise swirl within $A$.

Note that there are cases where a hemisphere contains the eye of exactly one swirl of a Diagram, as shown in Figure 11.

Figure 11: A hemisphere may contain the eye of only one swirl

**Theorem 12.** Every Diagram has at least four swirls.

**Proof.** By Theorem 10 there are at least a clockwise swirl $S_1$ and a counterclockwise swirl $S_2$. Consider a great circle $C$ that intersects the interiors of the eyes of both $S_1$ and $S_2$. $C$ determines two hemispheres $H_1$ and $H_2$, none of which entirely contains the eye of $S_1$ or $S_2$. Hence, by Lemma 11 there must be a third swirl $S_3$ whose eye is entirely contained in $H_1$, and a fourth swirl $S_4$ whose eye is entirely contained in $H_2$.

From Theorem 12 it follows that every Diagram has at least eight arcs (this result will appear in an upcoming paper). On the other hand, Figure 12 shows an example of a Diagram with exactly eight arcs and exactly four swirls.

Figure 12: A Diagram with eight arcs and four swirls

It is unclear if there exist Diagrams with a single clockwise swirl.

**Conjecture 13.** Every Diagram has at least two clockwise and two counterclockwise swirls.

### 5 Swirling Diagrams

This section is devoted to a special type of Diagram whose arcs always meet forming swirls. Similar patterns are found in modular origami, globe knots, rattan balls, etc.

**Definition 6.** A Diagram is swirling if every arc is part of two swirls.

An example of a swirling Diagram is found in Figure 2; further examples are in Figure 13. All of these Diagrams were obtained from convex polyhedra or, equivalently, from convex tilings of the sphere, by a process that we call swirlification.

**Definition 7.** A subdivision of the unit sphere into strictly convex spherical polygons is swirlable if each polygon of the subdivision has an even number of edges.

**Proposition 14.** A subdivision of the unit sphere into strictly convex spherical polygons is swirlable if and only if its 1-skeleton is bipartite.
Proof. The 1-skeleton is bipartite if and only if its has no odd cycles, which is true if and only if each face has an even number of edges.

Hence, we can always deform the 1-skeleton of a swirvable tiling, turning each of its vertices into a swirl, going clockwise or counterclockwise according to the bipartition of the 1-skeleton. Conversely, by “shrinking” the eye of each swirl of a swirling Diagram into a point, one obtains a swirvable subdivision of the sphere.

In other words, the swirlification operation establishes a natural correspondence between swirling Diagrams and swirvable subdivisions of the sphere.

Theorem 15. Every swirling Diagram is the swirlification of a swirvable subdivision of the sphere.

Note that we can also obtain a swirvable subdivision of the sphere by taking the dual of a subdivision whose vertices have even degree, or by truncating it. More generally, we have the following:

Proposition 16. A subdivision of the sphere is swirvable if and only if its truncated dual is swirvable.
6 Uniform Diagrams

We now turn to a class of Diagrams that generalizes the swirling ones.

Definition 8. A Diagram is uniform if every arc blocks exactly two arcs.

Proposition 17. A Diagram is uniform if and only if every arc blocks at most (respectively, at least) two arcs.

Proof. By Proposition 4, each arc hits exactly two distinct arcs. Hence, each arc blocks two arcs on average. Thus, if every arc blocks at most two arcs (or at least two arcs), it must block exactly two arcs.

Proposition 18. In a uniform Diagram, the eye of each swirl coincides with a single tile.

Proof. Let \( D \) be a uniform Diagram, and assume that the interior of the eye of a swirl of \( D \) contains some arcs. These arcs can be removed from \( D \), resulting in a set of arcs \( D' \subset D \) that still satisfies all Diagram axioms, and therefore is itself a Diagram. By Proposition 8, \( D \) is connected; thus, a removal of arcs from \( D \) causes some arcs to block fewer than two arcs. Since \( D \) is uniform, it follows that the arcs of \( D' \) block fewer than two arcs on average, contradicting Proposition 4.

Theorem 19. Every swirling Diagram is uniform.

Proof. In a swirling Diagram, each arc \( a \) is part of two distinct swirls. By Theorem 10, these two swirls share no arcs other than \( a \), and hence \( a \) must block one arc from each of them. Therefore, every arc in a swirling Diagram blocks at least two arcs, and by Proposition 17, the Diagram is uniform.

The converse of Theorem 19 is not true, as Figure 14 shows.

Figure 14: A uniform Diagram that is not swirling

Definition 9. An endpoint of an arc of a Diagram is called a non-swirling vertex if it is not incident to the eye of any swirl. A walk on a Diagram is non-swirling if it only touches non-swirling vertices and, whenever it touches an arc, it follows it until it reaches one of its endpoints, without touching any other arc along the way. A cyclic non-swirling walk is called a non-swirling cycle.

Observe that there is a non-swirling cycle that covers all the non-swirling vertices of the Diagram in Figure 14 (drawn in red). This is not a coincidence:

Theorem 20. In any uniform Diagram, all non-swirling vertices are covered by disjoint non-swirling cycles.

Proof. Consider a non-swirling walk \( W \) on a uniform Diagram terminating at a non-swirling vertex \( p_i \), endpoint of an arc \( a_i \), as Figure 15 illustrates. We will prove that \( W \) can be extended to a longer non-swirling walk in a unique way.

Let \( a_{i+1} \) be the arc that blocks \( a_i \) at \( p_i \). Since exactly two arcs feed into \( a_{i+1} \), there is exactly one endpoint of \( a_{i+1} \), say \( p_{i+1} \), that can be reached from \( p_i \) without touching any arc other than \( a_{i+1} \).

By definition of non-swirling walk, \( p_{i+1} \) can be used to extend \( W \) if and only if it is a non-swirling vertex. However, if \( p_{i+1} \) were incident to a swirl’s eye \( E \), then an arc of that swirl would either hit \( a_{i+1} \) between \( p_i \) and \( p_{i+1} \), contradicting the fact that \( a_{i+1} \) blocks exactly two arcs, or it would hit \( a_{i+1} \) on the other side of \( p_i \), implying that \( E \) contains the arc \( a_i \) in its interior, which contradicts Proposition 18.

Hence, \( W \) can be extended uniquely to a non-swirling walk. By a similar reasoning, we argue that \( W \) can also be uniquely extended backwards to a non-swirling walk. Thus, \( W \) is part of a unique non-swirling cycle. Now we conclude the proof by inductively repeating the same argument with any remaining non-swirling vertices.

We can construct uniform Diagrams with any number
of unboundedly long non-swirling cycles. Figure 16 shows an example with two non-swirling cycles.

![Figure 16: A uniform Diagram with two non-swirling cycles](image)

We observe that it is possible to systematically transform any uniform Diagram into a swirling Diagram by "sliding" arcs' endpoints along other arcs and "merging" coincident arcs. Figure 17 shows an example of how the Diagram in Figure 16 can be transformed into a swirling one.

In general, we may wonder what classes of Diagrams can be transformed into swirling ones by repeating these elementary operations on arcs. We know that not all Diagrams can be transformed in this way. For example, Figure 12 shows the unique configuration of any Diagram with eight or fewer arcs; since the Diagram itself is not swirling, it cannot be transformed into a swirling one by means of operations that only rearrange or merge arcs.

Identifying the class of Diagrams that can be reduced to swirling Diagrams by sequences of "elementary operations" (and defining suitable "elementary operations") is left as an open problem.

**Acknowledgments.** The author wishes to thank C. D. Tóth and J. Urrutia for fruitful discussions.
