(Dated: July 30, 2021)

We give a complete classification of fully symmetric as well as chiral $Z_2$ quantum spin liquids on the pyrochlore lattice using a projective symmetry group analysis of Schwinger boson mean-field states. We find 50 independent ansätze, including the 12 fully symmetric nearest-neighbor $Z_2$ spin liquids that have been classified by Liu et al. [Phys. Rev. B 100, 075125 (2019)]. For each class we specify the most general symmetry-allowed mean-field Hamiltonian. Additionally, we test the properties of a subset of the spin liquid ansätze by solving the mean-field equations for the spin-$1/2$ XXZ model near the antiferromagnetic Heisenberg point. We find that the ansatz with the lowest energy at mean-field level is a chiral spin liquid that breaks the screw symmetry of the lattice modulo time reversal symmetry. This state has a different symmetry than the previously studied monopole flux state. Moreover, this chiral spin liquid state has a substantially lower energy than all other symmetric spin liquid states, suggesting that it could be a stable ground state beyond the mean-field approximation employed in this work.

I. INTRODUCTION

Quantum spin liquids are phases of frustrated magnets which do not exhibit long-range magnetic order down to zero temperature and cannot be classified based on Landau’s theory of spontaneous symmetry breaking. In contrast to trivial paramagnetic phases, they exhibit topological order1 with long range entanglement and excitations that carry fractional quantum numbers and can have anyonic exchange statistics2.

A promising platform to study such exotic forms of quantum magnetism are materials where the interplay between electronic correlations and strong spin-orbit coupling gives rise to spin-orbital moments interacting via frustrated exchange interactions3,4. The 3d rare-earth pyrochlore magnets are an interesting family of frustrated quantum magnets in this class. They have the structure $R_2M_2O_7$, with $R$ a trivalent rare-earth ion and $M$ a non-magnetic tetravalent transition metal ion. The former
are arranged on a pyrochlore lattice, which consists of corner-sharing tetrahedra. For a subclass of these materials the strong spin-orbit coupling together with the crystal field splitting of the 4f orbitals leads to a \( j = 1/2 \) doublet\(^4\). The small effective spin and the geometrically frustrated pyrochlore lattice enhance spin fluctuations and suppress magnetic ordering in these systems. Prominent examples include \( Yb_2Ti_2O_7 \) and \( Tb_2Ti_2O_7 \), which show interesting paramagnetic behavior down to very low temperatures and potentially realize an exotic quantum spin-ice phase\(^5\)–\(^9\), where the spin dynamics is strongly constrained, following the “two in, two out” ice rule on each tetrahedron. Their low energy properties are described by compact \( U(1) \) gauge theories, which feature magnetic monopole excitations\(^10\). While the microscopic details of these materials are rather complex, their low-energy physics is governed by effective spin-1/2 moments, coupled by various symmetry-allowed exchange interactions. Minimal models exhibit dominant Heisenberg interactions, often with an easy axis exchange anisotropy\(^10\).

In this work we study the spin-1/2 nearest-neighbor XXZ Hamiltonian on the pyrochlore lattice as a minimal model for the description of the above mentioned quantum spin-ice phases. Since quantitatively reliable numerical methods to study frustrated quantum magnets in three dimensions for large system sizes are not available, several properties of its phase diagram are still under debate.

So far, most attention has been focused at the quantum spin-ice phase in the vicinity of the classical Ising limit, where antiferromagnetic easy-axis interactions dominate and transverse exchange interactions are small. Recent studies also found a nematic spin liquid for strong antiferromagnetic transverse exchange interactions, which breaks the \( U(1) \) spin rotation symmetry of the XXZ Hamiltonian in the easy-plane, as well as the \( C_3 \) rotation symmetry of the pyrochlore lattice\(^11\),\(^12\). The nature of the ground-state in the vicinity of the \( SU(2) \) symmetric Heisenberg point is still unclear, however. Various possible ground states have been suggested, including dimer-ordered\(^13\)–\(^18\) and symmetric spin liquid states\(^19\),\(^20\), as well as chiral spin liquid states\(^21\),\(^22\), which break time reversal symmetry.

In this work we use a projective symmetry group (PSG) approach together with a Schwinger boson representation of the spin operators to provide a complete classification of symmetric as well chiral \( Z_2 \) spin liquid states on the pyrochlore lattice. Here, chiral \( Z_2 \) spin liquids are gapped spin liquids which break time-reversal symmetry. Moreover, lattice symmetries can be broken up to a time reversal transformation. For the PSG construction of chiral spin liquid states we follow the work of Messio \textit{et al.}\(^23\). As a byproduct we recover the fully symmetric \( Z_2 \) spin liquids previously classified by Liu \textit{et al.}\(^24\). In order to characterize the newly constructed chiral ansätze we use Schwinger boson mean-field theory (SBMFT) and solve the mean-field equations to compare their ground-state energies. Furthermore, we calculate static spin structure factors to characterize spin correlations in these states.

The outline of the paper is as follows: In Sec. \textit{II} we introduce the local XXZ model and develop a general mean-field decoupling in terms of bond operators within SBMFT. In Sec. \textit{III} we use PSG to systematically classify symmetric and chiral mean-field ansätze. The detailed calculations can be found in Appendix \textit{D} and \textit{E}. After choosing reasonable ansätze (Sec. \textit{IV}) we diagonalize the Hamiltonian and calculate free energies in Sec. \textit{V}. In Sec. \textit{VI} we calculate equal-time spin structure factors. Finally, we discuss our results in Sec. \textit{VII}.

\section{Model and Methods}

\subsection{Pyrochlore lattice}

The lattice is spanned by the FCC-basis vectors \( \mathbf{a}_1 = \frac{1}{2}(0,1,1), \mathbf{a}_2 = \frac{1}{2}(1,0,1), \mathbf{a}_3 = \frac{1}{2}(1,1,0) \) and has four sublattices. We will include the zero vector as a fourth lattice vector for later convenience: \( \mathbf{a}_0 = (0,0,0) \). Also, for easier use of symmetries, we introduce the sublattice

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure1.png}
\caption{(Color online). (a): A unit cell of the pyrochlore lattice. nearest-neighbor sites are connected by bonds. Blue bonds (main tetrahedron) are within a unit cell and red bonds (inverse tetrahedron) are between neighboring unit cells. (b): The local spin basis of the inverse tetrahedron (A1). (c): The enlarged unit cell consisting of eight tetrahedra.}
\end{figure}
coordinates:
\[ r_\mu = (r_1, r_2, r_3)_\mu := r_1 a_1 + r_2 a_2 + r_3 a_3 + \frac{1}{2} a_\mu, \]
\[ = \frac{1}{2} (r_2 + r_3, r_1 + r_2, r_1 + r_3) + \frac{1}{2} a_\mu. \]
We will refer to the tetrahedra spanned by \( \{ r_\mu : \mu = 0, 1, 2, 3 \} \) and \( \{ r_\mu - a_\mu : \mu = 0, 1, 2, 3 \} \) as the main and inverse tetrahedron, respectively, and label them with \( r \).

The spin operators in the local basis are defined as:
\[ \hat{S}_{r_\mu} = (\hat{S}^x, \hat{S}^y, \hat{S}^z)_\mu = \hat{S}^x_{r_\mu} s^x_\mu + \hat{S}^y_{r_\mu} s^y_\mu + \hat{S}^z_{r_\mu} s^z_\mu. \]
The local basis vectors \( s^\mu_i \) are defined in Appendix A. The space group of the lattice is \( Fd\beta m \) (No.227) which we will later refer to as \( \chi \). It is generated by the translations \( T_i \) along the lattice vectors, a sixfold roto-reflection \( C_6 \) around the \( s^3_0 \) axis and a screw operation \( S \) around the \( a_3 \) axis.\(^{24}\) The roto-reflection can be constructed by inversion \( I \) and \( C_3 \) rotation around the \( s^3_0 \) axis: \( C_6 = C_3 I \).

We denote time reversal symmetry as \( T \). In Appendix A we list how the sublattice coordinates and local spin basis transforms under symmetries of the space group as well as the algebraic group relations.

**B. Model and Schwinger-boson mean-field theory**

The XXZ model is given by the following Hamiltonian:
\[ H = \sum_{\langle i,j \rangle} J_{ij} (\hat{S}^x_i \hat{S}^x_j + \hat{S}^y_i \hat{S}^y_j) + J_{zz} \hat{S}^z_i \hat{S}^z_j, \]
where \( \hat{S}^\gamma_i \) is the \( \gamma \in \{ x, y, z \} \) component of the spin-1/2 operator on lattice site \( i \) in the local basis and the sums run over nearest-neighbor bonds on the pyrochlore lattice. For \( J_{zz} = J_\perp \) the model reduces to the Heisenberg model in the local spin basis, which is the Klein dual of the Heisenberg model in the global spin basis.\(^{25}\) This will later enable us to compare results from both models. We use the parametrization
\[ J_{zz} = J \cos (\theta), \quad J_{\perp} = J \sin (\theta), \]
and set \( J = \sqrt{J_{zz}^2 + J_{\perp}^2} = 1 \). The spin operators can be represented in terms of Schwinger bosons
\[ \hat{S}^\gamma_i = \frac{1}{2} \hat{b}^\dagger_i \sigma^\gamma \hat{b}_i, \]
where \( \hat{b}^\dagger = (\hat{b}^\dagger_{i,\alpha}, \hat{b}^\dagger_{i,\downarrow}) \) are bosonic creation operators satisfying \( [\hat{b}^\dagger_{i,\alpha}, \hat{b}^\dagger_{j,\beta}] = \delta_{ij} \delta_{\alpha,\beta} \) and \( \sigma^m \) are the Pauli matrices. The Schwinger representation is invariant under U(1) gauge transformations
\[ G : \hat{b}_i \rightarrow e^{i \phi \alpha} \hat{b}^\dagger_i, \]
with \( \phi \alpha \) a lattice site dependent phase. To ensure that the operators in Eq. (5) obey the spin algebra we have to constrain the boson density per site to \( 2S \)
\[ \hat{n}_i = \hat{b}^\dagger_i \hat{b}_i = 2S. \]
This projection can be achieved by adding a site-dependent Lagrange multiplier \( \sum_i \lambda_i (\hat{n}_i - 2S) \) to the Hamiltonian.

At this point it is possible to decouple the Hamiltonian in terms of the hopping singlet \( \hat{B}_{ij} \) and triplet \( i^{\hat{b}_{ij}} \) as well as pairing singlet \( \hat{A}_{ij} \) and triplet \( i^{\hat{p}_{ij}} \) operators
\[ \hat{B}_{ij} = \frac{1}{2} \hat{b}^\dagger_i b_j, \quad \hat{A}_{ij} = \frac{1}{2} b_i (i \sigma^2) b_j, \]
with \( \gamma \in \{ x, y, z \} \) by using the identities
\[ \hat{S} \hat{S} = : \hat{B}_{ij} \hat{B}_{ij} : - \hat{A}_{ij} \hat{A}_{ij}, \]
where \( : \) denotes normal ordering. We arrive at a Hamiltonian of the form
\[ H = \sum_{\langle i,j \rangle} \hat{h}_{ij}(J^h_{ij} \hat{h}_{ij} + \hat{p}_{ij} J^p_{ij} \hat{p}_{ij} + C_{ij} + \lambda_i (\hat{n}_i - 2S), \]
where \( \hat{h}_{ij} = (\hat{B}_{ij}, \hat{p}_{ij}^{\hat{b}_{ij}}, \hat{p}_{ij}^{\hat{h}_{ij}}) \) and \( \hat{p}_{ij} = (\hat{A}_{ij}, \hat{p}_{ij}^{\hat{b}_{ij}}, \hat{p}_{ij}^{\hat{h}_{ij}}, \hat{p}_{ij}^{\hat{p}_{ij}}) \) are vectors of the hopping and pairing operators. \( J^h_{ij} \) and \( J^p_{ij} \) are the hopping and pairing coupling matrices that depend on \( J_{ij} \) and \( C_{ij} \) is a constant.
On an empty lattice \( |0 \rangle \) that satisfies \( \hat{b}_{i,\uparrow} |0 \rangle = \hat{b}_{i,\downarrow} |0 \rangle = 0 \) for all \( i \), \( \hat{A}_{ij} \) creates a spin singlet between sites \( i \) and \( j \). \( \hat{p}_{ij}^{\gamma} \) creates a spin triplet with direction \( \gamma \) between sites \( i \) and \( j \). The hopping operator \( \hat{B}_{ij} \) moves these singlet or triplet from the sites \( i \) and \( j \) to site \( i \) and \( k \):
\[ \hat{B}_{ij} \hat{A}_{ij} |0 \rangle \sim \hat{A}_{ik} |0 \rangle. \]
Finally, the triplet hopping operators also move the spin singlets and triplets around while simultaneously changing their flavor. For example:
\[ \hat{p}_{ik}^{\hat{b}_{ij}} \hat{A}_{ij} |0 \rangle \sim \hat{p}_{ik}^{\hat{h}_{ij}} |0 \rangle \text{ or } \hat{p}_{ik}^{\hat{p}_{ij}} |0 \rangle \sim \hat{p}_{ik}^{\hat{p}_{ij}} |0 \rangle. \]
Note, that the decoupling is not unique since for \( i \neq j \):
\[ \hat{B}_{ij} \hat{B}_{ij} : + \hat{A}_{ij} \hat{A}_{ij} = : \hat{p}_{ij}^{\hat{b}_{ij}} \hat{p}_{ij}^{\hat{h}_{ij}} : + \hat{p}_{ij}^{\hat{h}_{ij}} \hat{p}_{ij}^{\hat{b}_{ij}} = \frac{1}{4} \hat{n}_i \hat{n}_j = S^2, \]
where in the last equality we explicitly used the boson density constraint from Eq. (7). It is therefore possible to set either \( J^h_{ij} \) or \( J^p_{ij} \) to zero and only describe the system in terms of hopping or pairing terms. However, once we apply the mean-field approximation our choice of parametrization greatly effects our results. A theory with \( J^h_{ij} = 0 \) can only describe magnetically ordered states while a theory with \( J^p_{ij} = 0 \) has been shown to lead to quantitatively worse results for ground-state energy and dynamical spin structure factor.\(^{27,28}\)
We therefore choose to keep both terms. Another operator identity is:
\[ \hat{A}_{ij} \hat{A}_{ij} = -\hat{p}_{ij}^x \hat{p}_{ij}^x - \hat{p}_{ij}^y \hat{p}_{ij}^y - \hat{p}_{ij}^z \hat{p}_{ij}^z + 2S^2. \]  

We deal with this ambiguity by choosing parametrizations that preserve the SU(2) symmetry at the Heisenberg point explicitly (see Sec. IV).

To treat the parameterized Hamiltonian (10) we make two standard approximations. Firstly, we consider only a site independent Lagrange multiplier \( \lambda_i = \lambda \). This results in the boson density constraint (7) being fulfilled only on average. Secondly, we apply a mean-field approximation:

\[ \hat{h}_{ij}^h J_{ij}^h \hat{h}_{ij} \approx \hat{h}_{ij}^h J_{ij}^h \hat{h}_{ij} + h_{ij}^h J_{ij}^h \hat{h}_{ij} - h_{ij}^h J_{ij}^h \hat{h}_{ij}, \]  

\[ \hat{p}_{ij}^a J_{ij}^a \hat{p}_{ij} \approx \hat{p}_{ij}^a J_{ij}^a \hat{p}_{ij} + p_{ij}^a J_{ij}^a \hat{p}_{ij} - p_{ij}^a J_{ij}^a \hat{p}_{ij}, \]  

where

\[ h_{ij}^h = \langle \hat{h}_{ij} \rangle = (E_{ij}^{h \pm}, h_{ij}^{h z}, h_{ij}^{h y}, t_{ij}^{h z}), \]  

\[ p_{ij}^a = \langle \hat{p}_{ij} \rangle = (A_{ij}^{a \pm}, t_{ij}^{a \pm}, p_{ij}^{a y}, p_{ij}^{a z}). \]  

This leaves us with a Hamiltonian that is quadratic in boson operators
\[
H = \sum_{<i,j>} \hat{b}_{i}^\dagger u_{ij}^{\ \dagger} \hat{b}_{j} + \hat{b}_{i}^\dagger u_{ij}^{\ \dagger} \hat{b}_{j} + \text{h.c.} + f(h_{ij}, p_{ij}) \\
+ \lambda \sum_{i} \langle \hat{b}_{i}^\dagger \hat{b}_{i} - 2S \rangle.
\]

Here, \( f \) is given by
\[
f(h_{ij}, p_{ij}) = -h_{ij}^h J_{ij}^h h_{ij} - p_{ij}^a J_{ij}^a p_{ij} + C_{ij},
\]

where \( C_{ij} \) is constant while \( u_{ij}^{\ ^{\dagger}h} \) and \( u_{ij}^{\ ^{\dagger}p} \) are complex \( 2 \times 2 \) matrices defined by

\[
u_{ij}^{h} = \frac{1}{2} \sum_{m=0}^{3} i^{-\delta_{m,0}} (h_{ij}^h J_{ij}^h)^m \sigma^m
\]
\[
\equiv a_{ij}^h \sigma^0 + i(b_{ij}^h \sigma^1 + c_{ij}^h \sigma^2 + d_{ij}^h \sigma^3) \]  

\[
u_{ij}^{p} = \frac{1}{2} \sum_{m=0}^{3} i^{-\delta_{m,0}} (J_{ij}^p p_{ij}^a)^m \sigma^m(i\sigma^2) \]  

\[
\equiv a_{ij}^p i\sigma^2 + i(b_{ij}^p \sigma^1 + c_{ij}^p \sigma^2 + d_{ij}^p \sigma^3)i\sigma^2) \]

\[
\equiv (a_{ij}^p, b_{ij}^p, c_{ij}^p, d_{ij}^p).
\]

This notation is adapted from Liu et al.\cite{Liu:2022} and is particularly helpful, since \( a_{ij}^h \) and \( a_{ij}^p \) transform as scalars while \( (b_{ij}^h, c_{ij}^h, d_{ij}^h) \) and \( (b_{ij}^p, c_{ij}^p, d_{ij}^p) \) transform as \( SO(3) \) vectors. The parameters \( a_{ij}^h, \ldots, d_{ij}^p \) are functions of the mean-fields \( h_{ij} \) and the coupling matrix \( J_{ij}^p \) and appear as prefactors to the operators \( \hat{B}_{ij}, \ldots, h_{ij}^h \) in the Hamiltonian. Similarly the parameters \( a_{ij}^{h}, \ldots, d_{ij}^{p} \) are functions of the mean-fields \( p_{ij}^a \) and the coupling matrix \( J_{ij}^p \) and appear as prefactors to the operators \( \hat{A}_{ij}, \ldots, p_{ij}^a \) in the Hamiltonian. When exchanging \( i \leftrightarrow j \) the matrices \( u_{ij}^h, u_{ij}^p \) transform like \( u_{ij}^h = (u_{ij}^h)^T \) and \( u_{ij}^p = (u_{ij}^p)^T \) and the parameters transform like \( (a_{ij}^h, b_{ij}^h, c_{ij}^h, d_{ij}^h) = (a_{ij}^h, -b_{ij}^h, -c_{ij}^h, -d_{ij}^h) \) and \( (a_{ij}^p, b_{ij}^p, c_{ij}^p, d_{ij}^p) = (-a_{ij}^p, b_{ij}^p, c_{ij}^p, d_{ij}^p) \). The set of matrices \( u_{ij}^h \) and \( u_{ij}^p \) or rather the set of expectation values \( h_{ij} \) and \( p_{ij} \) are known as the mean-field ansatz.

The Hamiltonian (15) is the most general nearest-neighbor mean-field Hamiltonian. To investigate spin liquid states in the XXZ model we have to choose a mean-field decoupling of the model Hamiltonian (3) which fixes \( J_{ij}^h, J_{ij}^p \) and \( C_{ij} \) and an ansatz which fixes \( h_{ij} \) and \( p_{ij} \).

Once an ansatz is chosen the mean-field Hamiltonian (15) can be diagonalized by a Bogoliubov transform, a ground state can be constructed and the values of \( h_{ij} \) and \( p_{ij} \) have to be solved self consistently:
\[
h_{ij} = \langle \hat{h}_{ij} \rangle, \quad p_{ij} = \langle \hat{p}_{ij} \rangle, \quad 2S = \frac{1}{N} \sum_i \langle \hat{n}_i \rangle.
\]

### III. MEAN-FIELD ANSÄTZE

Motivated by the chiral spin liquid states found by Burnell et al.\cite{Burnell:2021} and Kim et al.\cite{Kim:2022} using a fermionic parton construction, we consider general chiral ansätze that fulfill all lattice symmetries modulo time reversal. We classify all possible ansätze with the PSG method introduced by Wen\cite{Wen:1991} for fermionic partons and later generalized by Wang and Vishvanath to Schwinger bosons\cite{Wang:2008} to symmetric spin liquids. In particular, we follow the strategy from Messio et al.\cite{Messio:2021}, who generalized the bosonic PSG to chiral ansätze where time reversal symmetry and lattice symmetries modulo time reversal are broken. Due to the U(1) gauge symmetry of the Schwinger boson representation (5) the mean-field ansatz does not have to be strictly symmetric under all lattice symmetries \( O \) but can in general be symmetric under the gauge enriched lattice symmetries \( \hat{O} \):
\[
\hat{O} = G_O : \hat{b}_i \rightarrow e^{i \phi_O(i)} U_O^\dagger \hat{b}_O(i).
\]

The set of gauge inequivalent phases \( \phi_O[i] \) are defined by the algebraic PSG. The gauge transformations \( G_O \) are elements of the so called Invariant Gauge Group (IGG). Since the pyrochlore lattice is not bipartite and we are interested in ansätze with both hopping and pairing terms we have to consider an IGG of \( \mathbb{Z}_2 \). Before classifying the chiral ansätze it is useful to first revisit the fully symmetric ansätze classified by Liu et al.\cite{Liu:2022}.
A. Symmetric ansätze

Fully symmetric ansätze can be constructed by fixing 
\( u_{0,0}^{i} = (a^{h}, b^{h}, c^{h}, d^{h}) \) and 
\( u_{0,0}^{p} = (a^{p}, b^{p}, c^{p}, d^{p}) \) on the bond \( 0_{0} \rightarrow 0_{1} \) and then mapping them onto all other bonds by symmetry operations:

\[
\begin{align*}
\phi_{O}(i;j) = U_{O} U_{I} U_{I}^{\dagger} e^{-i(\phi_{O}[i]-\phi_{O}[j])}, \quad (20a) \\
\phi_{P}(i;j) = U_{O} U_{I} U_{I}^{\dagger} e^{-i(\phi_{O}[i]+\phi_{O}[j])}, \quad (20b)
\end{align*}
\]

\( U_{O} \) are the \( SU(2) \) matrices associated with the symmetry operations \( O \) (Appendix C). The algebraic PSG has been solved by Liu et al.\textsuperscript{24}. They found 16 different \( Z_{2} \) PSG equivalent classes defined by the phases:

\[
\begin{align*}
\phi_{T_{1}}(\mu) = & 0, \quad (21a) \\
\phi_{T_{2}}(\mu) = & n_{1} \pi r_{1}, \quad (21b) \\
\phi_{T_{3}}(\mu) = & n_{1} \pi (r_{1} + r_{2}), \quad (21c) \\
\phi_{T_{4}}(\mu) = & 0, \quad (21d) \\
\phi_{T_{5}}(\mu) = & \delta_{\mu,1,2,3}(n_{ST_{1}} - n_{1}) \pi - r_{1} \delta_{\mu,2,3} n_{1} \pi \\
& - r_{2} n_{C_{6}T_{1}} \pi - r_{3} \delta_{\mu,2} n_{1} \pi \\
& - n_{1} \pi (r_{1} r_{2} + r_{1} r_{3}), \quad (21f)
\end{align*}
\]

where \( n_{1}, n_{ST_{1}}, n_{C_{6}T_{1}}, n_{C_{6}} \) are all \( Z_{2} \) parameters that are either 0 or 1. The ansätze will be labeled by \( n_{1} \pi - (n_{C_{6}T_{1}} n_{ST_{1}} n_{C_{6}}) \). When \( n_{1} = 1 \), translation symmetry is realized projectively and the unit cell is enlarged. Depending on the PSG equivalence class the ansatz forces some of the mean-field parameters \( a^{h}, b^{h}, c^{h}, d^{h}, a^{p}, b^{p}, c^{p}, d^{p} \) to be zero. Liu et al.\textsuperscript{24} give a table of all independent non-zero parameters in the local spin basis. We are, however, interested in the local basis. We transform their solution to the local spin basis by

\[
(a_{l}^{h}, b_{l}^{h}, c_{l}^{h}, d_{l}^{h})^{h} = U_{0}(a_{g}^{h}, b_{g}^{h}, c_{g}^{h}, d_{g}^{h}) U_{1}^{\dagger},
\]

where the subscripts \( l \) and \( g \) are for "local" and "global" respectively. The matrices \( U_{\mu} \) are the \( SU(2) \) matrices corresponding to the transformation from global to local spin basis on sublattice \( \mu \). They are specified in Appendix C. Eq. (22) gives us explicitly

\[
\begin{align*}
a_{l} &= -b_{g}, \quad (23a) \\
b_{l} &= \frac{1}{\sqrt{6}}(-2a_{g} + c_{g} - d_{g}), \quad (23b) \\
c_{l} &= \frac{1}{\sqrt{2}}(c_{g} + d_{g}), \quad (23c) \\
d_{l} &= \frac{1}{\sqrt{3}}(a_{g} + c_{g} - d_{g}), \quad (23d)
\end{align*}
\]

Based on Eq. (23) we can translate their solution into Table I. It lists all independent non zero nearest-neighbor parameters. We use the parameters \( n_{1} - n_{C_{6}T_{1}} n_{ST_{1}} n_{C_{6}} \) to label the states while Liu et al. use \( n_{1} - (n_{C_{6}T_{1}} n_{ST_{1}} n_{C_{6}}) \), where \( n_{C_{6}T_{1}} = n_{1} + n_{ST_{1}} + n_{C_{6}} \). The four classes \( (001n_{C_{6}}) \) have an accidental IGG of \( U(1) \) at nearest-neighbor level, since they don't allow any non-zero nearest-neighbor pairing fields. Therefore, one can construct 12 different fully symmetric \( Z_{2} \) spin liquid ansätze at nearest-neighbor level.

Table I. All independent non-zero nearest-neighbor mean-field parameters for the 16 different \( Z_{2} \) PSG equivalence classes in the local spin basis. Fields are fixed on bond \( 0_{0} \rightarrow 0_{1} \). All other nearest-neighbor parameters are constrained to be zero. The table is translated from Liu et al.\textsuperscript{24} (Table II) by using Eq. (23).

B. Chiral ansätze

Chiral spin liquids break time reversal symmetry and some lattice symmetries modulo a global spin flip (action of time reversal symmetry)\textsuperscript{23}. In the classical limit \( S \rightarrow \infty \) they correspond to non-coplanar spin states (i.e., they have non zero scalar spin chirality \( \langle \hat{S}_{i} \cdot (\hat{S}_{j} \times \hat{S}_{k}) \rangle \neq 0 \). To construct a chiral ansatz we start by defining a parity \( \epsilon_{O} \) for each symmetry operator \( O \in \chi \) in the lattice space group \( \chi = Fd3m \). \( \epsilon_{O} = 1 \) when an ansatz respects the symmetry and it is \( \epsilon_{O} = -1 \) when it only respects the ansatz modulo a time reversal. Let us define the subgroup \( \chi_{c} \) of all lattice symmetries that necessarily have even parity \( \epsilon_{O} = 1 \) and and the set of operators with undetermined parity as \( \chi_{a} = (\chi - \chi_{c}) \). \( \chi_{c} \) contains at least all squares of symmetry operators \( T_{1}^{2}, T_{2}^{2}, T_{3}^{2}, S^{2}, C_{6}^{2} = \hat{I}^{2} C_{2}^{2} = C_{3}^{-1} \) since their parities are \( \epsilon_{O} = (\pm 1)^{2} = 1 \). We can translate the algebraic group relations (Eq. (B3)) into equations for the parity to find more generators of \( \chi_{c} \). The nontrivial equations are:

\[
\begin{align*}
\epsilon_{ST_{1}} &= 1, \quad (24a) \\
\epsilon_{C_{3}T_{1}} &= \epsilon_{T_{1}+1} \epsilon_{C_{3}}. \quad (24b)
\end{align*}
\]

Eq. (24a) shows that \( T_{2} \) has even parity. Therefore, Eq. (24b) implies that this is also true for \( T_{1} \) and \( T_{2} \). The parities of \( C_{6} \) and \( S \) stay undetermined. This concludes the analysis following Messio et al.\textsuperscript{23}. We are, however, still missing one generator of \( \chi_{c} \). In general, once generators of even and undetermined parity are
found by inspecting the generators of the full symmetry group $\chi$, we also have to consider operators of the form $O_o^{-1} O_x O_o$ where $O_o \in \chi_o$ and $O_x \in \chi_e$. This can be repeated until no new generators of $\chi_e$ are found. With this approach we can construct the symmetry operator $C_3^a := ISCS IS = S^{-1} C_3 S$ which has even parity $e_{C_3} = s_3^a s_3^c = 1$. $C_3^a$ is a $\frac{2\pi}{3}$ rotation about the $s_3^a$ axis on the inverse tetrahedron. Since $C_3^a$ cannot be written as a product of the operators $\{I, T_1, T_2, T_3, C_3\}$ we have to add it to the set of generators. $I C_3^a = C_3$ gives no new generator and therefore $\chi_e$ is generated by $\{T_1, T_2, T_3, C_3, C_3^a\}$ while $\bar{\Omega}_6, S \in \chi_o$. The algebraic relations of $\chi_e$ are

\[
T_i T_{i+1}^{-1} T_{i+1}^{-1} = 1, \quad (25a)
\]

\[
C_3^3 = 1, \quad (25b)
\]

\[
C_3^a = 1, \quad (25c)
\]

\[
(C_3 C_3^a)^2 = 1, \quad (25d)
\]

\[
C_3 T_1 C_3 T_1^{-1} = 1, \quad (25e)
\]

\[
C_3^a T_1 (C_3 C_3^a)^{-1} T_1^{-1} = 1, \quad (25f)
\]

\[
C_3 T_2 (C_3 C_3^a)^{-1} T_2^{-1} = 1, \quad (25g)
\]

\[
C_3 C_3^a T_3 (C_3 C_3^a)^{-1} T_3^{-1} = 1, \quad (25h)
\]

where $i = i + 3$. The chiral algebraic PSG is then defined as the algebraic PSG of $\chi_e$. We solve the chiral algebraic PSG in Appendix D. The phases are given by:

\[
\phi_{T_1}[p_k] = 0, \quad (26a)
\]

\[
\phi_{T_2}[p_k] = n_1 \pi n_1, \quad (26b)
\]

\[
\phi_{T_3}[p_k] = n_1 \pi (r_1 + r_2), \quad (26c)
\]

\[
\phi_{C_3}[p_k] = \frac{2\pi}{3} \delta_{\mu,0} + n_1 \pi (r_1 r_2 + r_1 r_3), \quad (26d)
\]

\[
\phi_{C_3^a}[p_k] = -\frac{2\pi}{3} \delta_{\mu,3}
\]

\[
+ \left( \frac{2\pi}{3} + n_1 n_3 C_3^a + n_1 C_3^a T_3 \right) \left( \delta_{\mu,0} + \delta_{\mu,2} \right) \pi
\]

\[
+ r_1 \pi n_1 r_2 + r_3 \pi r_3 - \frac{1}{2} n_1 + n_1 \pi r_1 r_2
\]

\[
+ r_2 \pi (r_2 - r_3 - \frac{1}{2} n_1 + n_1 C_3^a T_2), \quad (26e)
\]

where $\xi \in \{-1, 0, 1\}$, $n_1, n_3, n_{3C_3^a}, n_{3C_3^a T_3} \in \{0, 1\}$. $n_1$ once again determines the size of the unit cell.

The next step is to find all compatible ansätze. Since elements of $\chi_e$ cannot map between main and inverse tetrahedra but from one bond on one main tetrahedron to every other bond on any main tetrahedron we have two independent bonds: One on a main and one on an inverse tetrahedron. We choose the bonds $0_1 (0_0 \to 0_1)$ and $0_1 (0_0 \to 0_1 - a_1)$. We label the mean-field parameters $(a_1^h, b_1^h, c_1^h, d_1^h)$ on bond 01 and $(a_2^p, b_2^p, c_2^p, d_2^p)$ on bond $0_1 0_1$ with $\xi \in \{h, p\}$. With Eqs. (20) the mean-field parameters of all other bonds can be calculated. The chiral ansätze can break $T$, $I$ and $S$ while satisfying $TI$ and $TS$. Therefore, the mean-field parameters are complex numbers in general: $a_1^h \to a_1^h e^{i\phi_{a_1^h}}, \ldots, a_i^p \to a_i^p e^{-i\phi_{a_i^p}}, \ldots$, where $a_1^h, \ldots, a_i^p, \ldots \in \mathbb{R}$. The different sign convention of the phases comes from the fact that $a_i^h$ depends on $b_j^h$ while $a_i^p$ depends on $p_j^p$. First we find all possible ansätze that respect the PSG of $\chi_e$ by mapping the bonds 01 and $I01$ onto themselves with $S^{-1} C_3 S C_3$ (note, that this also flips the bond). For the 01 bond this results in

\[
(a_1^h, b_1^h, c_1^h, d_1^h) = (-a_1^h, b_1^h, c_1^h, d_1^h) e^{-i\pi (n_1 + n_3 C_3^a + n_1 C_3^a T_3)},
\]

\[
(a_1^p, b_1^p, c_1^p, d_1^p) = (a_1^p, -b_1^p, -c_1^p, -d_1^p) e^{i\pi (n_1 + n_3 C_3^a + n_1 C_3^a T_3)},
\]

\[
(27)
\]

For the $I01$ bond this results in

\[
(a_2^h, b_2^h, c_2^h, d_2^h) = (-a_2^h, b_2^h, c_2^h, d_2^h) e^{-i\pi n_3 C_3^a + n_1 C_3^a T_3},
\]

\[
(a_2^p, b_2^p, c_2^p, d_2^p) = (a_2^p, -b_2^p, -c_2^p, -d_2^p) e^{i\pi n_3 C_3^a C_3^a T_3}.
\]

\[
(29)
\]

Table II lists all allowed nearest-neighbor mean-field parameters for ansätze respecting the symmetries of $\chi_e$. To get to all chiral ansätze we have to impose rotoreflection and screw symmetry modulo time reversal. Therefore, we have to fix the moduli of the mean-field parameters on the bonds 01 and $I01$ to be the same such that: $a_1^h = a_2^h = a_3^h, \ldots, a_1^p = a_2^p = a_3^p, \ldots$. Notice, that for $n_3 C_3^a T_3 = 1$ this is not possible for the pairing fields. Therefore, such ansätze either break $\bar{\Omega}_6$ and $S$ as well as $T \bar{\Omega}_6$ and $TS$ or have no pairing field and therefore an accidental IGG of $U(1)$. Either way, they
correspond to ansätze that we do not want to consider and we set \( n_{CITe} = 0 \) in the rest of this work. This means that \( a^p \) cannot appear in an ansatz together with \( b^p, c^p, d^p \). All further restrictions to the ansätze can be found by transformation of expectation values of gauge invariant loop operators\(^{23}\). For example: \( \hat{B}_{ij} \hat{B}_{jk} \hat{B}_{ki} \) or \( \hat{A}_{ij} \hat{A}_{jk} \hat{A}_{ki} \). These are analogous to the Wilson loop operators in gauge theory. The loop operators are directly related to products of spin operators and therefore have a straight forward physical interpretation. For example the triple product of the spins at sites i,j,k can be written using two of these loops:

\[
\hat{S}_i \cdot (\hat{S}_j \times \hat{S}_k) = -2i : (\hat{B}_{ij} \hat{B}_{jk} \hat{B}_{ki} - \hat{B}_{ij}^\dagger \hat{B}_{jk} \hat{B}_{ki}^\dagger) : \quad (31) \\
= 2i : (\hat{A}_{ij} \hat{A}_{jk} \hat{B}_{ki} - \hat{A}_{ij}^\dagger \hat{A}_{jk} \hat{B}_{ki}^\dagger) : . 
\]

(32)

In SBMFT the expectation values of loop operators can be written as products of the mean-fields:

\[
\langle \hat{B}_{ij} \hat{B}_{jk} \hat{B}_{ki} \rangle \simeq B_{ij} B_{jk} B_{ki}. 
\]

Using Eq. (31) we can directly see that ansätze that respect time reversal symmetry, i.e., where the mean-fields are real, do not give rise to non-coplanar spin configurations. The complex argument of the loops, called fluxes, boil down to a sum of complex arguments of the mean-field parameters, e.g:

\[
\text{Arg} \left( \langle \hat{B}_{ij} \hat{B}_{jk} \hat{B}_{ki} \rangle \right) = \text{Arg}(B_{ij}) + \text{Arg}(B_{jk}) + \text{Arg}(B_{ki}). 
\]

(33)

Under the action of an operator \( O_\alpha \in \chi_\alpha \), Eq. (33) transforms like

\[
O_\alpha \text{Arg} \left( \langle \hat{B}_{ij} \hat{B}_{jk} \hat{B}_{ki} \rangle \right) = \epsilon_{\chi_\alpha} \left[ \text{Arg}(B_{ij}) + \text{Arg}(B_{jk}) + \text{Arg}(B_{ki}) \right]. 
\]

(34)

The flux is invariant under \( O_\alpha \) if \( \epsilon_{\chi_\alpha} = 1 \) and the flux changes its sign if \( \epsilon_{\chi_\alpha} = -1 \). We can write down equations like Eq. (35) for all independent fluxes on the lattice and then solve for the phases \( \text{Arg}(B_{ij}) = \phi_{B_{ij}} \) depending on the parities of all elements in \( \chi_\alpha \). We choose to study the flux transformations under action of inversion \( I = \overline{C}_6 \) and mirror symmetry \( \Sigma = IS \) since the resulting phase equations have a particularly nice form. The calculations are performed in Appendix E. The solutions are presented in Tab. III.

The ansätze can be grouped into four groups corresponding to the parity of their underlying symmetries \((\epsilon_\Sigma, \epsilon_I)\). The 12 ansätze with \((\epsilon_\Sigma, \epsilon_I) = (1, 1)\) exactly reduce to the 12 fully symmetric ansätze that were characterized by Liu et al.\(^{24}\) once we impose time reversal symmetry which constrains \( c^h = 0 \). Comparison with the fully symmetric classification sheds light on why \((1, \epsilon_I)\) and \((1, p_1)\) support two families of ansätze. One with nonzero \( c^p \) and one with nonzero \( b^p \) and \( d^p \). Imposing \( \Sigma \) symmetry causes \((1, \epsilon_I)\) and \((1, p_1)\) to fractionalize into two new classes labeled by the \( Z_2 \) parameter \( n_{S\Sigma e} \). The fractionalized ansätze then fulfill the symmetry: \((\Sigma)^2 = (-1)^{n_{S\Sigma e}} \). The same happens for \((1, \epsilon_I)\) and \((0, p_1)\). However, the corresponding ansätze families do not allow any nearest-neighbor pairing fields and therefore do not correspond to nearest-neighbor \( Z_2 \) spin liquids in the same way as for the fully symmetric equivalence classes \( n_{1-(00\Sigma e)} \).

For \( \epsilon_I = 1 \) we can identify the \( Z_2 \) parameter \( p_1 + n_1 \) with \( n_{S\Sigma e} \) by comparing with the fully symmetric ansätze. The ansätze then fulfill \((\tilde{I})^2 = (-1)^{p_1+n_1} \). The ansätze with \((\epsilon_\Sigma, \epsilon_I) = (-1, -1)\) fractionalize similarly upon imposing screw symmetry \( S = IS \). Only the ansätze with \((\epsilon_\Sigma, \epsilon_I) = (1, -1)\) do not fractionalize in states labeled by \( p_1 \). Instead, they allow for continuously variable phases \( \phi_o, \phi_i, \phi_o^*, \phi_i^* \).

IV. CHOOSING ANSÄTZE

Now that we have characterized all symmetric and chiral mean-field ansätze, we have to choose meaningful ansätze as well as a suitable mean-field decoupling for the XXZ Hamiltonian (3). As mentioned previously the mean-field decouplings are ambiguous. We choose them in a way that preserves the SU(2) spin rotation symmetry at the Heisenberg point:

\[
H = \sum_{<ij>} J_{\perp} (\hat{S}_i^x \hat{S}_j^x + \hat{S}_i^y \hat{S}_j^y) + J_{zz} \hat{S}_i^z \hat{S}_j^z \quad (35) \\
= \sum_{<ij>} \frac{J_{\perp} + J_{zz}}{2} \hat{S}_i^x \hat{S}_j^x + \frac{\Delta J}{2} \hat{S}_i^z \hat{S}_j^z - \frac{\Delta J}{2} (\hat{S}_i^y \hat{S}_j^y + \hat{S}_i^y \hat{S}_j^y) \\
= \sum_{<ij>} \frac{J_{\perp} + J_{zz}}{2} : \hat{B}_{ij}^\dagger \hat{B}_{ij} : - J_{\perp} \hat{A}_{ij}^\dagger \hat{A}_{ij} \\
- \frac{\Delta J}{2} (\tilde{t}_{ij}^h \tilde{t}_{ij}^h : + : \tilde{t}_{ij}^h \tilde{t}_{ij}^h : - : \tilde{t}_{ij}^h \tilde{t}_{ij}^h : ) \\
+ \sum_i \lambda_i (\tilde{b}_{i0}^b \tilde{b}_{i0}^b - 2S).
\]

The mean-field decoupling is then defined by:

\[
J_{ij}^h = \frac{1}{2} \begin{pmatrix} J_{zz} + J_{\perp} & J_{\perp} - J_{zz} & J_{\perp} - J_{zz} \\ J_{\perp} - J_{zz} & J_{zz} - J_{\perp} & J_{zz} - J_{\perp} \end{pmatrix}, \quad (36a) \\
J_{ij}^p = \begin{pmatrix} -J_{\perp} & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad (36b) \\
C_{ij} = 0. \quad (36c)
\]

This particular decoupling allows the resulting spin liquid state to break the U(1) spin rotation symmetry by acquiring different expectation values for \( \tilde{t}_{ij}^h \) and \( \tilde{t}_{ij}^h \). This choice is motivated by findings of Benton et al.\(^{11}\),
where a transition from a U(1) symmetric to a nematic state is observed at the Heisenberg point.

In the following sections we solve the mean-field equations for the ansätze $(1,1)\cdot n_1\cdot(0, p_1)\cdot(0)$ and $(-1,\epsilon)\cdot n_1\cdot(0, p_1)\cdot(\xi)$. We choose them because they can include $SU(2)$ symmetric pairing fields $A_{ij}$ that capture the relevant physics at the antiferromagnetic Heisenberg point.

Ansätze $(1,1)\cdot n_1\cdot(0, p_1)\cdot(0)$ are fully symmetric. Therefore, they fulfill all lattice symmetries and correspond to coplanar spin liquids.

Ansätze $(-1,-1)\cdot n_1\cdot(0, p_1)\cdot(0)$ are chiral and they break $\mathcal{T}$, $I$ and $\Sigma$ but preserve $T\mathcal{I}$ and $T\Sigma$. Therefore, they also respect screw symmetry. Every $SU(2)$ symmetric triangular flux operator has an expectation value of $\pm\frac{\pi}{2}$. Therefore, they have the same symmetry and flux structure as the monopole flux and the $(\pm\frac{\pi}{2},\pi)$ state considered by Burnell et al.\textsuperscript{21}. For $B=0$ the ansätze reduce to the fully symmetric $(1,1)\cdot n_1\cdot(0, p_1)\cdot(0)$.

Ansätze $(-1,1)\cdot n_1\cdot(0, p_1)\cdot(0)$ are chiral and they break $\mathcal{T}$ and $\Sigma$ while preserving $I$ and $T\Sigma$. Therefore, they also break $S$ modulo time reversal. Every $SU(2)$ symmetric triangular flux has a value of $\frac{\pi}{2}$. Therefore, they have a similar flux structure as the $\frac{\pi}{2},\frac{\pi}{2},\frac{\pi}{2}$ state considered by Kim et al.\textsuperscript{22}. For $B=0$ the ansätze reduce to the fully symmetric $(1,1)\cdot n_1\cdot(0, p_1)\cdot(0)$.

Ansätze $(-1,\epsilon)\cdot n_1\cdot(0, p_1)\cdot(\xi)\neq 0$ are chiral and they have the same symmetries as $(-1,1)\cdot n_1\cdot(0, p_1)\cdot(0)$. Their characteristic property is that the expectation value of every rhombus flux operator has a value of $\frac{\pi}{2}$. This leads to the identity:\textsuperscript{23}

\[ S\left( \langle \hat{S}_0 - \hat{S}_3 \rangle \cdot (\hat{S}_1 \times \hat{S}_2) + (\hat{S}_2 - \hat{S}_3) \cdot (\hat{S}_3 \times \hat{S}_0) \right) = 8A^4 \sin \left( \frac{\pi}{3} \right), \]

which implies non-zero scalar spin chirality. The ansätze for $\xi = 1$ and $\xi = -1$ can be mapped onto each other by the action of $\mathcal{T}$.

V. CALCULATION OF THE FREE ENERGY

Now that a mean-field decoupling and ansätze are chosen we can apply the Fourier transform

\[ b_{r,\mu} = \sqrt{\frac{N_{\text{SL}}}{N}} \sum_k b_{k,\mu} e^{-i k r_{\mu}}, \]

(38)

to the Hamiltonian in Eq. (15) and bring it to the form:

\[ H = \frac{1}{2} \sum_k \hat{\Psi}_k \mathcal{H}(k) \hat{\Psi}_k + 3N f(h, p) - N\lambda(2S + 1), \]

(39)

where $N$ is the number of atoms on the lattice and $\mathcal{H}(k)$ has the form

\[ \mathcal{H}(k) = \begin{pmatrix} H^b(k) & H^p(k) \\ (H^p(k))^T & (H^b(-k))^T \end{pmatrix} + \lambda b_4 N_{\text{SL}}. \]

(40)
For \((n_1 = 1) n_1 = 0\) \(\hat{\Psi}_k\) is a (64) 16 component spinor and \((N_{SL} = 16) N_{SL} = 4\) is the number of sublattices in the (enlarged) unit cell: \(\hat{\Psi}_k = (\hat{\psi}_k, \hat{\psi}_{\tau k}^\dagger)\) with \(\hat{\psi}_k = (\hat{b}_{k,1}, \hat{b}_{k,2}, \ldots, \hat{b}_{k,N_{SL}})\). The explicit form of \(H^b\) and \(H^p\) are given in Appendix F. The Hamiltonian (39) can be diagonalized by a Bogoliubov transform\(^{29} \). We therefore introduce Bogoliubov transformation matrices \(V(k)\) such that:

\[
\hat{\psi}_k = V(k)\hat{\Gamma}_k,
\]

\[
V(k)^\dagger \hat{\beta}^\dagger V(k) = \tau^3,
\]

\[
V(k)^\dagger \hat{H}(k)V(k) = \Omega(k).
\]

Here \(\hat{\Gamma}_k = (\hat{\gamma}_{k,1}, \ldots, \hat{\gamma}_{k,2N_{SL}}, \hat{\gamma}_{k,1}^\dagger, \ldots, \hat{\gamma}_{k,2N_{SL}}^\dagger)\) is the Bogoliubov spinor, \(\tau^3 = \sigma^3 \otimes \mathbb{1}_{2N_{SL}}\) and \(\Omega(k)\) is a diagonal matrix where the first \(2N_{SL}\) entries \(\omega_i(k)\) \((i \in \{1, 2N_{SL}\})\) and the last \(2N_{SL}\) entries are \(\omega_i(-k)\). They are the positive and negative eigenvalues of the matrix \(\tau^3 \hat{H}(k)\) respectively\(^{29} \). Eq. (42) ensures that the new bosonic operators \(\hat{\gamma}_k, \hat{\gamma}_k^\dagger\) preserve the bosonic commutation relations \([\hat{\gamma}_{k,i}, \hat{\gamma}_{k',j}^\dagger] = 0\), \([\hat{\gamma}_{k,i}, \hat{\gamma}_{k',j}^\dagger] = \delta_{i,j} \delta_{k,k'}\). Thus, we can write (39) as

\[
H(k) = \sum_{k} \sum_i \omega_i(k) \hat{\gamma}_k^\dagger \hat{\gamma}_k + \frac{1}{2} \sum_{i} \omega_i(k) (44a)

+ 3Nf(h, p) - N\lambda(2S + 1).
\]

The mean-field free energy per site is thus given by

\[
f_{\text{MF}} = \frac{1}{2\text{Vol}_{B,Z}N_{SL}} \int_{B,Z} \text{dk}^3 \sum_{i} \omega_i(k) + 3f(h, p) - \lambda(2S + 1).
\]

where we exchanged the sum by an integral in the thermodynamic limit \(\sum_k \rightarrow \frac{1}{\text{Vol}_{B,Z}N_{SL}} \int_{B,Z} \text{dk}^3\). This reduces to

\[
f_{\text{MF}} = 3h^1 J_0 p + 3p^1 J_0 p + 3C,
\]

after solving the mean-field equations.

As a final step we find the correct values of the mean-field by solving the self-consistency equations (18).

The solutions are listed in Table IV. Self-consistent mean-field parameters. The values with asterisk are determined self consistently in the gapped spin liquid phase for the physical spin value of \(S = 0.5\). All other values are set by symmetry of the particular ansätz. "\(c\)" labels states that are condensed at \(S = 0.5\), i.e., are magnetically ordered.

The fact that these states are gapped suggests that a chiral spin-liquid phase is stable in the vicinity of the \(SU(2)\) symmetric Heisenberg point, corresponding to the chiral \((\pi, 0, \pm \pi)\) state. Moreover, note that we have chosen a decoupling of the XXZ Hamiltonian in Eqs. (36) which is expected to capture the relevant physics in the vicinity of the antiferromagnetic Heisenberg point and selected corresponding ansätz. However, other mean-field decouplings and ansätz with focus on the vicinity of the classical Ising limit \(J_\perp = 0\) or the easy-plane limit \(J_{xx} = 0\) can lead to stable non \(SU(2)\) symmetric spin liquids that might be non-chiral. Indeed, in a preliminary study of the fully symmetric ansätz we have found the ansätz \((1, 1)-n_1-(1, p_1)-(0)_{xx}\) to have non zero \(t^b \cdot z\) in

loops: \((\phi_0, \phi_0, \phi_0) = (p_1, p_1 + n_1, 1 + \frac{2\pi}{3})\). We have found the \(SU(2)\) symmetry to be stable even beyond the Heisenberg point. We have explicitly checked this for coupling angles \(\theta \in [0, \pi]\). The normalized free energies of the spin liquid states can be found in Table V. The only dependence of the free energy on \(\theta\) comes from \(J_\perp\). The chiral state \((\pi, 0, \pm \pi)\) has the lowest free energy. It is about 20% lower than the next higher state \((0, \pi, \pi)\) while the other energies differ only by less than 2%.

The loops: \((\phi_0, \phi_0, \phi_0) = (p_1, p_1 + n_1, 1 + \frac{2\pi}{3})\) for the \(SU(2)\) symmetric states have been arbitrarily chosen. However, other mean-field decouplings and ansätz with focus on the vicinity of the classical Ising limit \(J_\perp = 0\) or the easy-plane limit \(J_{xx} = 0\) can lead to stable non \(SU(2)\) symmetric spin liquids that might be non-chiral. Indeed, in a preliminary study of the fully symmetric ansätz we have found the ansätz \((1, 1)-n_1-(1, p_1)-(0)_{xx}\) to have non zero \(t^b \cdot z\) in

loops: \((\phi_0, \phi_0, \phi_0) = (p_1, p_1 + n_1, 1 + \frac{2\pi}{3})\). We have found the \(SU(2)\) symmetry to be stable even beyond the Heisenberg point. We have explicitly checked this for coupling angles \(\theta \in [0, \pi]\). The normalized free energies of the spin liquid states can be found in Table V. The only dependence of the free energy on \(\theta\) comes from \(J_\perp\). The chiral state \((\pi, 0, \pm \pi)\) has the lowest free energy. It is about 20% lower than the next higher state \((0, \pi, \pi)\) while the other energies differ only by less than 2%.
they preserve the expectation values $t^{p,x}$ and $t^{p,y}$ in the vicinity of the easy plane limit, respectively. At this point ansätze $(1, 1)-0-(1, 0)-0$ have non zero energy. Ansätze $(1, 1)-n_1-(1, p_1)-(0), xz$ and $(1, 1)-n_1-(1, p_1)-(0), y$ have the lowest energy. These break the $U(1)$ spin rotation symmetry in accordance with the nematic spin liquids found by Benton et al. However, contrary to the nematic states of Benton et al. they preserve the $C_3$ lattice symmetry by construction. The energies of these spin liquids at mean-field level are highly dependent on the choices of the mean-field decouplings. Therefore, the ambiguity of choosing non $SU(2)$ symmetric mean-field decouplings described in Sec. II B prevents an appropriate comparison of mean-field energies from different mean-field decouplings. A generalization of the large-$N$ $Sp(N)$ approach together with arguments from the symplectic $N$ approach to non $SU(2)$ symmetric Hamiltonians might shed some light on this issue.

Finally, note that interactions beyond nearest neighbors could in principle stabilize the chiral saddle points of $(−1, −1) - n_1 - (0, p_1) - (0)$. 

VI. SPIN STRUCTURE FACTORS

To compare the mean-field states to experiment and other numerical studies of the XXZ model we calculate the spin-spin correlations in local and global basis. The spin-spin correlations in the local spin basis is given by the tensor

$$S^{α,β}(q) = \frac{1}{3N} \sum_k \text{Tr} \left( V^\dagger_{12}(k) \Sigma^α V_{11}(k - q) | V^\dagger_{21}(k - q) (\Sigma^β)^T V_{22}(k) + V^\dagger_{11}(k - q) \Sigma^β V_{12}(k) \right).$$

(48)

where

$$V(k) = \begin{pmatrix} V_{11}(k) & V_{12}(k) \\ V_{21}(k) & V_{22}(k) \end{pmatrix}, \quad \Sigma^γ = 1_{N_{zL}} \otimes \sigma^γ. \quad (49)$$

Since all our spin liquid states turned out to be $SU(2)$ symmetric the only independent nonzero component of $S^{α,β}(q)$ is $S^{z,\pm}(q)$. We plot $S^{z,\pm}$ along $[h, h, l]$ plane in Figure 2.

The spin-spin correlation in the local spin basis $S^{α,β}(q)$ can be calculated by using Eq. (48) and replacing $\Sigma^γ \rightarrow U \Sigma^γ U^\dagger$ with

$$U = 1_{N_{zL}} \otimes \begin{pmatrix} U_0 & U_1 \\ U_2 & U_3 \end{pmatrix}. \quad (50)$$

$U_μ$ are the $SU(2)$ matrices that rotate from the global to the local basis (see Appendix C).

Neutron scattering experiments do not directly measure components of $S^{α,β}(q)$ but instead measure the neutron scattering amplitude$^{12}$:

$$S_{\text{TOT}}(q) = (\delta_{α,β} - \frac{q^α q^β}{|q|^2})S^{α,β}(q). \quad (51)$$

Following Fennell et al.$^{31}$ we calculate the neutron scattering amplitude along the $[h, h, l]$ plane and split the total scattering amplitude $S_{\text{TOT}}(q)$ into a spin flip (SF) channel

$$S_{\text{SF}}(q) = \frac{(|P × q|^α (P × q)^{β})}{|q|^2} \tilde{S}^{α,β}(q), \quad (52)$$

and a no spin flip (NSF) channel

$$S_{\text{NSF}}(q) = P^{α,β} \tilde{S}^{α,β}(q), \quad (53)$$

where $P = \frac{1}{\sqrt{3}}(1, -1, 0)$ is the polarization vector of the neutrons. In the $[h, h, l]$ plane they fulfill $S_{\text{TOT}}(q) = S_{\text{SF}}(q) + S_{\text{NSF}}(q)$. Experimentally splitting up measurements into the polarization channels is advantageous since the pinch points that are characteristic for spin ice phase are only visible in the SF channel. When measuring $S_{\text{TOT}}(q)$ the contributions from the NSF channel smear out the features$^{11}$. 

A. Correlation results

The spin-spin correlations in the local spin basis can be seen in Figure 2. Their main features are the broadened pinch points at $q = (0, 0, ±4\pi)$, $q = (±2\pi, ±2\pi, ±2\pi)$ and symmetry related points. In case of the classical Heisenberg model these pinch points have been argued to be caused by the ice-rule: The sum of all spins on every tetrahedron has to vanish$^{32–34}$. The quantum fluctuations break this ice rule which result in smeared out
pinch points\textsuperscript{19,20,35–39}. For the Heisenberg model on the pyrochlore lattice, two types of pinch points have previously been reported. The spin-singlet correlation either has a maximum\textsuperscript{18,36} or a saddle point at the pinch points\textsuperscript{19,39}. Plots of the spin correlations in the vicinity of the pinch points for the five spin-liquid states considered here can be found in Figure 3. For the $(0, \pi, \pi)$ state and the $(\pi, 0, \pi)$ state, the $S^{z,z}$ correlator has a saddle point while for the $(0, 0, \pi)$ state, $(\pi, \pi, \pi)$ state and the $(\pi, 0, \pm \frac{\pi}{3})$ state, the $S^{z,z}$ correlator has a maximum at the pinch points.

For $S^{z,z}$ the state $(\pi, 0, \pi)$ shows good qualitative agreement with previous theoretical work using pseudo fermion functional renormalization group (PFFRG) studies\textsuperscript{20,39,40} and exact diagonalization of small clusters\textsuperscript{19} of the Heisenberg and XXZ model. The state $(0, 0, \pi)$ shows good qualitative agreement with a PFFRG result on the $J_1$ $- J_2$ model for antiferromagnetic $J_2$.\textsuperscript{20}

The results for $S_{\text{TOT}}$ as well as the SF and NSF channel can be seen in Figure 4, 5, 6, respectively. Our results can be compared to the PFFRG results of Ritter\textsuperscript{10} and the classical Monte Carlo result of Taillefumier et al.\textsuperscript{12}. We should emphasize that Ritters results are for a coupling angle of $\theta = 20^\circ$. The resulting PFFRG ground state only slightly breaks $SU(2)$ symmetry and the neutron scattering amplitudes show the same features as the mean-field results presented here. This observation matches with the stability of the $SU(2)$ symmetric mean-field states beyond the Heisenberg point which we have found in our analysis.

Since most numerical methods rule out time reversal symmetry breaking states by construction, we are not aware of numerical data to compare our results for the chiral $(\pi, 0, \pm \frac{\pi}{3})$ state.
Figure 4. (Color online). The normalized total neutron scattering amplitude $S_{\text{TOT}}(q)$ plotted along the $[h,h,l]$ plane. The spin liquid states are labeled by the fluxes of the $A$ operators on the hexagonal, bow tie and rhombus loops: $(\phi_0, \phi_{\alpha}, \phi_{\beta}) = (p_1, p_1 + n_1, 1 + \frac{2\pi}{3})\pi$.

Figure 5. (Color online). The normalized spin flip channel of the neutron scattering amplitude $S_{\text{SF}}(q)$ plotted along the $[h,h,l]$ plane. The spin liquid states are labeled by the fluxes of the $A$ operators on the hexagonal, bow tie and rhombus loops: $(\phi_0, \phi_{\alpha}, \phi_{\beta}) = (p_1, p_1 + n_1, 1 + \frac{2\pi}{3})\pi$.

VII. CONCLUSIONS

Using a PSG approach we classified all fully symmetric and chiral $Z_2$ Schwinger boson mean-field ansätze on the pyrochlore lattice. To the best of our knowledge, this is the first time this has been done for a 3D lattice. We went beyond the formalism of Messio et al.\textsuperscript{23} by including triplet fields into our chiral PSG analysis. Furthermore, we computed the ground-state energy for 16 chiral and four fully symmetric ansätze within a mean-field approximation for the XXZ model near the Heisenberg point. Remarkably, all of the ansätze where bosonic spinons do not condense reduce to five $SU(2)$ symmetric spin liquid states, regardless of the coupling angle $\theta$. The four states $(0,0,\pi), (\pi,\pi,\pi), (0,\pi,\pi)$ and $(\pi,0,\pi)$ can be described by the fully symmetric ansätze previously characterized by Liu et al.\textsuperscript{24}. We identified the chiral spin liquid state $(\pi,0,\pm\frac{\pi}{3})$ as mean-field ground states with a 20% lower mean-field free energy than the energetically next higher state $(0,\pi,\pi)$. Its characteristic feature is a $\pm\frac{\pi}{3}$ flux that is enclosed by the $A_{ij}$ operators on rhombus loops of length four and differs from previously studied chiral states featuring a flux of $\pi/2$ through triangular loops.\textsuperscript{21,22} It breaks time reversal symmetry $T$, mirror symmetry $\Sigma$ and a screw symmetry $S$, while it is symmetric under $T\Sigma$ and $T S$. 

\[ S_{\text{TOT}}(0,0,\pi) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \]
the results of Benton et al.

Moreover, we computed spin-spin correlations as well as neutron scattering amplitudes and compared them to previously published work. Our new chiral state \((\pi, 0, \pm \frac{\pi}{2})\) may be further explored by calculating the dynamical structure factor, where time reversal symmetry breaking can be explicitly seen. It might also be worthwhile to further study the ansätze \((-1, 1)-(0,0)-(1), (-1, 1)-(0,0)-(1), (1,1)-(0,0)-(1)\), where the spinons condense and give rise to magnetic order.

While ansätze \((-1, \epsilon, 1)-(0,0)-(0)\) have similar flux structures as the chiral states considered by Burnell et al.\(^{21}\) and Kim et al.\(^{22}\), the saddle points for these states that we found in our mean-field analysis give rise to fully symmetric spin liquids. Here, further neighbor interactions might stabilize the chirality. Finally, in the present study we have not solved the mean-field equation for the ansätze \((1, -1)-(0,0)-(0)\) which allow a continuous flux \(2\phi_A\) that is enclosed by the \(A_{ij}\) operators on bow-tie loops. It remains to be seen if their mean-field saddle points describe non-chiral, fully symmetric states, or if \(\phi_A\) acquires a non trivial value, giving rise to a different chiral spin liquid.

It is important to note, however, that our analysis of the XXZ Heisenberg model is based on decoupling of the Hamiltonian which is expected to work well only in the vicinity of the SU(2) symmetric Heisenberg point. Since the form of the decoupling is ambiguous, different decouplings will favor non SU(2) symmetric spin liquids that might result in non-chiral ground states in the vicinity of the classical Ising limit \(\theta = 0\), as well as in the easy-plane limit \(\theta = \pi/2\), for example. Indeed, within a preliminary analysis of the fully symmetric ansätze we find a \(U(1)\) symmetric ground-state close to the classical limit and a \(U(1)\) symmetry breaking ansatz as ground state close to the easy plane limit, in accordance with the results of Benton et al.\(^{11}\).

Appendix A: Local spin basis vectors

The local spin basis vectors first introduced in Eq. (2) are\(^{41}\):

\[
\begin{align*}
\mathbf{s}_\mu^x &= \frac{1}{\sqrt{3}}(1, 1, 1) - \frac{4}{\sqrt{3}} \mathbf{a}_\mu, \\
\mathbf{s}_\mu^y &= \mathbf{s}_\mu^x \times \mathbf{s}_\mu^z, \\
\mathbf{s}_\mu^z &= \frac{1}{\sqrt{6}}(-2, 1, 1), \\
\mathbf{s}_\mu^+ &= \frac{1}{\sqrt{6}}(-2, -1, -1), \\
\mathbf{s}_\mu^- &= \frac{1}{\sqrt{6}}(2, 1, -1), \\
\mathbf{s}_\mu^- &= \frac{1}{\sqrt{6}}(2, -1, -1).
\end{align*}
\]

Appendix B: Transformation of sublattice coordinates and local spin basis

The space group generators transform the different coordinates as follows:
where $\pi_{123}(\mu)$ and $\pi_{03}(\mu)$ cyclically permute sites $1, 2, 3$ and $0, 3$ respectively. The local spins transforms like:

$$T_i r_\mu = (r_1 + \delta_{i,1}, r_2 + \delta_{i,2}, r_3 + \delta_{i,3})_\mu,$$

(B1a)

$$C_6 r_\mu = (-r_3 - \delta_{\mu,3}, -r_1 - \delta_{\mu,1}, -r_2 - \delta_{\mu,2})_{\pi_{123}(\mu)},$$

(B1b)

$$S r_\mu = (-r_1 - \delta_{\mu,1}, -r_2 - \delta_{\mu,2},$$

$$r_1 + r_2 + r_3 + 1 - \delta_{\mu,0})_{\pi_{03}(\mu)},$$

(B1c)

$$I r_\mu = (-r_1 - \delta_{\mu,1}, -r_2 - \delta_{\mu,2}, -r_3 - \delta_{\mu,3})_\mu,$$

(B1d)

$$\Sigma r_\mu = (r_1, r_2, -r_1 - r_2 - r_3)_{\pi_{03}(\mu)},$$

(B1e)

$$C_3 r_\mu = (r_3, r_1, r_2)_{\pi_{123}(\mu)},$$

(B1f)

$$C_3^2 r_\mu = (1 - r_1 - r_2 - r_3, r_1, r_3)_{\pi_{03}(\mu)},$$

(B1g)

$$T r_\mu = r_\mu,$$

(B1h)

The symmetry group generators fulfill the following algebraic group relations

$$T_i T_{i+1} T_{i+1}^{-1} T_i^{-1} = 1,$$

(B3a)

$$C_6^6 = 1,$$

(B3b)

$$S_2 T_3^{-1} = 1,$$

(B3c)

$$C_6 T_i C_6^{-1} T_i = 1,$$

(B3d)

$$S T_i S^{-1} T_3^{-1} = 1, \quad i \in \{1, 2\},$$

(B3e)

$$ST_3 S^{-1} T_3^{-1} = 1,$$

(B3f)

$$(C_6 S)^4 = 1,$$

(B3g)

$$(C_6^3 S)^2 = 1,$$

(B3h)

$$T^2 = -1,$$

(B3i)

$$T O T^{-1} O^{-1} = 1,$$

(B3j)

where $i = 1, 2, 3$ and $i + 3 = i$. $O$ is a placeholder for an arbitrary space group generator: $O \in \{T_1, T_2, T_3, C_6, S\}$.

### Appendix C: SU(2) matrices

The SU(2) matrices $U_\mu$ associated with the symmetry operations that appear in Eq. (20) are:

$$U_{T_i} = \sigma_0,$$

(C1)

$$U_{C_6} = U_{C_3} = e^{-\frac{i}{2} \pi \hbar (0,0,1)^\sigma},$$

(C2)

$$U_{S_{1,2}} = (-1)^{1-\delta_{1,3}} e^{-\frac{i}{2} \pi \hbar (\sqrt{3},0,0)^\sigma}.$$

(C3)

The matrix for the screw operation depends on which sublattice it acts on. Spins on sublattice 1 are rotated the other way around than spins on sublattice 2. Spins on sublattices 0 and 3 are rotated and then projected onto the local spin basis of the other sublattice. This results in an effective $\pi$ rotation about the $(\sqrt{3}T^2, 1, 0)$ axis. The sign of the effective rotation can be chosen freely and different signs correspond to different gauges. Here we chose the signs of rotation to be equal on sublattice 0, 2, 3. The SU(2) matrices $U_\mu$ that transform from global to local basis on sublattice $\mu$ (See Eq. (22)) are given by

$$U_0 = \left( \begin{array}{cc} 1 & e^{i \frac{2\pi}{3}} \\ -\frac{1}{\sqrt{3}} & e^{-i \frac{2\pi}{3}} \end{array} \right),$$

(C4a)

$$U_1 = \left( \begin{array}{cc} 1 & e^{-i \frac{2\pi}{3}} \\ -\frac{1}{\sqrt{3}} & e^{i \frac{2\pi}{3}} \end{array} \right),$$

(C4b)

$$U_2 = \left( \begin{array}{cc} e^{i \frac{2\pi}{3}} & 1 \\ -\frac{1}{\sqrt{3}} & e^{-i \frac{2\pi}{3}} \end{array} \right),$$

(C4c)

$$U_3 = \left( \begin{array}{cc} e^{i \frac{2\pi}{3}} & 1 \\ -\frac{1}{\sqrt{3}} & e^{-i \frac{2\pi}{3}} \end{array} \right),$$

(C4d)

### Appendix D: Solution of the chiral algebraic PSG

The symmetry enriched algebraic relations of $\chi_\mu$ are

$$(G_T T_i)(G_{T_{i+1}} T_{i+1})^{-1}(G_{T_{i+1}} T_i)^{-1} \in \mathbb{Z}_2,$$

(D1a)

$$(G_{C_3} C_3)^3 \in \mathbb{Z}_2,$$

(D1b)

$$(G_{C_3} C_3')^3 \in \mathbb{Z}_2,$$

(D1c)

$$(G_{C_3} C_3)(G_{C_3} C_3')(G_{C_3} C_3)(G_{C_3} C_3') \in \mathbb{Z}_2,$$

(D1d)

$$(G_{C_3} C_3)(G_{C_3} T_i)(G_{C_3} C_3)^{-1}(G_{T_{i+1}} T_{i+1})^{-1} \in \mathbb{Z}_2,$$

(D1e)

$$(G_{C_3} C_3')(G_{T_i} T_1)(G_{C_3} C_3')^{-1}(G_{T_2} T_2)^{-1}(G_{T_3} T_3)^{-1} \in \mathbb{Z}_2,$$

(D1f)

$$(G_{C_3} C_3')(G_{T_2} T_2)(G_{C_3} C_3')^{-1}(G_{T_1} T_1) \in \mathbb{Z}_2,$$

(D1g)

$$(G_{C_3} C_3')(G_{T_3} T_3)(G_{C_3} C_3')^{-1}(G_{T_3} T_3)^{-1}(G_{T_1} T_1) \in \mathbb{Z}_2.$$
These can be rewritten into the following phase equations
\begin{align}
\phi_T[r_{\mu}] + \phi_{T+1}[T^{-1}_i(r_{\mu})] - \phi_{T+1}[T^{-1}_i(r_{\mu})] - \phi_{T+1}[r_{\mu}] &= \pi n_i, \\
\phi_C_3[r_{\mu}] + \phi_C_3[(C_3)^{-1}(r_{\mu})] + \phi_C_3[(C_3C_3')^{-1}(r_{\mu})] + \phi_C_3'[C_3'(r_{\mu})] &= \pi n_{C_3,C_3'}, \\
\phi_C_3[r_{\mu}] + \phi_C_3[C_3^{-1}(r_{\mu})] + \phi_C_3[C_3^{-2}(r_{\mu})] &= \pi n_{C_3}, \\
\phi_C_3[r_{\mu}] + \phi_{C_3}(C_3)^{-1}(r_{\mu})] + \phi_C_3[(C_3')^{-2}(r_{\mu})] &= \pi n_{C_3'}, \\
\phi_C_3[r_{\mu}] + \phi_T[T^{-1}_i(r_{\mu})] - \phi_{T+1}[T^{-1}_i(r_{\mu})] - \phi_{T+1}[r_{\mu}] &= \pi n_{C_T}, \\
\phi_C_3[r_{\mu}] + \phi_T_1[(C_3)^{-1}(r_{\mu})] - \phi_{C_3}[T^{-1}_1T_2(r_{\mu})] - \phi_{T_1}[T^{-1}_2(r_{\mu})] + \phi_T[T_1(r_{\mu})] &= \pi n_{C_3'T_1}, \\
\phi_C_3[r_{\mu}] + \phi_T_2[(C_3')^{-1}(r_{\mu})] - \phi_{C_3}[T^{-1}_1(r_{\mu})] + \phi_T[T_1(r_{\mu})] &= \pi n_{C_3'T_2}, \\
\phi_C_3[r_{\mu}] + \phi_{T_3}[C_3^{-1}(r_{\mu})] - \phi_{C_3}[T^{-1}_1T_3(r_{\mu})] - \phi_{T_1}[T^{-1}_3T_3(r_{\mu})] + \phi_T[T_1(r_{\mu})] &= \pi n_{C_3'T_3}. 
\end{align}

where \( n_X \in \{0, 1\} \).

Our goal is to find all phases \( \phi_C[r_{\mu}] \) as functions of \( \nabla_\mu \) and \( n_X \). However, a general gauge transformation \( G \) (See Eq. (6)) changes the phases given by the PSG phase equations like 24:

\[ \phi_C[r_{\mu}] \rightarrow \phi_C[r_{\mu}] + \phi_C[O^{-1}(r_{\mu})] \]  

To ultimately get an unambiguous result we have to fix the gauge in the process of solving the phase equations. Since we have four FCC sublattices we have freedom to choose 16 independent local gauges. Four for every direction \( r_1, r_2, r_3 \) and a constant one for every sublattice \( \mu = 0, 1, 2, 3 \):

\begin{align}
G_1 : \phi_{G_1}[r_{\mu}] &= n_{G_1,\mu} \pi r_1, \\
G_2 : \phi_{G_1}[r_{\mu}] &= n_{G_2,\mu} \pi r_2, \\
G_3 : \phi_{G_1}[r_{\mu}] &= n_{G_3,\mu} \pi r_3, \\
G_4 : \phi_{G_1}[r_{\mu}] &= \phi_\mu. 
\end{align}

Due to IGG = \( \mathbb{Z}_2 \), we are also free to add a site independent \( \mathbb{Z}_2 \) phase to any of our 5 phases \( \phi_C[r_{\mu}] \). That makes 16 local gauge and 5 IGG choices in total. With the first 12 gauge choices (equation (D4a)-(D4c)) we can fix the phases associated with the translation operators to \( \phi_{G_1}[r_{\mu}] = \phi_{G_2}[r_{\mu}] = \phi_{G_3}[r_{\mu}] = \phi_{G_4}[r_{\mu}] = 0 \). Note, that this can only be satisfied for open boundary conditions\(^{26}\) (Appendix A).

Using this choice equation (D2a) is solved by:

\begin{align}
\phi_T[r_{\mu}] &= 0, \\
\phi_{T_2}[r_{\mu}] &= n_1 \pi r_1, \\
\phi_{T_3}[r_{\mu}] &= n_2 \pi r_2. 
\end{align}

Writing out equation (D2c) we get:

\begin{align}
\phi_C_3[r_{\mu}] - \phi_C_3[(1, 2, 3)_\mu] &= (n_{C_3T_1} + n_{r_1, r_2, r_3}) \pi, \\
\phi_C_3[r_{\mu}] - \phi_C_3[(1, 2, 3 + 1)_\mu] &= (n_{C_3T_2} + n_{r_1, r_2, r_3}) \pi, \\
\phi_C_3[r_{\mu}] - \phi_C_3[(1 + 1, 2, 3)_\mu] &= (n_{C_3T_3} + n_{r_1, r_2, r_3}) \pi. 
\end{align}

This is solved by

\begin{align}
\phi_C_3[r_{\mu}] &= f_1(r_1, r_3) - r_2(n_{C_3T_1} + n_{r_1, r_2, r_3}) \pi, \\
\phi_C_3[r_{\mu}] &= f_2(r_1, r_2) + n_3 \pi r_1 - n_{r_1, r_2, r_3} \pi, \\
\phi_C_3[r_{\mu}] &= f_3(r_2, r_3) - n_3 \pi r_2 - n_{r_1, r_2, r_3} \pi. 
\end{align}

where \( f_3(r_1, r_3) \) is some function of \( r_1 \) and \( r_3 \). Since the function \( f_2(r_1, r_3) \) in (D9a) can not include any terms that feature \( r_2 \) it can not include terms like \( r_1 r_2 r_3 \pi \) that have to appear in \( \phi_C_3[r_{\mu}] \) due to (D9c). To fulfill equations (D9a) - (D9c) we have to infer a relationship between \( n_1, n_2, n_3 \). With \( n_1 = n_2 = n_3 \) we have the following solution:

\[ \phi_C_3[r_{\mu}] = \phi_C_3[0_{\mu}] - n_1 \pi (r_1 r_2 + r_1 r_3) - (r_1 n_{C_3T_2} + r_2 n_{C_3T_1} + r_3 n_{C_3T_3}) \pi \]

Plugging equation (D10) into (D2c) gives:

\[ = n_{C_3} \pi \]

which constrains \( \sum_j n_{C_3 T_j} = 0 \). \( \pi_{123}(\mu) \) permutes \( \mu \) in the cycle (123).
Writing out Eq. (D2e) we get:
\[ \phi_{C_4}[r_\mu] - \phi_{C_4}[(r_1 - 1, r_2 + 1, r_3)_\mu] \] (D12a)\n\[ = n_{C_4}T_1 \pi + n_1 \pi (r_1 + 1), \]
\[ \phi_{C_4}[r_\mu] - \phi_{C_4}[(r_1 - 1, r_2, r_3)_\mu] \] (D12b)\n\[ = n_{C_4}T_2 \pi + n_1 \pi r_2, \]
\[ \phi_{C_4}[r_\mu] - \phi_{C_4}[(r_1 - 1, r_2, r_3 + 1)_\mu] \] (D12c)\n\[ = n_{C_4}T_3 \pi + n_1 \pi (r_2 + r_3). \]

From Eq. (D12b) we can infer that
\[ \phi_{C_4}[r_\mu] = f_{C_4}(r_2, r_3) + n_1 \pi r_2 + n_{C_4}T_2 \pi r_1, \] (D13)
where \( f_{C_4}(r_2, r_3) \) is some function of \( r_2 \) and \( r_3 \). Using this and Eq. (D12c) we get
\[ \phi_{C_4}[r_\mu] = f_{C_4}(r_2) + n_1 \pi r_2 + n_{C_4}T_2 \pi r_1 \] + \( r_3 \pi \left( \frac{r_3 - 1}{2} n_1 + n_{C_4}T_2 + n_{C_4}T_3 \right) \). (D14)

Plugging this into Eq. (D12a) finally gives
\[ \phi_{C_4}[r_\mu] = \phi_{C_4}[0_\mu] + r_1 \pi n_{C_4}T_2 + n_1 \pi r_1 r_2 \] + \( r_3 \pi \left( \frac{r_3 - 1}{2} n_1 + n_{C_4}T_2 + n_{C_4}T_3 \right) \) + \( r_2 \pi \left( \frac{r_2 - 1}{2} n_1 + n_{C_4}T_2 + n_{C_4}T_3 \right) \). (D15)

Inserting Eq. (D15) into Eq. (D2d) gives
\[ \phi_{C_4}[0_\mu] + \phi_{C_4}[\pi_{021}(\mu)] + \phi_{C_4}[\pi_{120}(\mu)] \] + \( r_3 \pi (n_{C_4}T_1 + n_{C_4}T_2 + n_{C_4}T_3) \) = \( (n_{C_4} + n_{C_4}T_1 + n_1) \pi \),
which gives two constraints
\[ n_{C_4}T_1 + n_{C_4}T_2 + n_{C_4}T_3 = 0, \] (D16)
\[ \phi_{C_4}[0_\mu] + \phi_{C_4}[\pi_{021}(\mu)] + \phi_{C_4}[\pi_{120}(\mu)] = (n_{C_4}C_4 + n_{C_4}T_2 + n_{C_4}T_3) \pi. \] (D17)

The last phase equation (D2b) is then
\[ \phi_{C_4}[0_\mu] + \phi_{C_4}[\pi_{132}(\mu)] + \phi_{C_4}[\pi_{201}(\mu)] + \phi_{C_4}[\pi_{201}(\mu)] = (n_{C_4}C_4 + n_{C_4}T_2 + n_{C_4}T_3) \pi. \] (D18)

By fixing the IGG choices Eqs. (D11) and (D17) are reduced to
\[ 3\phi_{C_4}[0_\mu] = 0, \]
\[ \phi_{C_3}[0_1] + \phi_{C_3}[0_2] + \phi_{C_3}[0_3] = 0, \]
\[ 3\phi_{C_3}[0_3] = 0, \]
\[ \phi_{C_3}[0_1] + \phi_{C_3}[0_2] + \phi_{C_3}[0_0] = 0. \]

The form of equations (D19) is invariant under gauge transformations. That is why we can fix the constant gauge on sublattices 0, 1, 2, 3 to set \( \phi_{C_4}[0_2] = \phi_{C_4}[0_3] = 0 \) as well as \( \phi_{C_3}[0_1] = 0 \). Eqs. (D19) and (D17) then also imply \( \phi_{C_3}[0_1] = 0 \) and \( \phi_{C_3}[0_2] = -\phi_{C_3}[0_0] \). Eq. (D18) then reduces to
\[ \phi_{C_3}[0_0] - \phi_{C_3}[0_2] = (n_{C_3}C_4 + n_{C_3}C_3) \pi, \] (D20)
\[ \phi_{C_3}[0_2] + \phi_{C_3}[0_3] = (n_{C_3}C_4 + n_{C_3}C_3) \pi. \] (D21)

Therefore, \( \phi_{C_3}[0_0] = -\phi_{C_3}[0_3] = \frac{2\pi}{3} \xi \) where \( \xi \in \{-1, 0, 1\} \) and \( \phi_{C_3}[0_2] = \phi_{C_3}[0_0] + (n_{C_3}C_4 + n_{C_3}C_3) \pi \).

The final solution is then:
\[ \phi_{T_1}[r_\mu] = 0, \] (D22a)
\[ \phi_{T_2}[r_\mu] = n_1 \pi r_1, \] (D22b)
\[ \phi_{T_2}[r_\mu] = n_1 \pi (r_1 + r_2), \] (D22c)
\[ \phi_{C_3}[r_\mu] = \frac{2\pi}{3} \xi \delta_{\mu,0} + n_1 \pi (r_1 r_2 + r_1 r_3), \] (D22d)
\[ \phi_{C_3}[r_\mu] = -\frac{2\pi}{3} \xi \delta_{\mu,3} + r_2 \pi \left( \frac{r_2 - 1}{2} n_1 + n_{C_3}T_2 \right) \] + \( r_1 \pi n_{C_3}T_2 + r_3 \pi \left( \frac{r_3 - 1}{2} n_1 + n_1 \pi r_1 r_2 \right) + \left( \frac{2\pi}{3} \delta n_{C_3}C_4 + n_{C_3}T_3 \right)(-\delta_{\mu,0} + \delta_{\mu,2}) \pi, \] where \( \xi \in \{-1, 0, 1\} \) and \( n_1, n_{C_3}C_4, n_{C_3}T_2 \in \{0, 1\} \).

Appendix E: Classification of chiral ansätze

We use the short notation \( \mathcal{B}_{0,0} = \mathcal{B}_{\mu\nu} \) for bonds on the main tetrahedron and \( \mathcal{B}_{I(0_3)}(0_n) = \mathcal{B}_{I\mu\nu} \) for bonds on the inverse tetrahedron.

As described by Messio et al., we can classify all possible ansätze by looking at the transformation of the minimal set of linearly independent fluxes under elements in \( \chi_\alpha \). All elements of \( \chi_\alpha \) can be written as compositions of \( I, \Sigma \) and elements of \( \chi_\varepsilon \). The elements of \( \chi_\varepsilon \) leave the fluxes invariant so we only have to consider the action of \( I, \Sigma \) on the fluxes. It is equally valid to consider the actions of \( \mathcal{C}_6 \) and \( S \) on the fluxes but the calculations are a bit more involved. Since \( \mathcal{C}_6 = IC_3 \) and \( \Sigma = S\mathcal{C}_6 \) their parities are related like \( \epsilon_1 = \epsilon_\sigma \) and \( \epsilon_2 = \epsilon_\sigma \).

Fluxes are independent if they can not be mapped onto each other by symmetry operations in \( \chi_\varepsilon \) and can not be created by adding other independent fluxes. The number of independent fluxes depends on the number of present
mean-field parameters as well.
To find out how many independent fluxes there are we start with how many independent loops of even and odd length there are in the pyrochlore lattice independent of possible bond variables.

1. Trivial Loop (Loop size = 2): There are two independent bonds. One on the main and one on the inverse tetrahedron. The trivial loop is going back and forth along a bond.

2. Triangle (Loop size = 3): There are 8 triangles in the pyrochlore unit cell. There are two sets of three triangles that can be mapped onto each other by C3 which leaves us with 2 triangle loops on the inverse and main tetrahedron. These can be mapped onto each other by C3 rotation and translation. In total we therefore have two independent triangle loops.

3. Rhombus (Loop size = 4): There are 6 rhombi in the pyrochlore unit cell. Three on each tetrahedron. All rhombi on a tetrahedron can be mapped onto each other by C3 which leaves us with two independent rhombi.

4. Bow tie (Loop size = 6): There are 12 bow ties and 24 "bent" bow tie in the unit cells (0,0,0) and the three main tetrahedra of the cells (0,0,-1), (-1,0,0), and (1,0,0): 9 per two adjacent tetrahedra. By C3 mapping we can reduce the number to 12. 3 in the tetrahedra of (0,0,0) and 9 in the tetrahedra of e.g. (0,0,0) and (-1,0,0).
   We can further reduce the number by realizing that if we add a rhombus to a bow tie we get a bent bow tie. This reduces the number of loops to 12. These can finally be mapped onto each other by C3 rotation which leaves one independent bow tie flux.

5. Hexagon (Loop size = 6): Four unit cells always enclose a hexagon. There are 4 different hexagons that can not be mapped onto each other by translations. By C3 symmetry we can reduce this to 2 and by C3 symmetry to one independent hexagon.

6. Bigger loops (Loop size > 6): All loops with size larger than 6 can be created by adding loops of smaller size and therefore do not add to the linearly independent loops.

The trivial, triangle and rhombus loops on the main tetrahedron can be mapped to the same loops on the inverse tetrahedron by I. From the algebraic relations we can see that \( \Sigma = S^2 I \Sigma \). So \( \Sigma \) and \( I \) commute modulo \( S^{-2} \in \chi \) which leaves fluxes invariant. Therefore, transformation of trivial, triangle and rhombus fluxes on the main and inverse tetrahedron give the same constraints. We therefore only consider them on the inverse tetrahedron.

Transformation of hexagonal loops give the same constraints as the bow ties. We therefore not consider the

hexagonal fluxes here explicitly. Figure 7 show how all independent loops transform under \( \Sigma \) and \( I .. \) When we now specify fluxes by adding bond operators we can transform these loops diagram into equations. Fluxes can in principle consist of one, two or many different types of bond operators. E.g. \( \text{Arg}(B_{12} B_{23} B_{31}) \), \( \text{Arg}(A_{12} B_{23}^{h,z} A_{31}^{t}) \), \( \text{Arg}(B_{12} t_{h,x}^{p,z} t_{h,z}^{p,z}) \). We only have to consider fluxes with one or two fields. Fluxes with three or more fields can be constructed from these.

Before we can start turning the diagrams into equations we have to define our bond fields. Since there are two independent bonds we have two independent phases for each field.

We fix these as \( B_{01} = e^{-i \phi_{B1}} \), \( A_{01} = e^{-i \phi_{A1}} \) (on the main tetrahedron) and \( B_{I01} = e^{-i \phi_{B2}} \), \( A_{I01} = e^{-i \phi_{A2}} \) (on the inverse tetrahedron) and equivalently for \( t_{ij}^{h,z} \) and \( p_{ij}^{p,z} \).

Transformation of x and y triplet operators is not as trivial because symmetry operations change the direction. For example:

\[
C_3(C_3(t_{01}^{p,x})) = C_3(-\frac{1}{2} t_{02}^{p,x} + \frac{\sqrt{3}}{2} t_{02}^{p,y}) = -\frac{1}{2} t_{03}^{p,x} - \frac{\sqrt{3}}{2} t_{03}^{p,y},
\]

(E1a)

\[
C_3(C_3(t_{01}^{p,y})) = C_3(-\frac{\sqrt{3}}{2} t_{02}^{p,x} - \frac{1}{2} t_{02}^{p,y}) = -\frac{\sqrt{3}}{2} t_{03}^{p,x} - \frac{1}{2} t_{03}^{p,y}.
\]

(E1b)

We define new operators with easier transformation properties:

\[
t_{03}^{h,x'} := C_3(t_{01}^{h,x'}),
\]

(E2a)

\[
t_{12}^{h,x'} := C_3(t_{03,1}^{h,x'}),
\]

(E2b)

and equivalently for the bonds on the inverse tetrahedron, the pairing triplet operators and the y-triplet fields. The operators \( t_{ij}^{h,x} \) and \( t_{ij}^{h,y} \) are linearly independent on every bond. We fix their expectation values as \( p_{01}^{p,x} = t_{01}^{p,x} e^{-i \phi_{p,x}^{0,1}}, p_{01}^{p,y} = t_{01}^{p,y} e^{-i \phi_{p,y}^{0,1}}, t_{01}^{p,y} = t_{01}^{p,y} e^{-i \phi_{p,y}^{0,1}} \), \( t_{01}^{p,y} = t_{01}^{p,y} e^{-i \phi_{p,y}^{0,1}} \) and equivalently for the hopping triplet fields.

The operators transform as

\[
\hat{B}_{ji} = \hat{B}_{ij}^t, \quad t_{ji}^{h,\gamma} = -(t_{ij}^{h,\gamma})^t, \quad \hat{A}_{ji} = -\hat{A}_{ij}, \quad p_{ji}^{p,\gamma} = t_{p,\gamma}^{p,\gamma}.
\]

(E3)

To keep calculations short we use the superscript \( \gamma \in \{x', y', z\} \) to label the triplet operators. Also note that the triplet x' and z operators pick up an extra \( \pi \) phase when acted upon by \( \Sigma \) compared to the singlet and triplet y operators. This is not due to a gauge transformation added to the screw operation but solely due to the spin rotation (see Table VI).

In the following subsections we consider all one and two operator fluxes and translate their transformation behav-
ior into constraints for the phases $\phi_{O,0}$. The solutions to the equations can be found in Tab. III.

1. **Fluxes with $B_{ij}$ fields**

Hopping operators can be written in gauge invariant loops of odd size. For $B_{ij}$ fields, the only independent loops we have to consider are the triangles (Fig. 7(a)).

$$\text{Arg}(B_{101}B_{112}B_{120}).$$

(E4)

If we use the transformation property $B_{ij} = B^*_{ij}$ (see Eq. (E3)) we can turn Fig. 7(a) into equations for the phases:

$$\phi_{B_1} + \frac{4\xi_1 \pi}{3} + n_1 \pi = \epsilon_I \phi_{B_1} + \frac{4\xi_1 \pi}{3},$$

(E5a)

$$\phi_{B_2} + \frac{4\xi_2 \pi}{3} = 3\epsilon_{\Sigma} \phi_{B_2}.$$  

(E5b)

2. **Fluxes with $A_{ij}$ fields**

Pairing operators can only be written in gauge invariant loops of even length, where $A$ and $A^*$ alternate. Therefore, we have to consider the rhombus and bow tie loops of Fig. 7(b,c).

$$\text{Arg}(A_{101}A_{112}A_{123}A^*_{130}),$$

(E6a)

$$\text{Arg}(A_{101}A_{112}A_{120}A^*_{101}A_{12}A^*_{20}).$$

(E6b)

The rhombus fluxes give constraints for the PSG parameter $\xi$:

$$\frac{4\xi_1 \pi}{3} = \epsilon_I \frac{4\xi_1 \pi}{3},$$

(E7a)

$$\frac{4\xi_2 \pi}{3} = \epsilon_{\Sigma} \frac{2\xi_2 \pi}{3}.$$  

(E7b)

Therefore, there $\xi \neq 0$ only if $\epsilon_I = -\epsilon_{\Sigma} = 1$.

The bow tie loops give constraints for the phases

$$(\phi_{A_1} - \phi_{A_2}) = \epsilon_I (\phi_{A_2} - \phi_{A_1}),$$

(E8a)

$$(\phi_{A_1} - \phi_{A_2}) = \epsilon_{\Sigma} (\phi_{A_1} - \phi_{A_2}).$$

(E8b)

3. **Fluxes with $t^{h,\gamma}_{ij}$ fields**

As for the $B_{ij}$ fields we only have to consider triangle flux:

$$\text{Arg}(t^{h,\gamma}_{121}t^{h,\gamma}_{122}t^{h,\gamma}_{123}).$$

(E9)

Using $t^{h,\gamma}_{ij} = -t^{h,\gamma*}_{ij}$ we get the phase equations

$$\phi_{t^{h,\gamma}_{12}} + \frac{4\xi_2 \pi}{3} + n_1 \pi = \epsilon_I (\phi_{t^{h,\gamma}_{12}} + \frac{4\xi_2 \pi}{3}),$$

(E10a)

$$\phi_{t^{h,\gamma}_{12}} + \frac{4\xi_2 \pi}{3} = 3\epsilon_{\Sigma} \phi_{t^{h,\gamma}_{12}} + \delta_{\gamma,y} \pi.$$  

(E10b)

The term $\delta_{\gamma,y} \pi$ comes from the spin rotation part of $\Sigma$.

4. **Fluxes with $t^{p,\gamma}_{ij}$ fields**

Since $t^p$ are pairing fields, we have to consider the even rhombi and bow tie loops.

$$\text{Arg}(t^{p,\gamma}_{101}t^{p,\gamma}_{112}t^{p,\gamma}_{123}t^{p,\gamma}_{130}),$$

(E11a)

$$\text{Arg}(t^{p,\gamma}_{112}t^{p,\gamma}_{120}t^{p,\gamma}_{101}t^{p,\gamma}_{12}t^{p,\gamma}_{20}).$$

(E11b)
The rhombus fluxes give the same constraints ($\xi \neq 0$ only if $(\epsilon_I, \epsilon_{\Sigma}) = (1, -1)$) as Eq. (E7). The bow tie fluxes give:

\[
(\phi_{[2]}^{\gamma} - \phi_{[2]}^{\gamma'}) = \epsilon_I (\phi_{[2]}^{\gamma} - \phi_{[2]}^{\gamma'}), \quad (E12a)
\]

\[
(\phi_{[2]}^{\gamma} - \phi_{[2]}^{\gamma'}) = \epsilon_{\Sigma} (\phi_{[2]}^{\gamma} - \phi_{[2]}^{\gamma'}). \quad (E12b)
\]

5. Fluxes with $A_{ij}$ and $B_{ij}$ fields

We only have to consider triangle loops with one $B_{ij}$ field.

\[
\text{Arg}(B_{I10}A_{I12}^*A_{I20}). \quad (E13)
\]

These give the constraints:

\[
\phi_{B_2} + (1 + n_1)\pi = \epsilon_I \phi_{B_1} + \pi, \quad (E14a)
\]

\[
\phi_{B_2} + \pi = \epsilon_{\Sigma} (\phi_{B_2} + \frac{2\xi\pi}{3}). \quad (E14b)
\]

Using Eq. (E5) and (E7) we can reduce this to:

\[
\xi = 0, \quad (E15a)
\]

\[
\epsilon_{\Sigma} = -1, \quad (E15b)
\]

\[
2\phi_{B_1} = \pi, \quad (E15c)
\]

\[
\phi_{B_2} = \epsilon_I \phi_{B_1} + \pi n_1. \quad (E15d)
\]

6. Fluxes with $A_{ij}$ and $t_{i,j}^{h,\gamma}$ fields

We only have to consider the triangle loops with one $t_{i,j}^{h,\gamma}$ field:

\[
\text{Arg}(t_{I10}^{h,\gamma}A_{I12}^*A_{I20}). \quad (E16)
\]

They give constraints

\[
\phi_{[2]}^{\gamma} + (1 + n_1)\pi = \epsilon_I \phi_{[2]}^{\gamma} + \pi, \quad (E17a)
\]

\[
\phi_{[2]}^{\gamma} = \epsilon_{\Sigma} (\phi_{[2]}^{\gamma} + \frac{2\xi\pi}{3} + \delta_{\gamma,y'}\pi). \quad (E17b)
\]

Using Eq. (E10) we can rewrite this to

\[
\xi = 0, \quad (E18a)
\]

\[
\delta_{\gamma,y'} = 0, \quad (E18b)
\]

\[
2\phi_{[2]}^{\gamma} = \epsilon_I \phi_{[2]}^{\gamma} + n_1\pi. \quad (E18c)
\]

\[
\phi_{[2]}^{\gamma} = \epsilon_I \phi_{[2]}^{\gamma} + n_1\pi. \quad (E18d)
\]

Eq. (E18b) says that there are no valid chiral ansätze with both $A_{ij}$ and $t_{i,j}^{h,\gamma}$ fields.

7. Fluxes with $A_{ij}$ and $t_{i,j}^{p,\gamma}$ fields

As established in the main text $A_{ij}$ and $t_{i,j}^{p,\gamma}$ Fields can not appear simultaneously in an ansatz. Therefore, we do not have to consider loops with both of these fields.

8. Fluxes with $B_{ij}$ and $t_{i,j}^{h,\gamma}$ fields

Here we have to consider similar triangle loops as for $A_{ij}$ and $B_{ij}$ fields

\[
\text{Arg}(B_{I01}t_{I12}^{h,\gamma}B_{I20}). \quad (E19)
\]

These lead to the constraints:

\[
\phi_{B_2} + n_1\pi = \epsilon_I \phi_{B_1}, \quad (E20a)
\]

\[
\phi_{B_2} = \epsilon_{\Sigma} (\phi_{B_2} + \frac{2\xi\pi}{3}). \quad (E20b)
\]

With Eq. (E5) these can be reduced to:

\[
\xi = 0, \quad (E21a)
\]

\[
2\phi_{B_1} = 0, \quad (E21b)
\]

\[
\phi_{B_1} = \epsilon_I \phi_{B_2} + n_1\pi. \quad (E21c)
\]

9. Fluxes with $B_{ij}$ and $t_{i,j}^{h,\gamma'}$ fields

For $B_{ij}$ and $t_{i,j}^{h,\gamma'}$ fields we only have to consider the trivial flux:

\[
\text{Arg}(B_{I01}t_{I10}^{h,\gamma'}). \quad (E22)
\]

which gives the constraints:

\[
(\phi_{[2]}^{\gamma} - \phi_{B_2}) = \epsilon_I (\phi_{[2]}^{\gamma} - \phi_{B_1}) \quad (E23)
\]

\[
(1 - \epsilon_{\Sigma}) (\phi_{[2]}^{\gamma} - \phi_{B_2}) = \pi (1 - \delta_{\gamma,y'}). \quad (E24)
\]

10. Fluxes with $t_{i,j}^{p,\gamma}$ and $t_{i,j}^{h,\gamma'}$ fields

We have to consider the triangle loop

\[
\text{Arg}(t_{I01}^{h,\gamma'}t_{I12}^{p,\gamma}t_{I20}). \quad (E25)
\]

which give constraints:

\[
\phi_{[2]}^{\gamma} + n_1\pi = \epsilon_I \phi_{[2]}^{\gamma}, \quad (E26a)
\]

\[
\phi_{[2]}^{\gamma} = \epsilon_{\Sigma} (\phi_{[2]}^{\gamma} + \frac{2\xi\pi}{3} + \pi (1 - \delta_{\gamma,y'}). \quad (E26b)
\]

which can be reduced with Eq. (E10) to

\[
\xi = 0, \quad (E27a)
\]

\[
2\phi_{[2]}^{\gamma} = \pi, \quad (E27b)
\]

\[
\phi_{[2]}^{\gamma} = \epsilon_I \phi_{[2]}^{\gamma} + n_1\pi. \quad (E27c)
\]

11. Fluxes with $t_{i,j}^{p,\gamma}$ and $t_{i,j}^{p,\gamma'}$ fields

We have to consider the trivial flux:

\[
\text{Arg}(t_{I01}^{p,\gamma}t_{I10}^{p,\gamma'}). \quad (E28)
\]
which gives the constraints:
\[
\phi_{t_2, \gamma} - \phi_{t_2, \gamma'} = \epsilon_I (\phi_{t_1, \gamma} - \phi_{t_1, \gamma'}), \\
(1 - \epsilon_S)(\phi_{t_1, \gamma} - \phi_{t_1, \gamma'}) = \pi (\delta_{\gamma, y'} + \delta_{\gamma', y'}). 
\]
(29a) (29b)

When \(\epsilon_S = 1\) there are no solutions for \(\gamma \neq \gamma'\).

12. Fluxes with \(t^{h, \gamma}\) and \(t^{h, \gamma'}\) fields

We have to consider the trivial flux:
\[
\text{Arg}(t^{h, \gamma}_1 t^{h, \gamma}_1), 
\]
which gives the constraints:
\[
(\phi_{t_2, \gamma} - \phi_{t_2, \gamma'}) = \epsilon_I (\phi_{t_2, \gamma} - \phi_{t_2, \gamma'}), \\
(1 - \epsilon_S)(\phi_{t_2, \gamma} - \phi_{t_2, \gamma'}) = \pi (\delta_{\gamma, y'} + \delta_{\gamma', y'}). 
\]
(31a) (31b)

13. Solutions of phase equations

We organize the solutions to the phase equations in Table III. We only list \(Z_2\) spin liquid ansätze with at least one pairing field. Ansätze with only hopping fields can also be derived by the phase equations. They are, however, behaving like U(1) spin liquids and are thus subject to the Higgs mechanism. The phases of the mean-field parameters \(\phi_{\gamma, \gamma'}, \phi_{\gamma, \gamma'}, \phi_{\gamma, \gamma'}\) have to be related to the phases of the mean-fields \(\phi_{A_1}, \phi_{A_1}, \phi_{A_1}\) like
\[
(\phi_{t_2, \gamma}, \phi_{t_2, \gamma'}) = (\phi_{A_1}, \phi_{A_1}, \phi_{A_1}), \\
(\phi_{t_2, \gamma}, \phi_{t_2, \gamma'}) = (\phi_{A_1}, \phi_{A_1}, \phi_{A_1}), \\
(\phi_{t_2, \gamma}, \phi_{t_2, \gamma'}) = (\phi_{A_1}, \phi_{A_1}, \phi_{A_1}), \\
(\phi_{t_2, \gamma}, \phi_{t_2, \gamma'}) = (\phi_{A_1}, \phi_{A_1}, \phi_{A_1}). 
\]
(32) (33) (34) (35)

for the mean-field Hamiltonian to have the same symmetry as the state that we want to construct.

Appendix F: Hamiltonians for \(n_1 = 0\) and \(n_1 = 1\)

We give the explicit form of the submatrices of Eq. (40) for both \(n_1 = 0\) and \(n_1 = 1\). To keep things compact we introduce the notation \(t^{h, \gamma}(k)\) and for \(n_1 = 0\) and \(n_1 = 1\) we only need to give the upper triangular part to fully determine the whole matrices. For \(n_1 = 0\), \(H^t(k)\) is \(8 \times 8\) matrices given by
\[
H^t(k) = \begin{pmatrix}
0 & u_{01} + u_{101} & u_{02} + u_{102} & u_{03} + u_{103} \\
0 & u_{12} + u_{21} & u_{13} + u_{23} & u_{23} + u_{23}
\end{pmatrix}. 
\]
(3.3)

For \(n_1 = 1\), \(H^t(k)\) is \(32 \times 32\) matrices:
\[
H^t(k) = \begin{pmatrix}
H^t_{11}(k) & H^t_{12}(k) & H^t_{13}(k) & H^t_{14}(k) \\
H^t_{21}(k) & H^t_{22}(k) & H^t_{23}(k) & H^t_{24}(k) \\
H^t_{31}(k) & H^t_{32}(k) & H^t_{33}(k) & H^t_{34}(k) \\
H^t_{41}(k) & H^t_{42}(k) & H^t_{43}(k) & H^t_{44}(k)
\end{pmatrix}. 
\]
(4.4)

The unit cell consists out of four main tetrahedra \(q \in \{1, 2, 3, 4\}\) and the submatrices \(H^t_{q_1, q_2}\) include all bonds between main tetrahedron \(q_1\) and \(q_2\). They are given by:
\[
H^t_{ii}(k) = \begin{pmatrix}
0 & u_{01} e^{\epsilon^{\gamma_1, \pi}(\delta_{1, 2} + \delta_{1, 3})} & u_{02} & u_{03} \\
0 & u_{12} & u_{13} & u_{23}
\end{pmatrix}, 
\]
(5.5)
For the chiral PSG the $u'_{ij}$ matrices are given by
\[ u'_{01} = (a'_1, b'_1, c'_1, d'_1), \]
\[ u'_{02} = (a'_1, -\frac{1}{2}(b'_1 + \sqrt{3}c'_1), \frac{1}{2}(\sqrt{3}b'_1 - c'_1), d'_1)e^{-i\frac{2\pi}{3}}, \]
\[ u'_{03} = (a'_2, -\frac{1}{2}(b'_2 - \sqrt{3}c'_2), \frac{1}{2}(\sqrt{3}b'_2 + c'_2), d'_2)e^{-i\frac{4\pi}{3}}, \]
\[ u'_{12} = (a'_1, -\frac{1}{2}(b'_1 - \sqrt{3}c'_1), \frac{1}{2}(\sqrt{3}b'_1 + c'_1), d'_1)e^{-i\frac{2\pi}{3}}e^{in_c c'_3 \pi}, \]
\[ u'_{31} = (a'_1, -\frac{1}{2}(b'_1 + \sqrt{3}c'_1), \frac{1}{2}(\sqrt{3}b'_1 - c'_1), d'_1)e^{-i\frac{2\pi}{3}}e^{in_c c'_3 \pi}, \]
\[ u'_{23} = (a'_1, b'_1, c'_1, d'_1)e^{-i\frac{2\pi}{3}}e^{in_c c'_3 \pi}, \]
\[ u'_{01} = (a'_1, b'_1, a'_2, d'_2), \]
\[ u'_{02} = (a'_2, -\frac{1}{2}(b'_2 + \sqrt{3}c'_2), \frac{1}{2}(\sqrt{3}b'_2 - c'_2), d'_2)e^{-i\frac{2\pi}{3}}, \]
\[ u'_{03} = (a'_2, -\frac{1}{2}(b'_2 - \sqrt{3}c'_2), \frac{1}{2}(\sqrt{3}b'_2 + c'_2), d'_2)e^{-i\frac{4\pi}{3}}, \]
\[ u'_{12} = (a'_2, -\frac{1}{2}(b'_2 - \sqrt{3}c'_2), \frac{1}{2}(\sqrt{3}b'_2 + c'_2), d'_2)e^{-i\frac{2\pi}{3}}e^{i(n_1 + n_c c_3 \pi)}, \]
\[ u'_{31} = (a'_2, -\frac{1}{2}(b'_2 + \sqrt{3}c'_2), \frac{1}{2}(\sqrt{3}b'_2 - c'_2), d'_2)e^{-i\frac{2\pi}{3}}e^{i(n_1 + n_c c_3 \pi)}, \]
\[ u'_{23} = (a'_2, b'_2, c'_2, d'_2)e^{-i\frac{2\pi}{3}}e^{i(n_1 + n_c c_3 \pi)}. \]
