

Local positioning system as a classic alternative to atomic navigation.

(Dated: January 26, 2022)

A local positional system (LPS) is proposed, in which particles are launched at given velocities, and a sensor system measures the trajectory of particles in the platform frame. These measurements allow us to restore the position and orientation of the platform in the frame of the rotating Earth, without solving navigation equations. When the platform velocity is known and if the platform orientation stays the same, the LPS-technique allows a navigational accuracy of 100μ per one hour to be achieved. In this case, the LPS technique is insensitive to the type of platform trajectory. If there are also velocimeters installed on the platform, then one can restore the velocity and angular rate of the platform rotation in respect to the Earth. Instead of navigational equations, it is necessary to obtain the classical trajectory of a particle in the field of a rotating gravity source. Taking into account the gravity-gradient, Coriolis, and centrifugal forces, the exact expression for this trajectory is derived, which can be widely used in atomic interferometry. A new iterative method for restoring the orientation of the platform without using gyroscopes is developed. The simulation allowed us to determine the conditions under which the LPS-navigation error per hour is about 10m.

I. INTRODUCTION

Since its birth about 40 years ago [1], the field of atom interferometry has matured significantly. The current state and prospects in this area are presented, for example, in the reviews [2] and the proposals [3–8].

Among other applications, atom interferometers (AIs) are now proposed to use as inertial measurement units (IMUs) in navigation.

The precision accuracy of AI allows us to hope for significant progress, improving the accuracy and duration of the navigation. These applications are based on the possibility of using AI as an accelerometer [10]. If the atoms move with acceleration a , then the AI phase is given by

$$\phi = \mathbf{k} \cdot \mathbf{a}T^2, \quad (1)$$

where \mathbf{k} is the effective wave vector of the Raman pulses, T is the delay time between these pulses. The error of the acceleration measurement is

$$\delta a = \phi_{err}/kT^2, \quad (2)$$

where ϕ_{err} is the accuracy of the AI phase measurement. To date, for example, the accuracy of differential acceleration measurements has reached

$$\delta a = 1.4ppt \quad (3)$$

at the delay time

$$T = 955ms. \quad (4)$$

For navigation applications, a system of 6 AIs was created and tested [12]. However, the direct use of precise

AI as an IMU is difficult. Matter of fact is that the IMUs data should be substituted into the navigation equations, and for an accurate numerical solution of these equations, the IMUs measurements should be repeated with a time step of at least $\tau \sim 1ms$ [13]. To do this, the interrogation time of the AI must be no more than τ , and therefore $T \lesssim \tau/2$. Thus, with the same accuracy of the phase measurement ϕ_{err} and the effective wave vector k , the acceleration measurement error increases by 6 orders of magnitude to the level of 5ppm. With such an inaccuracy, atomic interferometers will be even an order of magnitude worse than conventional accelerometers [14] and will not result in any progress in navigation.

Two methods have been proposed to avoid this difficulty. In one method, AIs is used in a hybrid mode together with conventional IMUs [15–19]. Another option [20] is related to the fact that one can restore the position of the platform directly from the AI phase. without measuring the atomic acceleration and, in principle, without any use of conventional IMUs. To understand why this is possible, one notes that Eq. (1) is valid only for the uniform accelerated motion of the atom. If the atomic cloud moves in the platform frame, then, ignoring the quantum effects, for the phase instead of (1) one gets

$$\phi = \mathbf{k} \cdot \mathbf{p}, \quad (5a)$$

$$\mathbf{p} = \mathbf{x}(t_3) - 2\mathbf{x}(t_2) + \mathbf{x}(t_1), \quad (5b)$$

where $\mathbf{x}(t)$ is the classical trajectory of the cloud in the platform frame. Knowing the trajectory at the previous moments t_1 and $t_2 = t_1 + T$ and measuring the phase of AI, one restores the trajectory at the moment $t_3 = t_1 + 2T$. At the same time, there is no need to solve navigation equations, and as a result, the restriction on the feasible delay time T is removed. One sees that when using AI as an IMU, one actually does double work: first, by measuring the trajectory, $\mathbf{x}(t_3)$, gets

*Electronic address: bdubetsky@gmail.com

the acceleration, and then from the navigation equations gets the trajectory.

The error of measuring the position $\mathbf{x}(t_3)$ is given by

$$\delta_x \sim \phi_{err}/k \sim 1.3\text{pm}, \quad (6)$$

where to estimate the parameter ϕ_{err}/k , one can use the Eqs. (3-4). Despite the fact that at each step the error (6) does not depend on T , the total error ΔX during navigation time t_n accumulates after repeated measurement of phases at times multiple to T , . For the given t_n , the number of steps

$$n \sim t_n/T. \quad (7)$$

The use of AIs with a longer interrogation time leads to a reduction in the number of steps and, consequently, to a reduction in the accumulated error. Thus, one sees that, proposed in [20], the rejection of the use of AIs as accelerometers, allows the use of an unprecedentedly high accuracy of trajectory measurement (6) for an unprecedentedly accurate navigation.

Atom interference is an exclusively quantum phenomenon. Nevertheless, the expression (5) for the phase is purely classical. This means that instead of quantum objects, atoms, one can use classical material points, which in the future we will call particles. We do not specify the kind of particles. However, we assume that the mass of the particle M is sufficiently large to neglect the recoil velocity $\hbar k/M$, where, in our case, $\hbar k$ is the change in momentum that accompanies the measurement of the particle position.

Like in the patent [20], in this article, we propose to abandon the use of accelerometers, gyroscopes, and navigation equations, and instead measure the trajectories of particles that are launched in the platform system from certain points, at certain speeds, and with a time interval T . We will develop a theory of such navigation here and perform numerical simulations. The obvious advantages of classical objects are a dramatic mitigation in the requirements of high vacuum, disappearing the necessity to solve the problem of the phase multiple ambiguity, and the absence of a recoil effect. The obvious disadvantage of our method is that for classical objects, the accuracy of the measurement (6) of their position is hardly achievable at the present time. We have, however, developed methods here that will significantly relax the requirements for δ_x . The ultimate goal of numerical simulation is to answer the question of what the accuracy of measuring the coordinates and velocities of particles should be in order to achieve a given accuracy of navigation ΔX for a given period of time t_n . Specifically, we will find the answer to this question for

$$t_n = 1\text{h}, \quad (8a)$$

$$\Delta X = 10\text{m}. \quad (8b)$$

The accelerometer in conventional navigation measures the acceleration of particle \mathbf{a} in the platform system. For

FIG. 1: Exploiting the measurement of the particle position in the platform frame for navigation. The trajectories of the platform and the particle are shown with solid and dotted curves.

\mathbf{a} in the absence of rotation one has

$$\mathbf{a} = \mathbf{g} - \mathbf{A}, \quad (9)$$

where \mathbf{g} and \mathbf{A} are the gravitational field of the Earth and the acceleration of the platform. Knowing \mathbf{g} and measuring \mathbf{a} , one obtains the acceleration of platform \mathbf{A} , substituting it into the navigation equation

$$\ddot{\mathbf{X}}(t) = \mathbf{A}, \quad (10)$$

to determine the trajectory of the platform $\mathbf{X}(t)$.

In Ref. [20], it is actually proposed to replace the accelerations \mathbf{a} and \mathbf{A} , with the trajectories $\mathbf{x}(t)$ and $\mathbf{X}(t)$. The procedure for determining the position of the platform by measuring the position of the particle in the absence of rotation of the platform is illustrated in Fig. 1.

We are interested in the trajectory of the platform $\mathbf{X}(t)$ in the coordinate system $\{X, Y, Z\}$ rotating with the Earth. On the platform, one installs a local frame $\{x, y, z\}$ with the origin at the point $\mathbf{X}(t)$ and sensors that measure the position of the particle $\mathbf{x}(t)$ in that local frame. At the moment of time t_1 one launches the particle. After the launch, the particle is completely decoupled from the platform and moves along the trajectory $\mathbf{X}_E(t)$ in a vacuum under the influence of only the rotating Earth. Knowing the potential of the Earth's gravitational field and the velocity of the Earth rotation $\vec{\Omega}_E(t)$, one can obtain the trajectory $\mathbf{X}_E(t)$. At time t_2 one measures the position of the particle \mathbf{x} . Then from Fig. 1 one gets for the platform trajectory

$$\mathbf{X}(t_2) = \mathbf{X}_E(t_2) - \mathbf{x}. \quad (11)$$

The position of the particle at the time of launch in the system $\{X, Y, Z\}$, obviously coincides with the position of the platform, $\mathbf{X}_E(t_1) = \mathbf{X}(t_1)$. To determine the

FIG. 2: The green curves are the time dependences of the navigation error $\Delta X(t)$ for an ensemble of 30 randomly generated platform trajectories $\mathbf{X}(t)$. The red curve is the average error in the ensemble $\langle \Delta X(t) \rangle$, the black curve is SD $\sqrt{\langle [\Delta X(t)]^2 \rangle - \langle \Delta X(t) \rangle^2}$.

trajectory $\mathbf{X}_E(t)$, it is also necessary to get the initial velocity of the particle, $\mathbf{v}_E(t_1)$, and it depends on the velocity of the platform $\vec{V}(t_1)$, the velocity of the particle \mathbf{v} in the platform frame, the initial orientation of the platform, the rotation matrix $R(t_1)$, and the initial rate of the platform rotation $\Omega(t_1)$. It is also necessary to take into account that at the moment t_2 the orientation of the system changes, the rotation matrix $R(t_2) \neq R(t_1)$ and one must rotate the vector \mathbf{x} from the frame $\{x, y, z\}$ in which it is measured to the frame $\{X, Y, Z\}$. Below we will derive an obvious generalization of the formula (11) taking into account all these factors. But here we would like to note that for successful navigation, restoring the position of the platform, it is also necessary to restore the parameters

$$Z = \{\mathbf{V}(t), \Omega(t), R(t)\}. \quad (12)$$

However, in order to demonstrate the power of the navigation method we are considering here, let's assume that these parameters are known exactly. We also assume that the particles are launched with a step $T = 300\text{ms}$, and the position of the particle is measured with accuracy [standard deviation (SD)]

$$\delta_x = 1\mu. \quad (13)$$

Then the time dependence of the navigation error is shown in Fig.2.

We assume that the accuracy of measuring the trajectory of a classical particle (13) is 6 orders of magnitude worse than the accuracy of measuring (6) the trajectory of a quantum atomic cloud, achievable by atomic interferometry methods [1]. **And nevertheless, ideally, the accuracy of navigation in 1 hour does not exceed 150μ and practically remains the same for different trajectories.**

Following [14], in the future we will assume that the north-east-down (NED) local frame is installed on the

FIG. 3: LPS - measurement of the particle's coordinates. From the distances to three red satellites, one determines two positions of the particle, true white and false red. Similarly, for green satellites, one gets true white and false green. The true solution is obviously the same for the red and green satellites.

platform. Likewise GPS, we propose to install in NED-frame a sensor system to measure the distance to the particle, which we will call the local positioning system (LPS), see Fig. 3.

As in GPS, we will call these sensors satellites. Our code can be used for any satellite location. However, in the simulation, we use only satellites located on the frame axes. When three satellites are located on the positive semi-axes of the system, the vector connecting the particle and the satellites do not lie in the same plane, and the coordinates of the vector \mathbf{x} can be obtained from the distances to the satellites. The equations for \mathbf{x} have two solutions, one true, the other false. To overcome this ambiguity, one can use an additional system of satellites located, for example, symmetrically on negative semi-axes and choose as true the solution that is the same for both satellite systems. During the simulation, pseudo-random corrections were made to the exact distances using the normal random number generator [21] with SD δ_x .

At the launching time, we need to restore the values of the parameters (12). Errors in restoring these parameters degrade navigation accuracy by several orders of magnitude. These parameters can be restored using conventional IMUs. In this case, we come to another kind of hybrid. Our code can be included in the code of operation of such a hybrid. In this paper, however, we will consider the possibilities of reconstructing Z by launching particles with different velocities and simultaneously measuring their coordinates and velocities through time T .

The most significant factor affecting the accuracy of navigation is the platform rotation. In the case of atomic navigation, it was proposed to use the gimbal [22] to reduce the effect of rotation. In this paper, we also assume the presence of gimbal, which we define as reference systems that perform only noisy rotations at small angles, with zero mean value and SD δ_g . In the future, we will determine the quality of the gimbals, SD δ_g , to achieve the ultimate goal of navigation (8).

An elementary loop of the navigation is the restoration of the position, velocity, orientation and rate of rotation of the platform at the time $t_2 = t_1 + T$ from their values at the time of the particle launch t_1 . Then the restored parameters at the time t_2 are used for navigation at the time $t_3 = t_2 + T$ and so on. We will call this method first order navigation. Due to the large Doppler broadening of the spectral lines, one could not use both the atomic interferometry [1] and the Ramsey fringes [23] for this method. We propose installing in the NED-frame velocimeters together with satellites. Measuring the velocity of a particle in the platform frame will restore the velocity of the platform $V(t_2)$, while measuring the distance difference between particles launched at different velocities will restore the orientation of the platform $R(t_2)$, and finally, measuring the velocity difference of these particles will restore the rotation rate of the platform $\Omega(t_2)$.

The severe requirements on the platform velocity recovery can be mitigated in the case of the 2nd order navigation, when one measures particle's positions at three times $\{t_1, t_2 = t_1 + T, t_3 = t_1 + 2T\}$ and employs the 2nd order difference (5b) to restore platform position $\mathbf{X}(t_3)$. The reason here is that even with an arbitrary trajectory of the platform, the difference (5b) does not depend on the initial velocity of the particle, if the platform does not rotate, and the Earth's gravitational field is uniform. The weak inhomogeneity of the field and the noisy, small rotation of the gimbal lead to such a weak dependence of \mathbf{p} on the platform velocity that there is no need in velocimeters.

The requirements for the quality of the gimbal can also be relaxed if one launches simultaneously 3 particles with different velocities and restores the orientation of the gimbal from the differences in their trajectories. In the case of the atom interferometry, iterative method of this kind restoration was developed in [22]. Here we generalize this method to the case of LPS-navigation (LPS-N).

We offer here 5 varieties of LPS-N:

- 1.1 1st order LPS-N, the quality of the gimbal is high enough to neglect its rotation;
- 1.2 1st order LPS-N, the quality of the gimbal is sufficient to neglect its rotation, but one does not neglect the rate of rotation, and restores it applying data of velocimeters;
- 1.3 1st order LPS-N, one restores the orientation and rotation rate of the gimbal applying satellites' and velocimeters' data;

- 2.1 2nd order LPS-N, the quality of the gimbal is high enough to neglect its rotation;
- 2.2 2nd order LPS-N, one restores the orientation of the gimbal from satellite data.

The article is arranged as follows. The exact expression for the trajectory of a particle in the field of the rotating Earth, when the potential of this field is expanded to the 1st order gravity-gradient terms, is obtained in [20]. For the completeness of this study, we derive this expression in the next section. The technique of restoring the orientation, rotation rate, velocity, and then the position of the platform is described in Sec. III for LPS-N of the 1st order and in Sec. IV for LPS-N of the 2nd order. The results of the simulation and their discussion were carried out in the Sec. V. In the appendix Sec. C we describe the model of the Earth's gravitational field accepted in our code.

II. PARTICLE TRAJECTORY

If the source of gravity rotates at a constant velocity Ω_E , then the trajectory of the particle obeys the following equation of motion

$$\ddot{\mathbf{X}}_E = -\nabla U(\mathbf{X}_E) - \Omega_E \times (\Omega_E \times \mathbf{X}_E) - 2\Omega_E \times \mathbf{v}_E, \quad (14)$$

where $\mathbf{v}_E = \dot{\mathbf{X}}_E$ is the velocity of the particle in the rotating Earth frame, $U(\mathbf{X})$ is the potential of the gravitational field. If the motion occurs in a small vicinity of the point \mathbf{X}_c , then expanding the potential to the second order terms,

$$U(\mathbf{X}_E) \approx U(\mathbf{X}_c) - \mathbf{g}_E(\mathbf{X}_c) \cdot \mathbf{x}_E - \frac{1}{2} \mathbf{x}_E^T \underline{\Gamma}(\mathbf{X}_c) \mathbf{x}_E, \quad (15)$$

where

$$\mathbf{x}_E = \mathbf{X}_E - \mathbf{X}_c, \quad (16)$$

and

$$\mathbf{g}_E(\mathbf{X}) = -\vec{\nabla} U(\mathbf{X}), \quad (17a)$$

$$\underline{\Gamma}(\mathbf{X}) = -\partial_{\mathbf{X}} \partial_{\mathbf{X}}^T U(\mathbf{X}) \quad (17b)$$

are the gravitational acceleration and the 1st order gravity-gradient tensor, one comes to the equation of motion

$$\ddot{\mathbf{X}}_E = \mathbf{g}(\mathbf{X}_c) - 2\Omega_E \times \mathbf{v}_E + \underline{q}(\mathbf{X}_c) \mathbf{x}_E, \quad (18)$$

where

$$\mathbf{g}(\mathbf{X}_c) = \mathbf{g}_E(\mathbf{X}_c) - \Omega_E \times (\Omega_E \times \mathbf{X}_c), \quad (19a)$$

$$\underline{q}(\mathbf{X}_c) = \underline{\Gamma}(\mathbf{X}_c) - \underline{\Omega}_E^2, \quad (19b)$$

and the tensor $\underline{\Omega}_E$ is given by

$$\underline{\Omega}_{Eik} = -\varepsilon_{ikm} \Omega_{Em}. \quad (20)$$

Despite the fact that Eq. (18) is a linear system of equations with permanent coefficients, most of the papers used expansions of $\mathbf{x}_E(t)$ into power series over time. In the Refs. [24, 25], the terms up to the 4th order were calculated, the 5th and 6th order terms were obtained in Ref. [26], the expansion to the 7th order was obtained in the article [27]. The exact solution of the equation (18) is obtained in the patent [20]. Here we derive exact solutions for arbitrarily large values of the tensor $q(\mathbf{X}_c)$ and the rate of rotation of the gravity field source, $\mathbf{\Omega}_E$. In this case, we are using the method proposed in [28]. Consider first the homogeneous equation $[\mathbf{g}(\mathbf{X}_c) = 0]$. Its solution is $\mathbf{x}_E(t) = \mathbf{x}(\omega) e^{-i\omega t}$, where ω and $\mathbf{x}(\omega)$ are the eigenvalue and eigenvector of the matrix

$$\underline{A}(\omega) = \underline{q}(\mathbf{X}_c) + \omega^2 I + 2i\omega \underline{\Omega}_E, \quad (21)$$

where I is the unity matrix. One notices that owing the symmetry of the tensor $\underline{q}(\mathbf{X}_c)$, the determinant $|\underline{A}(\omega)|$ is an even function ω , $|\underline{A}(\omega)| = |\underline{A}(-\omega)|$, and, therefore, the characteristic equation

$$|\underline{A}(\omega)| = 0, \quad (22)$$

is reduced to the 3rd order equation for ω^2

$$\omega^6 + a_2 \omega^4 + a_1 \omega^2 + a_0 = 0, \quad (23)$$

where

$$a_0 = |q(\mathbf{X}_c)|, \quad (24a)$$

$$a_1 = \frac{1}{2} \{Tr^2[\underline{q}(\mathbf{X}_c)] - Tr[\underline{q}^2(\mathbf{X}_c)]\} - 4\Omega_E^T \underline{q} \Omega_{En}, \quad (24b)$$

$$a_2 = Tr[\underline{q}(\mathbf{X}_c)] - 4\Omega_E^2. \quad (24c)$$

Eq. (23) has 6 roots

$$\omega_i = \sqrt{z_i - \frac{a_2}{3}}, \text{ for } i = 1, 2, 3 \quad (25a)$$

$$\{\omega_4, \omega_5, \omega_6\} = -\{\omega_1, \omega_2, \omega_3\}, \quad (25b)$$

where z_i is the root of the equation $z^3 + pz + s = 0$ and

$$p = a_1 - \frac{a_2^2}{3}, \quad (26a)$$

$$s = a_0 - \frac{a_2 a_1}{3} + \frac{2a_2^3}{27}. \quad (26b)$$

The eigenvectors are given by

$$\mathbf{x}(\omega) = \begin{pmatrix} A_{22}(\omega) A_{33}(\omega) - A_{23}(\omega) A_{32}(\omega) \\ A_{23}(\omega) A_{31}(\omega) - A_{21}(\omega) A_{33}(\omega) \\ A_{21}(\omega) A_{32}(\omega) - A_{22}(\omega) A_{31}(\omega) \end{pmatrix}. \quad (27)$$

Let's return now to the equation (18). We introduce a 6-dimensional vector

$$\mathbf{y} = \begin{pmatrix} \mathbf{x}_E \\ \mathbf{v}_E \end{pmatrix}, \quad (28)$$

which obeys the equation

$$\dot{\mathbf{y}} = \begin{pmatrix} 0 & I \\ \underline{q} & -2\underline{\Omega}_E \end{pmatrix} \mathbf{y} + \begin{pmatrix} 0 \\ \mathbf{g} \end{pmatrix}. \quad (29)$$

One gets that solution is given by

$$\mathbf{y}(t) = \underline{\Phi}(t) \mathbf{y}(0) + \int_0^t dt' \underline{\Phi}(t-t') \begin{pmatrix} 0 \\ \mathbf{g} \end{pmatrix}, \quad (30)$$

$$\underline{\Phi}(t) = \underline{Y}(t) \underline{Y}^{-1}(0), \quad (31)$$

where 6×6 matrix $\underline{Y}(t)$ is composed of eigenvectors,

$$\underline{Y}(t) = \{\mathbf{y}_1 e^{-i\omega_1 t}, \dots, \mathbf{y}_6 e^{-i\omega_6 t}\}. \quad (32)$$

Since

$$\mathbf{y}_m = \begin{pmatrix} \mathbf{x}_m \\ -i\omega_m \mathbf{x}_m \end{pmatrix}, \quad (33)$$

one can represent the matrix (32) as

$$\underline{Y}(t) = \begin{pmatrix} \underline{x}_+ e^{-i\tilde{\omega} t} & \underline{x}_- e^{i\tilde{\omega} t} \\ -i\underline{x}_+ \tilde{\omega} e^{-i\tilde{\omega} t} & i\underline{x}_- \tilde{\omega} e^{i\tilde{\omega} t} \end{pmatrix}, \quad (34)$$

where 3×3 -matrices \underline{x}_{\pm} and ω are composed of eigenvectors (27) and eigenfrequencies

$$\underline{x}_{\pm} \equiv \{\mathbf{x}(\pm\omega_1), \mathbf{x}(\pm\omega_2), \mathbf{x}(\pm\omega_3)\}, \quad (35a)$$

$$\tilde{\omega} = \text{diag}(\omega_1, \omega_2, \omega_3). \quad (35b)$$

To inverse the matrix $\underline{Y}(0)$, one can use the method developed in [29]. It is convenient to represent the 6×6 -matrices $\underline{\Phi}(t)$ and $\underline{Y}^{-1}(0)$ as 2×2 -matrices

$$\underline{\Phi}(t) = \begin{pmatrix} \underline{x}_x(t) & \underline{x}_v(t) \\ \underline{\dot{x}}_x(t) & \underline{\dot{x}}_v(t) \end{pmatrix}, \quad (36a)$$

$$\underline{Y}^{-1}(0) = \begin{pmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{pmatrix}, \quad (36b)$$

in which the matrix elements are 3×3 -matrices. Then one gets for b_{mn}

$$\underline{x}_+ b_{11} + \underline{x}_- b_{21} = I, \quad (37a)$$

$$\underline{x}_+ \tilde{\omega} b_{11} - \underline{x}_- \tilde{\omega} b_{21} = 0, \quad (37b)$$

$$\underline{x}_+ \tilde{\omega} b_{12} - \underline{x}_- \tilde{\omega} b_{22} = i, \quad (37c)$$

$$\underline{x}_+ b_{12} + \underline{x}_- b_{22} = 0. \quad (37d)$$

Solving the Eqs. (37) and substituting their solutions consequently in the Eqs. (31) and (30), after integrating into the Eq. (30), one arrives at the next exact solution of the Eq. (18)

$$\mathbf{x}_E(t) = \underline{x}_x(t) \mathbf{x}_E(0) + \underline{x}_v(t) \mathbf{v}_E(0) + \underline{x}_g(t) \mathbf{g}(\mathbf{X}_c), \quad (38a)$$

$$\underline{x}_x(t) = (\underline{x}_+ e^{-i\tilde{\omega} t} + \underline{x}_- e^{i\tilde{\omega} t} \tilde{\omega}^{-1} \underline{x}_+^{-1} \underline{x}_+ \tilde{\omega}) \underline{x}_i, \quad (38b)$$

$$\underline{x}_v(t) = i(\underline{x}_+ e^{-i\tilde{\omega} t} \underline{x}_+^{-1} \underline{x}_- - \underline{x}_- e^{i\tilde{\omega} t}) \underline{v}_i \quad (38c)$$

$$\underline{x}_g(t) = \left(\underline{x}_+ \frac{e^{-i\tilde{\omega} t} - 1}{\tilde{\omega}} \underline{x}_+^{-1} \underline{x}_- + \underline{x}_- \frac{e^{i\tilde{\omega} t} - 1}{\tilde{\omega}} \right) \underline{v}_i, \quad (38d)$$

where

$$\underline{x}_i = (x_+ + x_- \tilde{\omega}^{-1} x_-^{-1} x_+ \tilde{\omega})^{-1}, \quad (39a)$$

$$\underline{v}_i = (x_- \tilde{\omega} + x_+ \tilde{\omega} x_+^{-1} x_-)^{-1}. \quad (39b)$$

III. 1ST ORDER LPS-N

Suppose that in the platform frame, one launches a particle at the time $t = 0$ from the point $\mathbf{x}(0)$ at the velocity $\mathbf{v}(0)$. After the interrogation time T , one measures the position and velocity of the particle $\{\mathbf{x}(T), \mathbf{v}(T)\}$ using the local system of satellites and velocimeters and applying Eqs. (A1, A4). The navigation purpose is to restore the position, orientation, velocity, and rotation rate of the platform, $\{\mathbf{X}(T), R(T), \mathbf{V}(T), \boldsymbol{\Omega}(T)\}$, from these measurements.

After the launch, the particles are decoupled from the platform and move into the Earth gravitational and inertial fields.. Its position in respect to the Earth origin is given by

$$\mathbf{X}_E(t) = \mathbf{X}_c + \mathbf{x}_E(t), \quad (40)$$

where $\mathbf{x}_E(t)$ one obtains from Eq. (38a). If the origin of the platform frame moves along the trajectory $\mathbf{X}(T)$, then

$$\mathbf{x}(T) = R(T) [\mathbf{x}_E(T) + \mathbf{X}_c - \mathbf{X}(T)]. \quad (41)$$

Since the derivative of the rotation matrix is determined by the rotation rate, $\dot{R}(T) = -\underline{\boldsymbol{\Omega}}(T) R(T)$, one obtains for the particle velocity

$$\mathbf{v}(T) = -\boldsymbol{\Omega}(T) \times \mathbf{x}(T) + R(T) [\mathbf{v}_E(T) - \mathbf{V}(T)]. \quad (42)$$

The particle is detached from the platform only after launch, at $T > 0$. If $T = 0$, one gets from Eqs. (41, 42)

$$\mathbf{x}_E(0) = \mathbf{X}(0) - \mathbf{X}_c + R^T(0) \mathbf{x}(0), \quad (43a)$$

$$\mathbf{v}_E(0) = \mathbf{V}(0) + R^T(0) [\mathbf{v}(0) + \boldsymbol{\Omega} \times \mathbf{x}(0)]. \quad (43b)$$

Then one gets

$$\begin{aligned} \mathbf{x}(T) = & R(T) \{ \underline{x}_x(T) [\mathbf{X}(0) - \mathbf{X}_c + R^T(0) \mathbf{x}(0)] \\ & + \underline{x}_v(T) [\mathbf{V}(0) + R^T(0) (\mathbf{v}(0) + \boldsymbol{\Omega}(0) \times \mathbf{x}(0))] \\ & + \underline{x}_g(T) \mathbf{g}(\mathbf{X}_c) + \mathbf{X}_c - \mathbf{X}(T) \}; \end{aligned} \quad (44a)$$

$$\begin{aligned} \mathbf{v}(T) = & -\boldsymbol{\Omega}(T) \times \mathbf{x}(T) + R(T) \\ & \times \{ \underline{x}_x(T) [\mathbf{X}(0) - \mathbf{X}_c + R^T(0) \mathbf{x}(0)] \\ & + \underline{x}_v(T) [\mathbf{V}(0) + R^T(0) (\mathbf{v}(0) + \boldsymbol{\Omega}(0) \times \mathbf{x}(0))] \\ & + \underline{x}_g(T) \mathbf{g}(\mathbf{X}_c) - \mathbf{V}(T) \}. \end{aligned} \quad (44b)$$

The equation (44a) gives the exact trajectory of the particle in the platform frame, which can, for example, be used to exact calculation of the AI phase, instead of the approximate calculations in the articles [24–27]. Like in the previous studies [20, 22], here we are going to use Eq. (44) to restore the position and velocity of the platform.

For them, one has

$$\begin{aligned} \mathbf{X}(T) = & \mathbf{X}_c + \underline{x}_x(T) [\mathbf{X}(0) - \mathbf{X}_c + R^T(0) \mathbf{x}(0)] \\ & + \underline{x}_v(T) [\mathbf{V}(0) + R^T(0) (\mathbf{v}(0) + \boldsymbol{\Omega}(0) \times \mathbf{x}(0))] \\ & + \underline{x}_g(T) \mathbf{g}(\mathbf{X}_c) - R^T(T) \mathbf{x}(T), \quad (45) \\ \mathbf{V}(T) = & \underline{x}_x(T) [\mathbf{X}(0) - \mathbf{X}_c + R^T(0) \mathbf{x}(0)] \\ & + \underline{x}_v(T) [\mathbf{V}(0) + R^T(0) (\mathbf{v}(0) + \boldsymbol{\Omega} \times \mathbf{x}(0))] \\ & + \underline{x}_g(T) \mathbf{g}(\mathbf{X}_c) - R^T(T) [\mathbf{v}(T) + \boldsymbol{\Omega}(T) \times \mathbf{x}(T)]. \end{aligned} \quad (46)$$

A. Rotation rate restore

One sees that in order to obtain the position and velocity of the platform, it is necessary to initially restore the rotation rate $\boldsymbol{\Omega}(T)$ and the rotation matrix $R(T)$. For these restorations, one can use a differential technique. If from the same point one launches 3 particles with velocities \mathbf{v} , \mathbf{v}' and \mathbf{v}'' , then using Eq.. (44b) to get the velocity differences at the time T

$$\delta \mathbf{v}_1(T) = \mathbf{v}(T) - \mathbf{v}'(T), \quad (47a)$$

$$\delta \mathbf{v}_2(T) = \mathbf{v}(T) - \mathbf{v}''(T). \quad (47b)$$

one arrives to the following equations for $\boldsymbol{\Omega}(T)$

$$\mathbf{a}_i \times \boldsymbol{\Omega}(T) = \mathbf{b}_i, \quad (48)$$

where

$$\mathbf{a}_i \equiv \delta \mathbf{x}_i(T), \quad (49a)$$

$$\mathbf{b}_i \equiv \delta \mathbf{v}_i(T) - R(T) \dot{x}_v(T) R^T(0) \delta \mathbf{v}_i, \quad (49b)$$

$$\delta \mathbf{v}_i \equiv \delta \mathbf{v}_i(0). \quad (49c)$$

One sees that one velocity difference, for example $\delta \mathbf{v}_1$, is not sufficient, it allows us to restore only the component of the rotation rate perpendicular to \mathbf{a}_1 . That is why one starts 3 particles and considers 2 velocity differences. Decomposing $\boldsymbol{\Omega}(T)$ as

$$\boldsymbol{\Omega}(T) = \boldsymbol{\Omega}_\perp(T) + \Omega_\parallel(T) \mathbf{a}_1, \quad (50)$$

one gets from Eq. (48) for $i = 1$

$$\boldsymbol{\Omega}_\perp(T) = \frac{\mathbf{b}_1 \times \mathbf{a}_1}{a_1^2} \quad (51)$$

Substituting Eq.. (51) in Eq. (50) and then in Eq. (48) for $i=2$, one obtains the equation for $\Omega_\parallel(T)$. After solving it, one arrives to the following result

$$\boldsymbol{\Omega}(t) = \mathbf{f}(\mathbf{a}_i, \mathbf{b}_i), \quad (52a)$$

$$\begin{aligned} \mathbf{f}(\mathbf{a}_i, \mathbf{b}_i) = & \frac{\mathbf{b}_1 \times \mathbf{a}_1}{a_1^2} \\ & + \frac{\mathbf{a}_1 \cdot \{ [\mathbf{b}_2 a_1^2 - \mathbf{b}_1 (\mathbf{a}_1 \cdot \mathbf{a}_2)] \times \mathbf{a}_2 \}}{(\mathbf{a}_2 \times \mathbf{a}_1)^2 a_1^2} \mathbf{a}_1. \end{aligned} \quad (52b)$$

B. Rotation matrix restore

Here, also, one should use the differential technique [20, 22]. For the same 3 particles with launch velocities \mathbf{v} , \mathbf{v}' and \mathbf{v}'' instead of the velocities' difference (47), one now measures the positions' differences

$$\delta \mathbf{x}_1(T) = \mathbf{x}(T) - \mathbf{x}'(T), \quad (53a)$$

$$\delta \mathbf{x}_2(T) = \mathbf{x}(T) - \mathbf{x}''(T), \quad (53b)$$

which depend only on the rotation matrices,

$$\delta \mathbf{x}_i(T) = r \mathbf{a}_i, \quad (54a)$$

$$r = R(T) R^T(0), \quad (54b)$$

$$\mathbf{a}_i = R(0) \underline{x}_v(T) R^T(0) \delta \mathbf{v}_i, \quad (54c)$$

where $\delta \mathbf{v}_i$ is defined in Eq. (49c). The matrix r in the Rodriguez representation [30] is given by

$$r = \cos \delta + \frac{(1 - \cos \delta)}{\delta^2} \boldsymbol{\delta} \boldsymbol{\delta}^T - \frac{\sin \delta}{\delta} \underline{\boldsymbol{\delta}}, \quad (55)$$

where the vector $\boldsymbol{\delta}$ contains 3 parameters that define the rotation. In the Ref. [22], an iterative method was proposed for calculating the angle of rotation $\boldsymbol{\delta}$ from the phase differences of 6 AIs, in which the atoms were launched at different speeds, and the wave vectors did not lie in the same plane. Here we adapt this method for the case of LPS.

In the case of rotation at a small angle, $\delta \ll 1$, when $r \approx 1 - \underline{\boldsymbol{\delta}}$, and matrix δ defined as

$$\underline{\delta}_{ik} = -\varepsilon_{ikm} \delta_m, \quad (56)$$

one gets that

$$\mathbf{a}_i \times \boldsymbol{\delta} = \mathbf{b}_i, \quad (57)$$

where

$$\mathbf{b}_i = \delta \mathbf{x}_i(T) - \mathbf{a}_i, \quad (58)$$

and $|b_i| \ll |a_i|$. This equation coincides with Eq. (48), and hence,

$$\boldsymbol{\delta} = \mathbf{f}(\mathbf{a}_i, \mathbf{b}_i), \quad (59)$$

where \mathbf{f} is the vector function defined in Eq. (52b).

Let us now turn to the general case. Then, from Eq. (54a), one gets

$$\sin \delta \mathbf{a}_i \times \mathbf{n} + (1 - \cos \delta) [\mathbf{n}(\mathbf{n} \mathbf{a}_i) - \mathbf{a}_i] - \mathbf{b}_i = 0, \quad (60)$$

where $\mathbf{n} = \boldsymbol{\delta} / \delta$. One can introduce the parameter

$$\sigma = |\mathbf{f}(\mathbf{a}_i, \mathbf{b}_i)| \quad (61)$$

and expand the solutions of Eq. (60) in the series

$$\delta = \sum_{s=1}^{\infty} \delta^{(s)} \sigma^s, \quad (62a)$$

$$\mathbf{n} = \sum_{s=0}^{\infty} \mathbf{n}^{(s)} \sigma^s \quad (62b)$$

The lower order terms in these series are equal

$$\delta^{(1)} = 1, \quad (63a)$$

$$\mathbf{n}^{(0)} = \mathbf{f}(\mathbf{a}_i, \mathbf{b}_i) / \sigma \quad (63b)$$

In Appendix B, we have derived the recurrence relations for the coefficients $\{\mathbf{n}^{(s-1)}, \delta^{(s)}\}$.

IV. 2ND ORDER LPS-N

In this case, one restores the trajectory and orientation of the platform $\{\mathbf{X}(2T), R(2T)\}$ from their previous values at moments $t = 0$ and $t = T$, using a second-order difference

$$\mathbf{p} = \mathbf{x}(2T) - 2\mathbf{x}(T) + \mathbf{x}(0), \quad (64)$$

in which the particle positions in the platform frame, $\mathbf{x}(T)$ and $\mathbf{x}(2T)$ are measured using satellites.

An important advantage of such navigation is a tremendous decrease of the navigation sensitivity to the initial velocity of the platform. For successful navigation, it is sufficient to put [20, 22]

$$\mathbf{V}(0) = \frac{\mathbf{X}(T) - \mathbf{X}(-T)}{2T}, \quad (65)$$

where, for a given loop of the navigation cycle, $t \in [0, 2T]$, the positions of the platform $\mathbf{X}(-T)$ and $\mathbf{X}(T)$ are restored in the previous loops.

If all the particles are launched from the center of the platform $[\mathbf{x}(0) = 0]$, then the lever=arm term, $\boldsymbol{\Omega}(0) \times \mathbf{x}(0)$, disappears, and simultaneously the need to restore the angular velocity of the platform rotation $\boldsymbol{\Omega}(0)$ disappears also. Let's also assume for simplicity that $\mathbf{X}_c = \mathbf{X}(0)$. Then

$$\begin{aligned} \mathbf{p} = & [R(2T) \underline{x}_v(2T) - 2R(T) \underline{x}_v(T)] \\ & \times [\mathbf{V}(0) + R^T(0) \mathbf{v}(0)] \\ & + [R(2T) \underline{x}_g(2T) - 2R(T) \underline{x}_g(T)] \mathbf{g}(\mathbf{X}(0)) \\ & - R(2T) [\mathbf{X}(2T) - \mathbf{X}(0)] + 2R(T) [\mathbf{X}(T) - \mathbf{X}(0)] \end{aligned} \quad (66)$$

In the absence of rotation $[R(t) = I]$ and for a uniform, non-rotating gravitational field

$$\underline{x}_v(t) = t; \quad (67)$$

the first term in Eq. (66) disappears and the difference \mathbf{p} does not depend on the initial velocity of the platform. The simulation showed that despite the weak inhomogeneity of the field, the presence of inertial forces due to the rotation of the Earth and the small rotations of the gimbal, the first term remains so small that the error in restoring the velocity (65) has a much smaller impact on the accuracy of navigation than other factors, and one

may not take it into account. Then the coordinate of the platform $\mathbf{X}(2T)$ is restored as

$$\begin{aligned} \mathbf{X}(2T) = & R^T(2T) \{ -\mathbf{p} + [R(2T)\underline{x}_v(2T) - 2R(T)\underline{x}_v(T)] \\ & \times [\mathbf{V}(0) + R^T(0)\mathbf{v}(0)] \\ & + [R(2T)\underline{x}_g(2T) - 2R(T)\underline{x}_g(T)] \mathbf{g}(\mathbf{X}(0)) \\ & + 2R(T)\mathbf{X}(T) + [R(2T) - 2R(T)]\mathbf{X}(0) \}. \end{aligned} \quad (68)$$

If one neglects the rotation of the gimbal, assuming $R(2T) = R(T) = R(0)$, then no further steps are required. Otherwise, like in Sec. IIIB, one launches simultaneously from the origin 3 particles with velocities $\mathbf{v}(0) = \mathbf{v}, \mathbf{v}',$ and \mathbf{v}'' and measures the double differences

$$\delta\mathbf{p}_1(T) = \mathbf{p}(T) - \mathbf{p}'(T), \quad (69a)$$

$$\delta\mathbf{p}_2(T) = \mathbf{p}(T) - \mathbf{p}''(T), \quad (69b)$$

which lead to the equations for the rotation matrix $R(2T)$. In this case, one comes to the equation

$$\delta\mathbf{p}_i + 2R(T)\underline{x}_v(T)R^T(0)\delta\mathbf{v}_i = r\mathbf{a}_i \quad (70)$$

where

$$r = R(2T)R^T(0), \quad (71a)$$

$$\mathbf{a}_i = R(0)\underline{x}_v(2T)R^T(0)\delta\mathbf{v}_i, \quad (71b)$$

where $\delta\mathbf{v}_i$ is defined in Eq. (49c). After that one follows the method of solving Eq. (54a), described above and in appendix B, with the only difference that now \mathbf{a}_i is given by Eq. (71b) and

$$\mathbf{b}_i = \delta\mathbf{p}_i + 2R(T)\underline{x}_v(T)R^T(0)\delta\mathbf{v}_i - \mathbf{a}_i. \quad (72)$$

V. SIMULATION RESULTS

We perform testing the LPS-N on an ensemble of 30 randomly generated platform trajectories, shown in Fig. 4.

Regarding the orientation, we assume that the North-East-Down (NED) frame has been installed initially on the platform, i.e. the initial gimbal rotation matrix is given by

$$R(0) = \begin{pmatrix} -\sin\phi\cos\lambda & -\sin\phi\sin\lambda & \cos\phi \\ -\sin\lambda\cos\lambda & \cos\lambda & 0 \\ -\cos\phi\cos\lambda & -\cos\phi\sin\lambda & -\sin\phi \end{pmatrix}, \quad (73)$$

where ϕ and λ are initial latitudes and longitude of the platform. Later on gimbal commits only random noisy rotations at small angles of the order of gimbal stabilization level δ_g , in the frequency band $f_g = 100\text{Hz}$.

Our navigation code consists of the following points

1. One calculates the exact values of the particle's coordinate and velocity using the Eqs. (44, 38b - 38d) and exact expressions for the trajectory and rotation matrix of the platform and the Earth's gravitational field (see appendix C below).

2. Coordinates and velocities provide us accurate "readings" of satellites and velocimeters. One exploits the pseudo-random normal number generators [21] with SD δ_x and δ_v to make corrections to the sensors' readings
3. The sensor data are the input parameters for restoring the coordinates and velocities in the platform frame using Eqs. (A1, A4).
4. The orientation of the gimbal is either assumed unchanged (for methods 1.1, 1.2, 2.1), or restored (for methods 1.3 and 2.2). In the last case, one solves Eq. (60) using the iterative method (see appendix B).
5. If necessary, one restores the instantaneous rotation rate of the gimbal $\boldsymbol{\Omega}(T)$ [according to the formula (52a)].
6. Finally, after restoring the velocity of the platform [see Eqs. (46) or (65)], one obtains the desired coordinates of the platform from the Eqs. (45) or (68)

With the exception of the first, in the each loop of the navigation cycle, one uses the initial position, speed, orientation, and rotation speed of the platform restored in the previous loop. As a result, the navigation error ΔX accumulates and increases on 7 orders of magnitude, from 1μ to 10m at the end of the cycle.

The accuracy of navigation increases with more accurate measurement of the position of the particles in the platform frame. To achieve it, we propose using not one set of satellites and velocimeters, but ensembles of these sensors. Specifically, during the simulation, we assumed that there are n_x satellites located in the platform on each of the semi-axes. Then, it is obvious that the ensemble of measured coordinates consists of

$$N_x = n_x^6 \quad (74)$$

elements. At the same time, on each of the axes, we have arranged $n_v = n_x^2$ velocimeters so that the ensemble of velocity measurements consists of the same number of elements

$$N_v = n_v^3 = N_x. \quad (75)$$

The simulation showed that the navigation error on the one side is not sensitive to the position of satellites and velocimeters, and on the other side depends on the values of particles' launch velocities. We have not been able to find any qualitative or quantitative criteria to minimize this dependence. We emphasize that we are talking about a 9-dimensional velocity space $\{\mathbf{v}, \mathbf{v}', \mathbf{v}''\}$. Therefore, we randomly selected the velocity components in a given range, gradually increasing the size of this range until, at $n_x = 1$, the navigation accuracy drops to the value of $\Delta X(t_n) \sim 100\text{m}$. We expected that with an increase in the number of satellites along each of the semi-axes n_x and a simultaneous increase in the number of

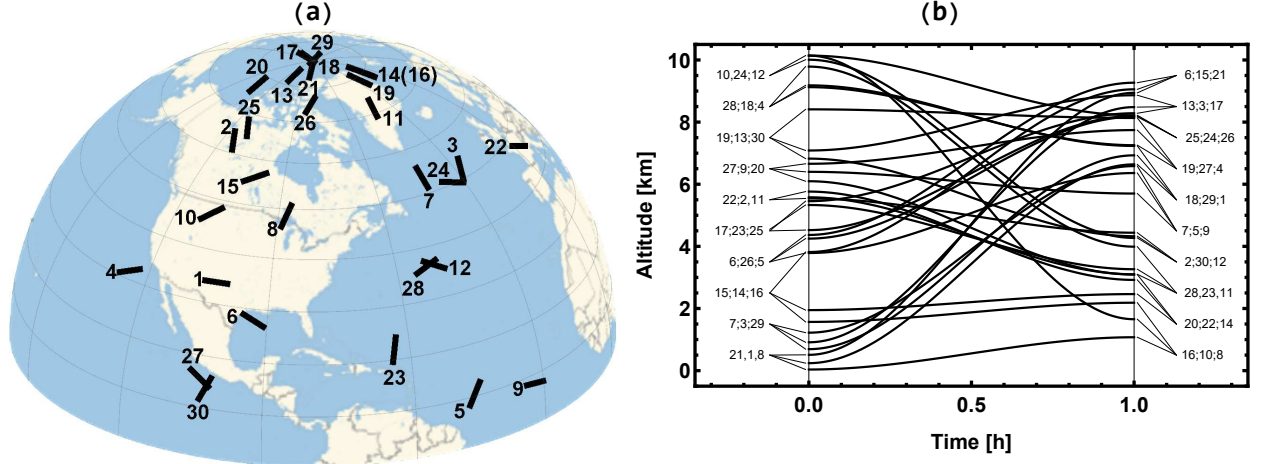

FIG. 4: Platform trajectories. Platform moves along each trajectory during the time $t_n = 1$ hour. The trajectories are chosen so that the platform velocity $V(0) = V(t_n) = 0$ and it reaches a maximum at $t = t_n/2$. Only those trajectories were selected for which $V(t_n/2) \in [200\text{m/s}, 240\text{m/s}]$. (a) Trajectories latitudes and longitudes. (b) Time dependences of the platform trajectories' altitudes. (The trajectories were randomly generated in the western part of the Earth northern hemisphere for the sole purpose that they were visible in Fig. 4a)

velocimeters $n_v = n_x^2$, the error of the navigation will drop to the desired level of $\Delta X(t_n) \sim 10\text{m}$. The simulation confirmed this expectation (see the red curves in the fourth column in Fig. 6). The values of launching velocities chosen for the simulation are given in the table I.

We assume that a navigation cuboid with dimensions $\{L_N, L_E, L_D\}$ is installed in the (NED)-coordinate system of the platform, which is shielded from all fields and in which a vacuum is maintained sufficient for one to believe that particles move freely only under the action of the Earth gravitational field. The minimal sizes of the cuboid at which there will be no collision of particles with the cuboid walls are also given in the table I. Since in the 2nd order LPS-N one observes the particle motion during the time $2T$, then the sizes of the cuboid are larger than for the 1st order LPS-N at the given T .

To illustrate the LPS-N, the build up in time of the navigation errors when the platform moves along the trajectory 20 (see Fig. 4) is shown in Fig. 5. Although the various plots on this and next figures may be difficult to read at standard magnification, they can be read easily using the zoom feature when read online in PDF format. The navigation method 1.3 is used here. In this method, the largest number of platform parameters are restored, the orientation of the gimbal, then sequentially the rotation rate of the gimbal, the velocity and, finally, the position of the platform. At the same time, only an error in restoring orientation is caused with the accuracy of measuring the difference in the coordinates of particles launched at different velocities. Errors in restoring the subsequent parameter are related both to the quality of satellites and velocimeters, and to the accuracy of restoring previous parameters. It is for this reason that the error in Fig. 5b' is 5 orders of magnitude larger than

TABLE I: Launching velocities chosen for navigation simulations and corresponding sizes of the navigation cuboids.

Method	Launching velocities [m/s]	Minimal cuboid size [m]
1.1	$v_N = -0.40$ $v_E = -0.40$ $v_D = -0.99$	$L_N = 0.12$ $L_E = 0.12$ $L_D = 0.20$
1.2	$v_N = -0.40$ $v'_N = -0.40$ $v''_N = 0.40$ $v_E = -0.40$ $v'_E = 0.40$ $v''_E = -0.40$ $v_D = -1.55$ $v'_D = -3.04$ $v''_D = -1.79$	$L_N = 0.12$ $L_E = 0.12$ $L_D = 0.49$
1.3	$v_N = 2.06$ $v'_N = -1.96$ $v''_N = 0.13$ $v_E = -0.29$ $v'_E = 0.76$ $v''_E = 0.67$ $v_D = -4.54$ $v'_D = -2.00$ $v''_D = 1.15$	$L_N = 1.2$ $L_E = 0.3$ $L_D = 1.7$
2.1	$v_N = 1.77$ $v'_N = 1.77$ $v''_N = -1.77$ $v_E = 1.77$ $v'_E = -1.77$ $v''_E = 1.77$ $v_D = 2.37$ $v'_D = 2.05$ $v''_D = 1.51$	$L_N = 2.1$ $L_E = 2.1$ $L_D = 2.4$

the error in Fig. 2.

The simulation results are summarized in the table in Fig. 6.

The five rows of this table correspond to three 1st order LPS-N methods (1.1, 1.2, and 1.3) and two 2nd order LPS-N methods (2.1 and 2.2). One sees that in method 1.1, when it is assumed that the quality of the gimbal is sufficient to neglect the rotation at all, in order to achieve the ultimate goal of navigation (8), it is necessary to use a gimbal with a rms of $\delta_g = 10^{-7}\text{rad}$ and velocimeters with an accuracy of $\delta_v = 20\mu\text{/s}$. The requirements can be

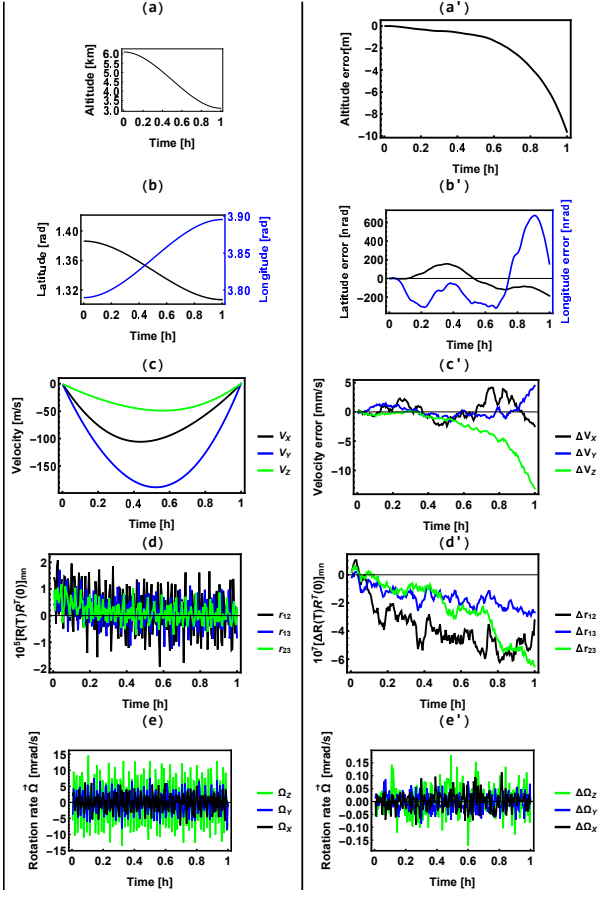

FIG. 5: The time dependence of the parameters of the platform motion and rotation (plots i) and the errors of their restoring (plots i'), where $i = a, \dots, e$. Trajectory 20 (see fig. 4). LPS-N method 1.3. Plots $\{a, a'\}$ for the altitude of the platform origine trajectory, plots $\{b, b'\}$ for the latitude and longitude of this trajectory, $\{c, c'\}$ for the platform velocity $\mathbf{V}(t)$, $\{d, d'\}$ for the matrix elements of the rotation matrix $r(t) = R(t)R^T(0)$, $\{e, e'\}$ for the platform rotation rate $\mathbf{\Omega}(t)$.

mitigated for the gimbal by an order of magnitude, and for the velocimeters by a factor of 2.5 if one uses method 1.2, when only the angular rate of the gimbal rotation is restored. Moreover, one can weaken the requirement for a gimbal by an order of magnitude in the method 1.3, when both the rate of rotation and the orientation of the gimbal are restored, but satellites with an rms error of $\delta_x = 100\text{nm}$ are needed. We have verified that with another random choice of trajectories and orientations, the navigation error $\Delta X(t)$ remains the same in the order of its magnitude.

If the 2nd order difference (5b) is used, then, due to its low sensitivity to the platform velocity, one may not use the velocimeters at all. For both 2nd order LPS-N methods, 2.1 and 2.2, we verified that even the use of ideal velocimeters, with zero error of velocity measurement, has no effect on the navigation error $\Delta X(t)$. In addition, the lever-arm term disappears, when one launches

all three particles from the same point [see Eq. (66)], and therefore the platform rotation rate may not be restored. Finally, with the 2nd order LPS-N, the requirements for the quality of gimbal are weakened by an order of magnitude (compare the 4th and 1st rows in the table in Fig. 6).

In conclusion, the simulation showed that the LPS can provide navigation accuracy in 1 hour of the order of 10m, if a gimbal with rms $\delta_g = 10^{-6}\text{rad}$ and satellites, distance sensors, with an error $\delta_x = 1\mu$ are used.

However, the reverse formulation of the question is also possible. If the accuracy of the satellites and velocimeters, the rms of gimbal, and the navigation box sizes are given, then our code will allow us to determine the expected accuracy of LPS-navigation ΔX for a given time t_n .

Acknowledgments

The author is grateful to Drs. K. Tintschurin, B. Young, I. Teper, and A. Zorn for the fruitful discussions.

Appendix A: Particle's position and velocity measurements in the platform frame

1. LPS - measurement of the position

Let's assume that there are 3 satellites installed on the platform at the points $\mathbf{s}_i = (x_i, y_i, z_i)^T$, which measure the distances to a given point $\mathbf{x} = (x, y, z)^T$, $r_i = |\mathbf{x} - \mathbf{s}_i|$. Then for the point coordinates one has [31]

$$z = \left(-b \pm \sqrt{b^2 - ac}\right) / a, \quad (\text{A1a})$$

$$x = b_{0x} + b_{1x}z, \quad (\text{A1b})$$

$$y = b_{0y} + b_{1y}z, \quad (\text{A1c})$$

$$b = b_{0x}b_{1x} + b_{0y}b_{1y} - b_{1x}x_1 - b_{1y}y_1 - z_1, \quad (\text{A1d})$$

$$a = 1 + b_{1x}^2 + b_{1y}^2, \quad (\text{A1e})$$

$$c = \rho_1^2 - r_1^2 + b_{0x}^2 + b_{0y}^2 - 2(b_{0x}x_1 + b_{0y}y_1), \quad (\text{A1f})$$

$$b_{0x} = (a_2y_{31} - a_3y_{21}) / \Delta, \quad (\text{A1g})$$

$$b_{1x} = (z_{31}y_{21} - z_{21}y_{31}) / \Delta, \quad (\text{A1h})$$

$$b_{0y} = (x_{21}a_3 - x_{31}a_2) / \Delta, \quad (\text{A1i})$$

$$b_{1y} = (x_{31}z_{21} - x_{21}z_{31}) / \Delta, \quad (\text{A1j})$$

$$\Delta = x_{21}y_{31} - y_{21}x_{31}, \quad (\text{A1k})$$

$$\rho_i = |\mathbf{s}_i|, \quad (\text{A1l})$$

$$a_i = \frac{1}{2}(\rho_i^2 - \rho_1^2 - r_i^2 + r_1^2), \quad (\text{A1m})$$

$$(x_{ik}, y_{ik}, z_{ik}) = (\mathbf{s}_i - \mathbf{s}_k)^T. \quad (\text{A1n})$$

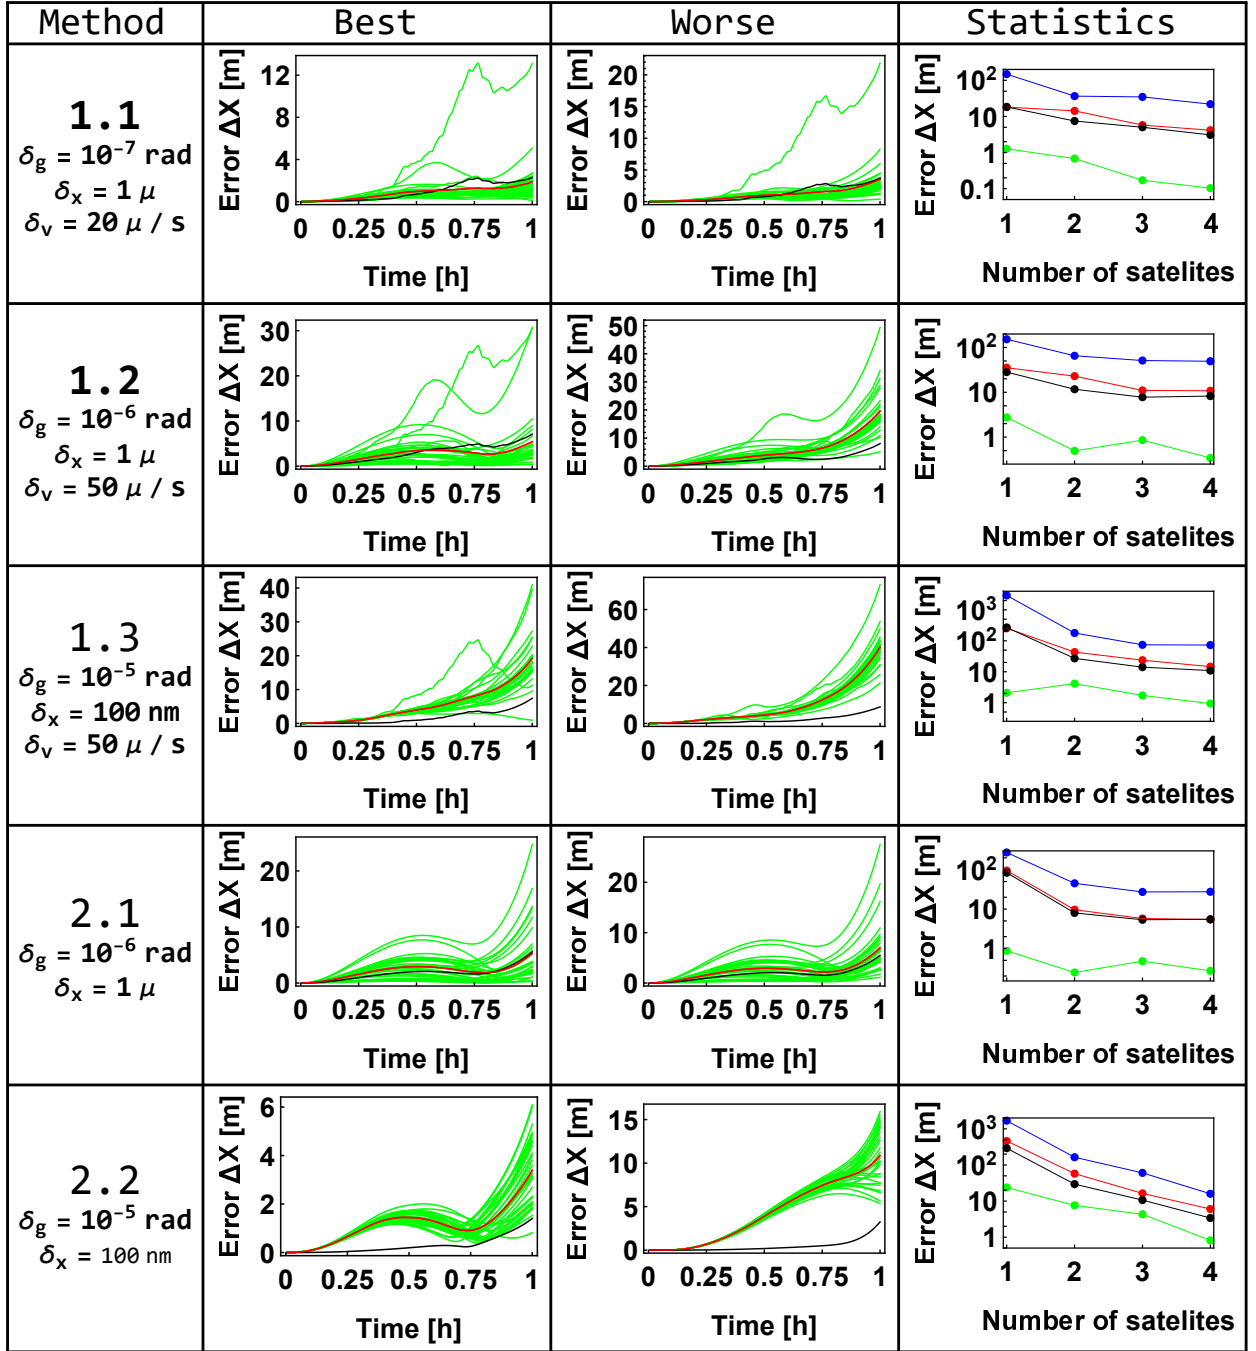

FIG. 6: Five LPS-N methods. Results of simulations. For the same 30 trajectories as in FIG. 1 one generated a navigation process. This was done for 11 sets of pseudo-random errors of satellites and velocimeters. As a result, one has ensemble of 330 $\Delta X(t)$ –dependences. The average over this ensemble errors for $t_n = 1$ hour of the navigation are shown by red dots in the 4th column. In the same plots, the blue, green and black dots show the maximum and minimum values of the error and SD for the entire ensemble, respectively. The $\Delta X(t)$ –dependences for 30 platform trajectories with a given set of sensors' errors are shown in the 2nd and 3rd columns. They contain plots for those sets of sensor errors at which one of the $\Delta X(t)$ curves reaches the minimum (best) or maximum (worst) value of $\Delta X(t_n)$.

2. Velocity measurement

For the 1st order LPS-N, one must measure the velocity \mathbf{v} of a particle in the platform frame at a given point

x. If 3 velocimeters, located at points \mathbf{s}_{vi} , measure the projection of the particle velocity

$$v^{(i)} = \mathbf{n}_i \cdot \mathbf{v}, \quad (\text{A2})$$

where

$$\mathbf{n}_i = \frac{\mathbf{x} - \mathbf{s}_{vi}}{|\mathbf{x} - \mathbf{s}_{vi}|}. \quad (\text{A3a})$$

then for the particle velocity one gets

$$\mathbf{v} = \underline{n}^{-1} \begin{pmatrix} v^{(1)} \\ v^{(2)} \\ v^{(3)} \end{pmatrix}, \quad (\text{A4})$$

where the matrix \underline{n} is given by

$$\underline{n} = \begin{pmatrix} \mathbf{n}_1^T \\ \mathbf{n}_2^T \\ \mathbf{n}_3^T \end{pmatrix}. \quad (\text{A5})$$

Appendix B: Recurrent relations

To decompose

$$\sin \delta = \sum_{s=0}^{\infty} \frac{(-1)^s \sigma^{2s+1}}{(2s+1)!} \left(\frac{\delta}{\sigma} \right)^{2s+1} \quad (\text{B1})$$

one needs to get a series for a degree

$$\left(\frac{\delta}{\sigma} \right)^p = p! \sum_{v=0}^{\infty} \delta_v^{(p)} \sigma^v \quad (\text{B2})$$

To calculate the coefficient $\delta_v^{(p)}$, one truncates the row (62) with the first $(\nu+1)$ terms

$$\delta = \sigma \sum_{i=1}^{\nu+1} \delta^{(i)} \sigma^{i-1}. \quad (\text{B3})$$

Then

$$\begin{aligned} (\delta/\sigma)^p &= p! \sum_{r_1=0}^p \dots \sum_{r_{\nu+1}=0}^p \delta_{p, \sum_{i=1}^{\nu+1} r_i} \\ &\quad \times \sigma \sum_{i=1}^{\nu+1} \delta_{r_i(i-1)} \prod_{i=1}^{\nu+1} \frac{[\delta^{(i)}]^{r_i}}{r_i!}, \end{aligned} \quad (\text{B4})$$

where δ_{ik} is the Kronecker symbol, and so

$$\begin{aligned} \delta_v^{(p)} &= \sum_{r_1=0}^p \dots \sum_{r_{\nu+1}=0}^p \delta_{p, \sum_{i=1}^{\nu+1} r_i} \\ &\quad \times \delta_{\nu, \sum_{i=1}^{\nu+1} r_i(i-1)} \prod_{i=1}^{\nu+1} \frac{[\delta^{(i)}]^{r_i}}{r_i!}. \end{aligned} \quad (\text{B5})$$

Substituting the decomposition (B2) in Eq. (B1), one finds that

$$\sin \delta \equiv \sum_{s=0}^{\infty} u_s \sigma^{s+1}, \quad (\text{B6a})$$

$$u_s = \sum_{s'=0}^{[s/2]} (-1)^{s'} \delta_{s-2s'}^{(2s'+1)}, \quad (\text{B6b})$$

where $[a]$ is the Entire part of a . Similarly, one gets

$$1 - \cos \delta = \sum_{s=0}^{\infty} c_s \sigma^{s+2}, \quad (\text{B7a})$$

$$c_s = \begin{cases} \sum_{s'=0}^{[s/2]} (-1)^{s'} \delta_{s-2s'}^{(2s'+2)}, & \text{for } s \geq 0 \\ 0, & \text{for } s < 0 \end{cases}. \quad (\text{B7b})$$

Multiplying the power series in Eq. (60) one comes to the following equation for the coefficients

$$\sum_{s_1=0}^{s-1} \mathbf{w}_{is_1} - \mathbf{a}_i c_{s-2} + \sum_{s_1=0}^{s-2} c_{s_1} \sum_{s_2=0}^{s-s_1-2} \mathbf{n}^{(s_2)} \left(\mathbf{n}^{(s-s_1-2-s_2)} \mathbf{a}_i \right) = \frac{\mathbf{b}_i}{\sigma} \delta_{s1}. \quad (\text{B8})$$

where

$$\mathbf{w}_{is_1} = u_{s_1} \mathbf{a}_i \times \mathbf{n}^{(s-s_1-1)} \quad (\text{B9})$$

It follows from Eqs. (B6b, B5, 63a) that

$$u_0 = 1 \quad (\text{B10})$$

and for $s = 1$ one gets the equation

$$\mathbf{a}_i \times \mathbf{n}^{(0)} = \frac{\mathbf{b}_i}{\sigma} \quad (\text{B11})$$

the solution of which, taking into account the normalization condition, $|\mathbf{n}^{(0)}| = 1$, coincides with (63).

The coefficients of the our interest, $\{\mathbf{n}^{(s-1)}, \delta^{(s)}\}$ are contained only in the terms \mathbf{w}_{i0} and $\mathbf{w}_{i(s-1)}$. For \mathbf{w}_{i0} from Eq. (B10) one has,

$$\mathbf{w}_{i0} = \mathbf{a}_i \times \mathbf{n}^{(s-1)}, \quad (\text{B12})$$

and from Eqs. (B6b, B11) one gets

$$\mathbf{w}_{i(s-1)} = \left(\delta_{s-1}^{(1)} + q_s \right) \frac{\mathbf{b}_i}{\sigma} \quad (\text{B13})$$

where

$$q_s \equiv \sum_{s'=1}^{[(s-1)/2]} (-1)^{s'} \delta_{s-1-2s'}^{(2s'+1)}. \quad (\text{B14})$$

From Eq. (B5) for $p = 1$ and $\nu = s - 1$, one sees that $\delta_{s-1}^{(1)}$ contains only one term at $\{r_1 \dots r_s\} = \{0 \dots 01\}$, which is equal to

$$\delta_{s-1}^{(1)} = \delta^{(s)}. \quad (\text{B15})$$

Then, with $s > 1$, one can rewrite Eq. (B8) as

$$\mathbf{a}_i \times \mathbf{n}^{(s-1)} = - \left(\delta^{(s)} + q_s \right) \frac{\mathbf{b}_i}{\sigma} + \mathbf{b}_i^{(s)}, \quad (\text{B16a})$$

$$\begin{aligned} \mathbf{b}_i^{(s)} &= \mathbf{a}_i c_{s-2} - \sum_{s_1=1}^{s-2} \mathbf{w}_{is_1} \\ &\quad - \sum_{s_1=0}^{s-2} c_{s_1} \sum_{s_2=0}^{s-s_1-2} \mathbf{n}^{(s_2)} \left(\mathbf{n}^{(s-s_1-2-s_2)} \cdot \mathbf{a}_i \right). \end{aligned} \quad (\text{B16b})$$

This is an equation of the same type as Eq. (48) for the speed of rotation and Eq. (57) for the angle of rotation δ . By analogy with those equations, the solution of Eq. (19a) is

$$\mathbf{n}^{(s-1)} = -\left(\delta^{(s)} + q_s\right) \mathbf{n}^{(0)} + \mathbf{f}\left(\mathbf{a}_i, \mathbf{b}_i^{(s)}\right), \quad (\text{B17})$$

where the function \mathbf{f} is given by Eq. (52b). Let us consider the normalization condition $\mathbf{n}^2 = 1$. It means that

$$\begin{aligned} & 2 \left[\mathbf{n}^{(0)} \cdot \mathbf{n}^{(s-1)} + \sum_{s_1=1}^{[s/2]-1} \mathbf{n}^{s_1} \mathbf{n}^{s-s_1-1} \right] \\ &= -\delta_{s,2[s/2]+1} \left[\mathbf{n}^{((s-1)/2)} \right]^2 \end{aligned} \quad (\text{B18})$$

Substituting here. Eq. (B17) one arrives to the expression for the coefficient $\delta^{(s)}$,

$$\begin{aligned} \delta^{(s)} &= -q_s + \mathbf{n}^{(0)} \mathbf{f}\left(\mathbf{a}_i, \mathbf{b}_i^{(s)}\right) + \\ & \sum_{s_1=1}^{[s/2]-1} \mathbf{n}^{s_1} \mathbf{n}^{s-s_1-1} + \frac{1}{2} \delta_{s,2[s/2]+1} \left[\mathbf{n}^{((s-1)/2)} \right]^2. \end{aligned} \quad (\text{B19})$$

The expressions (B17, B19) are the desired recurrent relations.

Consider them for the lowest orders. If $s = 2$, then from the Eqs. (B7a, B14) it is obvious that $c_0 = \frac{1}{2}$ and $q_2 = 0$, which means that

$$\mathbf{b}_i^{(2)} = \frac{1}{2} \left[\mathbf{a}_i - \mathbf{n}^{(0)} \left(\mathbf{n}^{(0)} \cdot \mathbf{a}_i \right) \right]. \quad (\text{B20})$$

and, therefore,

$$\delta^{(2)} = \mathbf{n}^{(0)} \cdot \mathbf{f}\left(\mathbf{a}_i, \mathbf{b}_i^{(2)}\right), \quad (\text{B21a})$$

$$\mathbf{n}^{(1)} = -\delta^{(2)} \mathbf{n}^{(0)} + \mathbf{f}\left(\mathbf{a}_i, \mathbf{b}_i^{(2)}\right). \quad (\text{B21b})$$

For $s = 3$, one consequently finds that

$$c_1 = u_1 = \delta^{(2)}, \quad (\text{B22a})$$

$$\mathbf{w}_{i1} = \delta^{(2)} \mathbf{a}_i \times \mathbf{n}^{(1)}, \quad (\text{B22b})$$

after that

$$\begin{aligned} \mathbf{b}_i^{(3)} &= \delta^{(2)} \left[\mathbf{a}_i - \mathbf{a}_i \times \mathbf{n}^{(1)} - \mathbf{n}^{(0)} \left(\mathbf{n}^{(0)} \cdot \mathbf{a}_i \right) \right] \\ & - \frac{1}{2} \left(\mathbf{n}^{(0)} \left(\mathbf{n}^{(1)} \cdot \mathbf{a}_i \right) + \mathbf{n}^{(1)} \left(\mathbf{n}^{(0)} \cdot \mathbf{a}_i \right) \right) \end{aligned} \quad (\text{B23})$$

And since $q_3 = -\frac{1}{6}$, then

$$\delta^{(3)} = \frac{1}{6} + \mathbf{n}^{(0)} \cdot \mathbf{f}\left(\mathbf{a}_i, \mathbf{b}_i^{(3)}\right) + \frac{1}{2} \mathbf{n}^{(1)2}, \quad (\text{B24})$$

and, finally,

$$\mathbf{n}^{(2)} = \mathbf{f}\left(\mathbf{a}_i, \mathbf{b}_i^{(3)}\right) - \mathbf{n}^{(0)} \left[\mathbf{n}^{(0)} \cdot \mathbf{f}\left(\mathbf{a}_i, \mathbf{b}_i^{(3)}\right) + \frac{1}{2} \mathbf{n}^{(1)2} \right]. \quad (\text{B25})$$

Appendix C: Earth gravitational field

We consider navigation in the gravitational field of a rotating Earth. This field consists of normal and anomaly parts

$$U(\mathbf{X}) = U_n(\mathbf{X}) + U_a(\mathbf{X}) \quad (\text{C1})$$

For the potential of the normal component, one has [32]

$$U_n(\mathbf{X}) = -\frac{GM}{X} \left(1 - \sum_{m=1}^{\infty} J_{2m} \left(\frac{a_E}{X} \right)^{2m} P_{2m}(\cos \theta) \right), \quad (\text{C2a})$$

$$J_{2m} = (-1)^{m+1} \frac{3e^{2m}}{(2m+1)(2m+3)} \left(1 - m \left(1 - \frac{5J_2}{e^2} \right) \right), \quad (\text{C2b})$$

where $GM = 3.986004418 \cdot 10^{14} \text{m}^3 \text{s}^{-2}$ is the geocentric gravitational constant, $a = 6.37813659 \cdot 10^6 \text{m}$ is the semimajor axis of the geoid, $e = \sqrt{f(2-f)}$ is the first eccentricity, f is polar flattening ($1/f = 298.25765$), $J_2 = 1.0826267 \cdot 10^{-3}$ is a dynamic form factor of the Earth [33], $P_n(x)$ is the Legendre polynomial, θ is the polar angle of the vector \mathbf{X} . From here one derives the following expressions for the normal components of the gravitational acceleration and the gravity-gradient tensor of the Earth

$$\mathbf{g}_{nE}(\mathbf{X}) = \mathbf{g} = -\frac{GM}{x^2} (b\mathbf{n} + b_1\mathbf{z}), \quad (\text{C3a})$$

$$\begin{aligned} \underline{\Gamma}_n(\mathbf{X}) &= \frac{GM}{x^3} (-b\delta_{ik} + b_2 n_i n_k + b_3 (n_i z_k + z_i n_k) \\ & + b_4 z_i z_k), \end{aligned} \quad (\text{C3b})$$

where

$$b = 1 - \frac{1}{\sin^2 \theta} \sum_{m=1}^{\infty} J_{2m} \left(\frac{a}{x} \right)^{2m} [P_{2m}(\cos \theta) (2m+1) - (4m+1) \cos^2 \theta] + 2m \cos \theta P_{2m-1}(\cos \theta), \quad (\text{C4a})$$

$$b_1 = \frac{1}{\sin^2 \theta} \sum_{m=1}^{\infty} J_{2m} \left(\frac{a}{x} \right)^{2m} 2m [P_{2m-1}(\cos \theta) - \cos \theta P_{2m}(\cos \theta)], \quad (\text{C4b})$$

$$b_2 = 3 - \frac{1}{\sin^4 \theta} \sum_{m=1}^{\infty} J_{2m} \left(\frac{a}{x} \right)^{2m} \{P_{2m}(\cos \theta) [(3+2m) \times (2m+1) - \cos^2 \theta (20m^2 + 28m + 6)] + \cos^4 \theta (16m^2 + 16m + 3)\} + 2m \cos \theta P_{2m-1}(\cos \theta) [5 + 4m - (3+4m) \cos^2 \theta], \quad (\text{C4c})$$

$$b_3 = \frac{1}{\sin^4 \theta} \sum_{m=1}^{\infty} J_{2m} \left(\frac{a}{x} \right)^{2m} 2m \{2P_{2m-1}(\cos \theta) (m+1) - m \cos^2 \theta\} - \cos \theta P_{2m}(\cos \theta) [4m+3 - (4m+1) \cos^2 \theta], \quad (\text{C4d})$$

$$b_4 = \frac{1}{\sin^4 \theta} \sum_{m=1}^{\infty} J_{2m} \left(\frac{a}{x} \right)^{2m} 2m \times \{[2m+1 - (2m-1) \cos^2 \theta] P_{2m}(\cos \theta) - 2 \cos \theta P_{2m-1}(\cos \theta)\} \quad (\text{C4e})$$

\mathbf{z} is a unit vector along the Z-axis.

For the anomaly part of the potential $U_a(\mathbf{X})$, we could not find an analytical expression. Nevertheless, it is known [34] that the rms of anomalous acceleration

$$g_a \sim 30 \text{mGal} \quad (\text{C5})$$

and from Plate 5 in Ref. [35] one can conclude that the rms of the anomaly part of the gravity-gradient tensor $\Gamma_a \sim 100\text{E}$. It follows that the typical size of the anomaly

field oscillations in space is

$$L_a \sim g_a / |\Gamma_a| \sim 3 \text{km}. \quad (\text{C6})$$

Unfortunately, the known analytical [36] or numerical [37, 38] approaches to the calculation of the gravitational field in the space around the Earth, including its anomalous part, cannot be used in our calculations, since they assume a known field on the Earth's surface. Therefore, for our code, we assumed that the anomalous potential consists of the sum of sinusoidal terms

$$U_a(\mathbf{X}) = \sum_{j=1}^{n_a} h_{aj} \cos(\mathbf{k}_{aj} \cdot \mathbf{X}), \quad (\text{C7})$$

in which the wave vectors were generated by the formula

$$k_{aji} = \pm 2\pi / L_a (1 + 2r), \quad (\text{C8})$$

where r is a pseudo-random number uniformly distributed over the interval $[0, 1]$, and for amplitudes h_{aj} , a generator of normal pseudo-random numbers was used, after which they were normalized by the condition

$$g_a^2 = \frac{1}{2} \sum_{j=1}^{n_a} h_{aj}^2 k_{aj}^2. \quad (\text{C9})$$

Of course, Eq. (C7) has nothing common with reality [it follows, for example, that particles move in a hypothetical medium with a density of $\rho = -4\pi \Delta U_a(\vec{r}) / G \neq 0$, which can even be negative. Despite this, we accept it, since at $n_a \gg 1$, the anomalous field has a rms (C5) and a spatial period (C6). In addition, the representation of the anomalous potential in the form of sums of harmonic terms can qualitatively correspond to the topographic undulations observed by the GRACE and GOCE satellites.
