# A QUANTITATIVE APPROACH TO DISJOINTLY NON-SINGULAR OPERATORS 

MANUEL GONZÁLEZ AND ANTONIO MARTINÓN

#### Abstract

We introduce and study some operational quantities which characterize the disjointly non-singular operators from a Banach lattice $E$ to a Banach space $Y$ when $E$ is order continuous, and some other quantities which characterize the disjointly strictly singular operators for arbitrary $E$.

## 1. Introduction

The disjointly strictly singular operators (DSS operators) were introduced in [12] as those operators $T: E \rightarrow Y$ from a Banach lattice $E$ into a Banach space $Y$ such that $T$ is not an isomorphism in any subspace of $E$ generated by a disjoint sequence of non-zero vectors. These operators have been useful in the study of the structure of Banach lattices (see [2, 3] and references therein). More recently, the disjointly non-singular operators (DN-S operators) where introduced in [6] (see also [1]) as those operators $T: E \rightarrow Y$ that are not strictly singular in any subspace of $E$ generated by a disjoint sequence of non-zero vectors. Note that the properties in the definition of these two classes are opposite.

In this paper we study the classes of operators DSS and DN-S from a quantitative point of view by introducing four operational quantities $\Gamma_{d}(T), \Delta_{d}(T), \tau_{d}(T)$ and $\kappa_{d}(T)$. When $E$ is order continuous, $T \in \mathrm{DN}-\mathrm{S}(E, Y)$ is equivalent to $\Gamma_{d}(T)>0$, or $\kappa_{d}(T)>0$; and for $E$ arbitrary, $T \in \operatorname{DSS}(E, Y)$ is equivalent to $\Delta_{d}(T)=0$, or $\tau_{d}(T)=0$. These four quantities are inspired by some others introduced by Schechter [19] in his study of Fredholm theory.

In [6], the quantity $\beta(T)=\inf _{\left(x_{n}\right)} \liminf _{n \rightarrow \infty}\left\|T x_{n}\right\|$, where the infimum is taken over the normalized disjoint sequences $\left(x_{n}\right)$ in $E$, was defined. We show that $T \in \operatorname{DN}-\mathrm{S}(E, Y)$ if and only if $\beta(T)>0$ when $E$ is order continuous. This result was proved in [1, Theorem 5.7] using different techniques. We also prove that $\beta(T) \leq \Gamma_{d}(T)$, but there is no $C>0$ such that $\Gamma_{d}(T) \leq C \beta(T)$ for each $T \in \mathrm{~L}\left(\ell_{2}, Y\right)$; hence $\Gamma_{d}$ and $\beta$ are not equivalent. Moreover, $\tau_{d}(T) \leq \Delta_{d}(T)$, but the quantities $\tau_{d}$ and $\Delta_{d}$ are not equivalent.

We also prove some inequalities for these operational quantities; e.g., for $T, S \in \mathrm{~L}(E, Y)$, we have $\Gamma_{d}(T+S) \leq \Gamma_{d}(T)+\Delta_{d}(S)$. When $E$ is order continuous, this inequality allows us to improve the stability result for DN-S operators under DSS perturbations obtained in [6].

Notation. Throughout the paper $X$ and $Y$ are Banach spaces, and $E$ is a Banach lattice. The unit sphere of $X$ is $S_{X}=\{x \in X:\|x\|=1\}$, and for a sequence $\left(x_{n}\right)$ in $X,\left[x_{n}\right]$ denotes the closed subspace generated by $\left(x_{n}\right)$.

[^0]All the operators are linear and bounded, and $\mathrm{L}(X, Y)$ denotes the set of all the operators from $X$ into $Y$. Given $T \in \mathrm{~L}(X, Y)$, its injection modulus is $j(T):=\inf _{\|x\|=1}\|T x\|$. Recall that $j(T)>0$ if and only if $T$ is an isomorphism from $X$ onto $T X$. We denote by $T_{M}$ the restriction of $T \in \mathrm{~L}(X, Y)$ to a closed subspace $M$ of $X$.

If $(\Omega, \Sigma, \mu)$ is a measure space, the domain of a measurable function $f: \Omega \rightarrow \mathbb{R}$ is the set $D(f)=\{t \in \Omega: f(t) \neq 0\}$, and $1_{A}$ denotes the characteristic function of $A \in \Sigma$. We write $L_{p}$ for $L_{p}[0,1], 1 \leq p \leq \infty$.

## 2. Preliminaries

An operator $T \in \mathrm{~L}(X, Y)$ is strictly singular if there is no closed infinite dimensional subspace $M$ of $X$ such that the restriction $T_{M}$ is an isomorphism, and $T$ is upper semi-Fredholm if its kernel is finite dimensional and its range is closed.

An operator $T \in \mathrm{~L}(E, Y)$ is disjointly strictly singular if there is no disjoint sequence of nonzero vectors $\left(x_{n}\right)$ in $E$ such that $T_{\left[x_{n}\right]}$ is an isomorphism. We denote by $\operatorname{DSS}(E, Y)$ the set of all $T \in \mathrm{~L}(E, Y)$ which are disjointly strictly singular. The class DSS was introduced by Hernández and Rodríguez-Salinas in [12]. More information on this class can be found in [11].

An operator $T \in \mathrm{~L}(E, Y)$ is disjointly non-singular if there is no disjoint sequence of nonzero vectors $\left(x_{n}\right)$ in $E$ such that $T_{\left[x_{n}\right]}$ is strictly singular. We denote DN-S $(E, Y)$ the set of all $T \in \mathrm{~L}(E, Y)$ which are disjointly non-singular. These operators were recently introduced in [6], and have been studied by Bilokopytov in 1]. They are related to the tauberian operators, defined by Kalton and Wilansky [13]; in fact, they coincide when $E=L_{1}$ (see [4] and [6]). We refer to [9] and [5] for additional information on tauberian operators.

The disjointly non-singular operators can be characterized as follows.
Theorem 2.1. [6, Theorem 2.8] For $T \in L(E, Y)$, the following assertions are equivalent:
(1) $T$ is disjointly non-singular.
(2) There is no disjoint sequence of non-zero vectors $\left(x_{n}\right)$ in $E$ such that the restriction $T_{\left[x_{n}\right]}$ is a compact operator.
(3) For every disjoint sequence of non-zero vectors $\left(x_{n}\right)$ in $E$, the restriction $T_{\left[x_{n}\right]}$ is an upper semi-Fredholm operator.
(4) For every normalized disjoint sequence $\left(x_{n}\right)$ in $E, \liminf _{n \rightarrow \infty}\left\|T x_{n}\right\|>0$.

It was proved in [4, Proposition 14] and [6, Theorem 3.15] that, for $1 \leq p<\infty, \operatorname{DSS}\left(L_{p}, Y\right)$ is the perturbation class of $\mathrm{DN}-\mathrm{S}\left(L_{p}, Y\right)$.

Representation of Banach lattices. It is well-known (see [16, Theorem 1.b.14]) that every order continuous Banach lattice with a weak unit $E$ admits a representation as a Köthe function space, in the sense that there exists a probability space $(\Omega, \Sigma, \mu)$ so that

- $L_{\infty}(\mu) \subset E \subset L_{1}(\mu)$ with $E$ dense in $L_{1}(\mu)$ and $L_{\infty}(\mu)$ dense in $E$,
- $\|f\|_{1} \leq\|f\|_{E} \leq 2\|f\|_{\infty}$ when $f \in L_{\infty}(\mu)$,
and the order in $E$ is the order induced by $L_{1}(\mu)$.
The following fact will allow us to state some of our results omitting the existence of a weak unit in the Banach lattice.

Lemma 2.2. Let $E$ be an order continuous Banach lattice. Then each sequence in $E$ is contained in a closed ideal of $E$ with a weak unit.

Proof. If $\left(f_{n}\right)$ is a bounded sequence in $E$, then $e=\sum_{n=1}^{\infty}\left|f_{n}\right| / 2^{-n}$ is a weak unit in the closed ideal generated by $\left(f_{n}\right)$.

We also will need the following result.
Lemma 2.3. Let $E$ be an order continuous Banach lattice with a weak unit, and let $f \in E$. If $\left(A_{k}\right)$ is a disjoint sequence in the $\sigma$-algebra $\Sigma$ associated to the representation of $E$, then $\lim _{k \rightarrow \infty}\left\|f 1_{A_{k}}\right\|_{E}=0$.

Proof. Let $B_{k}=\cup_{i=k}^{\infty} A_{i}$. Since the norm on $E$ is order continuous, $\left(B_{k}\right)$ is decreasing and $\lim _{k \rightarrow \infty} \mu\left(B_{k}\right)=0$ we have $\lim _{k \rightarrow \infty}\left\|f 1_{B_{k}}\right\|_{E}=0$, hence $\lim _{k \rightarrow \infty}\left\|f 1_{A_{k}}\right\|_{E}=0$.

## 3. Operational quantities

An operational quantity is a map $a: \mathrm{L}(X, Y) \rightarrow[0, \infty)$ satisfying certain conditions. Given two operational quantities $a$ and $b$, we write $a \leq b$ when $a(T) \leq b(T)$ for each $T \in \mathrm{~L}(X, Y)$. Moreover, the quantities $a$ and $b$ are equivalent if there exist positive constants $c_{1}<c_{2}$ such that $c_{1} a \leq b \leq c_{2} a$.

We are interested in some classical operational quantities and some new ones that we introduce here. To describe the classical ones, let $S(X)$ be set of all closed infinite dimensional subspaces of $X$. Then, given an operational quantity $a: \mathrm{L}(X, Y) \rightarrow[0, \infty)$, we define two derived quantities $i a$ and $s a$ as follows:

$$
\begin{equation*}
i a(T):=\inf _{M \in S(X)} a\left(T_{M}\right) \quad \text { and } \quad s a(T):=\sup _{M \in S(X)} a\left(T_{M}\right) \tag{1}
\end{equation*}
$$

where $T \in \mathrm{~L}(X, Y)$.
Note that $a \leq b$ implies $i a \leq i b$ and $s a \leq s b$. Taking the operator norm as $a$ in (1), for $T \in \mathrm{~L}(X, Y)$ we obtain

- $\Gamma(T):=i\|T\|=\inf _{M \in S(X)}\left\|T_{M}\right\| \quad$ and
- $\Delta(T):=s \Gamma(T)=\sup _{M \in S(X)} \Gamma\left(T_{M}\right)=\sup _{M \in S(X)} \inf _{N \in S(M)}\left\|T_{N}\right\|$.

The quantities $\Gamma=i\|\cdot\|$ and $\Delta=i \Gamma$ were introduced by Gramsch and Schechter (see [19, 20]), who proved that $\Gamma(T)>0$ if and only if $T$ is upper semi-Fredholm, and $\Delta(T)=0$ if and only if $T$ is strictly singular.

To introduce the new quantities, we denote by $\mathrm{d}(E)$ the set of all sequences of disjoint nonzero vectors of $E$. Now, given an operational quantity $a: \mathrm{L}(F, Y) \rightarrow[0, \infty)$ defined for $F=E$ and $F \in \mathrm{~d}(E)$, for each $T \in \mathrm{~L}(E, Y)$ we define two derived quantities $i_{d} a$ and $s_{d} a$ as follows:

$$
\begin{equation*}
i_{d} a(T):=\inf _{\left(x_{n}\right) \in \mathrm{d}(E)} a\left(T_{\left[x_{n}\right]}\right) \quad \text { and } \quad s_{d} a(T):=\sup _{\left(x_{n}\right) \in \mathrm{d}(E)} a\left(T_{\left[x_{n}\right]}\right) \tag{2}
\end{equation*}
$$

Again, $a \leq b$ implies $i_{d} a \leq i_{d} b$ and $s_{d} a \leq s_{d} b$. We are interested in two operational quantities derived from the norm, whose notation is inspired by that of Schechter:

- $\Gamma_{d}(T):=i_{d}\|T\|=\inf _{\left(x_{n}\right) \in \mathrm{d}(E)}\left\|T_{\left[x_{n}\right]}\right\| \quad$ and
- $\Delta_{d}(T):=s_{d} \Gamma_{d}(T)=\sup _{\left(x_{n}\right) \in \mathrm{d}(E)} \Gamma_{d}\left(T_{\left[x_{n}\right]}\right)=\sup _{\left(x_{n}\right) \in \mathrm{d}(E)} \inf _{\left(y_{n}\right) \in \mathrm{d}\left(\left[x_{n}\right]\right)}\left\|T_{\left[y_{n}\right]}\right\|$,
that will allow us to characterize the operators in DN-S and DSS.
In a similar way, for $T \in \mathrm{~L}(X, Y)$ we consider two classical operational quantities derived from the injection modulus $j$ :
- $\tau(T):=s j(T)=\sup _{M \in S(X)} j\left(T_{M}\right) \quad$ and
- $\kappa(T):=i \tau(T)=\inf _{M \in S(X)} \tau\left(T_{M}\right)=\inf _{M \in S(X)} \sup _{N \in S(M)} j\left(T_{N}\right)$,
and derive two new quantities for $T \in \mathrm{~L}(E, Y)$ :
- $\tau_{d}(T):=s_{d} j(T)=\sup _{\left(x_{n}\right) \in \mathrm{d}(E)} j\left(T_{\left[x_{n}\right]}\right) \quad$ and
- $\kappa_{d}(T):=i_{d} \tau_{d}(T)=\inf _{\left(x_{n}\right) \in \mathrm{d}(E)} \tau_{d}\left(T_{\left[x_{n}\right]}\right)=\inf _{\left(x_{n}\right) \in \mathrm{d}(E)} \sup _{\left(y_{n}\right) \in \mathrm{d}\left(\left[x_{n}\right]\right)} j\left(T_{\left[y_{n}\right]}\right)$,

The operational quantities $\tau=s j$ and $\kappa=i \tau$ were introduced in [19] and [7], where it was proved that $\tau(T)=0$ if and only if $T$ is strictly singular, and $\kappa(T)>0$ if and only if $T$ is upper semi-Fredholm. We will show that the quantities $\tau_{d}$ and $\kappa_{d}$ characterize the operators in DSS and DN-S, respectively.

The proof of the next lemma shows that for each closed infinite dimensional subspace of a Banach space with a monotone basis $\left(x_{n}\right)$, in particular with a 1-unconditional basis, there is a block basis $\left(y_{k}\right)$ such that $\left[y_{k}\right]$ is 'arbitrarily close' (in the sense of the gap between subspaces; see [14, Section IV.2]) to a subspace $N$ of $M$; so the action of an operator on $\left[y_{k}\right]$ is also close to its action on $N$. This idea will appear several times in our arguments.

Lemma 3.1. Let $X$ be a Banach space with a monotone basis $\left(x_{n}\right)$, let $M \in S(X)$ and $0<\varepsilon<1$. Then there exist a normalized block basis $\left(y_{k}\right)$ of $\left(x_{n}\right)$ and a subspace $N \in S(M)$ such that for every operator $T \in L(X, Y)$,

$$
\left|\left\|T_{\left[y_{k}\right]}\right\|-\left\|T_{N}\right\|\right| \leq \varepsilon\|T\| \quad \text { and } \quad\left|j\left(T_{\left[y_{k}\right]}\right)-j\left(T_{N}\right)\right| \leq \varepsilon\|T\| .
$$

Proof. We will choose $\left(y_{k}\right)$ and $N$ so that the distance between the unit spheres of $N$ and $\left[y_{k}\right]$ is smaller than $\varepsilon$; hence for each $n \in S_{N}$ there is $y \in S_{\left[y_{k}\right]}$ with $\|n-y\|<\varepsilon$, and for each $z \in S_{\left[y_{k}\right]}$ there is $m \in S_{N}$ with $\|z-m\|<\varepsilon$. Clearly this fact implies our result.

Let $r=\varepsilon / 8$. Inductively, we will find integers $1=j_{1} \leq l_{1}<j_{2} \leq l_{2} \leq \cdots$ and a sequence $\left(a_{i}\right)$ of scalars so that $y_{k}=\sum_{i=j_{k}}^{l_{k}} a_{i} x_{i}$ satisfies $\left\|y_{k}\right\|=1$ and $\operatorname{dist}\left(y_{k}, M\right)<r / 2^{k+1}$.

Clearly, $y_{1}$ exists; so assume that $y_{k}$ has been found for $k \leq k_{0}$. Let $\left(x_{i}^{*}\right)$ be the sequence in $X^{*}$ such that $x_{i}^{*}\left(x_{j}\right)=\delta_{i, j}$. Since $M \cap\left(\cap_{i=1}^{l_{k_{0}}} N\left(x_{i}^{*}\right)\right)$ is infinite dimensional, $y_{k_{0}+1}$ exists.

Since $\left(y_{k}\right)$ is a monotone basic sequence (comment after [15, Definition 1.a.10]), there exists a sequence $\left(y_{k}^{*}\right)$ in $X^{*}$ with $\left\|y_{k}^{*}\right\| \leq 2$ and $y_{k}^{*}\left(y_{j}\right)=\delta_{k, j}$.

For each $k \in \mathbb{N}$ we choose $m_{k} \in M$ with $\left\|y_{k}-m_{k}\right\|<r / 2^{k+1}$, and define $K \in \mathrm{~L}(X)$ by

$$
K x:=\sum_{k=1}^{\infty} y_{k}^{*}(x)\left(y_{k}-m_{k}\right)
$$

Then $K$ is bounded with $\|K\| \leq \sum_{k=1}^{\infty}\left\|y_{k}^{*}\right\| \cdot\left\|y_{k}-m_{k}\right\|<r$; hence $I-K$ is bijective. Moreover $(I-K) y_{k}=m_{k}$ for each $k \in \mathbb{N}$. We take $N=\left[m_{k}\right]=(I-K)\left(\left[y_{k}\right]\right)$. Note that

$$
(I-K)^{-1}=\sum_{l=0}^{\infty} K^{l}=I-L \text { with }\|L\| \leq \sum_{l=1}^{\infty} r^{l}=r /(1-r)<2 r
$$

For $n \in S_{N}$ we take $y=\|(I-L) n\|^{-1}(I-L) n \in S_{\left[y_{k}\right]}$. Then $1-2 r<\|(I-L) n\|<1+2 r$ and

$$
\|n-y\|=\frac{\|(\|(I-L) n\|-1) n+L n\|}{\|(I-L) n\|} \leq \frac{4 r}{1-2 r}<8 r=\varepsilon
$$

Similarly, for each $z \in S_{\left[y_{k}\right]}$, we have $m=\|(I-K) z\|^{-1}(I-K) z \in S_{N}$ and $\|z-m\|<\varepsilon$.
A Banach lattice is called atomic if its order is induced by a 1-unconditional basis.
Proposition 3.2. Let $E$ be an atomic Banach lattice. For an operator $T \in L(E, Y)$,

$$
\Gamma_{d}(T)=\Gamma(T), \Delta_{d}(T)=\Delta(T), \tau_{d}(T)=\tau(T) \quad \text { and } \quad \kappa_{d}(T)=\kappa(T)
$$

Proof. The inequality $\Gamma_{d}(T) \geq \Gamma(T)$ is valid in general. The converse inequality is obtained by applying Lemma 3.1. Suppose without loss generality that $\|T\|=1$. Given $0<\varepsilon<1$ and a subspace $M$ of $E$, there is a block basis $\left(y_{k}\right)$ of the unconditional basis of $E$ such that $\left[y_{k}\right]$ is arbitrarily close to some subspace $N$ of $M$, and consequently

$$
\left|\left\|T_{\left[y_{k}\right]}\right\|-\left\|T_{N}\right\|\right| \leq \varepsilon .
$$

Hence $\Gamma_{d}(T) \leq\left\|T_{\left[y_{k}\right]}\right\| \leq\left\|T_{N}\right\|+\varepsilon \leq\left\|T_{M}\right\|+\varepsilon$. Therefore $\Gamma_{d}(T) \leq \Gamma(T)$.
The other equalities can be proved in a similar way.
Corollary 3.3. We have $s_{d} \Gamma_{d}=s_{d} \Gamma$ and $i_{d} \tau_{d}=i_{d} \tau$. Moreover $\Gamma_{d}=i_{d} \Gamma_{d}=i_{d} \Gamma$ and $\tau_{d}=s_{d} \tau_{d}=s_{d} \tau$.

Proof. For each $\left(x_{n}\right) \in \mathrm{d}(E),\left(x_{n}\right)$ is a 1-unconditional basis; hence $\left[x_{n}\right]$ is an atomic Banach lattice. Therefore

$$
s_{d} \Gamma_{d}(T)=\sup _{\left(x_{n}\right) \in \mathrm{d}(E)} \Gamma_{d}\left(T_{\left[x_{n}\right]}\right)=\sup _{\left(x_{n}\right) \in \mathrm{d}(E)} \Gamma\left(T_{\left[x_{n}\right]}\right)=s_{d} \Gamma(T)
$$

The proof of $i_{d} \tau_{d}=i_{d} \tau, i_{d} \Gamma_{d}=i_{d} \Gamma$ and $s_{d} \tau_{d}=s_{d} \tau$ is identical, and for the remaining equalities, note that $i_{d} i_{d} a=i_{d} a$ and $s_{d} s_{d} a=s_{d} a$ for any quantity $a$.

## 4. Operational quantities derived from the norm

Our first result gives some alternative expressions for $\Gamma_{d}(T)$ in terms of the classical quantities.
Proposition 4.1. For $T \in L(E, Y)$, we have $\Gamma_{d}(T)=i_{d} \Gamma(T)=i_{d} \Delta(T)$.
Proof. Note that $\Gamma_{d}=i_{d}\|\cdot\|$. Applying $i_{d}$ to the inequalities $\Gamma \leq \Delta \leq\|\cdot\|$, we obtain $i_{d} \Gamma \leq i_{d} \Delta \leq i_{d}\|\cdot\|$, and Corollary 3.3 completes the proof.

It was proved in [6] that $T \in \mathrm{~L}(E, Y)$ is disjointly non-singular if and only if for every $\left(f_{n}\right) \in \mathrm{d}\left(L_{p}\right)$, the restriction $T_{\left[f_{n}\right]}$ is upper semi-Fredholm. Next we give a quantitative version of this result when $E$ is an order continuous Banach lattice. Since $\Gamma_{d}(T)=i_{d} \Gamma(T)$ by Proposition 4.1. our result says that if $T \in \operatorname{DN}-\mathrm{S}(E, Y)$ then the restrictions $T_{\left[x_{n}\right]}$ are "uniformly" upper semi-Fredholm, in the sense that $\inf _{\left(x_{n}\right) \in \mathrm{d}(E)} \Gamma\left(T_{\left[x_{n}\right]}\right)>0$.

Theorem 4.2. Let $E$ be an order continuous Banach lattice, and let $T \in L(E, Y)$. Then $T \in D N-S$ if and only if $\Gamma_{d}(T)>0$.

Proof. Suppose that $\Gamma_{d}(T)>0$. For every $\left(f_{n}\right) \in d(E)$ we have that $\Gamma\left(T_{\left[f_{n}\right]}\right)>0$, hence $T_{\left[f_{n}\right]}$ is upper semi-Fredholm. Consequently, $T$ is disjointly non-singular (Theorem 2.1).

Conversely, we assume that $\Gamma_{d}(T)=0$. By Theorem[2.1, it is enough to construct a normalized sequence $\left(h_{n}\right) \in \mathrm{d}(E)$ such that $\lim _{n \rightarrow \infty}\left\|T h_{n}\right\|=0$.

For each $n \in \mathbb{N}$ there exists a normalized sequence $\left(f_{n, k}\right)_{k} \in \mathrm{~d}(E)$ such that $\left\|T_{\left[\left(f_{n, k}\right)_{k}\right]}\right\|<1 / n$, and by Lemma 2.2 we can assume that the functions $f_{n, k}(n, k \in \mathbb{N})$ are contained in a closed ideal of $E$ which has a representation as a Köthe space.

Let $g_{1}=f_{1,1}$. As $\lim _{k \rightarrow \infty} \mu\left(D\left(f_{2, k}\right)\right)=0$, by Lemma 2.3 we have $\lim _{k \rightarrow \infty}\left\|g_{1} 1_{D\left(f_{2, k}\right)}\right\|_{E}=0$. So we can find $k_{2}>1$ such that

$$
\left\|g_{1}\right\|=1,\left\|T g_{1}\right\|<1 \text { and }\left\|g_{1} 1_{D\left(f_{2, k_{2}}\right)}\right\|_{E}<\frac{1}{2^{2}}
$$

Then, taking $g_{2}=f_{2, k_{2}}$, a similar argument using Lemma 2.3 shows that there exists $k_{3}>k_{2}$ such that

$$
\left\|g_{2}\right\|=1,\left\|T g_{2}\right\|<\frac{1}{2} \text { and }\left\|g_{i} 1_{D\left(f_{3, k_{3}}\right)}\right\|_{E}<\frac{1}{2^{3}} \quad \text { for } 1 \leq i<3
$$

In this way we find a sequence $k_{1}=1<k_{2}<k_{3}<\cdots$ such that, taking $g_{l}=f_{l, k_{l}}$ for each $l \in \mathbb{N}$, we have

$$
\left\|g_{l}\right\|=1,\left\|T g_{l}\right\|<\frac{1}{l} \text { and }\left\|g_{i} 1_{D\left(f_{l, k_{l+1}}\right)}\right\|<\frac{1}{2^{l+1}} \quad(1 \leq i<l+1)
$$

Let $A_{k}=\cup_{j=k+1}^{\infty} D\left(g_{j}\right)$ and $\tilde{h}_{k}:=g_{k}-g_{k} 1_{A_{k}}$. For $k<l$ we have $D\left(\tilde{h}_{k}\right) \cap D\left(g_{l}\right)=\emptyset$ and $D\left(\tilde{h}_{l}\right) \subset D\left(g_{l}\right)$, hence $D\left(\tilde{h}_{k}\right) \cap D\left(\tilde{h}_{l}\right)=\emptyset$. Thus the sequence $\left(\tilde{h}_{k}\right)$ is disjoint. Since $\left\|g_{n}\right\|=1$,

$$
\begin{aligned}
\left|1-\left\|\tilde{h}_{n}\right\|\right| & \leq\left\|g_{n}-\tilde{h}_{n}\right\|=\left\|g_{n} 1_{A_{n}}\right\| \\
& \leq\left\|\sum_{i=n+1}^{\infty} g_{n} 1_{D\left(g_{i}\right)}\right\| \leq \sum_{i=n+1}^{\infty}\left\|g_{n} 1_{D\left(g_{i}\right)}\right\| \\
& \leq \sum_{i=n+1}^{\infty} \frac{1}{2^{i}}=\frac{1}{2^{n}}
\end{aligned}
$$

Taking $h_{n}=\left\|\tilde{h}_{n}\right\|^{-1} \tilde{h}_{n}$, we obtain $\left(h_{n}\right) \in \mathrm{d}(E)$ is normalized and

$$
\begin{aligned}
\left\|h_{n}-g_{n}\right\| & \leq\left\|\frac{\tilde{h}_{n}}{\left\|\tilde{h}_{n}\right\|}-\frac{g_{n}}{\left\|\tilde{h}_{n}\right\|}\right\|+\left\|\frac{g_{n}}{\left\|\tilde{h}_{n}\right\|}-g_{n}\right\| \\
& =\frac{\left\|\tilde{h}_{n}-g_{n}\right\|}{\left\|\tilde{h}_{n}\right\|}+\frac{\left|1-\left\|\tilde{h}_{n}\right\|\right|\left\|g_{n}\right\|}{\left\|\tilde{h}_{n}\right\|} \\
& \leq \frac{2\left\|\tilde{h}_{n}-g_{n}\right\|}{\left\|\tilde{h}_{n}\right\|} \leq \frac{1}{2^{n-1}\left\|\tilde{h}_{n}\right\|}
\end{aligned}
$$

Consequently $\lim _{n \rightarrow \infty}\left\|h_{n}-g_{n}\right\|=0$, and $\left\|T h_{n}\right\| \leq\left\|T\left(h_{n}-g_{n}\right)\right\|+\left\|T g_{n}\right\|$ and $\left\|T g_{n}\right\|<1 / n$; hence $\lim _{n \rightarrow \infty}\left\|T h_{n}\right\|=0$.

Next we give some alternative expressions for $\Delta_{d}(T)$.
Proposition 4.3. For $T \in L(E, Y)$, we have $\Delta_{d}(T)=s_{d} \Delta(T)=s_{d} \Gamma(T)$.
Proof. Note that $\Delta_{d}(T)=s_{d} \Gamma_{d}(T)$ and, by Corollary 3.3, $s_{d} \Gamma(T)=s_{d} \Gamma_{d}(T)$. So it is enough to observe that $s_{d} a(T)=s_{d} s_{d} a$ for any quantity $a$.

Proposition 4.4. $T \in L(E, Y)$ is disjointly strictly singular if and only if $\Delta_{d}(T)=0$.
Proof. As $\Delta_{d}(T)=s_{d} \Delta(T)$, we have that $\Delta_{d}(T)=0$ means that for every $\left(x_{n}\right) \in \mathrm{d}(E)$ we have that $\Delta\left(T_{\left[x_{n}\right]}\right)=0$; that is, all the restrictions $T_{\left[x_{n}\right]}$ are strictly singular. By [6, Proposition 2.6], that is equivalent to $T$ being disjointly strictly singular.

Obviously, given $T \in \mathrm{~L}(E, Y)$ and a scalar $\lambda, \Gamma_{d}(\lambda T)=|\lambda| \Gamma_{d}(T)$ and $\Delta_{d}(\lambda S)=|\lambda| \Delta_{d}(S)$. The following result complements these facts.

Proposition 4.5. For operators $T, S \in L(E, Y)$, we have the following inequalities:
(1) $\Gamma_{d}(T+S) \leq \Gamma_{d}(T)+\Delta_{d}(S)$ and
(2) $\Delta_{d}(T+S) \leq \Delta_{d}(T)+\Delta_{d}(S)$.

Proof. Let $\left(x_{n}\right) \in \mathrm{d}(E)$. Then $\left\|(T+S)_{\left[x_{n}\right]}\right\| \leq\|T\|+\left\|S_{\left[x_{n}\right]}\right\|$, and taking the infimum over $\left(x_{n}\right) \in \mathrm{d}(E)$ we obtain $\Gamma_{d}(T+S) \leq\|T\|+\Gamma_{d}(S)$. Therefore

$$
\Gamma_{d}(T+S) \leq \Gamma_{d}\left((T+S)_{\left[x_{n}\right]}\right) \leq\left\|T_{\left[x_{n}\right]}\right\|+\Gamma_{d}\left(S_{\left[x_{n}\right]}\right) \leq\left\|T_{\left[x_{n}\right]}\right\|+\Delta_{d}(S)
$$

and taking again the infimum over $\left(x_{n}\right) \in \mathrm{d}(E)$ we get (1).
Let $\left(x_{n}\right) \in \mathrm{d}(E)$. From (1) we derive

$$
\Gamma_{d}\left((T+S)_{\left[x_{n}\right]}\right) \leq \Gamma_{d}\left(T_{\left[x_{n}\right]}\right)+\Delta_{d}\left(S_{\left[x_{n}\right]}\right) \leq \Gamma_{d}\left(T_{\left[x_{n}\right]}\right)+\Delta_{d}(S)
$$

and taking the supremum over $\left(x_{n}\right)$ we get $\Delta_{d}(T+S) \leq \Delta_{d}(T)+\Delta_{d}(S)$.
Since $\Delta_{d}(T) \leq\|T\|$, Theorem 4.2 and part (1) of Proposition 4.5 improve the results proved in [6] that, under some conditions, $\mathrm{DN}-\mathrm{S}(E, Y)$ is stable under perturbation by small norm operators and DSS operators.

Corollary 4.6. Let $E$ be an order continuous Banach lattice. Then
(1) $D S S(E, Y)$ is a closed subspace of $L(E, Y)$;
(2) $D N-S(E, Y)$ is an open subset of $L(E, Y)$;
(3) If $S \in D S S(E, Y)$, then $\Gamma_{d}(T+S)=\Gamma_{d}(T)$, for all $T \in L(E, Y)$;
in particular, $T \in D N-S(E, Y)$ implies $T+S \in D N-S(E, Y)$.
Proof. (1) If $T, S \in \operatorname{DSS}(E, Y)$, then $\Delta_{d}(T+S) \leq \Delta_{d}(T)+\Delta_{d}(S)=0$, so $T+S \in \operatorname{DSS}(E, Y)$; and $\Delta_{d}(\lambda T)=|\lambda| \Delta_{d}(T)$ implies $\lambda T \in \operatorname{DSS}(E, Y)$.
(2) If $T \in \mathrm{DN}-\mathrm{S}(E, Y)$ and $S \in \mathrm{~L}(E, Y)$ with $\|S\|<\Gamma_{d}(T)$, then $\Gamma_{d}(T+S) \geq \Gamma_{d}(T)-\Delta_{d}(S) \geq$ $\Gamma_{d}(T)-\|S\|>0$. Hence $T+S \in \mathrm{DN}-\mathrm{S}(E, Y)$.
(3) Let $S \in \operatorname{DSS}(E, Y)$, so $\Delta_{d}(S)=0$. For all $T \in \mathrm{~L}(E, Y)$,

$$
\Gamma_{d}(T+S) \leq \Gamma_{d}(T)+\Delta_{d}(S)=\Gamma_{d}(T)
$$

and similarly $\Gamma_{d}(T)=\Gamma_{d}(T+S-S) \leq \Gamma_{d}(T+S)$.
Part (2) of Corollary 4.6 was proved by Bilokopytov [1] using different techniques.
A closed subspace $M$ of $E$ is said to be dispersed if there is no sequence $\left(x_{n}\right) \in \mathrm{d}(E)$ such that $\lim _{n \rightarrow \infty} \operatorname{dist}\left(x_{n}, M\right)=0$ (see [6, Definition 2.1]).

Remark 4.7. Let $M$ be a non-dispersed closed subspace of $E$. Denoting by $N D(M)$ the set of all closed subspaces of $M$ which are non-dispersed in $E$, it readily follows from Lemma 3.1 that, for $T \in L(E, Y)$,

$$
\Gamma_{d}(T)=\inf _{M \in N D(E)}\left\|T_{M}\right\| \quad \text { and } \quad \Delta_{d}(T)=\sup _{M_{1} \in N D(E)} \inf _{M_{2} \in N D\left(M_{1}\right)}\left\|T_{M_{2}}\right\|
$$

## 5. Operational quantities derived from the injection modulus

Next result gives other expressions for the quantity $\tau_{d}$.
Proposition 5.1. For $T \in L(E, Y)$, we have $\tau_{d}(T)=s_{d} \kappa(T)=s_{d} \tau(T)$.
Proof. As $j \leq \kappa \leq \tau$, we have $\tau_{d}=s_{d} j \leq s_{d} \kappa \leq s_{d} \tau$. Moreover, $s_{d} \tau=s_{d} \tau_{d}$ by Corollary 3.3, Hence

$$
s_{d} \tau(T)=s_{d} \tau_{d}(T)=s_{d} s_{d} j(T)=s_{d} j(T)=\tau_{d}(T)
$$

because $s_{d} s_{d} a=s_{d} a$ for every quantity $a$.
Proposition 5.2. Let $T \in L(E, Y)$. Then $T \in D S S$ if and only if $\tau_{d}(T)=0$.
Proof. We have that $\tau_{d}(T)=0$ is equivalent to $j\left(T_{\left[x_{n}\right]}\right)=0$, for every sequence $\left(x_{n}\right) \in \mathrm{d}(E)$. This means that $T$ is not an isomorphism on any subspace $\left[x_{n}\right]$ generated by a disjoint sequence. That is, $T$ is disjointly strictly singular.

Proposition 5.3. For an operator $T \in L(E, Y)$, we have $\kappa_{d}(T)=i_{d} \kappa(T)=i_{d} \tau(T)$.
Proof. By Proposition5.1, $\kappa \leq \tau_{d} \leq \tau$, hence $i_{d} \kappa \leq i_{d} \tau_{d}=\kappa_{d} \leq i_{d} \tau$. Moreover, arguing as in the proof of Corollary 3.3 we get $i_{d} \kappa=i_{d} \kappa_{d}=i_{d} i_{d} \tau_{d}=i_{d} \tau_{d}=i_{d} \tau$, and the result is proved.

Like Theorem 4.2, by Proposition 5.3 the following result says that $T \in \operatorname{DN}-\mathrm{S}(E, Y)$ if and only if the restrictions $T_{\left[x_{n}\right]}$ with $\left(x_{n}\right) \in \mathrm{d}(E)$ are "uniformly" upper semi-Fredholm, in the sense that $\inf _{\left(x_{n}\right) \in \mathrm{d}(E)} \kappa\left(T_{\left[x_{n}\right]}\right)>0$.

Theorem 5.4. Let $E$ be an order continuous Banach lattice and let $T \in L(E, Y)$. Then $T \in$ $D N-S$ if and only if $\kappa_{d}(T)>0$.

Proof. By Proposition 5.3, $\kappa_{d}(T)=i_{d} \tau(T)$. Then if $\kappa_{d}(T)>0$ and $\left(f_{n}\right) \in \mathrm{d}(E), \tau\left(T_{\left[f_{n}\right]}\right)>0$. Hence $T_{\left[f_{n}\right]}$ is not strictly singular, and $T$ is disjointly non-singular by Theorem 2.1.

Conversely, suppose that $\kappa_{d}(T)=0$. By Theorem[2.1, in order to show that $T$ is not disjointly non-singular, it is enough to find a normalized $\left(h_{n}\right) \in \mathrm{d}(E)$ such that $\lim _{n \rightarrow \infty} T h_{n}=0$.

For each $n \in \mathbb{N}$ there exists a normalized sequence $\left(f_{n, k}\right)_{k} \in \mathrm{~d}(E)$ such that

$$
\tau_{d}\left(T_{\left[f_{n, k}\right]_{k}}\right)<\frac{1}{n}
$$

and by Lemma 2.2 we can assume that the vectors $f_{n, k}$ are contained in a closed ideal that admits a representation as a Köthe space.

As $j\left(T_{\left[f_{1, k}\right]_{k}}\right)<1$, there exists $g_{1} \in\left[\left(f_{1, k}\right)_{k}\right]$ with $\left\|T g_{1}\right\|<1$. From $\lim _{k \rightarrow \infty} \mu\left(D\left(f_{2, k}\right)\right)=0$, by Lemma 2.3 we have $\lim _{k \rightarrow \infty}\left\|g_{1} 1_{D\left(f_{2, k}\right)}\right\|_{E}=0$. So we can to take $k_{2}>1$ such that

$$
\left\|g_{1}\right\|=1,\left\|T g_{1}\right\|<1 \text { and }\left\|g_{1} 1_{D\left(f_{2, k_{2}}\right)}\right\|_{E}<\frac{1}{2^{2}}
$$

Moreover, from

$$
j\left(T_{\left[\left(f_{2, k}\right)_{k \geq k_{2}}\right]}\right) \leq \tau_{d}\left(T_{\left[\left(f_{2, k}\right)_{k}\right]}\right)<\frac{1}{2}
$$

we obtain that there is $g_{2} \in\left[\left(f_{2, k}\right)_{k \geq k_{2}}\right]$ with $\left\|T g_{2}\right\|<1 / 2$. As $\lim _{k \rightarrow \infty} \mu\left(D\left(f_{3, k}\right)\right)=0$, by Lemma 2.3 we get $\lim _{k \rightarrow \infty}\left\|g_{i} 1_{D\left(f_{3, k}\right)}\right\|_{E}=0$, so we can take $k_{3}>k_{2}$ such that

$$
\left\|g_{2}\right\|=1,\left\|T g_{2}\right\|<\frac{1}{2} \text { and }\left\|g_{i} 1_{D\left(f_{3, k_{3}}\right)}\right\|_{E}<\frac{1}{2^{3}}(i \leq i<3)
$$

Now, proceeding as in the proof of Theorem 4.2, we take $A_{n}=\cup_{j=n+1}^{\infty} D\left(g_{j}\right)$ and obtain a normalized sequence $h_{n}:=\left\|g_{n}-g_{n} 1_{A_{n}}\right\|^{-1}\left(g_{n}-g_{n} 1_{A_{n}}\right)$ in $\mathrm{d}(E)$. Since $\lim _{n \rightarrow \infty}\left\|T h_{n}\right\|=0$, we conclude that $T \notin \mathrm{DN}-\mathrm{S}(E, Y)$.

To compare Theorem 5.4 with Theorem 4.2, observe that $\kappa_{d} \leq \Gamma_{d}$.
Proposition 5.5. For operators $T, S \in L(E, Y)$, we have the following inequalities:
(1) $\tau_{d}(T+S) \leq \tau_{d}(T)+\Delta_{d}(S)$ and
(2) $\kappa_{d}(T+S) \leq \kappa_{d}(T)+\Delta_{d}(S)$.

Proof. Since $j(T+S) \leq j(T)+\|S\|$, for each $\left(x_{n}\right) \in \mathrm{d}(E)$ we get

$$
j(T+S) \leq j\left((T+S)_{\left[x_{n}\right]}\right) \leq j\left(T_{\left[x_{n}\right]}\right)+\left\|S_{\left[x_{n}\right]}\right\| \leq \tau_{d}(T)+\left\|S_{\left[x_{n}\right]}\right\|
$$

and taking the infimum over $\left(x_{n}\right)$ we obtain $j(T+S) \leq \tau_{d}(T)+\Gamma_{d}(S)$.
(1) For $\left(x_{n}\right) \in \mathrm{d}(E)$, we have $j\left((T+S)_{\left[x_{n}\right]}\right) \leq \tau_{d}\left(T_{\left[x_{n}\right]}\right)+\Gamma_{d}\left(S_{\left[x_{n}\right]}\right) \leq \tau_{d}(T)+\Gamma_{d}\left(S_{\left[x_{n}\right]}\right)$, and taking the supremum over $\left(x_{n}\right)$ we get $\tau_{d}(T+S) \leq \tau_{d}(T)+\Delta_{d}(S)$.
(2) Applying (1), $\tau_{d}\left((T+S)_{\left[x_{n}\right]}\right) \leq \tau_{d}\left(T_{\left[x_{n}\right]}\right)+\Delta_{d}\left(S_{\left[x_{n}\right]}\right) \leq \tau_{d}\left(T_{\left[x_{n}\right]}\right)+\Delta_{d}(S)$ for each $\left(x_{n}\right) \in$ $\mathrm{d}(E)$. So taking the infimum over $\left(x_{n}\right)$, we obtain $\kappa_{d}(T+S) \leq \kappa_{d}(T)+\Delta_{d}(S)$.

From Proposition 5.5, we could derive an alternative proof of Corollary 4.6.
Remark 5.6. As in Remark 4.7, we can give expressions for $\kappa_{d}(T)$ and $\tau_{d}(T)$ in terms of the restrictions of $T$ to non-dispersed subspaces. For $T \in L(E, Y)$,

$$
\tau_{d}(T)=\sup _{M \in N D(E)} j\left(T_{M}\right) \quad \text { and } \quad \kappa_{d}(T)=\inf _{M_{1} \in N D(E)} \sup _{M_{2} \in N D\left(M_{1}\right)} j\left(T_{M_{2}}\right)
$$

## 6. The quantity $\beta$

For an operator $T \in \mathrm{~L}(E, Y)$, the following quantity was defined in [6]:

$$
\beta(T):=\inf \left\{\liminf _{n \rightarrow \infty}\left\|T x_{n}\right\|:\left(x_{n}\right) \text { normalized disjoint in } E\right\}
$$

We have shown in Theorem 4.2 that the quantity $\Gamma_{d}$ characterizes $\mathrm{DN}-\mathrm{S}(E, Y)$ for $E$ an order continuous Banach lattice. Moreover, it is related with $\beta$ as follows:

Proposition 6.1. Every operator $T \in L(E, Y)$ satisfies $\beta(T) \leq \Gamma_{d}(T)$.
Proof. Note that

$$
\beta(T)=\inf _{\left(x_{n}\right) \in \mathrm{d}(E)} \liminf \inf _{n \rightarrow \infty}\left\|T \frac{x_{n}}{\left\|x_{n}\right\|}\right\| \leq \inf _{\left(x_{n}\right) \in \mathrm{d}(E)}\left\|T_{\left[x_{n}\right]}\right\|=\Gamma_{d}(T)
$$

It was proved in [6, Proposition 3.1] (see [4] for $p=1$ ) that, for $1 \leq p<\infty$, an operator $T \in \mathrm{~L}\left(L_{p}, Y\right)$ is disjointly non-singular if and only if $\beta(T)>0$. Now we extend this result.

Proposition 6.2. Let $E$ be an order continuous Banach lattice. Then an operator $T \in L(E, Y)$ is disjointly non-singular if and only if $\beta(T)>0$.

Proof. If $\beta(T)>0$, then condition (4) in Theorem 2.1 is satisfied, hence $T \in \operatorname{DN}-\mathrm{S}(E, Y)$.
Suppose that $\beta(T)=0$. Then for every $n \in \mathbb{N}$ we can find a normalized disjoint sequence $\left(f_{n, k}\right)_{k \in \mathbb{N}}$ with $\left\|T f_{n, k}\right\|<1 / n$ for every $k \in \mathbb{N}$, and proceeding as in the proof of Theorem 4.2, for each $n$ we select $k_{n}$ so that taking $g_{n}=f_{n, k_{n}}$ we have $\left\|g_{i} 1_{D\left(g_{n}\right)}\right\|<2^{-n}$ for $1 \leq i<n$. The sequence $\left(g_{n}\right)$ is almost disjoint (there exists a normalized disjoint sequence $\left(h_{n}\right)$ in $E$ such that $\left.\lim _{n \rightarrow \infty}\left\|g_{n}-h_{n}\right\|_{E}=0\right)$. Then $\lim _{n \rightarrow \infty}\left\|T h_{n}\right\|=0$, hence $T \notin \operatorname{DN}-S(E, Y)$.

By Proposition 6.1, $\beta \leq \Gamma_{d}$. In some cases, these two quantities coincide; for example, if $1 \leq p<2$ and $M$ is a dispersed subspace of $L_{p}$, then the quotient map $Q_{M}: L_{p} \rightarrow L_{p} / M$ satisfies $\beta\left(Q_{M}\right)=1$ (see [6]), hence $\Gamma_{d}\left(Q_{M}\right)=\left\|Q_{M}\right\|=1$. However, using the fact proved by Odell and Schlumprecht in [18 that the Banach space $\ell_{2}$ is arbitrarily distortable, we show that these two quantities are not equivalent:

Example 6.3. For every $\lambda>1$ and $\varepsilon>0$, there exists a Banach space $Y_{\lambda}$ isomorphic to $\ell_{2}$ and an operator $T_{\lambda} \in L\left(\ell_{2}, Y_{\lambda}\right)$ such that $0<\lambda \cdot \beta\left(T_{\lambda}\right) \leq \Gamma_{d}\left(T_{\lambda}\right)+\varepsilon$. Thus there is no $C>0$ such that $\Gamma_{d} \leq C \cdot \beta$.

Proof. Since $\ell_{2}$ is arbitrarily distortable [18, for every $\lambda>1$ there is a norm $|\cdot|_{\lambda}$ on $\ell_{2}$ equivalent to the usual one $\|\cdot\|_{2}$ such that, for each closed infinite dimensional subspace $M$ of $\ell_{2}$,

$$
\begin{equation*}
\sup \left\{\frac{|x|_{\lambda}}{|y|_{\lambda}}: x, y \in M,\|x\|_{2}=\|y\|_{2}=1\right\}>\lambda . \tag{3}
\end{equation*}
$$

We denote $Y_{\lambda}=\left(\ell_{2},|\cdot|_{\lambda}\right)$ and $T_{\lambda}$ the identity operator from $\ell_{2}$ onto $Y_{\lambda}$.
Note that the operator $T_{\lambda}$ is bounded below, and passing to a closed infinite dimensional subspace of $\ell_{2}$ (that we can identify with $\ell_{2}$, with the lattice structure determined by any orthonormal basis) we can assume that $\left\|T_{\lambda}\right\|<\Gamma_{d}\left(T_{\lambda}\right)+\varepsilon$.

By inequality (3), $\lambda j\left(T_{\lambda}\right) \leq\left\|T_{\lambda}\right\|$ and there exists $g_{1}$ with $\left\|g_{1}\right\|_{2}=1$ and $\lambda \cdot\left|g_{1}\right|_{\lambda}<\Gamma_{d}\left(T_{\lambda}\right)+\varepsilon$. Moreover, by the denseness of the span of the basis $\left(e_{n}\right)$ of $\ell_{2}$, we can choose $g_{1} \in\left[e_{1}, \ldots, e_{m_{1}}\right]$ for some $m_{1} \in \mathbb{N}$. Similarly, there exists $g_{2} \in\left[e_{i}: i>m_{1}\right]$ with $\left\|g_{2}\right\|_{2}=1$ and $\lambda \cdot\left|g_{2}\right|_{\lambda}<\Gamma_{d}\left(T_{\lambda}\right)+\varepsilon$, and again we can choose $g_{2} \in\left[e_{m_{1}+1}, \ldots, e_{m_{2}}\right]$ for some $m_{2}>m_{1}$ in $\mathbb{N}$.

In this way we get a sequence $\left(g_{n}\right) \in \mathrm{d}\left(\ell_{2}\right)$ such that $\lambda \cdot\left|g_{n}\right|_{\lambda}=\lambda \cdot\left|T_{\lambda} g_{n}\right|_{\lambda} \leq \Gamma_{d}\left(T_{\lambda}\right)+\varepsilon$, which implies $\lambda \cdot \beta\left(T_{\lambda}\right) \leq \Gamma_{d}\left(T_{\lambda}\right)+\varepsilon$.

## 7. Order between operational quantities

The order between the operational quantities derived from the norm and the injection modulus $j$ is showed in the following diagram, where " $\rightarrow$ " means " $\leq$ ":

The vertical arrows in the above diagram connect quantities that characterize the same classes of operators: upper semi-Fredholm, DN-S, DSS and strictly singular. We observe that none of these pairs are equivalent quantities.

Indeed, the quantities $\kappa$ and $\Gamma$ are not equivalent because $\ell_{2}$ is arbitrarily distortable. Hence, by [8, Theorem 3.4 and Corollary 3.5], there exist spaces $Y_{n} \simeq \ell_{2}$ and operators $T_{n} \in \mathrm{~L}\left(\ell_{2}, Y_{n}\right)$ $(n \in \mathbb{N})$ such that $n \cdot \kappa\left(T_{n}\right) \leq \Gamma\left(T_{n}\right)$. Since $\ell_{2}$ is an atomic Banach lattice, $\kappa_{d}\left(T_{n}\right)=\kappa\left(T_{n}\right)$ and $\Gamma_{d}\left(T_{n}\right)=\Gamma\left(T_{n}\right)$; hence $\kappa_{d}$ and $\Gamma_{d}$ are not equivalent.

Similarly, by [17, Proposition 1], the operators $T_{n} \in \mathrm{~L}\left(\ell_{2}, Y_{n}\right)$ in the previous paragraph satisfy $n \cdot \tau\left(T_{n}\right) \leq \Delta\left(T_{n}\right)$, showing that $\tau$ and $\Delta$ are not equivalent, and also that $\tau_{d}$ and $\Delta_{d}$ are not equivalent.
7.1. Open Questions. We finish the paper stating some open questions.

Question 1. Is $\kappa_{d} \leq D \cdot \beta$ for some constant $D>0$ ?
If $E$ is an order continuous Banach lattice then $E$ is an ideal in $E^{* *}$ [16, Theorem 1.b.16], hence the quotient $E^{* *} / E$ is a Banach lattice [16, Section 1.a]. Moreover, every operator $T \in \mathrm{~L}(E, Y)$ induces a residuum operator $T^{c o} \in \mathrm{~L}\left(E^{* *} / E, Y^{* *} / Y\right)$ defined by $T^{c o}\left(x^{* *}+E\right)=T^{* *} x^{* *}+Y$.

Question 2. Suppose that $E$ is order continuous and $T \in D N-S(E, Y)$. Is $T^{c o} \in D N-S$ ?
It was proved in [4] that the answer is positive in the case $E=L_{1}$. We refer to [10] for information on the residuum operator $T^{c o}$.

In [6, Theorem 3.16] it is shown that for $1 \leq p<\infty, \operatorname{DSS}\left(L_{p}, Y\right)$ is the perturbation class of $\operatorname{DN}-\mathrm{S}\left(L_{p}, Y\right)$ in the sense that when $\operatorname{DN-S}\left(L_{p}, Y\right) \neq \emptyset, K \in \mathrm{~L}\left(L_{p}, Y\right)$ is DSS if and only if $T+K \in \mathrm{DN}-\mathrm{S}$ for each $T \in \mathrm{DN}-\mathrm{S}\left(L_{p}, Y\right)$.

Question 3. Suppose that $E$ is an order continuous Banach lattice and $D N-S(E, Y) \neq \emptyset$.
Is $D S S(E, Y)$ the perturbation class of $D N-S(E, Y)$ ?

Acknowledgements. We thank the referees for a careful reading of the manuscript and some suggestions that improved the paper.
