# On the $\nu$-zeros of the modified Bessel function $K_{i \nu}(x)$ of positive argument 

R. B. Paris<br>Division of Computing and Mathematics, Abertay University, Dundee DD1 1HG, UK

#### Abstract

The modified Bessel function of the second kind $K_{i \nu}(x)$ of imaginary order for fixed $x>0$ possesses a countably infinite sequence of real zeros. Recently it has been shown that the $n$th zero behaves like $\nu_{n} \sim \pi n / \log n$ as $n \rightarrow \infty$. In this note we determine a more precise estimate for the bahaviour of these zeros for large $n$ by making use of the known asymptotic expansion of $K_{i \nu}(x)$ for large $\nu$. Numerical results are presented to illustrate the accuracy of the expansion obtained.

Keywords: modified Bessel function, imaginary order, zeros, asymptotic expansion, method of steepest descents

## 1. Introduction

The modified Bessel function of the second kind (the Macdonald function) $K_{i \nu}(x)$ of purely imaginary order and argument $x>0$ is given by

$$
\begin{equation*}
K_{1 \nu}(x)=\int_{0}^{\infty} e^{-x \cosh t} \cos \nu t d t=\frac{1}{2} \int_{-\infty}^{\infty} e^{-x \cosh t+i \nu t} d t \tag{1.1}
\end{equation*}
$$

In a recent paper, Bagirova and Khanmamedov [1] have shown that $K_{i \nu}(x)$ has a countably infinite number of (simple) real zeros in $\nu$ when $x>0$ is fixed. We label the zeros $\nu_{n} \equiv \nu_{n}(x)$ ( $n=0,1,2 \ldots$ ) and observe that it is sufficient to consider only the case $\nu>0$ since $K_{i \nu}(x)=$ $K_{-i \nu}(x)$. By transforming the differential equation satisfied by $K_{i \nu}(x)$ into a one-dimensional Schrödinger equation with an exponential potential, these authors employed the well-known quantisation rule to deduce the leading asymptotic behaviour of the $n$th zero given by

$$
\begin{equation*}
\nu_{n} \sim \frac{\pi n}{\log n} \quad(n \rightarrow+\infty) . \tag{1.2}
\end{equation*}
$$

In this note, we consider the behaviour of the large- $n \nu$-zeros of $K_{1 \nu}(x)$ in more detail. To achieve this we make use of the known asymptotic expansion of $K_{i \nu}(x)$ for $\nu \rightarrow+\infty$ stated in Section 2. A typical plot of $e^{\pi \nu / 2} K_{i \nu}(x)$ as a function of $\nu$ is shown in Fig. 1.

## 2. Derivation of the equation describing the large- $n$ zeros

We start with the asymptotic expansion of $K_{i \nu}(x)$ for $\nu \rightarrow+\infty$ given by [5] (see alsd] [4, pp. 41-42])

$$
\begin{equation*}
e^{\pi \nu / 2} K_{i \nu}(x) \sim \Re \sqrt{\frac{2 \pi}{\nu \tanh \mu}} e^{i \Phi} \sum_{k=0}^{\infty} \frac{\left(\frac{1}{2}\right)_{k} C_{k}(\mu)}{\left(\frac{1}{2} i \nu \tanh \mu\right)^{k}}, \tag{2.1}
\end{equation*}
$$

[^0]

Figure 1: Plot of $e^{\pi \nu / 2} K_{i \nu}(x)$ as a function of $\nu$ when $x=1$.
where

$$
\Phi:=\nu(\mu-\tanh \mu)-\frac{\pi}{4}, \quad \cosh \mu=\frac{\nu}{x}
$$

and $(a)_{k}=\Gamma(a+k) / \Gamma(a)$ denotes the Pochhammer symbol. The first few coefficients $C_{k}(\mu)$ are

$$
C_{0}(\mu)=1, \quad C_{1}(\mu)=-\frac{1}{8}+\frac{5 \operatorname{coth}^{2} \mu}{24}, \quad C_{2}(\mu)=\frac{3}{128}-\frac{77 \operatorname{coth}^{2} \mu}{576}+\frac{385 \operatorname{coth}^{4} \mu}{3456}
$$

values of $C_{k}(\mu)$ for $k \leq 5$ are derived in the appendix. It is important to point out that the determination of the expansion (2.1) from the integral (1.1) involves (when $\nu>x$ ) an infinite number of contributing saddle points. The expansion (2.1) results from the two dominant saddles, the remaining saddles yielding an exponentially small contribution of $\mathrm{O}\left(e^{-\pi \nu}\right)$. Then, from (2.1), the zeros of $K_{i \nu}(x)$ are given asymptotically by

$$
\begin{aligned}
\cos \Phi\left\{1-\frac{3 C_{2}(\mu)}{(\nu \tanh \mu)^{2}}\right. & \left.+\frac{105 C_{4}(\mu)}{(\nu \tanh \mu)^{4}}+\cdots\right\} \\
& +\sin \Phi\left\{\frac{C_{1}(\mu)}{\nu \tanh \mu}-\frac{15 C_{3}(\mu)}{(\nu \tanh \mu)^{3}}+\frac{945 C_{5}(\mu)}{(\nu \tanh \mu)^{5}}+\cdots\right\}=0 .
\end{aligned}
$$

Let

$$
\begin{equation*}
\Phi=\left(n+\frac{1}{2}\right) \pi+\epsilon \tag{2.2}
\end{equation*}
$$

where $n$ is a large positive integer and $\epsilon$ is a small quantity. Then

$$
\begin{gathered}
\tan \epsilon=\frac{\frac{C_{1}(\mu)}{\nu \tanh \mu}-\frac{15 C_{3}(\mu)}{(\nu \tanh \mu)^{3}}+\frac{945 C_{5}(\mu)}{(\nu \tanh \mu)^{5}}+\cdots}{1-\frac{3 C_{2}(\mu)}{(\nu \tanh \mu)^{2}}+\frac{105 C^{4}(\mu)}{(\nu \tanh \mu)^{4}}+\cdots} \\
=\frac{1}{\nu \tanh \mu}\left\{C_{1}(\mu)+\frac{3\left(C_{1}(\mu) C_{2}(\mu)-5 C_{3}(\mu)\right)}{(\nu \tanh \mu)^{2}}\right. \\
\left.+\frac{9 C_{1}(\mu) C_{2}^{2}(\mu)-45 C_{2}(\mu) C_{3}(\mu)-105 C_{1}(\mu) C_{4}(\mu)+945 C_{5}(\mu)}{(\nu \tanh \mu)^{4}}+\cdots\right\},
\end{gathered}
$$

so that using $\arctan z=z-z^{3} / 3+z^{5} / 5-\ldots(|z|<1)$, we obtain

$$
\epsilon=\frac{a_{0}(\mu)}{\nu}+\frac{a_{1}(\mu)}{\nu^{3}}+\frac{a_{2}(\mu)}{\nu^{5}}+\cdots
$$

where

$$
a_{0}(\mu)=\frac{C_{1}(\mu)}{\tanh \mu}, \quad a_{1}(\mu)=\frac{3\left(C_{1}(\mu) C_{2}(\mu)-5 C_{3}(\mu)\right)-\frac{1}{3} C_{1}^{3}(\mu)}{\tanh ^{3} \mu}
$$

$$
\begin{aligned}
a_{2}(\mu)=\frac{1}{\tanh ^{5} \mu} & \left\{3\left(3 C_{1}(\mu) C_{2}^{2}(\mu)-15 C_{2}(\mu) C_{3}(\mu)-35\left(C_{1}(\mu) C_{4}(\mu)-9 C_{5}(\mu)\right)\right)\right. \\
& \left.-3 C_{1}^{2}(\mu)\left(C_{1}(\mu) C_{2}(\mu)-5 C_{3}(\mu)\right)+\frac{1}{5} C_{1}^{5}(\mu)\right\}
\end{aligned}
$$

Since $\tanh \mu=\sqrt{1-x^{2} / \nu^{2}}$, the coefficients $a_{k}(\mu)$ possess expansions in inverse powers of $\nu^{2}$. Some laborious algebra shows that

$$
\begin{aligned}
& a_{0}(\mu)=\frac{1}{12}+\frac{x^{2}}{4 \nu^{2}}+\frac{11 x^{4}}{32 \nu^{4}}+O\left(\nu^{-6}\right) \\
& a_{1}(\mu)=\frac{1}{360}-\frac{x^{2}}{4 \nu^{2}}+O\left(\nu^{-4}\right) \\
& a_{2}(\mu)=\frac{1}{1260}+O\left(\nu^{-2}\right)
\end{aligned}
$$

whence we obtain

$$
\begin{equation*}
\epsilon=\frac{1}{12 \nu}+\frac{1}{\nu^{3}}\left(\frac{1}{360}+\frac{x^{2}}{4}\right)+\frac{1}{\nu^{5}}\left(\frac{1}{1260}-\frac{x^{2}}{4}+\frac{11 x^{4}}{32}\right)+\cdots \tag{2.3}
\end{equation*}
$$

Making use of the expansion

$$
\mu-\tanh \mu=\log \lambda \nu+\frac{x^{2}}{4 \nu^{2}}+\frac{x^{4}}{32 \nu^{4}}+\frac{x^{6}}{96 \nu^{6}}+O\left(\nu^{-8}\right), \quad \lambda:=\frac{2}{e x}
$$

we then finally obtain from (2.2) and (2.3) the equation describing the large- $n$ zeros of $K_{i \nu}(x)$ given by

$$
\begin{equation*}
\nu \log \lambda \nu=m+\frac{A_{0}}{\nu}+\frac{A_{1}}{\nu^{3}}+\frac{A_{2}}{\nu^{5}}+\cdots \tag{2.4}
\end{equation*}
$$

where

$$
A_{0}=\frac{1}{12}-\frac{x^{2}}{4}, \quad A_{1}=\frac{1}{360}+\frac{x^{2}}{4}-\frac{x^{4}}{32}, \quad A_{2}=\frac{1}{1260}-\frac{x^{2}}{4}+\frac{11 x^{4}}{32}-\frac{x^{6}}{96}
$$

and, for convenience, we have put $m:=\left(n+\frac{3}{4}\right) \pi$.

## 3. Solution of the equation for the zeros

To solve (2.4) we expand $\nu$ as

$$
\nu_{n}=\xi+\frac{c_{0}}{\xi}+\frac{c_{1}}{\xi^{3}}+\frac{c_{2}}{\xi^{5}}+\cdots
$$

where the $c_{k}$ are constants to be determined and we suppose that $\xi$ is large as $n \rightarrow \infty$. Substitution in (2.4) then produces

$$
\begin{gathered}
\xi \log \lambda \xi+\frac{c_{0}(1+\log \lambda \xi)}{\xi}+\frac{c_{1}(1+\log \lambda \xi)+\frac{1}{2} c_{0}^{2}}{\xi^{3}}+\frac{c_{2}(1+\log \lambda \xi)+c_{0} c_{1}-\frac{1}{6} c_{0}^{3}}{\xi^{5}}+\cdots \\
=m+\frac{A_{0}}{\xi}+\frac{A_{1}-A_{0} c_{0}}{\xi^{3}}+\frac{A_{2}-3 A_{1} c_{0}+A_{0}\left(c_{0}^{2}-c_{1}\right)}{\xi^{5}}+\cdots
\end{gathered}
$$

Equating coefficients of like powers of $\xi$, we obtain

$$
\begin{equation*}
\xi \log \lambda \xi=m \tag{3.1}
\end{equation*}
$$

and

$$
c_{0}=\frac{A_{0}}{1+\log \lambda \xi}, \quad c_{1}=\frac{A_{1}-A_{0} c_{0}-\frac{1}{2} c_{0}^{2}}{1+\log \lambda \xi}
$$

$$
c_{2}=\frac{A_{2}-3 A_{1} c_{0}+A_{0}\left(c_{0}^{2}-c_{1}\right)-c_{0} c_{1}+\frac{1}{6} c_{0}^{3}}{1+\log \lambda \xi}
$$

The solution of (3.1) for the lowest-order term $\xi$ can be expressed in terms of the Lambert $W$ function, which is the (positive) solution ${ }^{2}$ of $W(z) e^{W(z)}=z$ for $z>0$. Rearrangement of (3.1) shows that

$$
\frac{m}{\xi} e^{m / \xi}=\lambda m
$$

whence

$$
\begin{equation*}
\xi=\frac{m}{W(\lambda m)} \tag{3.2}
\end{equation*}
$$

The asymptotic expansion of $W(z)$ for $z \rightarrow+\infty$ is [2], [3, (4.13.10)]
$W(z) \sim L_{1}-L_{2}+\frac{L_{2}}{L_{1}}+\frac{L_{2}^{2}-2 L_{2}}{2 L_{1}^{2}}+\frac{\left(6-9 L_{2}+2 L_{2}^{2}\right) L_{2}}{6 L_{1}^{3}}+\frac{\left(-12+36 L_{2}-22 L_{2}^{2}+3 L_{2}^{3}\right) L_{2}}{12 L_{1}^{4}}+\cdots$,
where $L_{1}=\log z, L_{2}=\log \log z$, from which it follows that
$\frac{1}{W(z)} \sim \frac{1}{L_{1}}\left\{1+\frac{L_{2}}{L_{1}}+\frac{L_{2}\left(L_{2}-1\right)}{L_{1}^{2}}+\frac{\left(1-5 L_{2}+2 L_{2}^{2}\right) L_{2}}{2 L_{1}^{3}}+\frac{\left(-6+21 L_{2}-26 L_{2}^{2}+6 L_{2}^{3}\right) L_{2}}{6 L_{1}^{4}}+\cdots\right\}$.
Then we have the expansion for $\xi$ as $\lambda m \rightarrow \infty$ given by

$$
\begin{equation*}
\xi \sim \frac{m}{\log \lambda m}\left\{1+\frac{\log \log \lambda m}{\log \lambda m}+\frac{\log \log \lambda m(\log \log \lambda m-1)}{(\log \lambda m)^{2}}+\cdots\right\} \tag{3.3}
\end{equation*}
$$

where we recall that $m=\left(n+\frac{3}{4}\right) \pi$.
If we define $\chi:=\xi / m$, so that by (3.1) $1+\log \lambda \xi=(1+\chi) / \chi$ and introduce the coefficients

$$
\begin{equation*}
B_{0}=\frac{A_{0}}{1+\chi}, \quad B_{1}=\frac{A_{1}-A_{0} c_{0}-\frac{1}{2} c_{0}^{2}}{\chi^{2}(1+\chi)}, \quad B_{2}=\frac{A_{2}-3 A_{1} c_{0}+A_{0}\left(c_{0}^{2}-c_{1}\right)-c_{0} c_{1}+\frac{1}{6} c_{0}^{3}}{\chi^{4}(1+\chi)} \tag{3.4}
\end{equation*}
$$

then we finally have the result:
Theorem 1. The expansion for the $n$th $\nu$-zero of $K_{1 \nu}(x)$ for fixed $x>0$ is

$$
\begin{equation*}
\nu_{n} \sim \frac{m}{W(\lambda m)}+\frac{B_{0}}{m}+\frac{B_{1}}{m^{3}}+\frac{B_{2}}{m^{5}}+\cdots \quad(n \rightarrow \infty) \tag{3.5}
\end{equation*}
$$

where $m=\left(n+\frac{3}{4}\right) \pi, \lambda=2 /(e x)$ and the coefficients $B_{k}$ are given in 3.4.

## 4. Numerical results

The leading form of $\xi$ from (3.3) is, with $\lambda=2 /(e x)$,

$$
\xi \sim \frac{\left(n+\frac{3}{4}\right) \pi}{\log \left(n+\frac{3}{4}\right) \pi+\log \lambda} \quad(n \rightarrow \infty)
$$

which yields the approximate estimate in (1.2). In numerical calculations it is found more expedient to use the expression for $\xi$ in terms of the Lambert function in (3.2), rather than (3.3), since the asymptotic scale in this latter series is $\log \lambda m$ and so requires an extremely large value of $n$ to attain reasonable accuracy.

We present numerical results in Table 1 showing the zeros of $K_{i \nu}(x)$ computed using the FindRoot command in Mathematica compared with the asymptotic values determined from the expansion (3.5) with coefficients $B_{k}, k \leq 2$, where $\xi$ is evaluated from (3.2). The value of the zeroth-order approximation $\xi=m / W(\lambda m)$ is shown in the final column. It is seen that there is excellent agreement with the computed zeros, even for $n=1$.

[^1]Table 1: Values of the zeros of $K_{i \nu}(x)$ and their asymptotic estimates when $x=1$.

## Appendix: The coefficients $C_{k}(\mu)$ in the expansion (2.1)

The integral in (1.1) can be cast in the form

$$
\begin{equation*}
K_{i \nu}(x)=\frac{1}{2} \int_{-\infty}^{\infty} e^{-x \psi(t)} d t, \quad \psi(t):=\cosh t-i t \cosh \mu \tag{A.1}
\end{equation*}
$$

where $\cosh \mu=\nu / x$. In the right-half plane, the dominant saddle point (where $\psi^{\prime}(t)=0$ ) is situated at $t_{0}=\mu+\frac{1}{2} \pi i$, with a similar saddle in the left-half plane at $-\mu+\frac{1}{2} \pi i$. When $\nu>x$, there are in addition two infinite strings of subdominant saddles at $\pm \mu+\left(2 k+\frac{1}{2}\right) \pi i$ $(k=1,2, \ldots)$ parallel to the positive imaginary axis over which the integration path in (A.1) is deformed; see [5], 4] pp. 41-42] for details.

We introduce the new variable $w$ by

$$
w^{2}=\psi(t)-\psi\left(t_{0}\right)=\frac{1}{2} i \sinh \mu\left(t-t_{0}\right)^{2}+\frac{1}{6} i \cosh \mu\left(t-t_{0}\right)^{3}+\frac{1}{24} i \sinh \mu\left(t-t_{0}\right)^{4}+\cdots
$$

to find with the help of Mathematica using the InverseSeries command (essentially Lagrange inversion)

$$
t-t_{0}=e^{-\pi i / 4} \sqrt{\frac{2}{\sinh \mu}} w+\frac{i \operatorname{coth} \mu}{2 \sinh \mu} w^{2}-i e^{-\pi i / 4} \sqrt{\frac{2}{\sinh \mu}} \frac{\left(-3+5 \operatorname{coth}^{2} \mu\right)}{36 \sinh \mu} w^{3}+\cdots .
$$

Differentiation then yields the expansion

$$
\begin{equation*}
\frac{d t}{d w} \stackrel{e}{=} e^{-\pi i / 4} \sqrt{\frac{2}{\sinh \mu}} \sum_{k \geq 0} \frac{C_{k}(\mu)}{\left(\frac{1}{2} i \sinh \mu\right)^{k}} w^{2 k} \tag{A.2}
\end{equation*}
$$

where $\stackrel{e}{=}$ signifies the inclusion of only the even powers of $w$, since odd powers will not enter into this calculation. The first few coefficients are found to be:

$$
\begin{gathered}
C_{0}(\mu)=1, \quad C_{1}(\mu)=-\frac{1}{8}+\frac{5 \operatorname{coth}^{2} \mu}{24}, \\
C_{2}(\mu)=\frac{3}{128}-\frac{77 \operatorname{coth}^{2} \mu}{576}+\frac{385 \operatorname{coth}^{4} \mu}{3456}, \\
C_{3}(\mu)=-\frac{5}{1024}+\frac{1521 \operatorname{coth}^{2} \mu}{25600}-\frac{17017 \operatorname{coth}^{4} \mu}{138240}+\frac{17017 \operatorname{coth}^{6} \mu}{248832}, \\
C_{4}(\mu)=\frac{35}{32768}-\frac{96833 \operatorname{coth}^{2} \mu}{4300800}+\frac{144001 \operatorname{coth}^{4} \mu}{1720320}-\frac{1062347 \operatorname{coth}^{6} \mu}{9953280}+\frac{1062347 \operatorname{coth}^{8} \mu}{23887872}, \\
C_{5}(\mu)=-\frac{63}{262144}+\frac{67608983 \operatorname{coth}^{2} \mu}{8670412800}-\frac{35840233 \operatorname{coth}^{4} \mu}{796262400}+\frac{3094663 \operatorname{coth}^{6} \mu}{31850496}
\end{gathered}
$$

$$
\begin{equation*}
-\frac{154040315 \operatorname{coth}^{8} \mu}{1719926784}+\frac{154040315 \operatorname{coth}^{10} \mu}{5159780352} \tag{A.3}
\end{equation*}
$$

Then the integral (A.1) resulting from the saddle $t_{0}$ can be expressed as

$$
\int_{-\infty}^{\infty} e^{-x w^{2}} \frac{d t}{d w} d w
$$

which, after substitution of the expansion (A.2) followed by routine integration and taking into account the contribution from the saddle at $t=-\mu+\frac{1}{2} \pi i$, then yields the expansion for $K_{i \nu}(x)$ stated in (2.1).
