## ABSTRACT

Effective decision-making for crisis mitigation increasingly relies on visualisation of large amounts of data. While interactive dashboards are more informative than static visualisations, their development is far more time-demanding and requires a range of technical and financial capabilities. There are few open-source libraries available, which is blocking contributions from low-resource environments and impeding rapid crisis responses. To address these limitations, we present *SeismographAPI*, an open-source library for visualising temporal-spatial crisis data on the country- and sub-country level in two use cases – *Conflict Monitoring Map* and *Pandemic Monitoring Map*. The library provides easy-to-use data connectors, broad functionality, clear documentation and run time-efficiency.

## CCS CONCEPTS

• **Human-centered computing** → Visualization toolkits; • **Information systems** → Spatial-temporal systems.

## KEYWORDS

Open-Source Software, Human-Centred Data Visualisation  
KDD Workshop on Data-driven Humanitarian Mapping

## 1 INTRODUCTION

For mitigating large-scale crises such as armed conflicts, pandemics and natural disasters, incorporation of data in decision-making is becoming indispensable [1, 3, 7, 10, 13]. However, insights from large amounts of data remain untapped if they are not detected and communicated by means of intuitive, accurate and preferably interactive scientific visualisation [5, 8]. Particularly, the development of interactive visualisation dashboards requires a broad skill set, ranging from statistical, design and programming knowledge to domain expertise [6]. Academic environments, non-governmental and humanitarian aid organisations often lack the required resources which hinders urgently needed contributions. The demand for quick crisis responses stands in stark contrast to time-consuming, expensive development stages. *SeismographAPI* is an actively maintained, open-source library for the visualisation of temporal-spatial crisis data that combines plug-and-play visualisations with versatile functionality.

## 2 EXEMPLARY USE CASES

*SeismographAPI* is designed for data analysts to identify patterns in rapid prototyping. Due to its run time and memory-efficiency, it can also be deployed as a permanent visualisation tool for use by

\*Both authors contributed equally to this work.

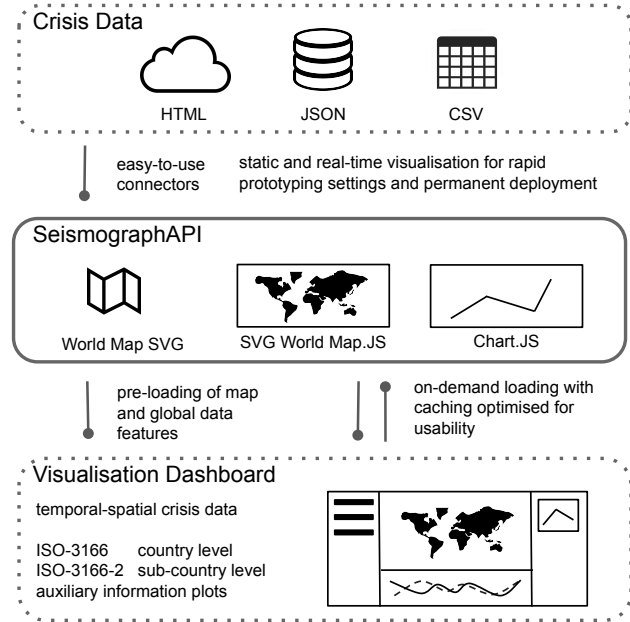

Figure 1: Technical overview of *SeismographAPI*

decision-makers. To motivate and demonstrate *SeismographAPI*, we sketch out two practical use cases that are inspired by real-world visualisation needs [2, 4, 7, 11, 13].

**Conflict Monitoring.** With the help of *SeismographAPI*, we visualise a huge dataset comprising 20 years of conflict data on 141 countries, constructed from *ACLED* [9] and *UCDP GED* [12] data. Per country and month, our dataset features 60 socio-economic and political indicators, which are all displayed in our *Conflict Monitoring Map*.

**Pandemic Monitoring.** Our second demonstration case is the *Pandemic Monitoring Map*, a visualisation of *COVID-19* infection numbers. The data is borrowed from Johns Hopkins University [2].

## 3 MAIN FUNCTIONALITY

**World Map (center).** The SVG Choropleth map represents the core part of *SeismographAPI*. It allows visualising data at the country- and subcountry-level (political subdivisions) based on the *ISO-3166* and *ISO-3166-2* norm. Additional information, such as country-level infection numbers, can be easily displayed on click and hover as exemplified in the *Pandemic Monitoring Map*.

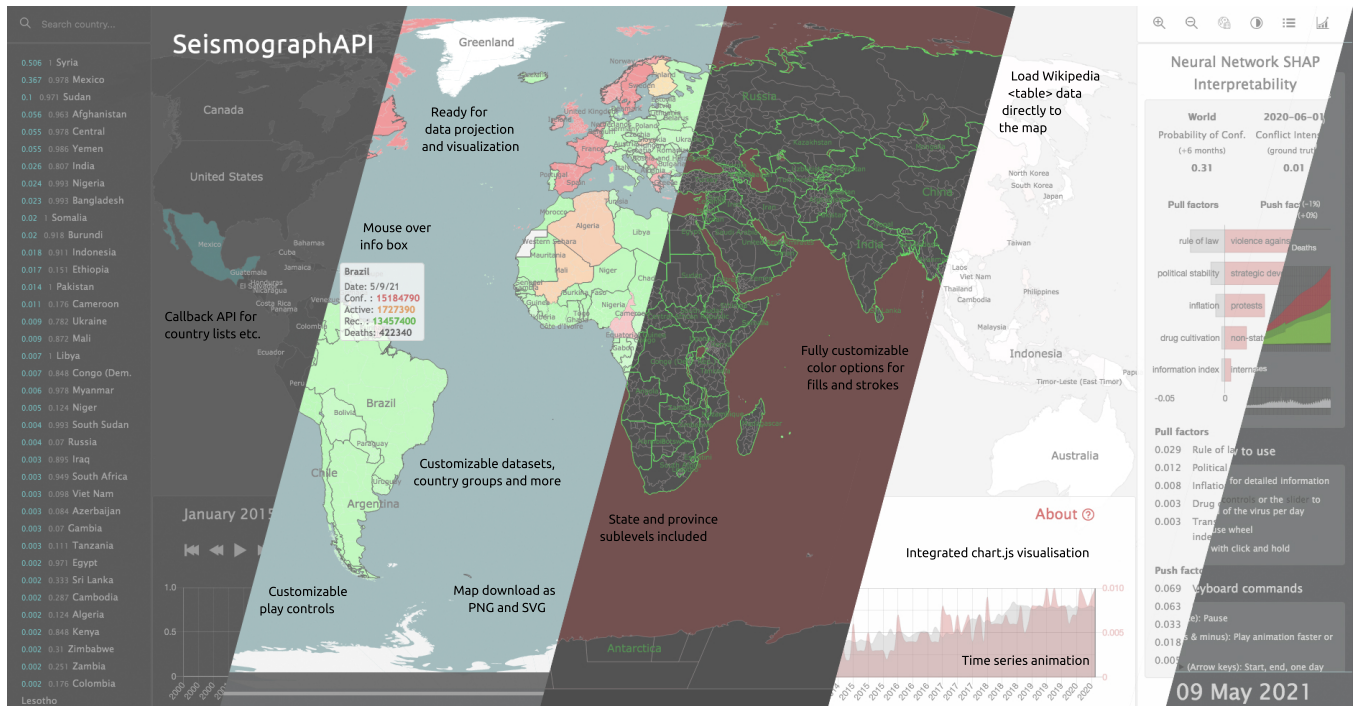

Figure 2: *Conflict Monitoring Map* and *Pandemic Monitoring Map*: two exemplary use cases of the *SeismographAPI*

**Time Series Chart (bottom).** The time series chart not only visualises, but allows navigating the temporal dimension. For instance, the *Conflict Monitoring Map* even features two time lines, one showing the prediction and another showing the ground truth conflict intensity. When hovering or clicking a point in time, all other panels synchronise. With the help of the “play” controls, users can watch all data panels as they change over time in a time-machine manner.

**Auxiliary Information Panel (right).** At the top of the auxiliary information panel, our library provides a menu allowing to interactively customise the dashboard. Users can hide information and panels, such as country names and the country list on the left hand side, zoom-in, choose a night mode and open a “help” window. To simplify the interface between analysis, report and decision-making, the library has built-in functionality for screen recording. Due to tight integration with *Chart.js*, any chart visualisation can be selected and displayed in the right-hand panel based on data suitability and information needs. For instance, the *Conflict Monitoring Map* displays the most important data features considered for conflict prediction as a horizontal bar chart. The *Pandemic Monitoring Map* relies on stacked line charts to map out infection numbers.

## 4 TECHNICAL BACKGROUND

**Run time and Memory.** *SeismographAPI* builds upon two fast, open-source libraries, *Chart.js* and *SVG World Map JS*. The time required for data loading is mainly determined by the size of the central SVG world map: ~1,3 MB for ISO-3166-2 country-level and ~3,8 MB including all subdivision data. Depending on the chosen

map, rendering starts between 300ms and 800ms, document completion is done between 400ms and 2.6s and the full loading time varies from ~3s to ~10s. To optimise loading and usability, *SeismographAPI* can also be initialised asynchronously with the JavaScript *async/await/resolve* method. After the first initialisation of the map, this enables loading data chunks on demand, which increases smoothness. This is demonstrated in the *Conflict Monitoring Map*, where all global conflict data (~1,1MB) is loaded at startup, but the large amount of detailed conflict data (~80KB per country, ~21MB in total) is loaded asynchronously on request. Thus, *SeismographAPI* is able to visualise more than  $N = 170,000$  data points in the *Conflict Monitoring Map* in about 3 seconds or nearly  $N = 400,000$  data points in the *Pandemic Monitoring Map* in about 10 seconds.

**Ease of Use.** With an intuitive interface and simple data connectors, *SeismographAPI* is designed for ease of use in common visualisation tasks and workflows. Data can be loaded directly via JSON, CSV or as an HTML table. We even offer a *Pandas* extension to load *Pandas Dataframes* (as JSON) and *Wikipedia tables*. The library features clear readme instructions and rich documentation.

## 5 CONCLUSION

Future versions will include more data connectors, default charts, more detailed guidelines for deployment and options for switching between different data within one map. We presented *SeismographAPI*, an open-source library aimed at reducing resource constraints and easing swift data visualisation, thereby improving data-driven decision-making for humanitarian purposes.
