(Dated: July 27, 2021)

In [1], we studied the problem for $\sigma^2 = 0$ identical for both the Born and the Born–Infeld electrodynamics. In this paper, we continue to investigate two counter–propagating electromagnetic waves in the vacuum in the Born–Infeld theory in quantum electrodynamics for the case $\sigma^2 \neq 0$ to complete the study. We show that the field equations decouple and the exceptional waves are the only physically relevant solutions, i.e. the exceptional wave solutions propagate with constant speed and the shock waves cannot be created. We discuss the phase shift for the process in our proposed experiment for direct detection of the photon–photon scattering. Finally, we discuss distinguishing the two theories Born–Infeld and the Heisenberg-Euler by precision test experiments based on the effective Lagrangian.

The first attempt to derive Born–Infeld nonlinear electrodynamics was made by Mie [24] based on construction of a purely electromagnetic theory of charged particles in order to obtain a model of classical electron. The theory can be considered as a covariant generalization of Mie’s theory which is in close correspondence to the principle of general covariance introduced by Einstein serving as a fundamental principle of general relativity [5]. Interestingly, the non-linear process of photon–photon scattering is present in the Born–Infeld electrodynamics already at the classical level, such studies were conducted by Schrödinger [6, 7].

The Born–Infeld theory gained a new interest in 1985, when it was found as limiting case of string theory. In [8], it was found that the Born–Infeld Lagrangian is the exact solution of a constant Abelian external vector field problem in the open Bose string theory with the number of spacetime dimension $D = 26$. In [9], they also showed that gauge fields on a D-brane are described by the same Dirac–Born–Infeld type of Lagrangian. Interestingly, let’s remark the duality between the brane velocity which is limited by the velocity of light and limiting electric fields in Born–Infeld theory [10]. The Born-Infeld action [11] to second order might be obtained from higher-curvature gravity in Kaluza-Klein theory [12–14] and it has also application in the supersymmetry [15].

The photon–photon scattering is one of the most important nonlinear processes in today’s particle physics. Off-shell photon–photon scattering [16] was indirectly observed in collisions of heavy ions in 2017 [17] [18–20]. The process is one of the oldest predictions of quantum electrodynamics (QED) and its convenient to use Heisenberg–Euler approximation in QED [21] [22] for calculations.

Historically, the investigation of the Heisenberg–Euler general formula for the quantum nonlinearities in the Lagrangian of QED, [16] [21] [24] was accompanied by an interest in a theory of QED with the upper limit on the strength of the electromagnetic field. Such a theory is known today as the Born–Infeld theory.

There is an interest in experimental research in the Born–Infeld theory next to its theoretical applications in the string theory. There is a need to test QED and non–standard models like Born–Infeld theory and scenarios where mini charged particles are involved or axion–like bosons [25]. For example, the PVLAS experiment [26] has obtained limits on the existence axion-like and milli-charged particles next to setting upper limits on the magnetic birefringence predicted by QED.

Thanks to the calculated phase shift that is produced when an ultra-intense laser beam crosses a low power beam, in the case of arbitrary polarizations, it is possible to propose a set of experiments allowing either to detect photon-photon scattering or to set new limits on the relevant parameters which might improve by several orders of magnitude the current constraints obtained by PVLAS collaboration.

A complete test of all the parameters appearing in the low energy effective photonic Lagrangian could be done newly including the parameter also for the Born–Infeld term thanks to the availability of the PW class lasers. The experiments can be performed at HERCULES [27] [28], at new laser ZEUS [29] at the University of Michigan, at new laser LUXE [30] at DESY, and more probably at ELI facility [31] or on 100 PW laser at SIOM [32] in the future, thus providing a new class of precision tests of the Standard Model and beyond. In other words, the photon–photon scattering provides a tool for the search for a new physics, in which new particles can participate, see search for the process in X–ray region [33].

Though Heisenberg–Euler theory is most probably preferred over the Born–Infeld theory in nature, the experimental observation and precision tests of the parameter for the Born–Infeld in the low energy effective Lagrangian are still waiting for reaching necessary sensitivity for its measurement in the process of photon–photon scattering.

The generalized Born–Infeld electrodynamics was investigated in Kruglov [34] given the effective Lagrangian...
considered as a combination of the Lagrangians of Born–Infeld and Heisenberg–Euler theory, where they obtained the upper bounds on the parameters in the effective Lagrangian from the PVLAS experimental data.

They have used the same effective Lagrangian as in the previous paper to show the lack of commutativity among quantized truncated actions and truncated quantized actions in Born–Infeld electrodynamics and Euler–Heisenberg like model was investigated in [35].

Except the Heisenberg–Euler electrodynamics and its variations [36], other non–linear electrodynamics have at least one free parameter which must be experimentally constrained [37]. The constraints can be found by direct measurements of atomic transitions [38, 39] or in photon–photon scattering process due to self–interaction in non–linear electrodynamics.

The hydrogen’s ionization energy was used to constrain the free parameter $b$ of three Born–Infeld–like electrodynamics namely Born–Infeld itself, Logarithmic electrodynamics and Exponential electrodynamics in [40].

Another way how to contrain the parameters is in an astrophysical context where the constraint is given by the photon splitting in the magnetars spectra [41]. Also lets not forget to mention the PVLAS experiment itself [26] where the contraints can be established by measurements of vacuum magnetic birefringence generated by passing of polarized laser beam through a magnetic dipole field, for non–linear electrodynamics with birefringence.

One of the results coming out of the photon–photon scattering experiment at LHC was the estimate of a constraint $b$ in the Born–Infeld theory [42]. The limit excludes a range of the mass scale of a nonlinear Born–Infeld extension of QED that is $M \lesssim 100$ GeV (the first limit in GeV range). The scale $M = \sqrt{b} \gtrsim 100$ GeV represents a lower limit on $b$ which is more than 3 orders of magnitude stronger than other lower limits in [37, 41, 43].

The angular dependence of the differential cross section of unpolarized light by light scattering summed over final polarizations is the same for any low energy effective theory of quantum electrodynamics including Born–Infeld one. If we include the dependency on polarization, ordinary quantum electrodynamics has interesting polarization patterns for linear polarizations, but supersymmetric quantum electrodynamics and Born–Infeld electrodynamics give simple forms, [44], which is thanks to their self–duality also responsible for the absence of vacuum birefringence in these two electrodynamics. Lets also mention that the mass of electron can be melted entirely by an external electric field near the critical field strength in the Born–Infeld theory. This effect also arises in QED and impacts pair production in strong fields [45].

Such studies of fundamental physics will become possible due to the increasing availability of high power lasers. It raises an interest in experimental observation and motivates theoretical studies of non–linear QED in the laser–laser scattering [27, 46, 57], and the interaction of relatively long wavelength radiation with the X-ray photons [28, 56, 57], nonlinear laser–plasma interaction [28, 59] and to complex problems on the boundary of non–linear QED.

In the limit of extremely intense electromagnetic fields the Maxwell equations are modified due to the nonlinear process of photon–photon scattering that makes the vacuum refraction index depend on the field amplitude. Due to the nonlinearity of the field equations, the electromagnetic field interacts with itself and generates deformations in the light cone [60]. In the context of the nonlinear electrodynamics, introducing the background field affects the propagation velocity of the electromagnetic wave and creates the birefringence effect, i.e. the speed of wave propagation depends on the wave polarization, [61, 62] and in the presence of electromagnetic waves with small but finite wavenumbers the vacuum behaves as a dispersive medium.

The phenomenon of birefringence exists in all physically acceptable nonlinear electrodynamics except for the Born–Infeld electrodynamics [63]. The Maxwell field equations are modified in the extremely intense limit of electromagnetic fields, thanks to the nonlinearity of the field equations, the electromagnetic field interacts with itself. Such introduction of background field influences the electromagnetic wave and the effect of birefringence is created, i.e. the propagation speed of the wave depends on the wave polarization [61, 62].

The Heisenberg–Euler approximation of QED exhibits the effect of birefringence. The quantum vacuum behaves as a dispersionless medium for the propagating electromagnetic wave. The refraction index of the media depends on the electromagnetic field of the wave. The wave development results into singularity creation and subsequently into shock wave formation [64]. This is accompanied by a subsequent generation of high order harmonics which can be powerful in exploration of the physics in vacuum.

The behaviour of shock waves in the Born–Infeld nonlinear electrodynamics was studied thoroughly. The early theoretical analysis was made by Boillat who showed that both polarization modes travel along the light cone of one optical metric in exceptional nonlinear electrodynamics like in the Born–Infeld [63, 65]. The shock waves in the Born and Born–Infeld theories were studied in [66]. The propagation of shock waves in theories which are nonlinear is determined by optical metrics and polarization conditions. They describe in general the propagation of two differently polarized waves where the effect of birefringence is just a special case. The two optical metrics reduce to the identical one for the Born–Infeld electrodynamics, i.e. Born–Infeld is a special case without birefringence.

Here, exceptional means that no shocks are formed (in the sense of Lax representation) [11, 63] and the fields on the wave–front always satisfy the field equations. In [67], the study was extended to the motion of more general discontinuity fronts. Considering the convexity of energy density, they derived relations concerning exceptional waves (linearly degenerated) and shock fronts with
the discontinuities of the field. They showed that the characteristic shocks, which are moving with the wave velocity, are unbounded, they allow arbitrary coefficients for the Born–Infeld electrodynamics. The discontinuities do not evolve into shocks, but when the shock exists at some initial time it propagates on characteristic surfaces, i.e. the Cauchy problem is well posed.

The problem of shock wave development still remained uncompleted till today. Quite recently, the general problem of shock formation was resolved by D. Christodoulou in [68] in 3D dimensions, where he proved that the shock waves are absent in 3D space for the Chaplygin gas known also as scalar Born–Infeld theory. There was provided a complete description of the maximal development of the initial data. This description is setting up the problem continuation of the solution beyond the point where it stops to be regular. Such solutions belong to the so-called free boundary category problems which possess additional property that the initial data have singular character because of the behaviour of the solutions at the blow up surface. Similar problem was investigated for the case with spherical symmetry for a barotropic fluid [69]. There is given a complete description of the singularities which are associated with the development of shocks in terms of smooth functions. Importantly, let us note that Boillat assumed in his works that Lax [63] one dimensional wave motion theorems would generalize to higher dimensional problems, therefore its not completely established yet and its not completely unreasonable to expect solutions with shocks from the nonlinear electrodynamic field equations of Boillat multi-parameter family.

Specifically in [71], the formation of singularities in the Born and Born–Infeld electrodynamics was studied for plane wave–pulse motions along one spatial direction. His results were based on earlier work on conservation laws in [71]. The set of Born–Infeld equations has been augmented to a 10×10 system of hyperbolic conservation laws, which share some similarities with magnetogydrodynamics equations as the existence of convex entropy, galilean invariance and full linear degeneracy. Only the existence of the local smooth solutions for smooth initial data can be insured, so the global smooth solutions can be expected at least for initial data which satisfy the smallness criterion. If the criterion is violated by the initial plane wave pulse, then it leads to the development of a singularity in a finite amount of time without creation of a shock wave. Such singularity is therefore not a shock and the Born–Infeld equations reduce to the Chaplygin gas equations. In the other case the solution stays smooth globally. The Born–Infeld and also the augmented system of Born–Infeld equations are therefore not globally well posed.

Let us mention that the global existence of classical smooth finite-energy solutions to the 3D for small amplitude initial data in the Maxwell–Born–Infeld system was proved in [72]. The Born-Infeld equations have been solved for transverse plane waves in a rectangular waveguide. Waveguides can be used to test non-linear effects in electrodynamics. It was shown that the energy velocity acquires a dependence on the amplitude and the harmonic components appear as a consequence of the non-linear behavior [72].

Geometrical aspects of light propagation in nonlinear electrodynamics, propagation of light in the modified QED vacuum were investigated in [74], where they show that the propagation of discontinuities of electromagnetic field is a nonlinear regime (in dielectrics or in modified QED vacua) can be described in terms of an effective modification of the Minkowskian geometry of spacetime. This property has been known in the Born–Infeld electrodynamics for a long time [72], and investigated more further in [74]. There exists an analogy between photon propagation in nonlinear electrodynamics and its behavior in an external gravitational field, also a possibility of existence of an electromagnetic analogue of the gravitational black hole.

The Fresnel equation of the wave propagation was analysed in nonlinear electrodynamics in [70]. The quartic Fresnel surface reduces to the two light cones for all nonlinear electrodynamics. Birefringence is absent (two light cones reduce to just one) if and only if the effective constitute tensor satisfies closure property.

Recently, we have investigated an analytical solution of the non–linear field equations in the Heisenberg–Euler approximation in QED which describes two counter–propagating waves in the QED quantum vacuum. [77], the solution was generalized in [78]. The solution of the field equations was found in the form of a simple wave. The finite amplitude wave evolution of the non–linear wave solution permits high order harmonic generation, wave steepening and formation of a shock waves in the vacuum. The resulting electromagnetic wave breaking had a rarefaction shock wave character. We proposed an experiment for the direct detection of photon–photon scattering in the quantum vacuum. Such observation has not been done yet. We suggested to reach realistic energies of the electron–positron pair cross section instead of targeting directly the Schwinger limit \( E \sim \) and detect the gamma–ray photons in the secondary processes of photon–photon scattering.

In the setup of two counter propagating electromagnetic waves we have presented new relativistic electromagnetic soliton solutions, [79]. These solitons can propagate over a large distance without changing their shape, this quality makes them a good object to be experimentally observed [80].

In this paper, we study two counter–propagating waves in the Born–Infeld electrodynamics for the case \( \mathcal{E}^2 \neq 0 \) and we look for the solution in the self–similar form. It is a continuation of our previous study of the crossed field case \( \mathbf{E} \cdot \mathbf{B} = 0 \), i.e. \( \mathcal{E}^2 = 0 \), which is identical for both the Born and the Born–Infeld electrodynamics, [1].

The paper is organized as follows. In Section 1 we review the Born–Infeld and the Born electrodynamics, their field equations and basic properties.
In Section II, we show that the Born–Infeld field equations can be solved using the similar method as in [71, 72], we show that the exceptional waves are the only solutions of the equations and thus demonstrate the absence of shock waves in the Born–Infeld theory.

In Section III we review and show the connection of the Born–Infeld and Heisenberg–Euler theories.

The Section IV is devoted to discussion of distinguishing the two theories Born–Infeld and the Heisenberg–Euler by precision test experiments.

The main results of the paper are summarized in concluding Section V.

I. BORN–INFELD AND BORN ELECTRODYNAMICS

A. The Born–Infeld and Born Lagrangians

The Born–Infeld electrodynamics is a unique nonlinear electrodynamics [81, 82] which is determined by the Lagrangian in a form

\[
\mathcal{L}_{BI} = -b^2 \left( \sqrt{1 - \frac{\mathbf{E}^2 - \mathbf{B}^2}{b^2}} - 1 \right),
\]

where \( \mathbf{E} \) and \( \mathbf{B} \) are electric and magnetic fields, \( b \) is the free Born–Infeld constant which has the dimension of the electromagnetic field and we use the units \( c = \hbar = 1 \).

The Born-Infeld theory is a unique theory because it does not lead to birefringence effect. Birefringence effect means that the propagation velocities of waves in all directions do not depend on the wave polarization. The Maxwell and the Born–Infeld theories are the only relativistic theories which lack birefringence, [61].

The original model was proposed by Born in 1933 in a form,

\[
\mathcal{L} = -b^2 \left( \sqrt{1 - \frac{\mathbf{E}^2 - \mathbf{B}^2}{b^2}} - 1 \right),
\]

where a new pseudoscalar invariant \( (\mathbf{E} \cdot \mathbf{B}) \) is missing which was added to the Born–Infeld Lagrangian while maintaining the Lagrangian as relativistic covariant.

The Born theory was not satisfactory in several directions, the main difficulties were connected to the fact that the self–energy of a point charge is infinite, unexplained facts concerning the existence of elementary particles, the construction of the nuclei and the conversion of these particles into other particles or photons, [83]. The Born theory holds just for the wave lengths long compared to the radius of the electron and they break down for shorter waves. The electromagnetic laws needed to be modified and the quantum laws adapted to the new field equations. The Born–Infeld electrodynamics then corresponds to the unitarian idea to find classical solutions representing electrically charged particles with finite self-energy. The relativistic mechanism which restricts the velocities to values smaller than \( c \) will restrict the electric field in the Born–Infeld theory to values smaller than the critical field \( b \). [82].

The Born-Infeld and the Born theories reduce to the linear Maxwell theory,

\[
\mathcal{L}_M = \frac{1}{2} (\mathbf{E}^2 - \mathbf{B}^2),
\]

in the classical linear electrodynamics when \( b \to \infty \), for fields which are much weaker than the critical field \( b \).

B. The field equations of Born–Infeld electrodynamics

The Born–Infeld field equations are given by

\[
\partial_\mu \left( \frac{\partial \mathcal{L}_{BI}}{\partial (\partial_\mu \Phi)} \right) - \frac{\partial \mathcal{L}_{BI}}{\partial \Phi} = 0, \quad \Phi = (-\phi, \mathbf{A}).
\]

The Lagrangian density can be any function of the scalar invariant \( \mathfrak{S} \) and the pseudoscalar invariant of the electromagnetic field tensor \( \mathfrak{S} \), the Poincaré invariants, as \( \mathcal{L}_{BI}(\mathfrak{S}, \mathfrak{S}) \),

\[
\mathfrak{S} = \frac{1}{4} F_{\mu \nu} F^{\mu \nu} = \frac{1}{2} (\mathbf{B}^2 - \mathbf{E}^2),
\]

\[
\mathfrak{S} = \frac{1}{4} F_{\mu \nu} \tilde{F}^{\mu \nu} = \mathbf{E} \cdot \mathbf{B},
\]

\[
\tilde{F}^{\mu \nu} = \frac{1}{2} \varepsilon^{\mu \nu \rho \sigma} F_{\rho \sigma},
\]

where \( \varepsilon^{\mu \nu \rho \sigma} \) is the Levi–Civita symbol in four dimensions.

The Born–Infeld and Born Lagrangians can be written as

\[
\mathcal{L}_{BI} = -b^2 \left( \sqrt{1 + \frac{2 \mathfrak{S}}{b^2}} - \frac{\mathfrak{S}^2}{b^4} - 1 \right),
\]

\[
\mathcal{L}_B = -b^2 \left( \sqrt{1 + \frac{2 \mathfrak{S}}{b^2}} - 1 \right).
\]

The field equations can be expressed in the relativistic tensor notation (Bianchi identities \( \partial_\mu F_{\nu \lambda} = 0 \)):

\[
\partial_\mu F_{\nu \lambda} + \partial_\nu F_{\lambda \mu} + \partial_\lambda F_{\mu \nu} = 0, \quad \partial_\mu h^{\mu \nu} = 0,
\]

where

\[
h^{\mu \nu} = \frac{\partial \mathcal{L}}{\partial \tilde{F}^{\mu \nu}} = \frac{\partial \mathcal{L}}{\partial \mathfrak{S}} F^{\mu \nu} + \frac{\partial \mathcal{L}}{\partial \mathfrak{S}} \tilde{F}^{\mu \nu}.
\]

The field equations consist of two sets of equations, the first pair of Maxwell field equations without sources reads

\[
\nabla \cdot \mathbf{B} = 0, \quad \nabla \times \mathbf{E} = -\partial_t \mathbf{B},
\]

and the second pair can be obtained by varying the Lagrangian \( \mathcal{L}_{BI} \) which gives the second pair of equations as

\[
\nabla \times \mathbf{H} = \partial_t \mathbf{D}, \quad \nabla \cdot \mathbf{D} = 0,
\]

together with the nonlinear constitutive relations,

\[
\mathbf{E} = \mathbf{E} (\mathbf{D}, \mathbf{B}), \quad \mathbf{H} = \mathbf{H} (\mathbf{D}, \mathbf{B}).
\]
C. The exceptional waves in the Born–Infeld electrodynamics

What definitely exists in the Born–Infeld electrodynamics are the exceptional traveling wave solutions which propagate with constant speed and they do not turn into shocks,\(^ {63, 65, 84}\). To demonstrate the difference between traveling waves and the exceptional traveling waves, we will start with investigation of the traveling waves. Thanks to that we will be able to discuss the shock wave development in the Born–Infeld theory and discuss its contribution to the resulting radiation to the cross-section of the photon–photon scattering process in our proposed experiment for direct detection of the cross-section of the photon–photon scattering process.

The resulting traveling wave equation can be written in a similar form,

\[
\partial_x a_z + v(a_z) \partial_t a_z = 0, \tag{12}
\]

the same form the resulting wave had in the Born theory,\(^ {1}\), and in the Heisenberg–Euler approximation\(^ {77, 78}\), with the factor \(v(a_z)\) as the velocity of the resulting wave.

The characteristic equation for the Eq. (12) is (the second one is trivial \(\frac{dt}{dt} = 1\))

\[
\frac{dx}{dt} = v(a_z), \tag{13}
\]

and the Eq. (12) is transformed into ordinary equation,

\[
\frac{da_z}{dt} = 0. \tag{14}
\]

We can write for any differentiable function \(A = A(x)\) the solution \(a_z\) in a form,

\[
a_z(x, t) = A_0(x_0) = A_0[x - v(a_z(x, t))t], \tag{15}
\]

where \(A_0\) is an arbitrary function determined by initial condition, \(a_z(x)|_{t=0} = A_0(x)\).

According to\(^ {11}\), a more general family of hypersurfaces \(S\) can be defined and written as

\[
S = n \cdot x - v(n, S)t, \tag{16}
\]

where \(n\) is the constant unit 3-vector, which fixes the direction of propagation, and the family of hyperplanes \(S = \text{const}\) in a flat space \(\mathbb{E}^3\) which are not parallel eventhough their intersections with any surface of constant time gives a family of parallel 2-planes in \(\mathbb{E}^3\). The wave moves in a constant direction but not with constant speed. The waves may slow down or speed up in a way that, when hyperplane passes a given point in space at a later times, it may have smaller or larger speed \(v(n, S)\).

In general such hyperplanes will intersect, the ansatz breaks down at the intersection locations and the neighbouring hyperplanes form a caustic hypersurface. We obtain a caustic hypersurface by eliminating \(S\) from the equations,

\[
S = n \cdot x - v(S)t, \tag{17}
\]

\[
1 = -v'(S)t, \tag{18}
\]

where \(\cdot\) indicates differentiation with respect to \(S\). The exceptional waves are defined as those for which

\[
v'(S) = 0. \tag{19}
\]

If all waves are exceptional \(v' = 0\ \forall S\), then parallel hyperplanes are possible. If \(v \neq 1\) such waves can be transformed to \(v' = 0\) by a Lorentz transformation. We obtain then constant (or stationary) solutions. Such solution was found in\(^ {84}\), where they found exact stationary solutions to Born–Infeld theory.

D. The characteristics and the absence of wave breaking

In the Born–Infeld theory, there should be no shock wave development. We are going to demonstrate that analytically here. The location where the wave breaks is determined by the gradient of function \(a_z(x, t)\), the wave breaks when gradient becomes infinite,\(^ {84}\). To demonstrate the difference of exceptional waves, the expressions\(^ {20}\) reduce thanks to the relation\(^ {19}\) to

\[
\partial_x a_z = \frac{A_0'(x_0)}{1 + A_0'(x_0)v' t}, \tag{20}
\]

\[
t_{br} = -\frac{1}{A_0'(x_0)v'}, \tag{21}
\]

where it is denoted \(A'(x_0) = dA_0/dx_0\) and \(v' = \partial_x v(a_z)\). For the case of exceptional waves, the expressions\(^ {20}\) reduce thanks to the relation\(^ {19}\) to

\[
\partial_x a_z = A_0'(x_0), \tag{21}
\]

\[
t_{br} \to \infty, \tag{22}
\]

where we observe that the gradient never becomes infinite contrary to the time when the wave breaks. The time of wave breaking is approaching infinity, in other words, the wave breaking will never happen.

To show an explicit example, we chose the same arbitrary function as \(a_z(x, t) = A_0(x_0) = a_m \sin(kx_0)\) giving

\[
a_z(x, t) = a_m \sin[k(x - v(a_z(x, t))t)], \tag{23}
\]

then we can write

\[
A_0'(x_0) = a_m k \cos(kx_0), \quad v' = 0, \tag{24}
\]

and the gradient and the wave breaking time \(t_{br} \to \infty\) have a form

\[
\partial_x a_z = a_m k \cos(kx_0), \quad t_{br} \to \infty. \tag{25}
\]

For our case\(^ {52}\), the hypersurface \(S = a_z(x, t) = A_0(x_0) = \text{const}\), i.e. the function \(a_z(x, t)\) remains unchanged along characteristic lines, and the only non-zero components of the unit vector \(n\) is \(n_x = 1\). Then we obtain the exceptional waves as

\[
1 = -v'(a_z(x, t))t, \tag{26}
\]
where $\prime$ indicates differentiation with respect to its argument. The exceptional waves are defined as

$$v'(a_z) = 0. \quad (27)$$

The characteristic lines (hyperplanes) are straight lines for the exceptional theories such as Born–Infeld, see the Fig. 1. The regularity arises for exceptional theories only, which have no shock formation.

![Fig. 1: The hyperplanes do not intersect in exceptional theories such as Born–Infeld theory, which has no shock wave formation.](image)

In [67], they have showed that the Cauchy problem is well posed in the Born–Infeld theory, the waves do not evolve into shocks, but when the shock exists at some initial time it propagates on characteristic surfaces.

The absence of shocks wave goes together with the absence of birefringence in the Born–Infeld theory, [61, 52]. To understand the physical significance of exceptionality in the sense of absence of shock waves, we should look at theories which are not exceptional and admit shock waves. Such theories are essentially incomplete and we need some extra assumptions to describe the evolution behind the shock wave front, [1]. That usually comes from some more fundamental underlying theory. In our case, it was the Heisenberg–Euler approximation in the full underlying QFT theory [77, 78] or the incomplete theory of Born. Basically, the predictions of classical theory cannot be trusted about presence of shock waves or other singularities, especially where they arise. In this point of view, the Born–Infeld theory resembles more Yang–Mills theory (complete, non-singular propagation for all times) than classical general relativity (complete, singularities).

II. ABSENCE OF SHOCK WAVES IN THE BORN–INFELD THEORY

In this section, we will derive and analyze the Born–Infeld field equations for the problem of two counter–propagating waves in the Born–Infeld electrodynamics for the case when the invariant $\mathcal{S}^2 \neq 0$.

The term $\mathcal{S}^2$ is of the fourth order in $F_{\mu\nu}$ and therefore can be neglected except in the immediate neighbourhood of singularities, i.e. electrons, in our case we are close to the creation of shock wave fronts, [83]. When $\mathcal{S}^2 \neq 0$ we are close to the singularities, shock wave fronts. In terms of energy, the integral around the position of the singularity is proportional to the nonzero angular momentum density $j$, which is nonvanishing and can't be neglected in the close proximity to the singularity.

Born–Infeld electrodynamics is called completely exceptional and it is the only completely exceptional regular nonlinear electrodynamics [82]. The electrodynamics shows special features as the absence of shock waves and birefringence.

In our previous paper [1], we have studied the problem for the crossed field case $\mathbf{E} \cdot \mathbf{B} = 0$, i.e. $\mathcal{S}^2 = 0$, which is identical for both the Born and the Born–Infeld electrodynamics. The only solutions were the exceptional traveling waves which propagate with constant velocity and do not turn into shocks.

In order to investigate closely the contribution of the electromagnetic waves in the Born–Infeld to the process of photon–photon scattering, we use our knowledge of solving the field equations for the Heisenberg–Euler Lagrangian of the two counter–propagating electromagnetic waves and our study of the problem in both Born and the Born–Infeld electrodynamics.

A. The Born–Infeld field equations

To investigate the problem in the case of the Born–Infeld Lagrangian, we have to generalize the setup to have $\mathbf{E} \cdot \mathbf{B} \neq 0$ in the calculation.

We will work in the orthogonal coordinate system, $(x, y, z)$, where the two waves propagate along the $x$–axes. Therefore we assume $\mathbf{E} = (0, E_y, E_z)$ and $\mathbf{B} = (0, B_y, B_z)$, which is the simplest generalization of the previous setup in the Born theory [1]. The functions $E_z$ and $B_y$ are functions of $(x, t)$, but the second equation in [9] allows us to have just $E_y$ dependent on $t$ and $B_z$ dependent on $x$ or $B_z$ equal to constant. To simplify our ansatz we have chosen to use $B_z = $ const and the constant to be zero $B_z = 0$ for simplicity. The setup is thus rather mathematical but is very useful for our task to study the physics: to solve the field equations and study the absence of the shock wave development in the Born–Infeld electrodynamics and its contribution to our experiment.

The field equations were found by varying the Lagrangian according to the potential $\mathbf{A}$:

$$\partial_t B_y = \partial_z E_z, \quad (28)$$

$$-\alpha \partial_t E_z + \beta [\partial_t B_y + \tau \partial_x E_z] + \gamma \partial_x B_y - \delta \partial_x E_y = 0, \quad (29)$$

$$-\epsilon \partial_t E_z + \zeta \partial_x B_y + \eta \partial_x B_y + \theta \partial_x E_z - i \partial_t E_y = 0, \quad (30)$$
where we have denoted the coefficients as

\[ \alpha = 1 + \frac{E_y^2}{b^2} \left( 1 - \frac{1}{b^2} - \frac{(E \cdot B)^2}{b^4} \right), \]

\[ \beta = \frac{1}{b^2} \left( \frac{E_z B_y}{b^2} \right), \]

\[ \gamma = 1 - \frac{1}{b^2} E_y^2 - \frac{B_y^2}{b^2} \left( 1 - \frac{1}{b^2} E_y^2 \right) \left( 1 - \frac{1}{b^2} - \frac{(E \cdot B)^2}{b^4} \right), \]

\[ \delta = \frac{1}{b^2} \left( \frac{E_z E_y}{b^2} \right) \left( 1 - \frac{1}{b^2} - \frac{(E \cdot B)^2}{b^4} \right), \]

and the coefficients in the second set of field equations,

\[ \epsilon = \frac{1}{b^2} \left( \frac{E_y E_z}{b^2} \right) \left( 1 - \frac{1}{b^2} \right) \left( 1 - \frac{1}{b^2} - \frac{(E \cdot B)^2}{b^4} \right), \]

\[ \zeta = \frac{E_y E_z}{b^2} \left( 1 - \frac{B_y^2}{b^2} \left( 1 - \frac{1}{b^2} \right) \left( 1 - \frac{1}{b^2} - \frac{(E \cdot B)^2}{b^4} \right) \right), \]

\[ \eta = -\frac{E_y B_y}{b^2} \left( 1 - \frac{1}{b^2} \right) \left( 1 + \frac{1}{b^2} \right) \left( 1 - \frac{1}{b^2} - \frac{(E \cdot B)^2}{b^4} \right), \]

and

\[ \theta = \frac{E_y B_y}{b^2}, \]

\[ \tau = 1 - \frac{1}{b^2} E_y^2, \]

where the equations reduce to the two field equations for Born theory \[1\] when we set \( E_y = 0 \). Also the condition \( 1 - (E^2 - B^2)/b^2 - (E \cdot B)^2/b^4 > 0 \) should be valid. We observe that the set of equations is the simplest generalization of our equations in Born theory, \[1\]. The equations will describe not just the ordinary wave but also the extraordinary wave propagation, which is determined by the only components \( E_y(t) \) and \( B_z = 0 \). The ordinary and extraordinary waves will have the same direction of propagation but different phase velocities thanks to the absence of birefringence effect in the Born–Infeld electrodynamics.

Again, we add the weak linear amplitude corrections to the fields,

\[ E_y = E_0 + a_y(t), \]

\[ E_z = E_0 + a_z(x, t), \]

\[ B_y = B_0 + b_y(x, t), \]

(34)

where the fields \( E_0, B_0 \) represent the constant electromagnetic background field and \( a_y(t), a_z(x, t) \) and \( b_y(x, t) \) are corrections, functions of \( x \) and \( t \).

The equations \[28,29,30\] can be rewritten as

\[ \partial_t b_y(x, t) = \partial_x a_z(x, t), \]

\[ -\alpha \partial_t a_z(x, t) + \beta [\gamma \partial_x a_z(x, t) + \partial_t b_y(x, t)] \]

\[ + \gamma \partial_x b_y(x, t) - \delta \partial_t a_y = 0, \]

(35)

\[ -\epsilon \partial_t a_z(x, t) + \zeta \partial_t b_y(x, t) + \eta \partial_x b_y(x, t) \]

\[ + \theta \partial_t a_z(x, t) - \epsilon \partial_t a_y = 0. \]

(36)

Now, we want to solve the equations by using the self–similar solutions, i.e. \( b_y = b_y(a_z) \) and the variable \( a_y(t) \) is general. Again we use the expressions with total differential, \( \partial_t b_y = (db_y/da_z) \partial a_z \) and \( \partial_t a_y = (db_y/da_z) \partial a_z \). We obtain the set of three equations,

\[ \partial_t a_z = \frac{da_z}{db_y} \partial_x a_z, \]

\[ \partial_t a_z = \frac{1}{\alpha} \left\{ \partial_x a_z \left[ (1 + \tau) \beta + \frac{db_y}{da_z} \right] - \delta \partial_t a_y \right\}, \]

(37)

\[ \partial_t a_z = \left[ -\epsilon + \frac{db_y}{da_z} \eta \right] = -\partial_x a_z \left( \frac{db_y}{da_z} \zeta + \theta \right) + \iota \partial_t a_y. \]

(38)

Then we solve the equations by equality of the Eq. \[38\] and \[39\] and Eq. \[38\] and \[39\], we obtain set of two equations for \( \partial_x a_z \) and \( \partial_t a_y \),

\[ \partial_x a_z \left( 1 - \frac{1}{\alpha} \frac{db_y}{da_z} \right) \left[ (1 + \tau) \beta + \frac{db_y}{da_z} \right] = -\partial_a_y \frac{\delta \partial b_y}{\alpha da_z}, \]

(41)

\[ \partial_x a_z \left[ -\epsilon + \frac{\eta db_y}{da_z} + \frac{db_y}{da_z} \left( \gamma db_y + \theta \right) \right] = \iota \partial_a_y \frac{db_y}{da_z}. \]

(42)

The two equations above should be equal therefore we obtain another quadratic equation for the total differential,

\[ \left( \frac{db_y}{da_z} \right)^2 \left( \delta \zeta + \iota \gamma \right) \]

\[ + \left( \frac{db_y}{da_z} \right) [\eta \delta + \theta \iota - \iota \beta (1 + \tau)] \]

\[ + \alpha \left( \epsilon + \epsilon \theta \right) = 0. \]

(43)

The quadratic equation \[44\] has solutions,

\[ \left( \frac{db_y}{da_z} \right)_{1,2} = \frac{-N \pm \sqrt{N^2 - 4\alpha(\delta \zeta + \iota \gamma)(\iota - \iota \delta / \alpha)}}{2(\delta \zeta + \iota \gamma)}. \]
where

\[ N = \left[ \delta(\eta + \theta) - i\beta^2(1 + \tau) \right]. \]  \hfill (45)

**B. The derivation of the phase velocity**

Now, we derive the phase velocity from the linearized equations, we use the relations

\[ a_z \propto \exp(-i\omega t + iqx), \quad b_y \propto \exp(-i\omega t + iqx), \]  \hfill (46)

where \( q \) is the wave number, \( \omega \) is the frequency, we define the phase velocity as \( v_{ph} = \omega/q \). Since the medium is without dispersion in the Born–Infeld electrodynamics, we denote the phase \( v_{ph} \) and the group \( v_g = \partial\omega/\partial q \) velocity as equal to each other \( v = v_{ph} = v_g \).

To obtain the algebraic expressions for \( v \), we substitute expressions (46) into the equations for the background field, Eqs. (35–39) with the constant coefficients \( a_0, b_0, \gamma, \delta, \epsilon, \zeta, \eta, \theta, \iota, \tau \) and \( \lambda_0 \), where the coefficients are listed in Appendix A. The coefficients are obtained by setting \( a_z(t,x) = b_y(t,x) = 0 \) and then we simplify the cross-field condition by setting \( B_0 = E_0 \). We obtain the equations,

\[ a_z + v b_y = 0, \]  \hfill (47)

\[ -v(-a_0 a_z + b_0 b_y - \delta_0 a_y) + 2\gamma_0 b_y + \beta_0 a_z = 0, \]  \hfill (48)

\[ v(\epsilon_0 a_z - b_y \eta_0 + \gamma_0 \tau_0 a_z) + b_y \zeta_0 + \alpha_0 \theta_0 = 0. \]  \hfill (49)

When substituting (47) into (48), we get quadratic equation for the phase velocity,

\[ -\alpha_0 v^2 - v M + \gamma = 0, \]  \hfill (50)

which has two solutions,

\[ v_{1,2} = \frac{M \pm \sqrt{M^2 + 4\alpha_0 \gamma}}{-2\alpha_0}, \]  \hfill (51)

where \( M = (1 + \tau_0) \beta_0 - \frac{\alpha_0}{b_y} \delta_0 \). The solutions generalize the case for Born theory, therefore these velocities describe the ordinary wave and just one velocity should be the physical one.

Again, when we substitute (47) into (49), we get quadratic equation for the phase velocity,

\[ -\epsilon_0 v^2 - v \left( \eta_0 + \theta_0 - \frac{\alpha_0}{b_y} \right) + \zeta_0 = 0, \]  \hfill (52)

which has two solutions too,

\[ v_{3,4} = \frac{\left( \eta_0 + \theta_0 - \frac{\alpha_0}{b_y} \right) \pm \sqrt{\left( \eta_0 + \theta_0 - \frac{\alpha_0}{b_y} \right)^2 + 4\epsilon_0 \zeta_0}}{-2\epsilon_0}. \]  \hfill (53)

These phase velocities are new therefore we assume they will describe the phase velocities of the extraordinary wave. Again just one of the velocities should be the physical one. We cannot derive more specific expressions now. In general, the phase velocities depend on the fraction of the two functions \( a_y/b_y \) and the other coefficients are constant. We will investigate them more in detail later in this section, see subsection [IIJ].

**C. Linearization of the coefficients**

We assumed the linearized coefficients \( \alpha, \beta, \gamma, \delta, \epsilon, \zeta, \eta, \theta, \iota, \tau \) in the form,

\[ \alpha = \alpha_0 + \alpha_0 a_z + \alpha_0 b_y + \alpha_0 a_y, \]

\[ \beta = \beta_0 + \beta_0 a_z + \beta_0 b_y + \beta_0 a_y, \]

\[ \gamma = \gamma_0 + \gamma_0 a_z + \gamma_0 b_y + \gamma_0 a_y, \]

\[ \delta = \delta_0 + \delta_0 a_z + \delta_0 b_y + \delta_0 a_y, \]

\[ \epsilon = \epsilon_0 + \epsilon_0 a_z + \epsilon_0 b_y + \epsilon_0 a_y, \]

\[ \zeta = \zeta_0 + \zeta_0 a_z + \zeta_0 b_y + \zeta_0 a_y, \]

\[ \eta = \eta_0 + \eta_0 a_z + \eta_0 b_y + \eta_0 a_y, \]

\[ \theta = \theta_0 + \theta_0 a_z + \theta_0 b_y + \theta_0 a_y, \]

\[ \iota = \iota_0 + \iota_0 a_z + \iota_0 b_y + \iota_0 a_y, \]

\[ \tau = \tau_0 + \tau_0 a_z + \tau_0 b_y + \tau_0 a_y, \]  \hfill (54)

where we have denoted,

\[ a_{az} = (\partial_a \alpha)|_{(a_z = b_y = a_y = 0)}, \]

\[ a_{by} = (\partial_b \alpha)|_{(a_z = b_y = a_y = 0)}, \]

\[ a_{ay} = (\partial_a \alpha)|_{(a_z = b_y = a_y = 0)}. \]  \hfill (55)

The other coefficients are denoted in the similar way.

The coefficients have the final form,

\[ \alpha_{az} = \frac{2E_0}{b^2 C} \left( 1 + \frac{E_0}{b^2} \right), \quad \alpha_{by} = -\frac{2E_0^3}{b^4 C^2} \left( 1 - \frac{E_0^2}{b^2} \right), \]

\[ \alpha_{ay} = \frac{2E_0^3}{b^4 C^2} \left( 1 + \frac{E_0^2}{b^2} \right), \]  \hfill (56)

\[ \beta_{az} = \frac{E_0}{b^2 C} \left( 1 + \frac{E_0}{b^2} \right), \quad \beta_{by} = \frac{E_0}{b^2 C} \left[ 1 - \frac{2E_0^2}{b^2 C} \left( 1 - \frac{E_0^2}{b^2} \right) \right], \]

\[ \beta_{ay} = \frac{2E_0^3}{b^4 C^2} \left( 1 + \frac{E_0^2}{b^2} \right), \]

\[ \gamma_{az} = -\frac{E_0}{b^2 C} \left( E_0^2 - \frac{2E_0^2}{b^2 C} \left( E_0^2 + \left( 1 - \frac{E_0}{b^2} \right)^2 \right) \right) \],  \hfill (57)

\[ \gamma_{by} = -\frac{2E_0}{b^2 C} \left( 1 - \frac{E_0^2}{b^2} \right) \left[ E_0^2 - \frac{2E_0^2}{b^2} \left( 1 - \frac{E_0^2}{b^2} \right) + \left( 1 - \frac{E_0^2}{b^2} \right)^2 \right], \]

\[ \gamma_{ay} = -\frac{E_0^3}{b^4 C^2} \left[ E_0^2 + \left( 1 - \frac{E_0^2}{b^2} \right)^2 \right], \]

\[ \gamma_{by} = \frac{E_0^3}{b^4 C} \left\{ -1 + \frac{2E_0}{b^2} \left( 1 - \frac{E_0^2}{b^2} \right) \left[ E_0^2 + \left( 1 - \frac{E_0^2}{b^2} \right)^2 \right] \right\}, \]
and
\[
\delta_{za} = \frac{E_0}{b^2 C} \left( 1 + \frac{2E_0^2}{b^2 C} \right),
\]
\[
\delta_{ba} = \frac{2E_0^3}{b^2 C^2} \left( 1 - \frac{E_0^3}{b^2} \right),
\]
\[
\delta_{av} = \frac{E_0}{b^2 C} \left[ 1 + \frac{2E_0^2}{b^2 C} \left( 1 + \frac{E_0^2}{b^2} \right) \right],
\]

and
\[
\epsilon_{za} = \frac{E_0}{b^2 C} \left( 1 + \frac{E_0}{b^2} \right) \left( 1 + \frac{2E_0^2}{b^2 C} \right),
\]
\[
\epsilon_{av} = \frac{E_0}{b^2 C} \left( 1 + \frac{E_0}{b^2} \right) \left[ 1 + \frac{2E_0^2}{b^2 C} \left( 1 + \frac{E_0^2}{b^2} \right) \right],
\]
\[
\epsilon_{ba} = \frac{2E_0^2}{b^2}.
\]

and
\[
\zeta_{za} = \frac{E_0}{b^2} \left[ 1 - \frac{E_0^2}{b^2 C^2} \left( 1 + \frac{2E_0^2}{b^2 C} \right) \right],
\]
\[
\zeta_{av} = \frac{E_0}{b^2} \left( 1 - \frac{E_0^2}{b^2} \right) \left[ 1 - \frac{E_0^2}{b^2} \right] \left( 1 + \frac{2E_0^2}{b^2 C} \left( 1 + \frac{E_0^2}{b^2} \right) \right) - 1,
\]
\[
\zeta_{ba} = -\frac{E_0^3}{b^2 C} \left[ \frac{E_0^3}{b^2} - \left( 1 - \frac{E_0^2}{b^2} \right) + \frac{E_0^2}{b^2 C} \left( 1 - \frac{E_0^2}{b^2} \right)^2 \right],
\]

and
\[
\eta_{za} = \frac{2E_0^3}{b^2 C^2} \left( 1 - \frac{E_0^3}{b^4} \right),
\]
\[
\eta_{av} = \frac{2E_0^3}{b^2 C} \left( 1 - \frac{E_0^2}{b^2} \right) \left[ \frac{1}{C} \left( 1 + \frac{E_0^2}{b^2} \right)^2 - 1 \right] - \frac{E_0}{b^2} \left[ 2 - \frac{1}{C} \left( 1 - \frac{E_0^3}{b^4} \right) \right],
\]
\[
\eta_{ba} = -\frac{2E_0^3}{b^2 C} \left( 1 + \frac{E_0^2}{b^2} \right) \left[ \frac{1}{C} \left( 1 - \frac{E_0^2}{b^2} \right)^2 + 1 \right] - \frac{E_0}{b^2} \left[ 2 - \frac{1}{C} \left( 1 - \frac{E_0^3}{b^4} \right) \right],
\]

and
\[
\theta_{za} = \frac{2E_0^3}{b^2 C^2} \left( 1 - \frac{E_0^3}{b^4} \right),
\]
\[
\theta_{av} = \frac{E_0^3}{b^2 C} \left[ \frac{2E_0^2}{b^2 C} \left( 1 + \frac{E_0^2}{b^2} \right) + E_0 \right],
\]
\[
\theta_{ba} = \frac{E_0^3}{b^2 C} \left[ 1 - \frac{2E_0^2}{b^2 C} \left( 1 - \frac{E_0^2}{b^2} \right) \right] + E_0,
\]

and
\[
\tau_{za} = \frac{2E_0^3}{b^2 C^2} \left( 1 - \frac{E_0^3}{b^4} \right),
\]
\[
\tau_{av} = \frac{2E_0}{b^2} + \frac{2E_0}{b^2 C} \left( 1 - \frac{E_0^3}{b^2} \right) \times \left[ 1 + \frac{2E_0}{b^2} + \frac{E_0^3}{b^2 C} \left( 1 + \frac{E_0^3}{b^2} \right)^2 \right],
\]
\[
\tau_{ba} = -\frac{2E_0^3}{b^2 C^2} \left( 1 + \frac{E_0^3}{b^4} \right) \left[ 1 + \frac{1}{C} \left( 1 - \frac{E_0^2}{b^2} \right)^2 \right],
\]
\[
\tau_{za} = 0, \tau_{av} = \frac{2E_0}{b^2}, \tau_{ba} = 0.
\]

The linearized coefficients \(\alpha, \beta, \gamma, \ldots\) contain information from the Lagrangian which is propagated into its coefficients \(\alpha_{za}, \alpha_{av}, \beta_{za}, \beta_{av}, \gamma_{za}, \gamma_{av}, \ldots\).  \[58 \quad 61 \quad 62 \quad 63 \quad 64\]

which we will use in the next Sections.

### D. Solving the first equation

The equations decouple and we can discuss their solutions and meaning. First, it is good to look at the first equation \[65\], which we have widely discussed in our previous work and rewrite it in a similar form as for the Born case,

\[
\partial_t a_z - \frac{1}{\nu} \partial_z a_z = 0,
\]

where the function \(\nu\) will be in a form after linearization,

\[
\frac{db_y}{da_z} = \nu, \quad \nu = \nu_0 + \nu_{a_z} a_z + \nu_{b_y} b_y + \nu_{a_y} a_y.
\]

The two sets of coefficients \(\nu_0, \nu_{a_z}, \nu_{b_y}\) can be derived for \(\frac{db_y}{da_z} \) \[66\]. The coefficients are listed in the Appendix \[53\] because of their complexity.

Now, we discuss the solution of the differential equation \[69\]. The equation can be rewritten in such a way as

\[
\frac{db_y}{da_z} = \nu, \quad \nu = \nu_0' + \nu_{a_z} a_z + \nu_{b_y} b_y,
\]

where the terms in the brackets on the right hand side are constant with respect to the variables in total differential and we denoted \(\nu_0'\) as

\[
\nu_0' = (\nu_0 + \nu_{a_z} a_y),
\]

which is a constant with respect to variable \(a_z\).

The equation can be solved by the method of integration factor, choosing it as \(m(a) = \exp(-\nu_{b_y} a_z)\). The dependence \(b_y = b_y(a_z)\) is determined by

\[
\frac{1}{\nu_{b_y}} \exp(-\nu_{b_y} a_z) \left( (\nu_0' + \nu_{b_y} b_y) + \frac{\nu_{a_z}}{\nu_{b_y}} (\nu_{b_y} a_z + 1) \right) = \delta_s,
\]

(69)
where \( \delta_1 \) is arbitrary constant. Therefore the function
\( b_y = b_y(z) \) has a form
\[
b_y = \delta_1 \exp(\nu_0 a_z) - \frac{\nu_0 a_z}{\nu_0} + 1 - \frac{\nu_0'}{\nu_0}. \tag{70}
\]

After using Taylor expansion of the first term in (70), the remaining constant \( \delta_1 \) can be determined by the initial condition \( b_y|z=0 = 0 \) and therefore it allows one to find the constant,
\[
\delta_1 = \frac{\nu_0 a_z + \nu_0' \nu_0}{\nu_0^2}. \tag{71}
\]

After expressing \( b_y \) using (71), we obtain
\[
b_y = \nu_0 a_z, \tag{72}
\]

which can be rewritten using \( \nu_0 \) \text{[85] as}
\[
b_y = (\nu_0 + \nu_{a_y} a_y)a_z, \tag{73}
\]

which we need to linearize to
\[
b_y = \nu_0 a_z. \tag{74}
\]

The function \( b_y \) has the same form as for the Heisenberg–Euler approximation, \text{[75].}

Since we have two solutions for \( \frac{d b_y}{d a_z} \text{[44]} \), we will get two sets of constant coefficients \( \nu_0, \nu_{a_y} \) and \( \nu_{a_z} \) for each case. Later on we have to choose one of the solutions as the physical ones according to the positive sign of the phase velocity. That will choose the right set of coefficients \( \nu_0, \nu_{a_y} \) and \( \nu_{a_z} \). After we substitute \( b_y \) \text{[48]} into \( \nu \) \text{[67]}, we obtain
\[
\nu = \nu_0 + (\nu_{a_z} + \nu_0 \nu_{a_y}) a_z + \nu_{a_y} a_y + \nu_{a_y} \nu_{a_y} a_y a_z, \tag{75}
\]

where we will neglect the last term since it breaks the linearity of the function \( \nu \), we considered from the start. In solving the first equation \text{[63]}, we need to evaluate \( 1/\nu(a_z, b_y) \). We use the Taylor expansion in two variables for that and we obtain,
\[
\frac{1}{\nu} = \frac{1}{\nu_0} \left[ 1 - \frac{1}{\nu_0} \left[ (\nu_{a_z} + \nu_0 \nu_{a_y}) a_z + \nu_{a_y} a_y \right] \right]. \tag{76}
\]

We can rewrite the Eq. \( \text{[65]} \) as
\[
\partial_t a_z + f(a_z, a_y) \partial_x a_z = 0, \tag{77}
\]

where \( f(a_z, a_y) = \frac{1}{\nu} \) as
\[
f(a_z, a_y) = -\frac{1}{\nu_0} \left[ 1 - \frac{1}{\nu_0} \left[ (\nu_{a_z} + \nu_0 \nu_{a_y}) a_z + \nu_{a_y} a_y \right] \right]. \tag{78}
\]

Furthermore we can put the Eq. \( \text{[77]} \) into a standard form \text{[80, 57]}, describing the non–linear wave without dispersion,
\[
\partial_t \pi_z + \left( -\frac{1}{\nu_0} + \pi_z + \pi_y \right) \partial_x \pi_z = 0, \tag{79}
\]

where
\[
\pi_z = \frac{1}{\nu_0} (\nu_{a_z} + \nu_0 \nu_{a_y}) a_z, \pi_y = \frac{\nu_{a_y}}{\nu_0} a_y. \tag{80}
\]

The final form of the equation should contain the information about the shock wave creation and subsequent effects such as higher-order harmonic generation. The formula is being solved for the variable \( a_z \) while there is a free given function \( a_y \).

In the limit \( a_z = a_y = 0 \), the wave will move with the velocity \(-1/\nu_0 \) as for the unperturbed case. We have two solutions for \( \nu_0 = \nu_0^\pm \), \( \nu_0^- \) for counter–propagating waves and \( \nu_0^+ \) for co–propagating waves, the direction of motion depends on the sign of the velocities \( \nu_0^\pm \), see the final summary \text{[11K].}

Here, we use the knowledge about the phase velocities for the Born electrodynamics \text{[1]}, where we have learned that the counter–propagating case is occuring for the phase velocity \( \nu_0 = (1 - E_2^2/b^2)/\left(1 + E_2^2/b^2\right) \) which is positive and less than the speed of light \( c = 1 \), and is related to the parameter \( \nu_0^- = -1/\nu_2 \). The co–propagating case occurs for the phase velocity \( \nu_1 = -1 \) which is the case where the beams do not interact, the relation to parameter \( \nu_0^+ = \nu_1 = -1 \).

The above form equation is the general result with profile distortion by the presence of functions \( a_z \) and \( a_y \) which suggest that wave steepening takes places. But lets check the physical relevance of our results before investigating the wave steepening.

\[\text{E. The characteristics of the first equation}\]

We will solve the Eq. \( \text{[85]} \) by the method of characteristics, see Section \text{[1Q].} The characteristic equation for the Eq. \( \text{[65]} \) and the resulting equation for \( a_z \),
\[
\frac{dx}{dt} = f(a_z, a_y), \frac{da_z}{dt} = 0. \tag{81}
\]

Again for any differentiable function \( A = A(x) \), we can write the self–similar solution \( a_z \) as,
\[
a_z(x, t) = A_0(x_0) = A_0[x - f(a_z(x, t), a_y(t))t], \tag{82}
\]

where \( A_0 \) is an arbitrary function determined by initial condition, \( a_z(x)|_{t=0} = A_0(x) \).

\[\text{F. The condition for existence of exceptional waves, wave steepening and physical solutions}\]

The phase velocities are dependent on the fraction \( a_y/b_y \), \( v_{1,2} = v_{1,2}(a_y/b_y) \) and \( v_{3,4} = v_{3,4}(a_y/b_y) \). In order to see the physically relevant phase velocities, we should use their property to have constant value just dependent on \( E_0 \). In this sense the fraction \( a_y/b_y \) should be constant.
In order to find the relation, we can start by using expression (74), and we get
\[ \frac{a_y}{b_y} = \frac{a_y}{\nu_0 a_z}, \quad (83) \]
which tells us to look for the fraction \( a_y/a_z \).

The knowledge that there exists exceptional waves might help. In order to see the exceptional waves, we will start to study the wave steepening. The hypersurface \( S = a_z(x,t) \), and the only non–zero components of the unit vector \( \mathbf{n} \) is \( n_x = 1 \). The characteristics have an envelope
\[ 1 = -\partial_{a_z} f(a_z(x,t), a_y(t)t), \quad (84) \]
and the exceptional waves are defined as
\[ \partial_{a_z} f(a_z, a_y) = 0. \quad (85) \]

The wave steepening will happen forward for \( \partial_{a_z} f(a_z, a_y) > 0 \) or backwards \( \partial_{a_z} f(a_z, a_y) < 0 \), or we get just exceptional waves for \( \partial_{a_z} f(a_z, a_y) = 0 \). The explicit expression for \( \partial_{a_z} f(a_z, a_y) \) is
\[ \partial_{a_z} f(a_z, a_y) = \frac{\nu_{a_z} + \nu_0 \nu_{a_y}}{\nu_0^2}. \quad (86) \]
The exceptional wave condition gives relation
\[ \nu_{a_z} = -\nu_0 \nu_{a_y}, \quad (87) \]
which only cancels the \( a_z \) term in (80) and the final equation becomes,
\[ \partial_t a_z + f(a_y) \partial_x a_z = 0, \quad (88) \]
where
\[ f(a_y) = -\frac{1}{\nu_0} \left( 1 - \frac{\nu_{a_y} a_y}{\nu_{a_y}} \right), \quad (89) \]
where the term \( f(a_y) \) remains dependent just on free function \( a_y \). By all of this we were not able to get more specific expression for \( a_y/a_z \), therefore without loss of generality we can choose \( a_y \) for all \( x \) to our convenience as
\[ a_y = -\frac{\nu_{a_z} + \nu_0 \nu_{a_y} a_z}{\nu_{a_y}}, \quad (90) \]
by setting the terms with \( a_y \) and \( a_z \) in (78) to zero, which gives the relation between \( a_z \) and \( a_y \) via constant factor. The relation shows the forced \( x \) dependence on the function \( a_y \), which is a consequence of our initial choice to have \( a_y \) just time dependent to simplify the calculation. The solution still satisfies the extraordinary wave condition and we get the final equation in a form:
\[ \partial_t a_z + f(\nu_0) \partial_x a_z = 0, \quad (91) \]
where
\[ f(\nu_0) = -\frac{1}{\nu_0}, \quad (92) \]
and the self–similar solution
\[ a_z(x,t) = A_0(\nu_0) = A_0 \left[ x + \frac{1}{\nu_0} t \right], \quad (93) \]
where the velocity of propagation is constant \(-1/\nu_0\) with initial condition, \( a_z(x)|_{t=0} = A_0(x) \). The direction of motion for two solutions \( \nu_0 = \nu_0^+ \), \( \nu_0^- \) for co–propagating waves and \( \nu_0^+ \) for counter–propagating waves, see the results in the final summary (II K), is given by the sign of the velocities \( \nu_0^\pm \), if \( \nu_0^+ > 0 \) than the wave moves to the left, otherwise the wave moves to the right along the \( x \) axes.

We were looking for physical phase velocities, we observed that we need to find constant fraction of \( a_y/a_z \). We were able to find this fraction by looking at the exceptional waves in our solutions and by setting the free function \( a_y \). Therefore we can claim that the first equation (55) has just exceptional waves as physically relevant solutions and the wave steepening does not take place in this case. Which is in agreement with so far published literature about the existence of shock waves in the Born–Infeld theory.

**G. Solving the second equation**

The other type of equation in our set are Eqs. (39) and (40), we will choose the first one Eqs. (39) to investigate,
\[ \partial_t a_z + g(a_z, a_y) \partial_x a_z = -\frac{\delta}{\alpha} \partial_t a_y, \quad (94) \]
where
\[ g(a_z, a_y) = -\frac{1}{\alpha} \left\{ (1 + \tau) \beta + \frac{db_y}{da_z} \gamma \right\}, \quad (95) \]
which we can rewrite using the result for \( db_y/da_z \) (74) as
\[ g(a_z, a_y) = -\frac{1}{\alpha} \left[ (1 + \tau) \beta + \gamma \nu \right]. \quad (96) \]
The main difference from the previous equation is the non–zero right hand side of the equation which suggests the presents of a source of radiation, a current determined by \( \partial_t a_y \). Since \( \partial_t a_y \neq 0 \), \( a_z \) will not be constant along the characteristics and generally the characteristics are not straight lines. We will investigate when the breaking might arise.

The Eq. (94) can be reduced to ordinary differential equation by the method of characteristics, it gives one characteristic equation,
\[ \frac{dx}{dt} = g(a_z, a_y), \quad (97) \]
and the Eq. (94) reduces then to
\[ \frac{da_z}{dt} = -\frac{\delta}{\alpha} \partial_y a_y. \] (98)

Before we can proceed, we need to linearize the function \( g(a_z, a_y) \) as
\[ g(a_z, a_y) = g_0 + (g_{a_z} + g_{a_y} a_y) a_z + g_{a_y} a_y, \] (99)
where the explicit coefficients can be found in the Appendix C. And we linearize also the coefficient \( \delta/\alpha \) and we denote it as \( q \).
\[ q = -\frac{\delta}{\alpha} = q_0 + q_{a_z} a_z + q_{a_y} b_y + q_{a_y} a_y, \]
where the coefficients are listed in the Appendix D.

**H. The Cauchy initial condition**

First, we analyze the Eq. (94) without its right hand side. We can use the relation for \( b_y = \nu_0 a_z \), (14), and we obtain
\[ g(a_z, a_y) = g_0 + (g_{a_z} + \nu_0 a_y) a_z + g_{a_y} a_y. \] (100)
The characteristic equations reduce to
\[ \frac{dx}{dt} = g(a_z, a_y), \quad \frac{da_z}{dt} = 0. \] (101)
and the self-similar solutions for \( a_z \) reads
\[ a_z(x, t) = A_0(x_0) = A_0[x - g(a_z(x, t), a_y(t))t], \] (102)
where \( A_0 \) is an arbitrary function together with the initial condition, \( a_z(x)|_{t=0} = A_0(x) \).
The envelope of characteristics becomes
\[ 1 = -(g_{a_z} + \nu_0 a_y) \partial_x g(a_z, a_y) t, \] (103)
where
\[ \partial_x g(a_z, a_y) = -\frac{1}{(g_{a_z} + \nu_0 a_y)}, \] (104)
is a constant expression, i.e. the wave breaks and it is a shock wave introduced by the initial condition. Again \( a_y \) does not contribute to the steepening factor and the wave steepens forward for \( \partial_x a_y > 0 \) or backwards \( \partial_x a_y > 0 \), or we get just exceptional waves for \( \partial_x g(a_z, a_y) = 0 \).
The exceptional wave condition gives the relation
\[ g_{a_z} = -\nu_0 g_{a_y}, \] (105)
which only cancels the \( a_z \) term and one term with \( a_y \) in (100), then the final equation becomes
\[ \partial_t a_z + g(a_y) \partial_x a_z = 0, \] (106)
where
\[ g(a_y) = g_0 + g_{a_y} a_y, \] (107)
where the term \( g(a_y) \) remains dependent just on free function \( a_y \) which in respect to variable \( a_z \) is a constant.
Therefore there is no shock wave creation and the only solutions are exceptional waves with velocity \( g(a_y) \).
But still it is not what we wanted to achieve, i.e. to get \( a_y/b_y \) for this specific equation. Therefore we can set \( a_y \) to a specific expression, without loss of generality, we can choose \( a_y \) to our convenience as,
\[ a_y = -\frac{(g_{a_z} + \nu_0 a_y) a_z}{g_{a_y}}, \] (108)
by setting the terms with \( a_y \) and \( a_z \) in (99) to zero, which gives the relation between \( a_z \) and \( a_y \) via constant factor.
The solution still satisfies the extraordinary wave condition and we get the final equation in a form:
\[ \partial_t a_z + g(a_y) \partial_x a_z = 0, \] (109)
where the explicit expression for \( g_0 \), (113),
\[ g_0 = -\left\{ \frac{1}{a_0} (1 + \tau_0) \beta_0 + \frac{\gamma_0}{a_0} \right\}, \] (110)
and then the self-similar solution for \( a_z \) reduces to
\[ a_z(x, t) = A_0(x_0) = A_0[x - g_0 t] \quad \forall x, \] (111)
where the velocity of propagation is constant \( g_0 \) moving to along the \( x- \)axes. The direction of motion depends on the two solutions \( g_0 = g_0^+ \). For the solutions \( g_0^+ > 0 \), the wave moves to the right and otherwise to the left along the \( x- \)axes, see discussion in final summary (II K).
As for the first equation, we were looking for physical phase velocities. We have observed that we need to find constant fraction of \( a_y/b_y \). We were able to find this fraction by looking at the exceptional waves in our solutions and by setting the free function \( a_y \).

**I. The solution with the right hand side**

The characteristic equation (108) then can be written by substituting \( b_y \) (14) and the relation for \( a_y \) (108),
\[ \frac{da_z}{dt} = \{ q_0 + [g_{a_z} + \nu_0 (q_{b_y} - q_{b_y})] a_z \} \partial_t a_y. \] (112)
The characteristic equation is then
\[ \frac{da_z}{dt} - M a_z \partial_t a_y = q_0 \partial_t a_y, \] (113)
where
\[ M = g_{a_z} - g_{a_z} + \nu_0 (q_{b_y} - q_{b_y}). \] (114)
We solve the left hand side first and then the particular solution for the right hand side. First, the solution of the equation,
\[
\frac{da_0^0}{dt} = Ma_z \partial_t a_y,
\] (115)
gives
\[
a_z^0(x, t) = ce^{M[a_y(t) - a_y(0)]} \text{ for } \forall x,
\] (116)
where \(c \neq 0\). Then we solve the Eq. (98) with the right hand side, we integrate for \(t > 0\), \(t \in (0, t)\) and \(-\infty < x < \infty\), we obtain a particular solution,
\[
a^\nu_z(x, t) = -\frac{q_0}{M}.
\] (117)

The general solution to the Eq. (116), we summarize (116) and (117) as
\[
a^\nu_z(x, t) = -\frac{q_0}{M} + ce^{M[a_y(t) - a_y(0)]} \text{ for } \forall x.
\] (118)

where \(c \in \mathbb{R}_1\).

Now, we put together the solution of Eq. (101), the initial value solution (111) and the previous general solution into final solution: from (117), we get \(x = g_0 t + x_0\) and we will get a singular solution,
\[
a^\nu_z(x, t) = A_0(x_0) - \frac{q_0}{M} + ce^{M[a_y(t) - a_y(0)]}
\] (119)
for \(\forall x\) and \(c \in \mathbb{R}_1\).

The final solution was solved by integrating the coupled ordinary differential Eqs. (97) and (98), the initial value problem with data \(a_z(x) = A_0(x)\) for \(t = 0\) is now modified by a constant to \(a^\nu_z(x) = A_0(x) - q_0/M\) for \(t = 0\).

Let's explicitly look at the function \(g\) and the envelope of characteristics,
\[
g(a_z, a_y) = g_0 + (g_a + g_b \nu_0)[A_0(x_0) - \frac{q_0}{M} + ce^{M[a_y(t) - a_y(0)]}] + g_a a_y,
\] (120)
and the envelope is given by
\[
1 = - (g_a + g_b \nu_0) \partial_x g(a_z, a_y) t,
\] (121)
where
\[
\partial_x g(a_z, a_y) = -\frac{1}{(g_a + g_b \nu_0)} \partial_x A_0(x_0),
\] (122)
which is equal to
\[
\partial_x A_0(x_0) = 0,
\] (123)
since \(x = g_0 t + x_0\) and \(g_0\) is a constant. Therefore again we claim that the second type of equation (111) has just exceptional waves as physically relevant solutions and the wave steepening does not take place.

The interpretation is that the source given by \(a_y\) on the right hand side of Eq. (111) is too weak to create a strong shock wave, the shock cannot be produced and is not required.

The results are in full agreement with the published literature about the exceptional waves which do not turn into shocks, [63] [64] [65], which is connected to the absence of birefringence in the Born–Infeld electrodynamics [66] [67].

J. The constant physical phase velocities

We need to determine which solution + or − corresponds to the two situations, i.e. the counter–propagating waves which interact with each other and the photon–photon scattering can happen and the co–propagating waves where the waves do interact with each other and the photon–photon scattering does not occur. We will discuss our solutions with respect to the two cases in this section and in the summary section (111).

The phase velocities originating from the first two equations (55) and (56) are the phase velocities \(v_{1.2}\). We need to evaluate the fraction \(a_y/b_y\) and then plot \(v_{1.2} = v_{1.2}(a_y/b_y)\) in the dependence on Eq.0.

Using the expression for exceptional waves (90) and (74), we obtain the fraction \(a_y/b_y\) as
\[
\frac{a_y}{b_y} = -\frac{\nu_a + \nu_0 \nu_y}{\nu_0 \nu_a},
\] (124)
which is a constant determined by two possible sets of constants.

Let's start with the case \(v_{1.2}\) and the its coefficients \(\nu_0, \nu_a, \nu_b\), to visualize \(v_{1.2} = v_{1.2}(a_y/b_y)\) [51] and determine the two cases, the counter–propagating and co–propagating case. The expression for the velocities \(v_{1.2}\) become constant using (124) as
\[
v_{1.2} = \frac{M \pm \sqrt{M^2 + 4 \alpha_0 \gamma_0}}{2 \alpha_0},
\] (125)
where \(M = (1 + \tau_0) \beta_0 + \frac{\nu_a + \nu_0 \nu_b}{\nu_0 \nu_a} \delta_0\).

Explicitly, the velocities \(v_{1.2}\) become using (124) and the two possible values of \(\nu_0^\pm [32], \nu_a^\pm [37], \nu_b^\pm [38]\) and \(\nu^\pm [39]\),
\[
v_1^\pm = \frac{M \pm \sqrt{M^2 + 4 \alpha_0 \gamma_0}}{2 \alpha_0},
\] (126)
where \(M_1 = (1 + \tau_0) \beta_0 \pm \frac{\nu_a + \nu_0 \nu_b}{\nu_0 \nu_a} \delta_0\) and the phase velocities \(v_2^\pm\) become
\[
v_2^\pm = \frac{M \mp \sqrt{M^2 + 4 \alpha_0 \gamma_0}}{2 \alpha_0},
\] (127)
where \( M_2 = (1 + \tau_0)\delta_0 + \left(\frac{\nu_0 + \nu_0\nu b_0}{\nu_0\nu a_y}\right) \pm \delta_0. \)

The phase velocity \( v_1^\pm \) and \( v_2^\pm \) are plotted in the Fig. 2 and Fig. 3. The phase velocity \( v_1^\pm \) or \( v_1^- \) seems to correspond to the counter-propagating case and \( v_2^\pm \) or \( v_2^- \) corresponds to the co-propagating case. In the graphs we have used the normalized \( E_0 \) to the Schwinger value \( E_S \), the value \( b = 10^{-3} \), to see the positive and negative values of the phase velocities. The values of the phase velocities are thus just for demonstration and we are only interested in their positive/negative values and whether they are approaching a constant value with increasing \( E_0 \).

Even though the different expressions for \( v_1^\pm \) were plotted on \( E_0 \) and have almost the same dependence on \( E_0 \) and are positive, therefore they correspond to the counter-propagating case. The same dependence might be caused by the behaviour of the fraction \( a_y/b_y \). We observe that there occur some numerical fluctuations as \( E_0 \) increases, they are consequences of the linear approximation in the coefficients we performed in our calculation.

Interestingly, lets visualize the fraction \( a_y/b_y \). We obtain the fraction \( a_y/b_y \) from the expression for exceptional waves \( \nu^{(108)} \) and the relation for \( b_y \) \( \nu^{(124)} \),

\[ \frac{a_y}{b_y} = \frac{g_{z} \pm \nu_0 g_{b_0}}{\nu_0 g_{a_y}} \]

which is determined by the constants \( g_{z} \pm \nu_0 g_{b_0} \) \( \nu^{(128)} \) and the two values of \( \nu_0 \) \( \nu^{(12)} \), \( \nu_{z}^{(17)} \), \( \nu_{b_0}^{(13)} \) and \( \nu_{a_y}^{(19)} \) \( \nu^{(19)} \).

The velocities \( v_{3,4} \) become constant using \( \nu^{(128)} \), the phase velocities \( v_3^\pm \) and \( v_4^\pm \) can have two possible values thanks to two possible values of \( \nu_0 \) \( \nu^{(12)} \), \( \nu_{z}^{(17)} \), \( \nu_{b_0}^{(13)} \) and \( \nu_{a_y}^{(19)} \) \( \nu^{(19)} \). The two possible values of \( v_3^\pm \) can be expressed as

\[ v_3^\pm = \frac{N + \sqrt{N^2 + 4\epsilon_0\xi_0}}{-2\epsilon_0}, \]

where \( N_3 = \eta_0 + \pm \left(\frac{g_{z} \pm \nu_0 g_{b_0}}{\nu_0 g_{a_y}}\right) \xi_0 \) and the velocities \( v_4^\pm \) become

\[ v_4^\pm = \frac{N - \sqrt{N^2 + 4\epsilon_0\xi_0}}{-2\epsilon_0}, \]

where \( N_4 = \eta_0 + \pm \left(\frac{g_{z} \pm \nu_0 g_{b_0}}{\nu_0 g_{a_y}}\right) \xi_0 \).

The phase velocities \( v_3^\pm \) and \( v_4^\pm \) are plotted in the Fig. 5 and Fig. 6. The phase velocity \( v_3^\pm \) and \( v_4^\pm \) seem to correspond to the co-propagating case since the values are positive. In the graphs we have used the normalized \( E_0 \) to the Schwinger value \( E_S \), the value \( b = 10^{-3} \), to see the positive and negative values of the phase velocities.
The same linear dependence might be caused by the behaviour of the fraction \( \frac{a_y}{b_y} \) which is so small that Mathematica was not able to display it. Its contribution is negligible therefore the curve remains linear.

FIG. 5: The physical phase velocity case \( v_3^\pm \). The values are negative for both cases \( v_3^\pm \).

The solutions of the second type of equations, has a form:

\[
\partial_t a_z + g_0^\pm \partial_x a_z = q \partial_t a_y, \tag{134}
\]

where the explicit expression for \( g_0 \), is

\[
g_0^\pm = -\left\{ \frac{1}{\alpha_0} (1 + \tau_0)\beta_0 + \frac{\gamma_0}{\alpha_0} \nu_0^\pm \right\}, \tag{135}
\]

and the final singular solution with \( x = g_0^\pm t + x_0 \) has a form,

\[
a_z^f(x,t) = A_0[x - g_0^\pm t] - \frac{q_0}{M} + ce^M[\alpha_0(t) - \alpha_0(0)] \tag{136}
\]

for \( \forall x \) and \( c \in \mathbb{R}_1 \), where the velocity of propagation is constant \( g_0 \) moving to along the \( x^- \)-axes. The direction of motion depends on the two solutions \( g_0 = g_0^\pm \), the solutions are both \( g_0^\pm < 0 \) and the wave moves to the left along the \( x^- \)-axes.

The final solution was solved by integrating the coupled ordinary differential Eqs. and , the initial value problem with initial data \( a_z(x) = A_0(x) \) for \( t = 0 \) is now modified by a constant to \( a_z^f(x) = A_0(x) - q_0/M \) for \( t = 0 \).

III. CONNECTION TO HEISENBERG–EULER THEORY

In this section we are going to investigate the connection of the Born–Infeld theory to the Heisenberg–Euler theory in more detail. In order to do that it is useful to demonstrate the calculation of the Heisenberg–Euler Lagrangian from the general Lagrangian, we have used the Heisenberg–Euler Lagrangian to the second order only in our previous papers [77, 78], for further comparison with the Born–Infeld Lagrangian [11].
The Heisenberg–Euler Lagrangian describing the electromagnetic field in the long-wavelength limit is given by \cite{21, 22, 80},

\[ \mathcal{L} = \mathcal{L}_0 + \mathcal{L}'_{HE}, \]  

(137)

where \( \mathcal{L}_0 = (m^4/16\pi^2)F_{\mu\nu}F^{\mu\nu} \) is the Lagrangian in classical electrodynamics, \( \alpha \) is the fine structure constant and \( m \) is the electron mass. \( F_{\mu\nu} \) is the electromagnetic field tensor \( F_{\mu\nu} = \partial_{\mu}A_{\nu} - \partial_{\nu}A_{\mu} \), \( \mu, \nu = 0, 1, 2, 3 \) and \( A_{\mu} \) is the 4-vector of the electromagnetic field and \( \mathcal{L}'_{HE} \) is the radiation correction in the Heisenberg–Euler theory.

The QED radiation corrections \( \mathcal{L}'_{HE} \) in the Heisenberg–Euler theory \cite{22} can be written as

\[ \mathcal{L}'_{HE} = \frac{m^4}{8\pi^2} \mathcal{M}(\epsilon, b) = \frac{m^4}{8\pi^2} \int_0^\infty \exp(-\eta) \times \]  

\[ \left\{ -\eta (\eta \cot \eta \epsilon)(\eta \coth \eta b) + 1 - \frac{\eta^2}{3}(\epsilon^2 - b^2) \right\} d\eta, \]  

(138)

where \( \epsilon \) and \( b \) are defined as

\[ \epsilon = \frac{|\epsilon|\hbar E}{mc^2} \quad \text{and} \quad b = \frac{|\epsilon|\hbar B}{mc^2}. \]

The parameters \( \epsilon \) and \( b \) can be rewritten in the invariant form,

\[ \epsilon = \frac{|\epsilon|\hbar}{\sqrt{2m^2c^3}} \left\{ \left( \frac{\Delta}{\gamma} + i\phi \right)^{1/2} + \left( \frac{\Delta}{\gamma} - i\phi \right)^{1/2} \right\}, \]

\[ b = \frac{|\epsilon|\hbar}{\sqrt{2m^2c^3}} \left\{ \left( \frac{\Delta}{\gamma} + i\phi \right)^{1/2} - \left( \frac{\Delta}{\gamma} - i\phi \right)^{1/2} \right\}, \]

together with the Poincaré invariants Eqs. \cite{5}, and the relation,

\[ \Delta + i\phi = \frac{1}{2}(E \pm iB)^2. \]  

(139)

The following relations are also valid for our initial choice of Eqs. \cite{5},

\[ \epsilon = \sqrt{\delta^2 + \phi^2 + \Delta} \quad \text{and} \quad b = \sqrt{\delta^2 + \phi^2 - \Delta}. \]  

(140)

Here and in the following text, and the electromagnetic field (\( \epsilon \) and \( b \)) is normalized on the QED critical field \( E_S = m^2c^3/\hbar \) and we use the units \( c = \hbar = 1 \).

The above formulae for Heisenberg–Euler Lagrangian \cite{138} can be used only for deriving the terms of the asymptotic series in powers of electric field \( \epsilon \) by formal expansion of \( \cot \epsilon \) \cite{22}. In this limit, the function \( \mathcal{M}(\epsilon, b) \) can be expanded in small arguments of \( \epsilon \) and \( b \), i.e. in weak fields \( \epsilon \ll 1, b \ll 1 \), and we obtain

\[ \mathcal{M}(\epsilon, b) = \left[ \frac{\epsilon^4 + b^4}{45} + \frac{\epsilon^2 b^2}{9} \right] + \frac{2}{45} \left[ \frac{2(\epsilon^6 - b^6)}{7} + \epsilon^2 b^2(\epsilon^2 - b^2) \right] + \ldots. \]  

(141)

When we substitute the expressions \( \epsilon \) and \( b \) \cite{140} into the \( \mathcal{L}'_{HE} \) \cite{138} and the above function \( \mathcal{M}(\epsilon, b) \) \cite{141}, the Lagrangian \( \mathcal{L'}_{HE} \) in the weak field Heisenberg–Euler approximation becomes (see also \cite{60, 91}),

\[ \mathcal{L}'_{HE} = \kappa \left[ \left( 4\delta^2 - 7\phi^2 \right) + \frac{4}{7} \phi \left( 8\delta^2 + 13\phi^2 \right) \right] + \ldots, \]  

(142)

where the constant \( \kappa \) equals \( \kappa = m^4/(45 \times 8\pi^2) \).

Expanding the Lagrangian \cite{138} in the series, we keep the terms to the third order in the field amplitude within the weak field approximation which we used in \cite{77} to describe the singular solutions. The contributions of the fourth order cancel each other in calculation of dispersive properties of the QED vaccum. The remaining contribution is of the same order as from the Heisenberg–Euler Lagrangian expansion to the sixth order in the fields. The first two terms on the right hand side in the Lagrangian \cite{138} describe four interacting photons and the last two terms correspond to six photon interaction. The field invariants \( \mathcal{F} = \mathcal{G} = 0 \) in the limit of co–propagating waves.

The Heisenberg–Euler Lagrangian \( \mathcal{L}'_{HE} \) \cite{138} can be rewritten as

\[ \mathcal{L}'_{HE} = 4p\delta^2 + q\phi^2 + \ldots, \]  

(143)

where we do not assume the third and fourth terms in \cite{138} because in experimental estimates we just need the dominant terms, and constants

\[ p = \kappa, \quad q = 7\kappa. \]  

(144)

In non–normalized units to the QED critical field \( E_S = m^2c^3/\hbar \) with use of \( c = \hbar = 1 \), the constants became

\[ p = \frac{2\alpha^2}{45m^4} \left( = \frac{2\alpha^2\hbar^6}{45mc^16} \right), \quad q = 7p, \]  

(145)

where the first two coefficients \( p \) and \( q \) agree with \cite{34}.

To compare the terms in the Heisenberg–Euler Lagrangian we need to express the Born–Infeld also in linearized form with Poincaré invariants. We assume the
fields $b^{-2}\delta$ and $b^{-4}\Omega^2$ weaker compared to the parameter $b$ following the limit from the Lagrangian to the Maxwell classical Lagrangian and perform Taylor expansion in two variables.

The Born–Infeld Lagrangian $L_{BI}$ can then be rewritten as

$$L_{BI} = -\delta + \frac{1}{2b^2}\delta^2 + \frac{1}{8b^4}\delta^4 + \ldots.$$  (146)

In the calculations we will use just the terms matching those in the Heisenberg–Euler Lagrangian to compare them. Therefore we obtain

$$L_{BI} = -\delta + \frac{1}{2b^2}\delta^2 + \ldots,$$  (147)

which we will use further. Thanks to the similar terms with the QED corrections at least in the perturbation theory, we can consider the approximation of the Born–Infeld Lagrangian together with the quantum corrections in a form of the effective Lagrangian density:

The effective Lagrangian $L_{eff}$ can be rewritten as

$$L_{eff} = L'_{HE} + L_{BI}$$  (148)

$$\simeq -\delta + \frac{1}{2\delta^2}\delta^2 + \frac{1}{\eta^2}\Omega^2,$$

and the newly defined constants,

$$\frac{1}{\delta^2} = \frac{1}{b^2} + 8p, \quad \frac{1}{\eta^2} = \frac{1}{b^2} + 2q.$$  (149)

The effective Lagrangian considers the photons below the threshold for the production of electron–positron pairs.

If the parameters $\delta \neq \eta$, the effective Lagrangian leads to birefringence, this case is natural because of the quantum corrections of Maxwell’s electrodynamics. If $\delta = \eta$, there is no birefringence as in the Born–Infeld electrodynamics. The Heisenberg–Euler Lagrangian can be obtained in the limit when $b \to \infty$. The case when $\delta$ is finite and $\eta \to \infty$ (ignoring relations) is used in the Kaluza–Klein theory with additional Gauss–Bonnet term.

It can be considered as a natural generalization of Born-Infeld electrodynamics with two different parameters $\delta$ and $\eta$, as

$$\mathcal{L} = \beta^2 \left(1 - \sqrt{1 + 2\delta^2 - \frac{\Omega^2}{\delta^2\eta^2}}\right),$$  (150)

where the Lagrangian leads to for small values of $\delta^2, \delta^2\eta^2$ This non–linear model can be considered as the effective electrodynamics theory for strong electromagnetic fields.

The model was used as an example of lack of commutativity among quantized truncated actions, in studying propagation of a linearly polarized laser beam in the external transverse magnetic field. Similar structure of Lagrangian was used in to do experimental estimates for precision tests of QED and non–standard models by searching photon–photon scattering in vacuum with PW lasers and in to study polarization effects in photon–photon scattering in Heisenberg–Euler and Born–Infeld electrodynamics.

### IV. EXPERIMENTAL DISTINGUISHING OF BORN–INFELD AND HEISENBERG–EULER THEORIES

Finally, we will discuss the possible distinguishing of the two theories Born–Infeld (and other non–standard models together with scenarios involving minicharged particles or axion-like bosons) and the Heisenberg-Euler by precision test experiments. It will be possible to fully analyze the effective Lagrangian and distinguish between QED and other models such as Born–Infeld theories at facilities such as ELI Beamlines in the near future.

We can rewrite effective Lagrangian as

$$L_{eff} \simeq -\delta + \zeta L\delta^2 + \zeta T\Omega^2,$$  (151)

and

$$\zeta L = \frac{1}{2\delta^2}, \quad \zeta T = \frac{1}{2\eta^2}.$$  (152)

By using the relations and knowing the constants $\zeta L$ (QED theory) and $\zeta T$ (Born–Infeld theory), we will be able to test and determine constants in the effective Lagrangian,

$$\kappa \simeq \frac{1}{3}(\zeta_T - \zeta_L), \quad b \simeq \frac{3}{2}(7\zeta_L - 4\zeta_T).$$  (153)

In the future experiments, we will be able to determine the precision estimates for $\zeta_T$ and $\zeta_L$, and by that estimate the QED parameter and the Born–Infeld free parameter $b$ - upper and lower bounds. In the following text, we will concentrate only on the Born–Infeld model.

#### A. The experimental estimates

When assuming the general form of the effective Lagrangian for the QED case, we identify $\zeta L^{QED} = \zeta T^{QED}$ as $\zeta$ as

$$\zeta \equiv 4\kappa = \frac{8\alpha^2}{45\pi^4} \simeq 6.7 \times 10^{-3} m^3 J.$$  (154)

When we want to identify the Born-Infeld theory, we obtain $\zeta L^{BI} = \frac{1}{4}\zeta T^{BI}$, from which we are not able to get definite prediction for the numerical value of both parameters. Previous experiments were sensitive only
to a difference $|4\zeta_T - 7\zeta_L|$ and therefore unable to set constraint on a pure Born–Infeld theory.

The search for photon–photon scattering in vacuum can be done by measuring phase shifts and ellipticities and can be used to determine both the coefficients $\zeta_L$ and $\zeta_T$. In the analytical theoretical calculation [40], they studied the scattering of orthogonally polarized (x and y directions, respectively) two counter-propagating waves which one of them represented an ultra high power beam. They derived the phase shifts,

$$\Delta \phi_L = 7\zeta_L Ik\tau, \quad \Delta \phi_T = 4\zeta_T Ik\tau,$$

(155)

where $I = \rho c$ is the intensity of the high power beam and $\tau = \Delta z/c$ is the time length. The ellipticity is a relative phase shift $\Delta \phi_b = \Delta \phi_T - \Delta \phi_L = (4\zeta_T - 7\zeta_L)Ik\tau$ between the transverse parallel polarizations of the low power beam. With the parameters for ELI Beamlines, we can achieve $I \approx 10^{23} W/cm^2$, the time length, $\tau \approx 10^{-14}s$ and wavelength $\lambda = 2\pi/k \approx 8 \times 10^{-7}m$, it gives $Ik\tau \approx 8 \times 10^{21} J/m^3$.

We have estimated such phase shift proportional to $10^{-4}$ for energy of the high power laser beam $10^{24} W/cm^2$ for the Born electrodynamics in [72], therefore we can expect $\Delta \phi_T$ to have similar proportions, see our estimate for the Born–Infeld in the next Subsection (IV.B). The sensitivity of the measurements can be done approximately till $10^{-10}$ in precision to our knowledge. Therefore ELI facility would be able to distinguish $\zeta_L$ and $\zeta_T$ small as $\zeta_L = 9 \times 10^{-31} m^3/J$ and $\zeta_T = 5 \times 10^{-31} m^3/J$ for a single crossing. The precision might increase with more crossings of the beams.

The numerical value of $b$ was determined by Born and Infeld as finite constant equal to the electromagnetic energy of the electron as

$$b = 1.2 \times 10^{20} \frac{V}{m},$$

(156)

such interpretation is not viable today, but still the value might serve as a fixed value for other comparable estimates.

Another way how to achieve relevant bound on the parameter $b$ is the low dispersion relations. In [41] they have showed that the lower experimental bound on $b$ from the QED contribution to the total absorption coefficient in the photon–photon splitting in the Born–Infeld would be close to the Born–Infeld value,

$$b \geq 2.0 \times 10^{19} \frac{V}{m},$$

(157)

where the estimate has been made by assuming just purely photonic processes without involvement of the electrostatic potential between point charges, just photon splitting in a magnetic background in QED and the Born-Infeld. The measurement of the QED refraction indices might be possible by large scale laser interferometers as LIGO, GEO or VIRGO [93] by introduction of interference in one leg by the magnetic field.

Another estimate constraining $b$ in the Born–Infeld theory from the photon–photon scattering experiment at LHC was determined in [42]. The scale $M = \sqrt{b} \geq 100$ GeV represents a lower limit on $b$ which is more than 3 orders of magnitude stronger than other lower limit [37, 41]. The two processes photon–photon scattering and photon splitting look the most promising in searching for the bound of the free Born–Infeld parameter $b$ today.

### B. The phase shift

We will use the first two equations [35] and [36] to derive the estimate for the phase shift for the Born–Infeld electrodynamics from our calculations to compare the result with the one for the Born electrodynamics, [1]. We use the equations with linearized coefficients with $a_z = a_y = b_y = 0$ as when we derived the phase velocities in Section (III.B). We need to find the small amplitude wave shift $b_y - a_z$ which is given by

$$u(x,t) = u_0 \left[ x \left( 1 + \frac{E_0^2}{b^2} \frac{1}{C} \right) - t \left( 1 - \frac{E_0^2}{b^2} \frac{1}{C} \right) \right],$$

(158)

where we have used the light cone coordinates $x_+, x_-$, and constant $C$ [37] is derived in Appendix A. We have neglected the terms of the order higher than $E_0^2$ in coefficients in front of $\partial_x a_z$ and approximated the coefficient in front of $\partial_y b_y$ as $1 - \frac{E_0^2}{b^2} C$ and neglected the term $\partial_y b_y$ to obtain the estimate for the phase shift.

We have expressed the variables $u, v$ as

$$x_+ = \frac{1}{\sqrt{2}}(x + t), \quad u = \frac{1}{\sqrt{2}}(b_y - a_z),$$

$$x_- = \frac{1}{\sqrt{2}}(x - t), \quad w = \frac{1}{\sqrt{2}}(a_z + b_y).$$

(159)

We rewrite the Eq. [35] in the light cone coordinates as $w, v = \partial_x u$,

$$w(x,t) = -\sqrt{2} \frac{E_0^2}{b^2} \frac{1}{C} u_0 \left[ x \left( 1 + \frac{E_0^2}{b^2} \frac{1}{C} \right) - t \left( 1 - \frac{E_0^2}{b^2} \frac{1}{C} \right) \right] + w_0(x + t),$$

(160)

which corresponds to the summation of $b_y + a_z$.

The functions $u_0$ and $w_0$ are determined by the initial conditions in Eqs. [158, 160]. Since we have $u(x,t)$ then we also observe the phase shift $\psi(x,t)$,

$$\psi(x,t) = \frac{1}{\sqrt{2}} \left[ x \left( 1 + \frac{E_0^2}{b^2} \frac{1}{C} \right) - t \left( 1 - \frac{E_0^2}{b^2} \frac{1}{C} \right) \right].$$

(161)

We can rewrite it using the phase $\phi$ as

$$\psi(x,t) = \frac{1 + \frac{E_0^2}{b^2} \frac{1}{C}}{\sqrt{2}} \phi(x,t),$$

(162)

where the phase $\phi$ is given by

$$\phi(x,t) = x - t \frac{1 - \frac{E_0^2}{b^2} \frac{1}{C}}{1 + \frac{E_0^2}{b^2} \frac{1}{C}}.$$

(163)
The phase should be time-independent \( d\phi/dt = 0 \), therefore

\[
\frac{d\phi}{dt} = \frac{1 - \frac{E_0^2}{b^2 C}}{1 + \frac{E_0^2}{b^2 C}}.
\]

(164)

When we measure the phase difference between the phase of the electromagnetic pulse colliding with the counter-propagating wave and the phase of the pulse which does not interact with high intensity wave, it is then equal to

\[
\Delta \psi = 4\pi d \frac{1}{\lambda} \frac{E_0^2}{b^2} \frac{1}{C} = 4\pi d \frac{1}{\lambda} \frac{1}{b^2} \frac{E_0^2}{C} \left( 1 - \frac{E_0^2}{b^2} \right),
\]

(165)

where \( \lambda \) is the wavelength of high frequency pulse, \( d \) is the interaction length. The phase shift plays a central role in discussion of experimental verification of the QED vacuum birefringence \cite{54,94}. The phase shift is slightly modified for the Born–Infeld electrodynamics compared to the phase shift for the Born electrodynamics by the factor \( 1/C = 1/(1 + E_0^2/b^2) \) originating from the square root in the Born–Infeld Lagrangian \cite{53} with \( G \neq 0 \). Importantly, we observe that the phase shift for Born–Infeld is bigger than the phase shift for the Born electrodynamics.

We will estimate the expression (165) for the following values: The 10 PW laser can generate the radiation intensity as high as \( 10^{24} \) W/cm\(^2\), which is \( E_0^2 \approx 10^{-5} \). We take the ratio equal to \( d/\lambda \approx 10^4 \), i.e. equal to the ratio between the optical and x-ray radiation wavelength. And we use for \( 1/b^2 \) estimate that \( 1/b^2 = 8\kappa = 2e_2 \approx 10^{-4} \), see \cite{77,43} and \cite{34}. After we perform the Taylor expansion in \( E_0^2/b^2 \) in (165), we obtain,

\[
\Delta \psi = 4\pi d \frac{1}{\lambda b^2} \frac{E_0^2}{b^2} \left( 1 + \frac{E_0^2}{2b^4} \right),
\]

(166)

and we find that \( \psi \sim 10^{-4} + 10^{-13} \approx 10^{-4} \). It gives effectively the same result as for the Born electrodynamics. The estimate of order \( 10^{-13} \) is out of range of todays experimental sensitivity which is around \( 10^{-10} \), therefore we can neglect it in our estimation.

### C. The cross section

In our previous papers \cite{77,78}, we proposed an experiment for direct detection of the photon–photon scattering by detecting the gamma-rays coming from the electron-positron pair formation in the secondary processes generated on the shock wave fronts. Such experiment might be able us to study also the Born–Infeld (BSM) contribution to the process.

Our previous calculation were performed in the Heisenberg–Euler electrodynamics in the low energy photon approximation \( \omega \ll m \), here, we would like to draw some conclusions about the situation in the Born–Infeld electrodynamics. The approximation is not valid for high velocity processes, therefore after the shock wave fronts are created we can only assume and estimate the processes. Our results are therefore limited to this low energy regime and they are losing validity if we approach the Swinger limit \( E_5 \). At the shock wave fronts produced by the the photon–photon scattering the real electron–positron pairs via Breit–Wheeler process \cite{95} can be created thanks to the saturation of wave steepening and the electromagnetic shock wave formation. By reaching the energies for the electron–positron generation we require much less intense laser intensities than by reaching directly the Schwinger field \( E_S \). Therefore we might be able to achieve necessary intensities \( I \approx 10^{22} \) W/cm\(^2\) in the near future at laser facilities as ELI Beamlines.

In the Born–Infeld, the shock wave fronts are not being developed but the exceptional waves contribute to the outgoing radiation either. The contribution is visible from the explicit cross–section for the photon–photon scattering.

In \cite{41,44}, the low energy cross section for the photon-photon scattering process in Born–Infeld and Heisenberg–Euler approximation (QED) was presented for unpolarized initial states with summation over final polarizations, i.e. for the effective Lagrangian \cite{118}, it becomes

\[
\sigma_{\gamma\gamma} = \left( \frac{1}{64b^4} + \frac{11\alpha^2}{720b^2m^4} + \frac{139\alpha^4}{32400m^8} \right) \frac{\omega^6}{\pi^2} \left( 3 + \cos^2 \theta \right)^2,
\]

(167)

where the parameters in the expressions are the scattering angle \( \theta \) and the photon frequency \( \omega \), the \( m \) and \( \alpha \).

We observe that the additional terms with the free Born–Infeld parameter \( b \) in the formulae suggests the additive character of the photon–photon process in the Born–Infeld electrodynamics. It can be interpreted as a contribution from the beyond standard model (BSM) particles.

According to the cross section formula \cite{167}, we can expect that the cross section \( \sigma_{\gamma\gamma \rightarrow e^-e^+} \) will include additive terms with the parameter \( b \) (to our knowledge such cross section was not published in the known literature). Therefore we might expect a contribution to the electron–positron pair production from the BSM physics, in our case from the Born–Infeld part, and contribution to the subsequent emission of the gamma-ray photons leading to the electron-positron avalanche thanks to the multiphoton Breit-Wheeler mechanism \cite{96}. It would be interesting to investigate also contributions from other non–standard models together with scenarios involving minicharged particles or axion-like bosons in BSM physics.
V. CONCLUSION

To conclude, we have studied two counter-propagating waves in the Born–Infeld electrodynamics for the case $\varphi^2 \neq 0$, i.e. problem describing the finite amplitude electromagnetic wave counter-propagating to the crossed electromagnetic field. The study was motivated by our previous work on photon–photon scattering in vacuum, in the Heisenberg–Euler theory. It is a continuation of our previous study of a problem for the crossed field case $E \cdot B = 0$, i.e. $\varphi^2 = 0$, which is identical for both the Born and the Born–Infeld electrodynamics. We have analyzed the direction of propagation of the Born–Infeld Lagrangian, we have generalized the setup to have $E \cdot B \neq 0$ for the calculation. We have assumed the most simplest and at the same time still useful ansatz we could use for our calculation and solve the field equations. The setup is thus rather mathematical but was very convenient for our task to study the physics: to solve the field equations, study the absence of the shock wave development in the Born–Infeld and discuss its contribution to the outgoing radiation in the proposed experiment, the direct detection of the photon–photon scattering. The setup with four components without simplifications would be technically much more difficult and probably unsolvable by the self–similar solution method we wanted to use.

We have solved the Born–Infeld field equations analytically by assuming the solution in the self–similar form, as in our previous work [77, 78]. We added the weak linear amplitude corrections and linearized the coefficients to study the singularity formation. We have obtained set of three equations for two variables $a_\nu(x, t)$ and $b_\nu(x, t)$ together with a free given function $a_y(t)$. We have further analyzed the equations by the method of characteristics which enabled us to discuss the possible shock wave development. The set of equations consists of two types of equations, first one is the non–linear wave equation and the second is the non–linear wave equations with right hand side. The equations contain information about the ordinary and also newly about the extraordinary wave in the vacuum. The first type of equation corresponds to the ordinary wave, the second type with $a_\nu$ on the right hand side corresponds to the extraordinary wave. The waves propagate in the same direction thanks to the absence of birefringence in the Born–Infeld electrodynamics but with different velocities.

The solutions have a form of a non–linear wave without dispersion in the linear approximation and the only physically relevant solutions are the exceptional waves which do not turn into shocks.

By analysing the shock wave development by the method of characteristics we have found the following properties. In the first type of equation we have showed that the requirement on the phase velocities to be constant (physically relevant) causes that the only relevant solutions of the equation are the exceptional waves, which have a rarefaction character. The rarefaction character as the direction of motion agrees with our results for Heisenberg–Euler theory [77, 78] and Born theory [1]. We were looking for physical phase velocities, we observed that we need to find constant fraction of $a_y/a_0$ to make the phase velocities constant. We were able to find this fraction by looking at the exceptional waves in our solutions and by setting the free function $a_y$. Therefore we can claim that the first equation [65] has just exceptional waves as physically relevant solutions and the wave steepening does not take place in this case.

The second type of equation with the right hand side $\partial_0 a_\nu$ also gives just exceptional waves as solutions. We showed that the only shock wave which exists in the Born–Infeld is the one given as the initial condition and it just propagates further. The interpretation is that the source given by $a_y$ on the right hand side of Eq. [64] in a form of a step function [117] is too weak to create a strong shock wave, shock cannot be produced and is not required [88].

The results are in full agreement with the published literature about the exceptional waves which do not turn into shocks [63, 65, 84], which is connected to the absence of birefringence in the Born–Infeld electrodynamics [66, 82].

We have analyzed and plotted the phase velocities and we have identified their cases of propagation. The phase velocities originating from the first two equations [65] and [66] are the phase velocities $v_{1,2}^\pm$. The phase velocities $v_3^\pm$ and $v_4^\pm$ are plotted in the Fig. 2 and Fig. 3. The phase velocities $v_1^\pm$ seem to correspond to the counter-propagating case and the phase velocities $v_3^\pm$ corresponds to the co–propagating case. The phase velocities $v_3^\pm$ originate from the first and the third equations [85] and [87]. The phase velocities $v_3^\pm$ and $v_4^\pm$ in the Fig. 3 and Fig. 6. The phase velocity $v_3^\pm$ and $v_4^\pm$ seem to correspond to the co–propagating case since the values are negative.

We have analyzed the direction of propagation of the exceptional solutions. The solution of the first type of equation, [65], where the velocity of propagation is constant $-1/v_0$, its direction of motion is given by the two solutions for $\nu_0 = \nu_0^\pm$. We observed that $\nu_0^+ > 0$ has positive values, therefore the wave moves to the right along the $x$ axes and corresponds to the counter–propagating case of the two beams, $\nu_0^- < 0$ negative values, therefore the wave moves to the left along the $x$ axes and corresponds to the co–propagating case of the two beams.

The solutions of the second type of equations, [84], their direction of motion depends on the two solutions $\nu_0 = \nu_0^\pm$, then the solutions $g_{\nu_0^\pm} < 0$ and the wave moves
to the left along the $x-$axes.

We have also presented explicit derivation of the Heisenberg–Euler Lagrangian in the weak field approximation from the full Heisenberg–Euler Lagrangian. We have showed that the Born–Infeld Lagrangian has similar linear structure in linear and quadratic terms $F^2$ and $G^2$, therefore it was possible to define so called generalized Born–Infeld electrodynamics based on effective Lagrangian which combines the two Lagrangians, which is very useful in deriving experimental estimates for precision test of QED and non-standard models. It was used in the search of photon–photon scattering in vacuum using PW lasers and also to study polarization effects in photon–photon scattering in the Heisenberg–Euler and Born–Infeld electrodynamics. We presented such derivation together with the estimates because we have not seen it in literature in a consistent way.

There is an interest in the possible distinguishing of the two theories Born–Infeld (and other non–standard models together with scenarios involving minicharged particles or axion-like bosons) and the Heisenberg–Euler by precision test experiments using the effective Lagrangian. We derive consistently the coefficients in the effective Lagrangian, $\zeta_L$ for the QED theory and $\zeta_T$ for the Born–Infeld theory, which need to be determined by the experiments. We review the known suggested experiments and we discuss in detail current opportunity presented by the PW laser facilities, which will enable the detection of the two parameters separately, which was not possible before, and thus give precise values for the above mentioned constants and enable the distinguishing of the theories. The measurement is based on the measuring the phase shifts and the ellipticities of the colliding laser beams, such measurement could be done with high precision today at PW laser facilities such as ELI Beamlines or ZEUS facility at DESY. We have presented estimated values for measurement with PW lasers at ELI Beamlines facility. Alternatively, the measurement of the QED refraction indices might be possible by large scale laser interferometers as LIGO, GEO or VIRGO.

The measurement of the $\zeta_T$ for the Born–Infeld theory will give the long time missing determination of the free Born–Infeld constant. In the introduction, we have reviewed all the possible experiments and fields in which such measurement was proposed and the value $b$ was estimated as an above bound or lower bound. Still the assumption that the numerical value of $b$ should be close to the finite value of the electromagnetic energy of electron is true.

Such studies are important from the fundamental physics point of view. The Heisenberg–Euler electrodynamics (QED) is considered to reflect the reality of our world better than the alternative nonlinear Born–Infeld electrodynamics. In the classical vacuum, the classical Born–Infeld electrodynamics with point charges is well-defined and does not have the UV–divergence problems as the Heisenberg–Euler QED in the quantum vacuum. The Born–Infeld quantisation occurs to not exist at moment and even if it exists the quantization might not be UV–divergence free and might not be able to explain all the electromagnetic phenomena. The measurement of the free Born–Infeld parameter $b$ would enable us to distinguish the right electrodynamics theory and to move the theoretical research further by cutting our the theories which are not correct. Let us mention that it would help to distinguish other non–standard models together with scenarios involving minicharged particles or axion-like bosons in BSM physics, possibly open the door to a new physics.

The importance of the investigation shows also the recent study from the photon–photon scattering experiment at LHC [42]. The process of photon–photon scattering is the most promising process to study today in order to receive some answers on fundamental question addressed in particle theoretical physics alongside with the photon splitting, especially in looking for the numerical value of the free Born–Infeld parameter $b$.

We investigated the numerical estimate for the phase shift from the first two field equations in our problem for the Born–Infeld electrodynamics. The phase shift is modified and is smaller for the Born–Infeld electrodynamics compared to the phase shift for the Born electrodynamics by the factor $1/C = 1/(1 + E^2_0/b^2)$ originating from the square root in the Born–Infeld Lagrangian with $G \neq 0$. We have estimated the phase shift $\psi \approx 10^{-4}$ effectively while neglecting the contribution lower than the $10^{-10}$ experimental sensitivity level for the 10 PW laser generating the intensity high as $10^{24}W/cm^2$. We have obtained effectively the same phase shift as for the Born electrodynamics.

We have reviewed the cross section for the photon–photon scattering in Born–Infeld electrodynamics. The cross section for the low energy photon–photon scattering in the Born–Infeld and QED contains the additional terms with the free Born–Infeld parameter $b$ which signifies the additive character of the photon–photon process in the Born–Infeld electrodynamics and can be seen as a contribution from the beyond standard model (BSM) particles. Similarly to the cross section, we can expect that the cross section $\sigma_{\gamma\gamma \rightarrow e^- e^+}$ will include additive terms with the parameter $b$. Therefore we might expect a contribution to the electron–positron pair production from the BSM physics, in our case from the Born–Infeld part, and contribution to the subsequent emission of the gamma-ray photons leading to the electron-positron avalanche thanks to the multiphoton Breit–Wheeler mechanism [94].

In other words, we can say that our recent proposal of the direct detection of the photon–photon scattering might be used to study the contributions from the BSM physics (presented by the Born–Infeld electrodynamics) and also we might get new experimental estimates for the parameters in QED and other non–standard models together with scenarios involving minicharged particles or axion-like bosons in BSM physics.
Appendix A: The coefficients for the background radiation

The coefficients $\alpha_0, \beta_0, \gamma_0, \delta_0, \epsilon_0, \zeta_0, \eta_0, \theta_0, \iota_0, \lambda_0$ have a form, after we assumed $a_y = a_z = b_y = 0$ and the crossed field condition $B_0 = E_0$,

$$\alpha_0 = 1 + \frac{E_0^2}{b^2} \frac{1}{C},$$
$$\beta_0 = \frac{1}{b^2} \frac{E_0^2}{C},$$
$$\gamma_0 = \left(1 - \frac{1}{b^2} E_0^2\right) - \frac{E_0^2 \left(1 - \frac{1}{b^2} E_0^2\right)^2 + \frac{1}{b^2} E_0^4}{b^2 C},$$
$$\delta_0 = \frac{1}{b^2} \frac{E_0^2}{C},$$

and the coefficients in the second set of field equations,

$$\epsilon_0 = \frac{1}{b^2} E_0^2 \frac{\left(1 + \frac{1}{b^2} E_0^2\right)}{C},$$
$$\zeta_0 = \frac{E_0^2}{b^2} \left(1 - \frac{E_0^2 \left(1 - \frac{1}{b^2} E_0^2\right)}{b^2 C}\right),$$
$$\eta_0 = -\frac{E_0^2}{b^2} \left(2 - \frac{\left(1 - \frac{1}{b^2} E_0^2\right) \left(1 + \frac{1}{b^2} E_0^2\right)}{C}\right),$$

and the coefficients in the last field equation,

$$\theta_0 = \frac{E_0^2}{b^2} \alpha_0,$$
$$\iota_0 = \left(1 + \frac{1}{b^2} E_0^2\right) + \frac{1}{b^2} E_0^2 \frac{\left(1 - \frac{1}{b^2} E_0^2\right) \left(1 + \frac{1}{b^2} E_0^2\right)}{C},$$
$$\tau_0 = 1 - \frac{E_0^2}{b^2},$$

where

$$C = 1 - \frac{E_0^4}{b^4}. \quad (A4)$$

Appendix B: The coefficients for the case 1 and 2

We obtained two cases for $\left(\frac{db_y}{da_z}\right)_{1,2}$ which have a form, (41) and (43):

$$\left(\frac{db_y}{da_z}\right)_{1,2} = -N \pm \sqrt{N^2 - 4\alpha(\delta \zeta + \iota \gamma)(\iota - \iota \delta / \alpha)\frac{2(\delta \zeta + \iota \gamma)}{2(\delta \zeta + \iota \gamma)}}, \quad (B1)$$

where

$$N = \left[\delta (\eta + \theta) - \iota \beta^2 (1 + \tau)\right].$$
The parameters for the ± solution are the following:

\[
\nu_0^\pm = \left(b^4 B^2 \left(2b^6 E_{10}^0 - b^4 E_{10}^0 - 2b^2 E_{10}^{10} + E_{10}^{12} + b^4 E_{0}^4 B + E_{0}^4 B^2 \pm B^4 T\right)\right) / 2B^3 A, \quad (B2)
\]

where

\[
A = b^{12} - 2b^{10} E_{10}^0 - 4b^8 E_{10}^4 + 6b^6 E_{0}^6 + 7b^4 E_{0}^8 - 2b^2 E_{0}^{10} - 2E_{0}^{12}, \quad (B3)
\]

\[
B = b^4 - b^2 E_{0}^2 - E_{0}^4, \quad (B4)
\]

\[
D = -4b^{30} + 12b^{28} E_{0}^2 + 36b^{26} E_{0}^4 - 104b^{24} E_{0}^6 - 152b^{22} E_{0}^8 + 352b^{20} E_{0}^{10} + 429b^{18} E_{0}^{12} - 618b^{16} E_{0}^{14} - 743b^{14} E_{0}^{16} + 536b^{12} E_{0}^{18}
\]

\[
+ 724b^{10} E_{0}^{20} - 168b^{8} E_{0}^{22} - 348b^6 E_{0}^{24} - 24b^4 E_{0}^{26} + 64b^2 E_{0}^{28} + 16 E_{0}^{30}, \quad (B5)
\]

\[
T = \sqrt{1/b^8 B^6} D. \quad (B6)
\]

The parameters \(\nu_{a_x}^\pm\) are:

\[
\nu_{a_x}^\pm = \left(\mp 4b^{42} E_{0}^0 \mp 80b^2 E_{0}^{41} \pm 16E_{0}^{43} \pm b^{24} E_{0}^{19}(3065 \mp 632T) \pm 2b^{16} E_{0}^{27}(1898 \mp 159T) \pm 2b^{32} E_{0}^{11}(354 \pm 61T)
\]

\[
\pm 2b^{38} E_{0}^{0}(1 \mp 10T) \pm b^{2} E_{10}^{2} (27 \mp 2T) + 2b^{36} E_{0}^{3} (\mp 95 + T) \pm 8b^4 E_{0}^{39} (\pm 3 + T) \pm b^{2} E_{0}^{6}(\mp 78 + T)
\]

\[
+ 2b^{40} E_{0}^{3}(\pm 11 + 2T) + 4b^{2} E_{0}^{13}(\mp 553 + 23T) + 14b^{20} E_{0}^{23}(\mp 289 + 40T) + 2b^{10} E_{0}^{33}(\mp 324 + 83T) + b^4 E_{0}^{3}(\pm 174 + 127T)
\]

\[
+ b^6 E_{0}^{13}(892 \mp 321T) + b^{2} E_{0}^{29}(432 \mp 361T) + b^{2} E_{0}^{15}(\mp 1725 + 416T) + b^2 E_{0}^{17}(\mp 2282 + 453T)
\]

\[
+ b^4 E_{0}^{15}(\pm 2489 + 481T) + b^2 E_{0}^{21}(3325 \mp 493T) / 2B^5 A^2 T, \quad (B7)
\]

the parameters \(\nu_{b_y}^\pm\) are:

\[
\nu_{b_y}^\pm = \left(\mp 4b^{42} E_{0}^0 \mp 72b^2 E_{0}^{41} \pm 16 E_{0}^{43} \pm b^{22} E_{0}^{21}(8689 \pm 1667T) \pm b^{24} E_{0}^{39}(6632 \pm 513T) \pm 2b^{24} E_{0}^{19}(3495 \mp 382T)
\]

\[
\pm 2b^{30} E_{0}^{13}(1306 \mp 337T) \pm 2b^{16} E_{0}^{27}(1190 \mp 73T) \pm 4b^{12} E_{0}^{31}(40 \mp 21T) \pm b^{2} E_{0}^{11}(23 \mp 5T) \pm 8b^4 E_{0}^{9}(\mp 2 + T)
\]

\[
\pm b^8 E_{0}^{3}(1 \mp 11 + T) + 2b^{38} E_{0}^{3}(1 \mp 11 + 2T) + b^{30} E_{0}^{3}(\mp 1006 + 5T) + 4b^6 E_{0}^{27}(\mp 132 + 37T) + 4b^6 E_{0}^{27}(\mp 132 + 37T)
\]

\[
+ 2b^{36} E_{0}^{2}(\mp 31 + 12T) + 2b^{38} E_{0}^{5}(5 \mp 12T) + 3b^2 E_{0}^{15}(\mp 511 + 44T) + 2b^{20} E_{0}^{23}(\mp 2211 + 245T)
\]

\[
+ b^6 E_{0}^{17}(\mp 4392 + 1063T) + b^4 E_{0}^{25}(\mp 10091 + 1355T) / 2B^5 A^2 T, \quad (B8)
\]

the parameters \(\nu_{a_y}^\pm\) are:

\[
\nu_{a_y}^\pm = \left(\mp 2b^{44} E_{0}^0 \pm 84b^2 E_{0}^{41} \mp 92b^4 E_{0}^{31} \mp 96b^2 E_{0}^{43} \pm 16E_{0}^{45} \mp 21b^{14} E_{0}^{31}(45 \mp 46T) + 8b^{28} E_{0}^{7}(\mp 7 + T)
\]

\[

\]

Appendix C: The coefficients for the function \(g(a_x, b_y, a_y)\)

The coefficient in the linearized form of \(g(a_x, a_y)\),

\[
g(a_x, a_y) = g_0 + g_0 a_x + g_0 b_y + g_0 a_y, \quad (C1)
\]

have a form:

\[
g_0 = \left\{ \frac{1}{\alpha_0}(1 + \tau_0)\beta_0 + \frac{\gamma_0}{\alpha_0} \nu_0^\pm \right\}, \quad (C2)
\]
and

\[ g_{a z}^\pm = \frac{\alpha_a}{\alpha_0} (\beta_0 + \gamma_0 \nu_0^\pm + \beta_0 \tau_0) - \frac{1}{\alpha_0} (\beta_{a z} + \gamma_{a z} \nu_0^\pm + \beta_{a z} \tau_0 + \beta_0 \tau_{a z}), \]
\[ g_{b y}^\pm = \frac{1}{\alpha_0} \left[ -2\alpha_a \alpha_{a z} (\beta_0 + \gamma_0 \nu_0^\pm + \beta_0 \tau_0) + \alpha_0 \alpha_{a z} (\beta_{a y} + \gamma_{a y} \nu_0^\pm + \gamma_0 \nu_{a y}^\pm + \beta_{a y} \tau_0 + \beta_0 \tau_{a y}) \right. \]
\[ \left. + \alpha_0 \alpha_{a z} (\beta_{a z} + \gamma_{a z} \nu_0^\pm + \gamma_0 \nu_{a z}^\pm + \beta_{a z} \tau_0 + \beta_0 \tau_{a z}) - \alpha_0^2 (\gamma_{a z} \nu_0^\pm + \gamma_{a z} \nu_{a z}^\pm + \beta_{a z} \tau_{a z} + \beta_{a z} \tau_{a z}) \right], \tag{C3} \]
\[ g_{a y}^\pm = \frac{1}{\alpha_0} \left\{ \alpha_0 \left( -2\alpha_a \alpha_{a z} (\beta_{b y} + \gamma_{b y} \nu_0^\pm + \gamma_0 \nu_{b y}^\pm + \beta_{b y} \tau_0 + \beta_0 \tau_{b y}) + \alpha_0 \alpha_{a z} (\gamma_{a y} \nu_{b y}^\pm + \gamma_{b y} \nu_{a y}^\pm + \beta_{a y} \tau_{b y} + \beta_{b y} \tau_{a y}) \right. \right. \]
\[ \left. + \alpha_0 \alpha_{a z} (\gamma_{a z} \nu_{b y}^\pm + \gamma_{b y} \nu_{a z}^\pm + \beta_{a z} \tau_{b y} + \beta_{b y} \tau_{a z}) \right) \right. \]
\[ + \alpha_0 \left( 6\alpha_a \alpha_{a z} (\beta_0 + \gamma_0 \nu_0^\pm + \beta_0 \tau_0) - 2\alpha_0 \alpha_{a z} (\beta_{a z} + \gamma_{a z} \nu_0^\pm + \gamma_0 \nu_{a z}^\pm + \beta_{a z} \tau_0 + \beta_0 \tau_{a z}) \right. \]
\[ \left. + \alpha_0 (-2\alpha_a (\beta_{a y} + \gamma_{a y} \nu_0^\pm + \gamma_0 \nu_{a y}^\pm + \beta_{a y} \tau_{a y}) + \alpha_0 (\gamma_{a z} \nu_{a y}^\pm + \gamma_{a y} \nu_{a z}^\pm + \beta_{a y} \tau_{a z} + \beta_{a z} \tau_{a z})) \right) \right\}. \]

**Appendix D: The coefficients for the function** $q(a_z, b_y, a_z)$

The coefficient in the linearized form of $q(a_z, a_y)$,

\[ q(a_z, a_y) = q_0 + a_z a_z + b_y b_y + a_y a_y, \tag{D1} \]

have a form:

\[ q_0 = -\frac{\delta_0}{\alpha_0}, \tag{D2} \]

and

\[ a_z = \frac{1}{\alpha_0} \left( \frac{\alpha_{a z} \delta_0}{\alpha_0} - \delta_{a z} \right), \]
\[ b_y = \frac{1}{\alpha_0} \left( -2\alpha_b \alpha_{a z} \frac{\delta_0}{\alpha_0} + \alpha_{a z} \delta_{b y} + \alpha_{b y} \delta_{a z} \right), \]
\[ a_y = \frac{1}{\alpha_0} \left[ 2\alpha_b \alpha_{a y} (3\alpha_{a y} \frac{\delta_0}{\alpha_0} - \delta_{a y}) - 2\alpha_a (\alpha_{a y} \delta_{b y} + \alpha_{b y} \delta_{a y}) \right]. \tag{D3} \]

**ACKNOWLEDGMENTS**

H. K. wishes to thank: prof. I. Bialynicki-Birula for pointing my attention to the beauty of the original Born–Infeld paper; Dr. T. Pecháček for reading the manuscript; prof. S. Bulanov for discussions; prof. G. Gregori for pointing our attention to the corrected version of the paper about PVLAS experiment.

ACKNOWLEDGMENTS

The work was supported by the project High Field Initiative (CZ.02.1.01/0.0/0.0/15_003/0000449) from European Regional Development Fund. H. K. was supported by the fellowship (award) Czech edition of L’Oréal UNESCO For Women In Science 2019.
