

# Maximal monotone operators with non-maximal graphical limit

Gerd Wachsmuth\*

October 22, 2021

We present a counterexample showing that the graphical limit of maximally monotone operators might not be maximally monotone. We also characterize the directional differentiability of the resolvent of an operator  $B$  in terms of existence and maximal monotonicity of the proto-derivative of  $B$ .

**Keywords:** Maximal monotone operator, graphical limit, proto-derivative, directional differentiability

**MSC (2020):** [49J53](#), [49J52](#), [49K40](#), [47H04](#)

## 1 Introduction

By means of a counterexample we show that the (non-empty) graphical limit of maximally monotone operators may fail to be maximally monotone. This was raised as an open question in [Adly, Rockafellar, 2020](#), Remark 6. We also shed some light on the relation of proto-differentiability of an operator and directional differentiability of its resolvent. Throughout this work, we use standard notation, see, e.g., [Adly, Rockafellar, 2020](#).

## 2 Graphical limits of maximally monotone operators

For all  $n \in \mathbb{N}$ , we define the auxiliary function  $f_n: [0, \infty) \rightarrow \mathbb{R}$  via

$$f_n(t) := \begin{cases} 0 & \text{if } t \leq 2^{-n-1} \text{ or } t \geq 2^{-n+2}, \\ 2(t - 2^{-n-1}) & \text{if } 2^{-n-1} \leq t \leq 2^{-n}, \\ 2^{-n} & \text{if } 2^{-n} \leq t \leq 2^{-n+1}, \\ \frac{1}{2}(2^{-n+2} - t) & \text{if } 2^{-n+1} \leq t \leq 2^{-n+2}. \end{cases}$$

Each  $f_n$  is globally Lipschitz continuous with Lipschitz constant 2, see also [Figure 1](#).

Figure 1: Plot of the functions  $f_n$ .

Let  $\ell^2$  be the Hilbert space of square-summable sequences (an analogue construction is possible in every infinite-dimensional Hilbert space). We define  $T: \ell^2 \rightarrow \ell^2$  via

$$T(x) := \sum_{n=1}^{\infty} f_n(\|x\|)e_n,$$

where  $(e_n)_n$  is the canonical orthonormal basis of  $\ell^2$ . This operator is well defined, since for each  $x \in \ell^2$ , the sum contains at most three non-vanishing terms.

**Lemma 1.** The operator  $T$  is globally Lipschitz continuous on  $\ell^2$  with Lipschitz constant at most  $\sqrt{17}/2$ . Moreover, for each  $x \in \ell^2$  with  $\|x\| \leq 1$  we have  $\|T(x)\| \geq \|x\|/2$ .

*Proof.* First of all, it can be checked easily that  $T$  is continuous on  $\ell^2$ . Now, let  $x, y \in \ell^2$  be given and we denote  $(x, y) := \{\lambda x + (1 - \lambda)y \mid \lambda \in (0, 1)\}$ .

We are going to utilize the mean value inequality from [Penot, 2013](#), Theorem 2.7. Since the functions  $f_n$  are directionally differentiable,  $T$  is directionally differentiable on  $(x, y) \setminus \{0\}$  and

$$T'(z; y - x) = \sum_{n=1}^{\infty} f'_n(\|z\|; \langle z, y - x \rangle / \|z\|) e_n \quad \forall z \in (x, y) \setminus \{0\}.$$

This yields the estimate

$$\|T'(z; y - x)\|^2 \leq \|y - x\|^2 \sum_{n=1}^{\infty} |f'_n(\|z\|; \text{sign}\langle z, y - x \rangle)|^2 \quad \forall z \in (x, y) \setminus \{0\}.$$

By construction of  $f_n$ , the sum contains at most two distinct addends from  $\{\frac{1}{2}, 2\}$ . Thus,

$$\|T'(z; y - x)\| \leq \sqrt{2^2 + 1/2^2} \|y - x\| = \sqrt{17}/2 \|y - x\| \quad \forall z \in (x, y) \setminus \{0\}.$$

Now, [Penot, 2013](#), Theorem 2.7 (together with the remark afterwards) yields the estimate  $\|T(y) - T(x)\| \leq \frac{\sqrt{17}}{2}\|y - x\|$  for all  $x, y \in \ell^2$ .

For every  $t \in [0, 1]$ , there exists  $n \in \mathbb{N}$  such that  $f_n(t) \geq t/2$ , cf. [Figure 1](#). This implies the second claim.

Combining [Lemma 1](#) with [Bauschke, Combettes, 2011](#), Example 20.26, we find that  $\text{Id} + \alpha T$  is maximally monotone for all  $\alpha \in \mathbb{R}$  with  $|\alpha| \leq 2/\sqrt{17}$ . For an arbitrary  $\alpha$  in this range, we set  $B := \text{Id} + \alpha T$ . For all  $m \in \mathbb{N}$ , we define the operator  $B_m: \ell^2 \rightarrow \ell^2$  via

$$B_m(x) := mB(x/m) = x + \alpha mT(x/m).$$

It is easy to check that all the operators  $B_m$  are again maximally monotone. However, their graphical limit fails to be maximally monotone in an extreme way.

**Theorem 2.** Let the maximally monotone operators  $B_m: \ell^2 \rightarrow \ell^2$  be given as above. Then, the graphical limit of  $B_m$  as  $m \rightarrow \infty$  is the operator  $Z: \ell^2 \rightrightarrows \ell^2$ , defined via  $\text{graph}(Z) = \{(0, 0)\}$ .

*Proof.* We start by the computation of the outer limit of  $\text{graph}(B_m)$ . For  $(x, y) \in \limsup_{m \rightarrow \infty} \text{graph}(B_m)$ , we find a sequence  $((x_{m_k}, y_{m_k}))_k$  with  $(x_{m_k}, y_{m_k}) \in \text{graph}(B_{m_k})$  and  $x_{m_k} \rightarrow x$ ,  $y_{m_k} \rightarrow y$ . In particular, we have

$$y_{m_k} = x_{m_k} + \alpha m_k T(x_{m_k}/m_k).$$

Since  $(x_{m_k})_k$  is bounded, we have  $x_{m_k}/m_k \rightarrow 0$ . Now, the structure of  $T$  implies that

$$[T(x_{m_k}/m_k)]_n = 0 \quad \text{for } k \text{ large enough}$$

for each fixed  $n$ . Since  $y_{m_k} - x_{m_k} = \alpha m_k T(x_{m_k}/m_k)$  converges, the limit can only attain the value 0 and, thus, we have  $x = y$ . Since  $x_{m_k}/m_k \rightarrow 0$ , we know  $\|m_k T(x_{m_k}/m_k)\| \geq \|x_{m_k}\|/2$ . Together with  $y_{m_k} - x_{m_k} = \alpha m_k T(x_{m_k}/m_k) \rightarrow 0$ , this gives  $x_{m_k} \rightarrow 0$ . Thus,  $(x, y) = (0, 0)$  is the only point in  $\limsup_{m \rightarrow \infty} \text{graph}(B_m)$ . Moreover,  $(0, 0) \in \text{graph}(B_m)$  shows that the limit of  $\text{graph}(B_m)$  is  $\{(0, 0)\}$ .

Clearly, the same argument can be used for the operators  $B_\tau: \ell^2 \rightarrow \ell^2$ ,  $\tau \in (0, 1)$ , defined via  $B_\tau(x) = \tau^{-1}B(\tau x)$  and for the limiting process  $\tau \searrow 0$ . Note that  $B_\tau$  is just the finite difference appearing in the definition of the proto-derivative of  $B$  at 0 relative to 0.

**Corollary 3.** The maximal monotone mapping  $B$  is proto-differentiable at 0 and the proto-derivative at 0 relative to  $0 = B(0)$  is given by the non-maximally monotone operator  $Z$  from [Theorem 2](#).

### 3 Directional differentiability of resolvents

Let  $H$  be a (real) Hilbert space. For a maximally monotone  $B: H \rightrightarrows H$ , we denote by  $J_B: H \rightarrow H$  its single-valued resolvent, i.e.,  $J_B := (\text{Id} + B)^{-1}$ . The next result characterizes the directional differentiability of  $J_B$ .

**Theorem 4.** Let  $B: H \rightrightarrows H$  be maximally monotone. For  $y \in H$  set  $x := J_B(y)$ . Then, the following are equivalent.

- (i)  $B$  is proto-differentiable at  $x$  relative to  $y - x \in B(x)$  and the proto-derivative  $D_p B(x | y - x): H \rightrightarrows H$  is maximally monotone,
- (ii)  $J_B$  is directionally differentiable at  $y$ , i.e., the limit  $J'_B(y; h) = \lim_{\tau \searrow 0} \frac{J_B(y + \tau h) - J_B(y)}{\tau}$  exists for all  $h \in H$ .

*Proof.* “ $\Rightarrow$ ” follows from [Adly, Rockafellar, 2020](#), Theorem 1 by setting  $A(t, x) := x$ ,  $B(t, x) := B(x)$ ,  $\xi(t) := y + th$ .

“ $\Leftarrow$ ”: From [Adly, Rockafellar, 2020](#), Remark 5, we get that  $J_B$  is proto-differentiable at  $y$  for  $x = J_B(y)$ . Consequently, [Adly, Rockafellar, 2020](#), Lemma 2 implies that  $B$  is proto-differentiable at  $x$  relative to  $y - x$ . Moreover, we get the formula

$$D_p J_B(y | x) = \{J'(y; \cdot)\} = (\text{Id} + D_p B(x | y - x))^{-1}$$

linking the derivatives of  $B$  and  $J_B$ . This shows that the resolvent of the monotone operator  $D_p B(x | y - x)$  is single-valued. By Minty’s theorem [Bauschke, Combettes, 2011](#), Theorem 21.1, we find that  $D_p B(x | y - x)$  is maximally monotone.

[Theorems 2](#) and [4](#) show that the requirement of the proto-derivative of  $B$  being maximally monotone in [Adly, Rockafellar, 2020](#), Theorem 1 cannot be dropped. The same result can be proved in the  $t$ -dependent case considered in [Adly, Rockafellar, 2020](#).
