Analysis of nonconforming IFE methods and a new scheme for elliptic interface problems

Haifeng Ji∗ Feng Wang† Jinru Chen‡ Zhilin Li§

Abstract

In this paper, an important discovery has been found for nonconforming immersed finite element (IFE) methods using integral-value degrees of freedom for solving elliptic interface problems. We show that those IFE methods can only achieve suboptimal convergence rates (i.e., $O(h^{1/2})$ in the $H^1$ norm and $O(h)$ in the $L^2$ norm) if the tangential derivative of the exact solution and the jump of the coefficient are not zero on the interface. A nontrivial counterexample is also provided to support our theoretical analysis. To recover the optimal convergence rates, we develop a new nonconforming IFE method with additional terms locally on interface edges. The unisolvence of IFE basis functions is proved on arbitrary triangles. Furthermore, we derive the optimal approximation capabilities of both the Crouzeix-Raviart and the rotated-$Q_1$ IFE spaces for interface problems with variable coefficients via a unified approach different from multipoint Taylor expansions. Finally, optimal error estimates in both $H^1$- and $L^2$- norms are proved and confirmed with numerical experiments.

1 Introduction

Let $\Omega \subset \mathbb{R}^2$ be a convex polygonal domain and $\Gamma$ be a $C^2$-smooth interface immersed in $\Omega$. Without loss of generality, we assume that $\Gamma$ divides $\Omega$ into two disjoint sub-domains $\Omega^+$ and $\Omega^-$ such that $\Gamma = \partial \Omega^-$, see Figure 1 for an illustration. We consider the following second-order elliptic interface problem

\begin{equation}
- \nabla \cdot (\beta(x) \nabla u(x)) = f(x) \quad \text{in } \Omega \setminus \Gamma,
\end{equation}

\begin{equation}
[u]_{\Gamma}(x) = 0 \quad \text{on } \Gamma,
\end{equation}

\begin{equation}
[\beta \nabla u \cdot n]_{\Gamma}(x) = 0 \quad \text{on } \Gamma,
\end{equation}

\begin{equation}
u(x) = 0 \quad \text{on } \partial \Omega,
\end{equation}

where $n(x)$ is the unit normal vector of the interface $\Gamma$ at point $x \in \Gamma$ pointing toward $\Omega^+$, and the notation $[v]_{\Gamma}$ is defined as

\begin{equation}
[v]_{\Gamma}(x) := \lim_{p \to x, p \in \Omega^+} v(p) - \lim_{p \to x, p \in \Omega^-} v(p) \quad \forall x \in \Gamma,
\end{equation}

for a piecewise continuous function \( v \). The coefficient \( \beta(x) \) can be discontinuous across the interface \( \Gamma \) and is assumed to be piecewise smooth

\[
\beta(x) = \beta^+(x) \text{ if } x \in \Omega^+ \text{ and } \beta(x) = \beta^-(x) \text{ if } x \in \Omega^-,
\]

with \( \beta^s(x) \in C^1(\overline{\Omega}^s) \), \( s = +, - \). We also assume that there exist two positive constants \( \beta_{\min} \) and \( \beta_{\max} \) such that \( \beta_{\min} \leq \beta^s(x) \leq \beta_{\max} \) for all \( x \in \Omega^s \), \( s = +, - \).

**Figure 1:** A diagram of the geometries of an interface problem.

It is well-known that traditional finite element methods using an interface-fitted mesh can solve the interface problem with optimal convergence rates, see for example [3, 5, 24]. For complicated interfaces or moving interfaces, unfitted meshes, which are not necessarily aligned with interfaces, have some advantages over interface-fitted meshes. However, traditional finite element methods using unfitted meshes only achieve suboptimal convergence rates (\( O(h^{1/2}) \) in the \( H^1 \) norm and \( O(h) \) in the \( L^2 \) norm) no matter how high degree of the polynomial is used, see [1, 7].

Immersed finite element (IFE) methods [19, 21, 9, 20, 13, 17, 11, 23] are designed to recover the optimal convergence rates of traditional finite element methods on unfitted meshes while keeping the degrees of freedom and the structure unchanged. The basic idea of IFEs is to modify traditional shape functions on interface elements to satisfy interface conditions approximately. However, these modifications are done on each interface elements independently, which may cause discontinuities of IFE basis functions across interface edges. Even for the \( P_1 \) conforming IFE method, these discontinuities are not negligible [13, 22] and the optimal convergence rates cannot be achieved if the discontinuities are not treated appropriately. To overcome the difficulty, Lin et al. [22] proposed a partially penalized IFE method where extra penalty terms at interface edges were added to penalize the discontinuity. For nonconforming IFE methods (i.e., a modification to the traditional Crouzeix-Raviart or the rotated-\( Q_1 \) finite element method), we can choose midpoint values or integral-values on edges as degrees of freedom. If we choose midpoint values on edges as degrees of freedom, the discontinuities of IFE basis functions are also not negligible and the optimal convergence rates can be obtained by adding partially penalized terms (see [25]). However, in the case that integral-values on edges are used as degrees of freedom, the IFE basis functions have less severe discontinuity across interface edges since they now maintain the integral-value continuous, and the authors [17, 23] claimed the optimal convergence rates can be obtained without requiring any penalty terms.

In this paper, we show that those nonconforming IFE methods using integral-value degrees of freedom cannot achieve the optimal convergence rates without penalty terms unless the tangential derivative of the exact solution \( u \) or the jump of the coefficient \( \beta \) is zero on the interface (see Theorem 4.5 and Remark 4.4). Furthermore, a nontrivial counter example (see Example 6.1) is constructed to support our theoretical analysis. The numerical examples in the literature [17, 23] show the optimal convergence rates for the nonconforming IFE methods using integral-value degrees of freedom because the constructed exact solutions are constants along the interface (i.e., the tangential
derivative is zero).

To achieve the optimal convergence rates, we develop a new nonconforming IFE method using either the Crouzeix-Raviart or the rotated-$Q_1$ element for solving interface problems with variable coefficients. The bilinear form of the new method includes some additional terms locally on interface edges to take into account of the contributions from the discontinuity of IFE basis functions. The method is symmetric and the coercivity is ensured without requiring a sufficient large parameter by using a special designed lifting operator defined locally on interface edges. To avoid integrating on curved regions, we approximate the interface by line segments connecting the intersection points of the mesh and the interface. We derive the optimal error estimates that are verified by numerical experiments.

There are other contributions of this paper. First, we prove that Crouzeix-Raviart IFE basis functions are unisolvent on arbitrary triangles. Our recent study in [10] shows that, for the IFEs using nodal values as degrees of freedom, the maximum angle condition, $\alpha_{\text{max}} \leq \pi/2$ on interface triangles, is necessary to ensure the unisolvence of the basis functions. The unisolvence of basis functions on arbitrary triangles is a significant advantage of the nonconforming IFEs using integral-value degrees of freedom over the IFEs using nodal values as degrees of freedom. Another contribution is a unified proof of the optimal interpolation error estimates for both the Crouzeix-Raviart and the rotated-$Q_1$ nonconforming IFE spaces for interface problems with piecewise smooth coefficients. Different from multipoint Taylor expansions [11], our proof is based on auxiliary functions constructed on interface elements and some useful inequalities developed by Li et al. in [18] and by Bramble and King in [2] for estimating errors in the region near the interface. The other contribution is a new theoretical result that the interpolation polynomial on one side of the interface can approximate the extensions of the exact solution optimally on the whole element $T$ no matter how small $T \cap \Omega^+$ or $T \cap \Omega^-$ might be (see Theorem 3.7 in Section 3.3). The result is useful for proving the optimal interpolation error estimates on interface edges (see (5.20) in the proof of Lemma 5.5).

The rest of the paper is organized as follows. In Section 2 we introduce some notations, assumptions, and basic lemmas that are needed for the analysis. In Section 3 we describe two nonconforming IFE spaces based on the Crouzeix-Raviart and the rotated-$Q_1$ elements with integral-value degrees of freedom and prove the unisolvence of IFE basis functions on arbitrary triangles. Furthermore, optimal approximation capabilities of these nonconforming IFE spaces are derived via a new approach. In Section 4, we show that the existing nonconforming IFE method using integral-value degrees of freedom only has suboptimal convergence rates. In Section 5 we develop a new nonconforming IFE method and derive optimal error estimates in $H^1$- and $L^2$-norms. Numerical examples are presented in Section 6 to validate our theoretical findings. We conclude in the last section.

2 Notations and preliminaries

Throughout the paper we adopt the standard notation $W^k_p(\Lambda)$ for Sobolev spaces on a domain $\Lambda$ with the norm $\| \cdot \|_{W^k_p(\Lambda)}$ and the seminorm $| \cdot |_{W^k_p(\Lambda)}$. Specially, $W^2_2(\Lambda)$ is denoted by $H^2(\Lambda)$ with the norm $\| \cdot \|_{H^2(\Lambda)}$ and the seminorm $| \cdot |_{H^2(\Lambda)}$. As usual $H^1_0(\Lambda) = \{ v \in H^1(\Lambda) : v = 0$ on $\partial \Lambda \}$. For a domain $\Lambda$, we define $\Lambda^* := \Lambda \cap \Omega^*$, $s = +, -, 0$ and a space

$$\bar{H}^2(\Lambda) := \{ v \in H^1(\Lambda) : v|_{\Lambda^*} \in H^2(\Lambda^*), s = +, -, [v]_{\Gamma \Lambda} = 0, [\beta \nabla v \cdot n]_{\Gamma \Lambda} = 0 \} \quad (2.1)$$

when $\Lambda^* \neq \emptyset$, $s = +, -$. The space $\bar{H}^2(\Lambda)$ is equipped with the norm $\| \cdot \|_{\bar{H}^2(\Lambda^+ \cup \Lambda^-)}$ and the semi-norm $| \cdot |_{\bar{H}^2(\Lambda^+ \cup \Lambda^-)}$ satisfying

$$\| \cdot \|^2_{\bar{H}^2(\Lambda^+ \cup \Lambda^-)} = \| \cdot \|^2_{\bar{H}^2(\Lambda^+)} + \| \cdot \|^2_{\bar{H}^2(\Lambda^-)}, \quad | \cdot |_{\bar{H}^2(\Lambda^+ \cup \Lambda^-)}^2 = | \cdot |_{\bar{H}^2(\Lambda^+)}^2 + | \cdot |_{\bar{H}^2(\Lambda^-)}^2.$$
By integrating by parts, we can immediately derive the following weak formulation of the interface problem (1.1)-(1.4): find $u \in H^1_0(\Omega)$ such that

$$a(u, v) := \int_\Omega \beta(x) \nabla u \cdot \nabla v dx = \int_\Omega fv dx \quad \forall v \in H^1_0(\Omega).$$

(2.2)

We have the following regularity theorem for the weak solution (see [15] for problems with piecewise smooth coefficients and [14, 6] for problems with piecewise constant coefficients)

**Theorem 2.1.** If $f \in L^2(\Omega)$, then the interface problem (1.1)-(1.4) has a unique solution $u \in \tilde{H}^2(\Omega)$ satisfying the following a priori estimate

$$\|u\|_{H^2(\Omega:\setminus\Omega^-)} \leq C\|f\|_{L^2(\Omega)},$$

where $C$ is a positive constant depending only on $\Omega$, $\Gamma$ and $\beta$.

Let $\{T_h\}_{h>0}$ be a family of triangular or rectangular subdivisions of $\Omega$ such that no vertex of any element lies in the interior of an edge of another element. The diameter of $T \in T_h$ is denoted by $h_T$. We define $h = \max_{T \in T_h} h_T$ and assume that $T_h$ is shape regular, i.e., for every $T$, there exists a positive constant $\rho$ such that $h_T \leq \rho r_T$ where $r_T$ is the diameter of the largest circle inscribed in $T$. Denote $E_h$ as the set of edges of the subdivision, and let $E^I_h$ and $E^b_h$ be the sets of interior edges and boundary edges. We adopt the convention that elements $T \in T_h$ and edges $e \in E_h$ are open sets. Then, the sets of interface elements and interface edges are defined as

$$T^\Gamma_h := \{T \in T_h : T \cap \Gamma \neq \emptyset\} \quad \text{and} \quad E^\Gamma_h := \{e \in E_h : e \cap \Gamma \neq \emptyset\},$$

and the sets of non-interface elements and non-interface edges are $T_h^{\text{non}} = T_h \setminus T^\Gamma_h$ and $E_h^{\text{non}} = E_h \setminus E^\Gamma_h$.

We can always refine the mesh near the interface to satisfy the following assumption.

**Assumption 2.2.** The interface $\Gamma$ does not intersect the boundary of any interface element at more than two points. The interface $\Gamma$ does not intersect the closure $\overline{\Omega}$ for any $e \in E_h$ at more than one point.

The interface $\Gamma$ is approximated by $\Gamma_h$ that is composed of all the line segments connecting the intersection points of the boundaries of interface elements and the interface. In addition, we assume that the approximated interface $\Gamma_h$ divides $\Omega$ into two disjoint sub-domains $\Omega^+_h$ and $\Omega^-_h$ such that $\Gamma_h = \partial \Omega^-_h$.

On each interface element $T \in T^\Gamma_h$, we denote the intersection points of $\Gamma$ and $\partial T$ by $D$ and $E$. The straight line $DE$ divides $T$ into $T^+_h = T \cap \Omega^+_h$ and $T^-_h = T \cap \Omega^-_h$, see Figure 2 for an illustration.

Let $n_h(x)$ be the unit normal vector of $\Gamma_h$ pointing toward $\Omega^+_h$. The tangent vector of $\Gamma_h$ can be defined as $t_h(x) = R_\alpha/2n_h(x)$, where $R_\alpha$ is a rotation matrix

$$R_\alpha = \begin{bmatrix} \cos \alpha & -\sin \alpha \\ \sin \alpha & \cos \alpha \end{bmatrix}.$$  

Denote $\text{dist}(x, \Gamma)$ as the distance between a point $x$ and the interface $\Gamma$, and $U(\Gamma, \delta) = \{x \in \mathbb{R}^2 : \text{dist}(x, \Gamma) < \delta\}$ as the neighborhood of $\Gamma$ of thickness $\delta$. Define the meshsize of $T^\Gamma_h$ by

$$h_\Gamma := \max_{T \in T^\Gamma_h} h_T.$$  

(2.4)

It is obvious that $h_\Gamma \leq h$ and $\bigcup_{T \in T^\Gamma_h} T \subset U(\Gamma, h_\Gamma)$. 

\[\]
We also define a signed distance function near the interface as

\[ \rho(x) = \begin{cases} \text{dist}(x, \Gamma) & \text{if } x \in \Omega^+ \cap U(\Gamma, \delta_0), \\ -\text{dist}(x, \Gamma) & \text{if } x \in \Omega^- \cap U(\Gamma, \delta_0). \end{cases} \]

**Assumption 2.3.** There exists a constant \( \delta_0 > 0 \) such that the signed distance function \( \rho(x) \) is well-defined in \( U(\Gamma, \delta_0) \) and \( \rho(x) \in C^2(U(\Gamma, \delta_0)) \). We also assume that \( h_\Gamma < \delta_0 \) so that \( T \subset U(\Gamma, \delta_0) \) for all interface elements \( T \in T_h^\Gamma \).

The assumption is reasonable since the interface \( \Gamma \) is in \( C^2 \). We extend the coefficients \( \beta^s(x) \), \( s = +, - \) smoothly to slight larger domains \( \Omega^e := \Omega^s \cup U(\Gamma, \delta_0) \), \( s = +, - \) such that

\[ \beta^s(x) \in C^1(\Omega^e) \quad \text{and} \quad \beta_{\min} \leq \beta^s(x) \leq \beta_{\max}, \quad s = +, - \tag{2.5} \]

Thus, there exists a constant \( C_\beta \) such that

\[ \| \nabla \beta^s \|_{L^\infty(\Omega^e)} \leq C_\beta, \quad s = +, - \tag{2.6} \]

By using the signed distance function \( \rho \), we can evaluate the unit normal and tangent vectors of the interface as

\[ \mathbf{n}(x) = \nabla \rho, \quad \mathbf{t}(x) = \left( -\frac{\partial \rho}{\partial x_2}, \frac{\partial \rho}{\partial x_1} \right)^T, \tag{2.7} \]

which are well-defined in the region \( U(\Gamma, \delta_0) \). We note that the functions \( \mathbf{n}_h(x) \) and \( \mathbf{t}_h(x) \) are also viewed as piecewise constant vectors defined on interface elements. On each interface element \( T \in T_h^\Gamma \), since \( \Gamma \) is in \( C^2 \), by Rolle’s Theorem, there exists at least one point \( x^* \in \Gamma \cap T \), see Figure 2, such that

\[ \mathbf{n}(x^*) = \mathbf{n}_h(x^*) \quad \text{and} \quad \mathbf{t}(x^*) = \mathbf{t}_h(x^*). \tag{2.8} \]

Since \( \rho(x) \in C^2(U(\Gamma, \delta_0)) \), we have

\[ \mathbf{n}(x) \in (C^1(\overline{T}))^2 \quad \text{and} \quad \mathbf{t}(x) \in (C^1(\overline{T}))^2 \quad \forall T \in T_h^\Gamma. \tag{2.9} \]

Using Taylor’s expansion at \( x^* \), we further have

\[ \| \mathbf{n} - \mathbf{n}_h \|_{L^\infty(T)} \leq Ch_T \quad \text{and} \quad \| \mathbf{t} - \mathbf{t}_h \|_{L^\infty(T)} \leq Ch_T \quad \forall T \in T_h^\Gamma. \tag{2.10} \]

The following lemma presents a \( \delta \)-strip argument that will be used for the error estimate in the region near the interface (see Lemma 2.1 in [13]).

**Lemma 2.4.** Let \( \delta \) be sufficiently small. Then it holds for any \( v \in H^1(\Omega) \) that

\[ \| v \|_{L^2(U(\Gamma, \delta))} \leq C\sqrt{\delta} \| v \|_{H^1(\Omega)}. \]

Furthermore, if \( v|_\Gamma = 0 \), then there holds

\[ \| v \|_{L^2(U(\Gamma, \delta))} \leq C\delta \| \nabla v \|_{L^2(U(\Gamma, \delta))}. \]

Recalling \( T^s = T \cap \Omega^s \), \( T_h^s = T \cap \Omega_h^s \), \( s = +, - \) for all \( T \in T_h^\Gamma \), we define

\[ T^\Delta := (T^- \cap T_h^+) \cup (T^+ \cap T_h^-). \tag{2.11} \]

Since \( \Gamma \) is in \( C^2 \), we have \( |T^\Delta| \leq Ch_T^3 \). We shall need the following estimate on the region \( T^\Delta \) (see Lemma 2 in [14]).

**Lemma 2.5.** Assume that \( v \in H^1(T) \) and \( T \in T_h^\Gamma \). Then there is a constant \( C \), independent of \( h \) and the interface location relative to the mesh, such that

\[ \| v \|_{L^2(T^\Delta)}^2 \leq C(h_T^2 \| v \|_{L^2(\Gamma \cap T)}^2 + h_T^4 \| \nabla v \|_{L^2(T^\Delta)}^2). \]
3 Nonconforming IFE spaces and their properties

In this section, we describe nonconforming IFE spaces based on the Crouzeix-Raviart element or the rotated-$Q_1$ element and present their properties. To begin with, we define IFE shape function spaces. On a non-interface element $T \in T_{h}^{\text{non}}$, we use the traditional shape function space

$$V_{h}(T) = \begin{cases} \text{Span}\{1, x_{1}, x_{2}\}, & \text{for the Crouzeix-Raviart element (} T \text{ is a triangle),} \\ \text{Span}\{1, x_{1}, x_{2}, x_{1}^{2} - (\kappa_{T} x_{2})^{2}\}, & \text{for the rotated-$Q_1$ element (} T \text{ is a rectangle),} \end{cases}$$

where $\kappa_{T} = |e_{1}|/|e_{2}|$, $e_{1}$ and $e_{2}$ are edges of the rectangle and parallel to the $x_{1}$-axis and the $x_{2}$-axis, respectively. On an interface element $T \in T_{h}^{\Gamma}$, the IFE shape function space $S_{h}(T)$ is defined as the set of the following functions

$$\phi(x) = \begin{cases} \phi^{+}(x) \in V_{h}(T) & \text{if } x = (x_{1}, x_{2})^{T} \in T_{h}^{+}, \\ \phi^{-}(x) \in V_{h}(T) & \text{if } x = (x_{1}, x_{2})^{T} \in T_{h}^{-}, \end{cases}$$

satisfying

$$[\phi]_{\Gamma_{h} \cap T}(x) = \phi^{+}(x) - \phi^{-}(x) = 0 \quad \forall x \in \Gamma_{h} \cap T,$$

$$\beta_{c}^{+}(\nabla \phi^{+} \cdot n_{h})(x_{p}) - \beta_{c}^{-}(\nabla \phi^{-} \cdot n_{h})(x_{p}) = 0,$$

where $x_{p}$ is an arbitrary point on $\Gamma_{h} \cap T$ and the constants $\beta_{c}^{+}$ and $\beta_{c}^{-}$ are chosen such that

$$\|\beta^{+}(x) - \beta_{c}^{-}\|_{L^{\infty}(T)} \leq C h_{T}, \quad s = +, -.$$

Actually, we can choose $\beta_{c}^{+} = \beta^{s}(x_{p}^{s})$ with arbitrary $x_{p}^{s} \in T$, $s = +, -$, to satisfy the condition since we know that $\beta^{s}(x) \in C^{1}(\overline{T})$, $s = +, -$ from \ref{eq:3.4}.

**Remark 3.1.** For the Crouzeix-Raviart element, the condition \ref{eq:3.2} is equivalent to

$$\phi^{+}(D) = \phi^{-}(D), \quad \phi^{+}(E) = \phi^{-}(E),$$

since $\phi^{s}(x), s = +, -$, are linear functions. For the rotated-$Q_1$ element, we can write $\phi^{s}(x)$ as

$$\phi^{s}(x) = a^{s} + b^{s} x_{1} + c^{s} x_{2} + d^{s}(x_{1}^{2} - (\kappa_{T} x_{2})^{2}); \quad x = (x_{1}, x_{2})^{T}, \quad s = +, -,$$

where $a^{s}, b^{s}, c^{s}, d^{s}, s = +, -$, are constants. If we define a functional $d : V_{h}(T) \to \mathbb{R}$ as

$$d(\phi^{s}) = \frac{1}{2} \frac{\partial^{2} \phi^{s}}{\partial x_{1}^{2}} = \frac{1}{\sqrt{(4\kappa_{T} + 4)|T|}}|\phi^{s}|_{H^{2}(T)},$$

then $d^{s} = d(\phi^{s})$. Similar to Lemma 2.1 in \cite{12}, the condition \ref{eq:3.3} is equivalent to

$$\phi^{+}(D) = \phi^{-}(D), \quad \phi^{+}(E) = \phi^{-}(E), \quad d(\phi^{+}) = d(\phi^{-}).$$

**Remark 3.2.** For the Crouzeix-Raviart element, $\beta_{c}^{+}(\nabla \phi^{s} \cdot n_{h}), s = +, -$, are constants on the interface element. Thus, the condition \ref{eq:3.3} is equivalent to

$$\beta_{c}^{+}(\nabla \phi^{+} \cdot n_{h})(x) = \beta_{c}^{-}(\nabla \phi^{-} \cdot n_{h})(x) \quad \forall x \in \Gamma_{h} \cap T.$$

However, for the rotated-$Q_1$ element, the relation \ref{eq:3.4} is no longer valid. In \cite{23}, the authors weakly enforce the continuity by using the following condition

$$\int_{\Gamma_{h} \cap T} \beta_{c}^{+}(\nabla \phi^{+} \cdot n_{h}) - \beta_{c}^{-}(\nabla \phi^{-} \cdot n_{h}) ds = 0$$

which is a particular case of \ref{eq:3.5} since there exists a point $x_{p} \in \Gamma_{h} \cap T$ such that

$$\int_{\Gamma_{h} \cap T} (\beta_{c}^{+} \nabla \phi^{+} - \beta_{c}^{-} \nabla \phi^{-}) \cdot n_{h} ds = |\Gamma_{h} \cap T| (\beta_{c}^{+} \nabla \phi^{+} - \beta_{c}^{-} \nabla \phi^{-})(x_{p}) \cdot n_{h}. $$
Let \( I = \{1, 2, 3\} \) for the Crouzeix-Raviart element and \( I = \{1, 2, 3, 4\} \) for the rotated-\( Q_1 \) element. The degrees of freedom are defined as the mean values over edges

\[
N_i(\phi) := \frac{1}{|e_i|} \int_{e_i} \phi ds, \quad i \in I,
\]

where \( e_i, i \in I \) are edges of the element \( T \), and \(|e_i|\) denotes the length of the edge \( e_i \). On an interface element \( T \in T^I_h \), the immersed finite element is defined as \((T, S_h(T), \Sigma_T)\) with \( \Sigma_T = \{N_i, i \in I\} \).

**The nonconforming IFE spaces.** The nonconforming IFE space \( V^{IFE}_h \) is defined as the set of all functions satisfying

\[
\begin{cases}
\phi|_T \in S_h(T) & \forall T \in T^I_h, \\
\phi|_T \in V_h(T) & \forall T \in T^{non}_h, \\
\int_e [\phi] ds = 0 & \forall e \in \mathcal{E}_h^b.
\end{cases}
\]

We also need a space for homogeneous boundary conditions

\[ V^{IFE}_{h,0} := \left\{ v \in V^{IFE}_h : \int_e v ds = 0 \; \forall e \in \mathcal{E}_h^b \right\}. \]

### 3.1 The unisolvence of IFE basis functions

It was proved in [11] that the function \( \phi \in S_h(T) \) is uniquely determined by \( N_i(\phi), i = 1, 2, 3, 4 \) for the rotated-\( Q_1 \) element, and \( i = 1, 2, 3 \) for the Crouzeix-Raviart element when the interface element is a right triangle. Now we prove that the result is also valid for arbitrary triangles in the following lemma. Note that for the IFEs using nodal values as degrees of freedom, the maximum angle condition, \( \alpha_{max} \leq \pi/2 \) on interface triangles, is necessary to ensure the unisolvence (see [16]). This property of the unisolvence of basis functions is one of advantages of nonconforming IFEs compared with the IFEs using nodal values as degrees of freedom.

![Figure 2: Typical interface elements. Left diagram: triangle element. Right diagram: rectangle element.](image)

**Lemma 3.3.** Let \( T \) be an arbitrary interface triangle. For the Crouzeix-Raviart element, the function \( \phi \in S_h(T) \) is uniquely determined by \( N_i(\phi), i = 1, 2, 3 \).

**Proof.** We use the argument proposed in [11] [10]. Consider a triangle \( \triangle A_1A_2A_3 \) with edges \( e_1 = A_2A_3 \), \( e_2 = A_1A_3 \) and \( e_3 = A_1A_2 \). The interface \( \Gamma \) cuts \( e_1 \) and \( e_2 \) at points \( D \) and \( E \), see Figure [2] for an illustration. Without loss of generality, we assume \( T^- = \triangle EDA_3 \) since the case \( T^+ = \triangle EDA_3 \) can be treated by reversing \( \beta^+ \) and \( \beta^- \). Let \( \lambda_i(x), i = 1, 2, 3 \), be basis functions in \( V_h(T) \) such that
\[ \frac{1}{|\gamma_j|} \int_{\gamma_j} \lambda_i(x)dx = \delta_{ij}, \ i, j = 1, 2, 3, \text{ where } \delta_{ij} \text{ is the Kronecker function. By using the condition (3.2) and } |e_2|^{-1} \int_{E} \phi ds = N_3(\phi), \text{ we can write the IFE shape function } \phi(x) \text{ in (3.1) as} \]

\[
\phi(x) = \begin{cases} 
\phi^+(x) = c_1\lambda_1(x) + c_2\lambda_2(x) + N_3(\phi)\lambda_3(x) & \text{if } x = (x_1, x_2)^T \in T_h^+, \\
\phi^-(x) = \phi^+(x) + c_0 n_h \cdot \vec{D}x & \text{if } x = (x_1, x_2)^T \in T_h^-, 
\end{cases}
\]

(3.7)

where \(c_0, c_1, c_2\) are unknowns. Applying the condition (3.3), the unknown \(c_0\) can be expressed as

\[
c_0 = (\beta_c^+ / \beta_c^- - 1) \nabla \phi^+ \cdot n_h = (\beta_c^+ / \beta_c^- - 1)(c_1 \nabla \lambda_1 + c_2 \nabla \lambda_2 + N_3(\phi) \nabla \lambda_3) \cdot n_h.
\]

(3.8)

Substituting (3.3) into (3.7) and using \(N_i(\phi) = |e_i|^{-1} \int_{E} \phi ds, i = 1, 2, \) we obtain the following linear system of equations for other coefficients (see [11][10] for details),

\[
(I + (\beta_c^+ / \beta_c^- - 1) \delta \gamma^T) c = b,
\]

(3.9)

where

\[
d = \left( |e_1|^{-1} \int_{A_1} L(x)ds, |e_2|^{-1} \int_{A_2} L(x)ds \right)^T, \quad L(x) = n_h \cdot \vec{D}x,
\]

\[
c = (c_1, c_2)^T, \quad \gamma = (\nabla \lambda_1 \cdot n_h, \nabla \lambda_2 \cdot n_h)^T,
\]

\[
b = \left( N_1(\phi) - \frac{(\beta_c^+ / \beta_c^- - 1) N_3(\phi) \nabla \lambda_3 \cdot n_h}{|e_1|} \int_{A_1} L(x)ds, \right.
\]

\[
N_2(\phi) - \frac{(\beta_c^+ / \beta_c^- - 1) N_3(\phi) \nabla \lambda_3 \cdot n_h}{|e_2|} \int_{A_2} L(x)ds \right)^T.
\]

(3.10)

Set \(k_1 = |A_3D||e_1|^{-1}\) and \(k_2 = |A_3E||e_2|^{-1}\). Let \(M_i\) be the midpoint of the edge \(e_i, i = 1, 2, 3,\) and \(Q\) be the orthogonal projection of \(M_2\) onto the line \(A_2A_3\). We can find out \(\gamma(1)\) and \(\delta(1)\) as below

\[
\gamma(1) = \nabla \lambda_1 \cdot n_h = |M_2Q|^{-1} \overrightarrow{M_2Q} \nabla \lambda_1 \cdot n_h = |M_2Q|^{-1} R_{\pi/2} \left( \overrightarrow{M_2Q} \nabla \lambda_1 \right) R_{\pi/2}(n_h)
\]

\[
= |M_2Q|^{-1} A_2A_3 |A_2A_3|^{-1} \cdot \nabla \lambda_1 \cdot n_h = \left( \frac{1}{2} |e_2| \sin \angle A_3 \right)^{-1} |e_1|^{-1} A_2A_3 \cdot \nabla \lambda_1 \cdot n_h,
\]

and

\[
\delta(1) = |e_1|^{-1} \int_{A_1} n_h \cdot \vec{D}xds = |e_1|^{-1} |A_3D| n_h \cdot \vec{D}H = - \frac{1}{2} k_1 |A_3A_3,1|,
\]

where \(\angle A_3 \in (0, \pi), H\) is the midpoint of the line segment \(A_3D\), and \(A_3,1\) is the orthogonal projection of \(A_3\) onto the line \(DE\). Thus,

\[
\gamma(1)\delta(1) = \nabla \lambda_1 \cdot n_h |e_1|^{-1} \int_{A_1} \vec{D}xds = - k_1 A_2A_3 \cdot \nabla \lambda_1 |A_3A_3,1| |e_1||e_2| \sin \angle A_3^{-1}
\]

\[
= - \overrightarrow{A_2A_3} \cdot \nabla \lambda_1 |A_3A_3,1| |e_1||e_2| \sin \angle A_3^{-1}.
\]

Analogously, we have

\[
\gamma(2)\delta(2) = \nabla \lambda_2 \cdot n_h |e_2|^{-1} \int_{A_2} \vec{D}xds = - \overrightarrow{A_3E} \cdot \nabla \lambda_2 |A_3A_3,1| |e_1||e_2| \sin \angle A_3^{-1}.
\]

Therefore,

\[
\gamma^T \delta = \overrightarrow{ED} \cdot \nabla \lambda_1 |e_1||e_2| \sin \angle A_3^{-1} = |DE||A_3A_3,1| |e_1||e_2| \sin \angle A_3^{-1}.
\]

As long as \(|\angle A_3ED| \in (0, \pi), it holds |A_3A_3,1| = k_2|e_2| \sin \angle A_3ED, which together with the relations \(|DE| \sin \angle A_3 = k_1|e_1| \sin \angle A_3ED\) yields

\[
\gamma^T \delta = k_1|e_1|(\sin \angle A_3ED)^{-1} k_2|e_2| (\sin \angle A_3ED) |e_1||e_2|^{-1} = k_1 k_2 \in [0, 1].
\]
From the above inequality, it holds
\[ 1 + (\beta^+ / \beta^- - 1)\gamma^T \delta \geq \min(1, \beta^+_c / \beta^-_c) \geq \beta_{\text{min}} / \beta_{\text{max}} > 0. \] (3.11)

Hence, by the well-known Sherman-Morrison formula, the linear system (3.9) has a unique solution
\[
c = b - \frac{(\beta^+ / \beta^- - 1)(\gamma^T b)\delta}{1 + (\beta^+_c / \beta^-_c - 1)\gamma^T \delta},
\] (3.12)
which implies the lemma. □

### 3.2 Estimates of IFE basis functions

On an interface element \( T \in T^I_h \), define IFE basis functions as
\[
\phi_i \in S_h(T), \quad N_j(\phi_i) = \delta_{ij} \forall i, j \in \mathcal{I}.
\] (3.13)

Also define functions \( \phi_i^s \in V_h(T) \), \( s = +, - \), \( i \in \mathcal{I} \) such that \( \phi_i^s = \phi_i|_{T^s_h} \). Let \( \lambda_i \) be traditional basis functions, i.e.,
\[
\lambda_i \in V_h(T), \quad N_j(\lambda_i) = \delta_{ij} \forall i, j \in \mathcal{I}.
\] (3.14)

Note that these functions depend on elements. We omit this dependence in our notation for simplicity. It is well-known that the traditional basis functions satisfy
\[
|\lambda_i|_{W^{m}(T)} \leq C h_T^{-m}, \quad i \in \mathcal{I}, \ m = 0, 1, 2,
\] (3.15)
where the constant \( C \) only depends on the shape regularity parameter \( \varrho \). The following lemma shows that the IFE basis functions also have similar estimates, which is one of essential ingredients for the success of IFE methods.

**Lemma 3.4.** There exists a constant \( C \), depending only on \( \beta^+_c, \beta^-_c \) and the shape regularity parameter \( \varrho \), such that
\[
|\phi_i^+|_{W^{m}(T)} \leq C h_T^{-m}, \quad |\phi_i^-|_{W^{m}(T)} \leq C h_T^{-m}, \quad i \in \mathcal{I}, \ m = 0, 1, 2,
\] (3.16)
\[
|\phi_i|_{W^{m}(T^+ \cup T^-)} \leq C h_T^{-m}, \quad i \in \mathcal{I}, \ m = 0, 1, 2.
\] (3.17)

**Proof.** See Theorem 4.2 in [11] for the estimate (3.17) for the rotated-\( Q_1 \) element and the Crouzeix-Raviart element on right triangles. The estimate (3.16) can also be obtained easily from the proof of Theorem 5.6 in [10]. Next, we give a proof for general triangles without the constraint \( \alpha_{\text{max}} = \pi / 2 \).

We just need to prove (3.16) since (3.17) is a direct consequence of (3.16). Using \( |N_j(\phi_i)| \leq 1 \), \( ||\nabla \lambda_i||_{L^\infty(T)} \leq C h_T^{-1} \), \( i, j \in \mathcal{I} \), we can estimate vectors in (3.10) as
\[
||b|| \leq C, \quad ||\gamma|| \leq C h_T^{-1}, \quad ||\delta|| \leq C h_T,
\]
which, together with (3.11) and (3.12) lead to \( ||e|| \leq C \), where the constant \( C \) is independent of \( h_T \) and the interface location relative to the mesh. Thus, from (3.7), it follows
\[
|\phi_i^+|_{W^{m}(T)} \leq C h_T^{-m}, \quad i \in \mathcal{I}, \ m = 0, 1,
\]
where we have used the fact \( |\lambda_i|_{W^{m}(T)} \leq C h_T^{-m} \). It follows from (3.8) that \( |c_0| \leq C h_T^{-1} \) which together with (3.7) yields
\[
|\phi_i^-|_{W^{m}(T)} \leq C h_T^{-m}, \quad i \in \mathcal{I}, \ m = 0, 1.
\] □
3.3 Optimal approximation capabilities of IFE spaces

On each element \( T \in \mathcal{T}_h \), define a local interpolation operator \( I_{h,T} : W(T) \to V_h(T) \) such that

\[
N_i(I_{h,T}v) = N_i(v), \quad i \in \mathcal{I},
\]

where \( W(T) = \{ v : N_i(v), i \in \mathcal{I} \text{ are well defined} \} \). Similarly, on each interface element \( T \in \mathcal{T}_h^\Gamma \), define \( I_{h,T}^{\Gamma} : W(T) \to S_h(T) \) such that

\[
N_i(I_{h,T}^{\Gamma}v) = N_i(v), \quad i \in \mathcal{I}.
\]  

(3.18)

The global IFE interpolation operator is defined by \( I_{h}^{\Gamma} : H^1(\Omega) \to V_h^{\Gamma} \) such that

\[
(I_{h}^{\Gamma}v)|_T = \begin{cases} 
I_{h,T}^{\Gamma}v & \text{if } T \in \mathcal{T}_h^\Gamma, \\
I_{h,T}v & \text{if } T \in \mathcal{T}_h^{\text{non}}.
\end{cases}
\]

For simplicity, define \( v^s := v|_{\Omega^s}, s = +, - \) for all \( v \in L^2(\Omega) \). With a small ambiguity of notation, given a function \( v_h \in S_h(T) \), we define \( v_h^s \in V_h(T), s = +, - \) such that

\[
v_h^s = v_h|_{T^s}, \quad s = +, -.
\]  

(3.19)

To show that functions in \( V_h^{\Gamma} \) can approximate a function \( v \) in \( \tilde{H}^2(\Omega) \) optimally, we need to interpolate extensions of \( v^s, s = +, - \). It is well-known that (see [8]) for any \( v \in \tilde{H}^2(\Omega) \) there exist extensions \( v_E^s \in H^2(\Omega), s = +, - \) such that

\[
v_E^s|_{\Omega^s} = v^s \quad \text{and} \quad |v_E^s|_{H^1(\Omega)} \leq C|v^s|_{H^1(\Omega^s)} , \quad i = 0, 1, 2, \quad s = +, -.
\]  

(3.20)

On each interface element \( T \in \mathcal{T}_h^\Gamma \), given two functions \( v^+ \in L^2(T) \) and \( v^- \in L^2(T) \), we define

\[
[v^+](x) := v^+(x) - v^-(x) \quad \forall x \in T.
\]

For example, for a function \( v \in \tilde{H}^2(\Omega), \)

\[
[v^+_E](x) = v^+_E(x) - v^-_E(x) \quad \forall x \in T,
\]

\[
[\beta^+ \nabla v^+_E \cdot n](x) = \beta^+(x) \nabla v^+_E(x) \cdot n(x) - \beta^-(x) \nabla v^-_E(x) \cdot n(x) \quad \forall x \in T,
\]

\[
[I_h v^+_E](x) = I_h v^+_E(x) - I_h v^-_E(x) \quad \forall x \in T,
\]

\[
[\beta^+ \nabla I_h v^+_E \cdot n_h](x) = \beta^+(x) \nabla(I_h v^+_E)(x) \cdot n_h(x) - \beta^-(x) \nabla(I_h v^-_E)(x) \cdot n_h(x) \quad \forall x \in T,
\]  

(3.21)

and for a function \( v_h \in V_h^{\Gamma} \),

\[
[v^+_h](x) = v^+_h(x) - v^-_h(x) \quad \forall x \in T,
\]

\[
[\beta^+_h \nabla v^+_h \cdot n_h](x) = \beta^+_h \nabla v^+_h(x) \cdot n_h(x) - \beta^-_h \nabla v^-_h(x) \cdot n_h(x) \quad \forall x \in T.
\]  

(3.22)

Note that the difference between \([\cdot](x)\) and \([\cdot]|_{\Gamma}(x)\) is the range of \( x \).

We introduce auxiliary functions on each interface element \( T \in \mathcal{T}_h^\Gamma \). Recalling that \( D \) and \( E \) are intersection points of \( \Gamma \) and \( \partial T \), define auxiliary functions \( \Upsilon_1(x), \Upsilon_2(x) \) and \( \Psi(x) \) as

\[
\Upsilon_i(x) := \begin{cases} 
\Upsilon_i^+(x) \in V_h(T) & \text{if } x = (x_1, x_2) \in T^+_h, \\
\Upsilon_i^-(x) \in V_h(T) & \text{if } x = (x_1, x_2) \in T^-_h,
\end{cases} \quad i = 1, 2,
\]

(3.23)

such that

\[
N_j(\Upsilon_i) = 0, \quad j \in \mathcal{I}, \quad [\Upsilon_i^+](D) = 0, \quad i = 1, 2,
\]

\[
[\beta^+_1 \Upsilon_1^+ \cdot n](x_p) = 1, \quad [\nabla \Upsilon_1^+ \cdot t](x_p) = 0, \quad [d(\Upsilon_1^+)] = 0,
\]

\[
[\beta^+_2 \nabla \Upsilon_2^+ \cdot n](x_p) = 0, \quad [\nabla \Upsilon_2^+ \cdot t](x_p) = 1, \quad [d(\Upsilon_2^+)] = 0,
\]  

(3.24)
and

\[ \Psi(x) := \begin{cases} 
\Psi^+(x) \in V_h(T) & \text{if } x = (x_1, x_2) \in T_h^+, \\
\Psi^-(x) \in V_h(T) & \text{if } x = (x_1, x_2) \in T_h^-, 
\end{cases} \]

(3.25)

such that

\[ N_j(\Psi) = 0, \ j = I, \quad [\Psi^\pm](D) = 1, \]

\[ [\beta_c^\pm \nabla \Psi^\pm \cdot n_h](x_p) = 0, \quad [\nabla \Psi^\pm \cdot t_h](x_p) = 0, \quad [d(\Psi^\pm)] = 0, \]

(3.26)

where \( d(\cdot) \) is defined in (3.3) and the point \( x_p \in \Gamma_h \cap T \) is the same as that in (3.3). For the rotated-\( Q_1 \) element, another auxiliary function is needed

\[ \Theta(x) := \begin{cases} 
\Theta^+(x) \in V_h(T) & \text{if } x = (x_1, x_2) \in T_h^+, \\
\Theta^-(x) \in V_h(T) & \text{if } x = (x_1, x_2) \in T_h^-, 
\end{cases} \]

(3.27)

such that

\[ N_j(\Theta) = 0, \ j = I, \quad [\Theta^\pm](D) = 0, \]

\[ [\beta_c^\pm \nabla \Theta^\pm \cdot n_h](x_p) = 0, \quad [\nabla \Theta^\pm \cdot t_h](x_p) = 0, \quad [d(\Theta^\pm)] = 1. \]

(3.28)

In order to have a unified analysis, we also define \( \Theta = 0 \) for the Crouzeix-Raviart element. Note that these auxiliary functions depend on the element \( T \). We omit the dependence for simplicity of notations.

**Lemma 3.5.** On each interface element \( T \in T_h^F \), these functions \( \Upsilon_1(x), \ Upsilon_2(x), \Psi(x) \) and \( \Theta \) defined in (3.25)-(3.28) exist and satisfy

\[ |\Upsilon_i|_{W^{2m}_s(T)} \leq Ch_T^{4-2m}, \quad m = 0, 1, 2, \ i = 1, 2, \ s = +, -, \]

\[ |\Psi|^2_{W^{2m}_s(T)} \leq Ch_T^{4-2m}, \quad |\Theta|^2_{W^{2m}_s(T)} \leq Ch_T^{6-2m}, \quad m = 0, 1, 2, \ s = +, -, \]

(3.29)

where the constant \( C \) depends only on \( \beta_c^+, \beta_c^- \) and the shape regularity parameter \( \varrho \).

**Proof.** We construct \( \Upsilon_i(x), \ i = 1, 2 \) as follows,

\[ \Upsilon_i = z_i - I_{h,T}^{1FE} z_i, \quad z_i = \begin{cases} 
2z_i^+ & \text{in } T_h^+, \\
0 & \text{in } T_h^-, 
\end{cases} \quad i = 1, 2, \]

(3.30)

where \( z_i^+ \) and \( z_i^- \) are linear and satisfy

\[ z_i^+(D) = 0, \quad \beta_c^+ \nabla z_i^+ \cdot n_h = 1, \quad \nabla z_i^+ \cdot t_h = 0, \]

\[ z_i^-(D) = 0, \quad \beta_c^- \nabla z_i^- \cdot n_h = 0, \quad \nabla z_i^- \cdot t_h = 1. \]

(3.31)

It is easy to verify that \( z_i^+ \) and \( z_i^- \) exist, and the constructed functions \( \Upsilon_i, \ i = 1, 2 \) satisfy (3.23) and (3.24). From (3.30), we have

\[ |z_i^+|_{L^\infty(T)} \leq Ch_T, \quad |\nabla z_i^+| \leq C, \quad |z_i^+|_{W^2_s(T)} = 0, \quad |z_i|_{L^\infty(T)} \leq Ch_T, \quad i = 1, 2. \]

(3.32)

Since \( I_{h,T}^{1FE} z_i = \sum_j N_j(z_i) \phi_j \), it follows from (3.16) that, for \( m = 0, 1, 2, \ i = 1, 2, \ s = +, - \),

\[ \left( I_{h,T}^{1FE} z_i \right)_{s} \leq \sum_{j \in I} |N_j(z_i)| |\phi_j|_{s} \leq C h_T^{-m} \sum_{j \in I} |N_j(z_i)|. \]

Noticing

\[ |N_j(z_i)| \leq |e_j|^{-1} \int_{e_j} |z_i| ds \leq |z_i|_{L^\infty(T)} \leq Ch_T, \]

11
we have
\[
\left| (I_{h,T}^{IE} z)^s \right|_{W^m(T)} \leq Ch_T^{1-m}, \quad m = 0, 1, 2, \ i = 1, 2, \ s = +, -,
\]
which together with (3.30) and (3.32) implies
\[
|\nabla_i|^2_{W^m(T)} \leq Ch_T^{1-m}, \quad m = 0, 1, 2, \ i = 1, 2, \ s = +, -.
\]
Finally, the first estimate in (3.29) is obtained by
\[
|\nabla_i|^2_{W^m(T)} \leq |\nabla_i|^2_{W^m(T)} |T| \leq Ch_T^{1-2m}, \quad m = 0, 1, 2, \ i = 1, 2, \ s = +, -.
\]
Other estimates in (3.29) can be proved similarly. We construct \( \Psi(x) \) as
\[
\Psi = z - I_{h,T}^{IE} z, \quad z = \begin{cases} 
z^+ = 1 & \text{in } T_h^+, \\
0 & \text{in } T_h^-.
\end{cases}
\]
It is easy to verify that the constructed function \( \Psi \) satisfies (3.25) and (3.26). Since
\[
|z^+|_{L^\infty(T)} = 1, \quad |z^+|_{W^m(T)} = 0, \quad |z|_{L^\infty(T)} = 1, \quad m = 1, 2,
\]
\[
|N_j(z)| \leq |e_j|^{-1} \int_{c_j} |z| ds \leq |z|_{L^\infty(T)} \leq 1, \quad j \in \mathcal{I},
\]
we get
\[
\left| (I_{h,T}^{IE} z)^s \right|_{W^m(T)} \leq \sum_{j \in \mathcal{I}} |N_j(z)||\phi_j^s|_{W^m(T)} \leq Ch_T^{-m} \sum_{j \in \mathcal{I}} |N_j(z)| \leq Ch_T^{-m}
\]
and
\[
|\Psi^s|_{W^m(T)} \leq Ch_T^{-m}, \quad s = +, -, \ m = 0, 1, 2,
\]
which implies
\[
|\Psi^s|^2_{W^m(T)} \leq |\Psi^s|^2_{W^m(T)} |T| \leq Ch_T^{2-2m}, \quad s = +, -, \ m = 0, 1, 2.
\]
For the rotated-\( Q_1 \) element, we construct \( \Theta(x) \) as
\[
\Theta = z - I_{h,T}^{IE} z, \quad z = \begin{cases} 
z^+ = (x_1 - m_1)^2 - \kappa_T^2(x_2 - m_2)^2 & \text{in } T_h^+,
0 & \text{in } T_h^-.
\end{cases}
\]
where \((m_1, m_2)\) is the center of the rectangle \( T \). Using (3.35), we easily verify that the constructed function \( \Theta \) satisfies (3.27) and (3.28). It follows that
\[
|z^+|_{L^\infty(T)} \leq Ch_T^2, \quad |z^+|_{L^\infty(T)} \leq Ch_T, \quad |z^+|_{W^m(T)} \leq C, \quad |z|_{L^\infty(T)} \leq Ch_T^2,
\]
\[
|N_j(z)| \leq |e_j|^{-1} \int_{c_j} |z| ds \leq |z|_{L^\infty(T)} \leq Ch_T^2, \quad j \in \mathcal{I},
\] (3.33)
which implies
\[
\left| (I_{h,T}^{IE} z)^s \right|_{W^m(T)} \leq \sum_{j \in \mathcal{I}} |N_j(z)||\phi_j^s|_{W^m(T)} \leq Ch_T^{-m} \sum_{j \in \mathcal{I}} |N_j(z)| \leq Ch_T^{2-m}
\]
and
\[
|\Theta^s|^2_{W^m(T)} \leq |\Theta^s|^2_{W^m(T)} |T| \leq |\Theta^s|^2_{W^m(T)} |T| \leq C \left( |(z)^s|^2_{W^m(T)} + \left| (I_{h,T}^{IE} z)^s \right|^2_{W^m(T)} \right) |T| \leq Ch_T^{6-2m}, \quad s = +, -, \ m = 0, 1, 2.
\] (3.34)
For the Crouzeix-Raviart element, the above inequality (3.34) is also valid since we have defined \( \Theta = 0 \) if \( T \) is a triangle.
Lemma 3.6. On each interface element \( T \in \mathcal{T}_h^i \), for any \( v \in \widetilde{H}^2(\Omega) \), the following identity holds

\[
(I_h v_E^\pm)(x) - (I_h^{IFE} v)^\pm(x) = a \Psi^\pm(x) + \sum_{i=1,2} b_i \Upsilon_i^\pm(x) + \sum_{i \in I} g_i \phi_i^\pm(x) + t \Theta^\pm(x) \quad \forall x \in T, \ s = +, -, \quad (3.35)
\]

with

\[
a = [I_h v_E^\pm](D), \ b_1 = [\beta_c^\pm \nabla (I_h v_E^\pm) \cdot \mathbf{n}_h](x_p), \ b_2 = [\nabla (I_h v_E^\pm) \cdot t_h](x_p),
\]

\[
g_i = |e_i|^{-1} \left( \int_{e_i^+} (I_h v_E^+ - v_E^+)^2 ds + \int_{e_i^-} (I_h v_E^- - v_E^-) ds \right), \ i \in I,
\]

\[
t = [d(I_h v_E^\pm)](D),
\]

where \( e_i^\pm = e_i \cap \Omega^\pm, \ s = +, -, \) and \( d(\cdot) \) is defined in (3.3). It is easy to see that \( g_i = 0 \) when \( e_i^+ = \emptyset \) or \( e_i^+ = e_i \).

Proof. For simplicity, define a function \( w_h \) such that

\[
w_h|_{\mathcal{T}_h^i} = w_h^s \quad \text{with} \quad w_h^s = I_h v_E^s - (I_h^{IFE} v)^s, \ s = +, -.
\]

(3.37)

It is obvious that \( w_h^s \in V_h(T), \ s = +, - \). Define another functions \( v_h \) by

\[
v_h := [w_h^s](D) \Psi(x) + [\beta_c^\pm \nabla w_h^\pm \cdot \mathbf{n}_h](x_p) \Upsilon_1(x)
\]

\[
+ [\nabla w_h^\pm \cdot t_h](x_p) \Upsilon_2(x) + \sum_{i \in I} N_i(w_h) \phi_i(x) + [d(w_h^\pm)] \Theta(x).
\]

(3.38)

Next, we prove \( w_h = v_h \). From (3.13), (3.14)-(3.3) and Remark 3.1, the IFE basis functions \( \phi_i, \ i \in I \) satisfy the following identities

\[
[\phi_i^\pm](D) = 0, \ \quad [\beta_c^\pm \nabla \phi_i^\pm \cdot \mathbf{n}_h](x_p) = 0, \ \quad [\nabla \phi_i^\pm](x_p) = 0,
\]

\[
[d(\phi_i^\pm)] = 0, \ N_i(\phi_i) = \delta_{i,j}, \ \ i, j \in I.
\]

(3.39)

Combining (3.33), (3.39) and (3.23)-(3.28), we find

\[
[\beta_c^\pm \nabla v_h^\pm \cdot \mathbf{n}_h](x_p) = [\beta_c^\pm \nabla w_h^\pm \cdot \mathbf{n}_h](x_p), \ N_i(v_h) = N_i(w_h), \ i \in I.
\]

(3.40)

and

\[
[v_h^\pm](D) = [w_h^\pm](D), \quad [\nabla v_h^\pm \cdot t_h](x_p) = [\nabla w_h^\pm \cdot t_h](x_p), \quad [d(v_h^\pm)] = [d(w_h^\pm)].
\]

(3.41)

It follows from (3.41) that \( v_h - w_h \) is continuous across \( \Gamma_h \cap T \), which together with (3.40) and (3.22)-(3.3), implies

\[
v_h - w_h \in S_h(T) \quad \text{and} \quad N_i(v_h - w_h) = 0, \ i \in I.
\]

Using the unisolvence of IFE shape functions (see Lemma 3.3), we know that the function \( v_h - w_h \) is unique and \( v_h - w_h = 0 \) through a simple verification. Thus, from (3.38), we have

\[
w_h = v_h = a \Psi(x) + b_1 \Upsilon_1(x) + b_2 \Upsilon_2(x) + \sum_{i \in I} g_i \phi_i(x) + t \Theta(x),
\]

(3.42)

where

\[
a = [w_h^\pm](D), \ b_1 = [\beta_c^\pm \nabla w_h^\pm \cdot \mathbf{n}_h](x_p), \ b_2 = [\nabla w_h^\pm \cdot t_h](x_p), \ g_i = N_i(w_h), \ t = [d(I_h v_E^\pm)].
\]

Using the following facts from (3.2)-(3.3)

\[
[I_h^{IFE} v]^\pm(D) = 0, \ [\beta_c^\pm \nabla (I_h^{IFE} v)^\pm \cdot \mathbf{n}_h](x_p) = 0, \ [\nabla (I_h^{IFE} v)^\pm \cdot t_h](x_p) = 0,
\]

13
we can further derive
\[ a = \|w_h^+\|_V(D) = \|I_h v_E^+ - (I_h^{IF} v)^+\|_V(D) = \|I_h v_E^+\|_V(D) - \|(I_h^{IF} v)^+\|_V(D) = \|I_h v_E^+\|_V(D), \]
\[ b_1 = [\beta_c^+ \nabla w_h^+ \cdot n_h](x_p) = [\beta_c^+ \nabla (I_h v_E^+ - (I_h^{IF} v)^+) \cdot n_h](x_p) = [\beta_c^+ \nabla (I_h v_E^+ \cdot n_h)(x_p), \]
\[ b_2 = \nabla (I_h v_E^+ \cdot n_h)(x_p) = \nabla (I_h v_E^+) \cdot t_h)(x_p) = \nabla (I_h v_E^+) \cdot t_h)(x_p). \]

It remains to consider \( g_i, i \in I \). Define
\[ I_{hB}^E v := \begin{cases} I_h v_E^+ & \text{in } T_h^+, \\ I_h v_E^- & \text{in } T_h^- \end{cases} \]
then we know from (3.37) that \( w_h = I_{hB}^E v - I_h^{IF} v \). Using the fact that \( N_i(v - I_h^{IF} v) = 0 \) on interface elements from (3.13), we obtain
\[ g_i = N_i(w_h) = N_i((I_{hB}^E v - I_h^{IF} v) = N_i(I_{hB}^E v - v + v - I_h^{IF} v) = N_i(I_{hB}^E v - v) = |e_i|^{-1} \left( \int_{e_i^+(I_{hB}^E v - v)ds + \int_{e_i^-} (I_{hB}^E v - v)ds \right). \]

**Theorem 3.7.** For any \( v \in \tilde{H}^2(\Omega) \), there exists a constant \( C \) independent of \( h \) and the interface location relative to the mesh such that
\[ \sum_{T \in T_h^k} |v_E^s - (I_h^{IF} v)^s|^2_{W^2(T)} \leq C h_T^{4-2m} \|v\|^2_{H^2(\Omega^+, \Omega^-, \Omega)} \quad m = 0, 1, 2, \quad s = +, - \]

where \( h_T \) is defined in (2.1).

**Proof.** On each interface element \( T \in T_h^k \), by the triangle inequality, we have
\[ |v_E^s - (I_h^{IF} v)^s|^2_{W^2(T)} \leq |v_E^s - I_h v_E^s|^2_{W^2(T)} + |I_h v_E^s - (I_h^{IF} v)^s|^2_{W^2(T)}, \quad s = +, - \]

The estimate of the first term is standard
\[ |v_E^s - I_h v_E^s|^2_{W^2(T)} \leq C h_T^{4-2m} \|v^s\|^2_{H^2(T)}, \quad m = 0, 1, 2, \quad s = +, -. \]

For the second term on the right-hand side of (3.43), from Lemma 3.6, Lemma 3.5 and (3.10), we have
\begin{align*}
&|I_h v_E^s - (I_h^{IF} v)^s|^2_{W^2(T)} \\
&\leq C \left( a^2 |\Psi|^2_{W^2(T)} + \sum_{i=1,2} b_i^2 |\Delta^i_{\Gamma} \cdot \nabla|^2_{W^2(T)} + \sum_{i \in I} g_i^2 |\phi_i|_{W^2(T)}^2 + t^2 |\Theta|^2_{W^2(T)} \right) \\
&\leq C h_T^{4-2m} \left( a^2 + \sum_{i \in I} g_i^2 \right) + C h_T^{4-2m} \sum_{i=1,2} b_i^2 + C h_T^{6-2m} t^2, \quad m = 0, 1, 2.
\end{align*}

Here the constants \( t, a, b_i, b_2 \) and \( g_i, i \in I \) are defined in (3.30). We now estimate these constants one by one. Firstly, (3.30) implies
\begin{align*}
t^2 &= \frac{|d(I_h v_E^s)|^2}{(4 k_T + 4)|T|} \leq \frac{1}{(4 k_T + 4)|T|} \|I_h v_E^s\|^2_{H^2(T)} \leq C h_T^{2} \sum_{s = +, -} |I_h v_E^s|^2_{H^2(T)} \\
&\leq C h_T^{4-2m} \sum_{s = +, -} \left( \|v_E^s\|^2_{H^2(T)} + \|v_E^s - I_h v_E^s\|^2_{H^2(T)} \right) \leq C h_T^{4-2m} \sum_{s = +, -} |v_E^s|^2_{H^2(T)}. \tag{3.46}
\end{align*}
Since \( v \in \widetilde{H}^2(\Omega) \), we have \( \|v_E^\pm\|^2(D) \), which leads to
\[
a^2 = [I_h v_E^\pm]^2(D) = [I_h v_E^\pm - v_E^\pm]^2(D) \leq \|I_h v_E^\pm - v_E^\pm\|^2_{L^\infty(T)}
\leq C \|I_h v_E^\pm - v_E^\pm\|^2_{L^\infty(T)} + C \|I_h v_E^- - v_E^-\|^2_{L^\infty(T)} \leq C h_T^2 \|v_E^\pm\|^2_{H^2(T)} + \|v_E^-\|^2_{H^2(T)},
\]
where the standard interpolation error estimate is used in the last inequality, see Theorem 4.4.20 in [4].

For the constant \( b_1 \), using the standard inverse inequality, we have
\[
b_1^2 = \|\beta_c^\pm \nabla(I_h v_E^\pm) \cdot n_h\|^2(x_p) \leq \|\beta_c^\pm \nabla(I_h v_E^\pm) \cdot n_h\|^2_{L^\infty(T)} \leq C h_T^2 \|\beta_c^\pm \nabla(I_h v_E^\pm) \cdot n_h\|^2_{L^2(T)}
\leq C h_T^2 \|\beta_c^\pm \nabla(I_h v_E^\pm) \cdot n_h\|^2_{L^2(T)} + C h_T^2 \|\beta_c^\pm \nabla(I_h v_E^\pm) \cdot n_h\|^2_{L^2(T)}.
\]

From (3.45), the second term can be estimate as
\[
h_T^{-2} \|\|\beta_c^\pm - \beta^*\| \nabla(I_h v_E^\pm) \cdot n_h\|^2_{L^2(T)} \leq C \sum_{s=1,\ldots} \|\nabla(I_h v_E^s) \cdot n_h\|^2_{L^2(T)} + \|\nabla v_E^s \cdot n_h\|^2_{L^2(T)} \leq \sum_{s=1,\ldots} |v_E^s|^2_{H^1(T)}.
\]

For the first term on the right-hand side of (3.48), using (2.10), we get
\[
h_T^{-2} \|\|\beta_c^\pm \nabla(I_h v_E^\pm) \cdot n_h\|^2_{L^2(T)} = h_T^{-2} \|\|\beta_c^\pm \nabla(I_h v_E^\pm) \cdot n_h\|^2_{L^2(T)} \leq C h_T^{-2} \|\|\beta_c^\pm \nabla(I_h v_E^\pm) \cdot n_h + \beta_c^\pm \nabla v_E^\pm \cdot (n_h - n + n)\|^2_{L^2(T)}
\leq C \sum_{s=1,\ldots} \|\nabla v_E^s\|^2_{H^1(T)} + \|v_E^s\|^2_{H^1(T)} \leq \sum_{s=1,\ldots} |v_E^s|^2_{H^1(T)}.
\]

Combining above three inequalities yields
\[
b_1^2 \leq C \sum_{s=1,\ldots} \|v_E^s\|^2_{H^2(T)} + \|v_E^s\|^2_{H^1(T)} + C h_T^{-2} \|\beta_c^\pm \nabla v_E^\pm \cdot n\|^2_{L^2(T)}.
\]

Analogously,
\[
b_2^2 = \|\nabla(I_h v_E^\pm) \cdot t_h\|^2(x_p) \leq \|\nabla(I_h v_E^\pm) \cdot t_h\|^2_{L^\infty(T)} \leq C h_T^{-2} \|\nabla(I_h v_E^\pm) \cdot t_h\|^2_{L^2(T)}
\leq C h_T^{-2} \|\|\beta_c^\pm \nabla(I_h v_E^\pm) \cdot t_h\|^2_{L^2(T)} + \|t_h \cdot t\|^2_{L^\infty(T)} \|\nabla v_E^\pm\|^2_{L^2(T)} + \|\nabla v_E^\pm \cdot t\|^2_{L^2(T)}
\leq C \sum_{s=1,\ldots} \|v_E^s\|^2_{H^1(T)} + \|v_E^s\|^2_{H^2(T)} + C h_T^{-2} \|\nabla v_E^\pm \cdot t\|^2_{L^2(T)}.
\]

Finally, the constants \( g_i, i \in \mathcal{I} \) in (3.50) can be estimated by the Cauchy-Schwarz inequality and the standard interpolation error estimate
\[
g_i^2 = |c_i|^{-2} \left| \int_{\gamma_i} (I_h v_E^\pm - v_E^\pm) ds + \int_{\gamma_i} (I_h v_E^- - v_E^-) ds \right|^2 \leq C \sum_{s=1,\ldots} \|I_h v_E^s - v_E^s\|^2_{L^2(\gamma_i)}
\leq C \sum_{s=1,\ldots} \|v_E^s\|^2_{H^2(T)} + \|v_E^s\|^2_{H^1(T)} \leq C h_T^{-2} \sum_{s=1,\ldots} \|v_E^s\|^2_{H^2(T)}.
\]

We now combine (3.43) \& (3.47), (3.49) \& (3.51) to obtain the error estimate on interface elements
\[
|v_E^\pm - (I_h^{FF} v)^\pm|^2_{W^0(T)} \leq C h_T^{-2m} \sum_{s=1,\ldots} \|v_E^s\|^2_{H^2(T)} + C h_T^{-2m} \left( \|\beta_c^\pm \nabla v_E^\pm \cdot n\|^2_{L^2(T)} + \|\nabla v_E^\pm \cdot t\|^2_{L^2(T)} \right).
\]
Summing up the estimate over all interface elements $T \in T^I_h$ and using Assumption (2.3), we get

$$
\sum_{T \in T^I_h} |v_E^I - (I^I_h v^I)^*|^2_{W^0_2(T)} \leq C h^{4-2m} \|v_E^I\|_{H^2(\Omega)}^2 + C h^{2-2m} \left( \left( \|\beta^\pm \nabla v_E^I \cdot n\|_{L^2_2(U(\Gamma, h_T))} \right)^2 + \|\nabla v_E^I \cdot t\|_{L^2_2(U(\Gamma, h_T))} \right)^2, \quad s = +, -, \quad m = 0, 1, 2,
$$

(3.52)

Since $v \in \widetilde{H}^2(\Omega)$, we know from the definition (2.1) that $\|\beta^\pm \nabla v_E^I \cdot n\|_{H^2(\Gamma, h_T)} = 0$ and $\|v_E^I\|_{H^2(\Gamma, h_T)} = 0$ for all $x \in \Gamma$, which also implies $\|\nabla v_E^I \cdot t\|_{H^2(\Gamma, h_T)} = 0$. Thus, by Lemma (2.4) and (2.5) - (2.6),

$$
\|\beta^\pm \nabla v_E^I \cdot n\|^2_{L^2(U(\Gamma, h_T))} \leq C h^{2} \|\beta^\pm \nabla v_E^I \cdot n\|^2_{H^1(U(\Gamma, h_T))} \leq C h^{2} \sum_{s=+,-} \|v^I_E\|^2_{H^2(\Omega)},
$$

$$
\|\nabla v_E^I \cdot t\|^2_{L^2(U(\Gamma, h_T))} \leq C h^{2} \|\nabla v_E^I \cdot t\|^2_{H^1(U(\Gamma, h_T))} \leq C h^{2} \sum_{s=+,-} \|v^I_E\|^2_{H^2(\Omega)}.
$$

Substituting the above inequalities into (3.52) and using the extension result (3.20) we complete the proof.

Now we prove the optimal approximation capabilities of the nonconforming IFE spaces $V^I_h$, where the errors resulting from the mismatch of $\Gamma$ and $\Gamma_h$ are taken into account.

**Theorem 3.8.** For any $v \in \widetilde{H}^2(\Omega)$, there exists a constant $C$ independent of $h$ and the interface location relative to the mesh such that

$$
\sum_{T \in T^I_h} |v - I^I_h v|^2_{W^0_2(T)} \leq C h^{4-2m} \|v\|^2_{H^2(\Omega)} + C h^{2-2m} |v|^2_{H^2(\Omega)}, \quad m = 0, 1.
$$

(3.53)

**Proof.** On each non-interface element $T \in T^{non}_h$, the following estimate is standard

$$
|v - I^I_h v|^2_{W^0_2(T)} = |v - I^I_h v|^2_{W^0_2(T)} \leq C h^{4-2m} |v|^2_{H^2(\Omega)}, \quad m = 0, 1.
$$

(3.54)

On each interface element $T \in T^I_h$, in view of the relations $T = T^+ \cup T^-$ and $T^s = (T^+ \cap T^+_h) \cup (T^+ \cap T^-_h), \quad s = +, -$, we have

$$
|v - I^I_h v|^2_{W^0_2(T)} = \sum_{s=+,-} |v^s - (I^I_h v)^s|^2_{W^0_2(T \cap T^s_h)} + |v^+ - (I^I_h v)^+|^2_{W^0_2(T^+ \cap T^-_h)} + |v^- - (I^I_h v)^-|^2_{W^0_2(T^- \cap T^+_h)}.
$$

(3.55)

By the triangle inequality,

$$
|v^s - (I^I_h v)^s|^2_{W^0_2(T \cap T^s_h)} \leq 2|v^s - v^s_E|^2_{W^0_2(T \cap T^s_h)} + 2|v^s_E - (I^I_h v)^s|^2_{W^0_2(T \cap T^s_h)},
$$

$$
|v^+ - (I^I_h v)^+|^2_{W^0_2(T^+ \cap T^-_h)} \leq 2|v^+ - v^+_E|^2_{W^0_2(T^+ \cap T^-_h)} + 2|v^+_E - (I^I_h v)^+|^2_{W^0_2(T^+ \cap T^-_h)},
$$

$$
|v^- - (I^I_h v)^-|^2_{W^0_2(T^- \cap T^+_h)} \leq 2|v^- - v^-_E|^2_{W^0_2(T^- \cap T^+_h)} + 2|v^-_E - (I^I_h v)^-|^2_{W^0_2(T^- \cap T^+_h)}.
$$

(3.56)

Substituting (3.56) into (3.53) and using the definition (2.11), we get

$$
|v - I^I_h v|^2_{W^0_2(T)} \leq C \sum_{s=+,-} |v^s - (I^I_h v)^s|^2_{W^0_2(T \cap T^s_h)} + C |v^+_E - v^+_E|^2_{W^0_2(T^+ \cap T^-_h)}, \quad m = 0, 1.
$$

(3.57)

It follows from Lemma (2.4) and the fact $\|v^+_E\|^2_{L^2(\Gamma, T \cap T^+)} = 0$ on $\Gamma \cap T$ that

$$
\|v^+_E - v^+_E\|^2_{L^2(\Gamma, T \cap T^+)} \leq C h^{-2} \|v^+_E\|^2_{H^2(\Gamma, T \cap T^+)} \leq C h^{-2} \sum_{s=+,-} |v^s_E|^2_{H^2(T)},
$$

$$
\|\nabla (v^+_E - v^+_E)\|^2_{L^2(\Gamma, T \cap T^+)} \leq C \left( h^{2} \|\nabla v^+_E\|^2_{L^2(\Gamma, T \cap T^+)} + h^{2} \|v^+_E\|^2_{H^2(T \cap T^+)} \right)
$$

$$
\leq C h^{2} \sum_{s=+,-} \|\nabla v^s_E\|^2_{L^2(\Gamma, T \cap T^+)} + C h^{2} \sum_{s=+,-} |v^s_E|^2_{H^2(T)},
$$

16
which implies
\[
|v_{E}^+ - v_{E}^-|_{W_{2}^{m}(\mathcal{T},\triangle)}^2 \leq C h_{I}^{-2m} \sum_{s=+,-} \left( |v_{s}^E|^2_{H^1(T)} + \|\nabla v_{s}^E\|_{L^2(T \cap T')}^2 \right), \quad m = 0, 1. \tag{3.58}
\]

Combining (3.54), (3.57) and (3.58), we arrive at
\[
\sum_{T \in \mathcal{T}_h} |v - I_{h}^{IFE} v|_{W_{2}^{m}(\mathcal{T},\triangle)}^2 \leq C h_{I}^{-2m} \sum_{T \in \mathcal{T}_h} |v|^2_{H^2(T)} + C \sum_{T \in \mathcal{T}_h} \sum_{s=+,-} |v_s - (I_{h}^{IFE} v)_s|^2_{W_{2}^{m}(\mathcal{T},\triangle)}
\]
\[+ C h_{I}^{-2m} \sum_{T \in \mathcal{T}_h} \sum_{s=+,-} |v_s|^2_{H^2(T)} + C h_{I}^{-2m} \|\nabla v_{E}\|_{L^2(\mathcal{T})}^2 \quad m = 0, 1,
\]
which together with Theorem 3.7, the extension result (3.20) and the following global trace inequality
\[
\sum_{s=+,-} \|\nabla v_{E}\|_{L^2(\mathcal{T})}^2 \leq C (\|v_{E}\|_{H^2(\Omega^+) + \|v_{E}\|_{H^2(\Omega^-)}}) \tag{3.59}
\]
yields the theorem.

\[\square\]

4 Error estimates of the existing nonconforming IFE method

In this section, we show that the existing nonconforming IFE method [17, 23] cannot achieve the optimal convergence rates unless \([\beta]_{1} \nabla u \cdot t = 0\) on \(\Gamma\). The existing nonconforming IFE method is to find \(u_{h} \in V_{h,0}^{IFE}\) such that
\[
a_{h}(u_{h}, v_{h}) := \sum_{T \in \mathcal{T}_h} \int_{T} \beta(x) \nabla u_{h} \cdot \nabla v_{h} \, dx = \int_{\Omega} f v_{h} \, dx \quad \forall v_{h} \in V_{h,0}^{IFE}. \tag{4.1}
\]

It is easy to see that \(a_{h}(\cdot, \cdot) = a(\cdot, \cdot)\) on \(H_{0}^{1}(\Omega)\) and it is positive-definite on \(V_{h,0}^{IFE}\) because \(a_{h}(v_{h}, v_{h}) = 0, v_{h} \in V_{h,0}^{IFE}\) implies \(v_{h} = 0\). Thus, the discrete problem (4.1) has a unique solution. We define the energy norm
\[
\|v\|_{a_{h}} := \sqrt{a_{h}(v, v)} \quad \forall v \in V_{h,0}^{IFE} + H_{0}^{1}(\Omega)
\]
and quote the following well-known second Strang lemma (see Lemma 10.1.9 in [4]).

**Lemma 4.1.** Let \(u\) and \(u_{h}\) be the solutions of the problems (2.2) and (4.1), respectively. Then
\[
\|u - u_{h}\|_{a_{h}} \leq C \left\{ \inf_{v_{h} \in V_{h,0}^{IFE}} \|u - v_{h}\|_{a_{h}} + \sup_{w_{h} \in V_{h,0}^{IFE} \setminus \{0\}} \frac{|a_{h}(u - u_{h}, w_{h})|}{\|w_{h}\|_{a_{h}}} \right\}. \tag{4.2}
\]

Since \(u \in \tilde{H}^{2}(\Omega)\), Theorem 3.8 implies
\[
\inf_{v_{h} \in V_{h,0}^{IFE}} \|u - v_{h}\|_{a_{h}} \leq \|u - I_{h}^{IFE} u\|_{a_{h}} \leq C h \|u\|_{H^{2}(\Omega^+ \cup \Omega^-)}. \tag{4.3}
\]

For the second term on the right-hand side of (4.1), we have
\[
a_{h}(u - u_{h}, w_{h}) = \sum_{T \in \mathcal{T}_h} \int_{T} \beta \nabla u \cdot \nabla w_{h} \, dx - \int_{\Omega} f w_{h} \, dx = \sum_{e \in \mathcal{E}_h} \int_{e} \beta \nabla u \cdot n_{e} [w_{h}]_{e} \, ds,
\]
where the jump \([w_{h}]_{e} n_{e}\) across an edge \(e\) is defined as follows. Let \(e\) be an interior edge shared by two elements \(T_{1}^{e}\) and \(T_{2}^{e}\), and \(n_{e}\) the unit normal of \(e\) pointing towards the outside of \(T_{1}^{e}\). Define
\[
[w_{h}]_{e} n_{e} := (w_{h}|_{T_{1}^{e}} - w_{h}|_{T_{2}^{e}}) n_{e} \quad \text{on } e.
\]
If $e$ is an edge on the boundary of $\Omega$, then define $[w_h]_e \cdot n_e = w_h n_e$, where $n_e$ is the unit normal of $e$ pointing towards the outside of $\Omega$. Given an edge $e$ and an element $T$, define the standard $L^2$ projection operators $P_0^e$ and $P_0^{T,e}$ as

$$P_0^e f = |e|^{-1} \int_e f \, ds, \quad P_0^{T,e} f = |T|^{-1} \int_T f \, dx.$$  

It follows from the fact $\int_e [w_h]_e \, ds = 0$ that

$$|a_h(u - u_h, w_h)| = \left| \sum_{e \in \mathcal{E}_h} \int_e \beta \nabla u \cdot n_e [w_h]_e \, ds \right| = \left| \sum_{e \in \mathcal{E}_h} \int_e (\beta \nabla u \cdot n_e - P_0^e (\beta \nabla u \cdot n_e)) [w_h]_e \, ds \right| \leq \left( \sum_{e \in \mathcal{E}_h} \|\beta \nabla u \cdot n_e - P_0^e (\beta \nabla u \cdot n_e)\|_{L^2(e)}^2 \right)^{1/2} \left( \sum_{e \in \mathcal{E}_h} \|[w_h]_e\|^2_{L^2(e)} \right)^{1/2}. \quad (4.4)$$

**Lemma 4.2.** There exists a constant $C$ independent of $h$ and the interface location relative to the mesh such that

$$\|[w_h]_e\|^2_{L^2(e)} \leq C|e| \left( |w_h|_{H^1(T_1^e)}^2 + |w_h|_{H^1(T_2^e)}^2 \right) \quad \forall e \in \mathcal{E}_h \quad \forall w_h \in V_h^{I,F}.$$  

**Proof.** Using the fact that $P_0^e (w_h|_{T_1^e}) = P_0^e (w_h|_{T_2^e})$, we have

$$\|[w_h]_e\|^2_{L^2(e)} = \int_e (w_h|_{T_1^e} - P_0^e (w_h|_{T_1^e}) - w_h|_{T_2^e} + P_0^e (w_h|_{T_2^e}))^2 \, ds \leq 2 \sum_{i=1,2} \int_e (w_h|_{T_i^e} - P_0^e (w_h|_{T_i^e}))^2 \, ds.$$  

By the property of $L^2$ projection

$$\|f - P_0^e (f)\|_{L^2(e)} \leq \|f - c_e\|_{L^2(e)} \quad \forall c_e \in \mathbb{R}$$

and the standard trace inequality, we get

$$\|[w_h]_e\|^2_{L^2(e)} \leq 2 \sum_{i=1,2} \int_e (w_h|_{T_i^e} - P_0^e (w_h|_{T_i^e}))^2 \, ds \leq 2 \sum_{i=1,2} \int_e \left( w_h|_{T_i^e} - P_0^{T_i^e} (w_h|_{T_i^e}) \right)^2 \, ds \leq C \sum_{i=1,2} \left( h_{T_i^e}^{-1} \quad w_h|_{T_i^e} - P_0^{T_i^e} (w_h|_{T_i^e}) \right)^2 + h_{T_i^e} \left| w_h|_{T_i^e} - P_0^{T_i^e} (w_h|_{T_i^e}) \right|^2_{H^1(T_i^e)} \leq C \left( h_{T_1^e} |w_h|_{H^1(T_1^e)}^2 + h_{T_2^e} |w_h|_{H^1(T_2^e)}^2 \right),$$

where the fact that $w_h|_{T} \in H^1(T)$ is used in the last inequality even though $T \in T_h^e$. \hfill \Box

If $e$ is an edge on the boundary of $\Omega$, we also have similar estimates. Thus,

$$\sum_{e \in \mathcal{E}_h} \|[w_h]_e\|^2_{L^2(e)} \leq Ch_h |w_h|_{\mathcal{O}_h}^2. \quad (4.5)$$

The next step is to estimate $\|\beta \nabla u \cdot n_e - P_0^e (\beta \nabla u \cdot n_e)\|_{L^2(e)}$ in (4.4). Let $T$ be an element such that $e \subset \partial T$. If $e \in \mathcal{E}_h^{om}$ and $T \in T_h^{om}$, using the property of the $L^2$ projection operator $P_0^e$ and the standard trace inequality, we have

$$\|\beta \nabla u \cdot n_e - P_0^e (\beta \nabla u \cdot n_e)\|_{L^2(e)} \leq \|\beta \nabla u \cdot n_e - P_0^e (\beta \nabla u \cdot n_e)\|_{L^2(e)} \leq Ch_{T}^{-1/2} \|\beta \nabla u \cdot n_e - P_0^e (\beta \nabla u \cdot n_e)\|_{L^2(T)} + Ch_{T}^{1/2} |\beta \nabla u \cdot n_e|_{H^1(T)} \leq Ch_{T}^{1/2} |u|_{H^2(T)}.$$
If \( e \in \mathcal{E}^\text{int}_h \) and \( T \in \mathcal{T}^\text{int}_h \), the term can be estimated by using the fact that \( e \in \Omega^s \), \( s = + \) or \(-\), and the extension (3.20),

\[
\| \beta \nabla u \cdot n_e - P^T_0(\beta \nabla u \cdot n_e) \|_{L^2(e)} \leq C h_T^{1/2} \| \beta \nabla u \cdot n_e \|_{L^2(T)} + C h_T^{1/2} |\beta \nabla u \cdot n_e|_{H^1(T)} \tag{4.7}
\]

Hence, it follows from (4.6) - (4.7) and the extension result (3.20) that

\[
\sum_{e \in \mathcal{E}^\text{ext}_h} \| \beta \nabla u \cdot n_e - P^T_0(\beta \nabla u \cdot n_e) \|_{L^2(e)}^2 \leq C h \sum_{i=+, -} |u|_{H^2}^2 \leq C h |u|^2_{H^2(\Omega^+ \cup \Omega^-)}. \tag{4.8}
\]

For interface edges \( e \in \mathcal{E}^\text{int}_h \), we cannot conclude the optimal estimate since \( (\beta \nabla u \cdot n_e)_e \) may have a jump across \( e \cap \Gamma \). Noticing that \( |u|_T = 0 \) implies \( |\nabla u \cdot t|_l = 0 \), the jump can be derived as

\[
[\beta \nabla u \cdot n_e]_l = [\beta \nabla u \cdot n]_l n \cdot n_e + [\beta \nabla u \cdot t]_l t \cdot n_e = [\beta]_l (\nabla u \cdot t)(t \cdot n_e),
\]

where we have used

\[
[\beta \nabla u \cdot n]_l = 0 \quad \text{and} \quad [\beta \nabla u \cdot t]_l = \frac{1}{2} (\beta^+ + \beta^-)[\nabla u \cdot t]_l + [\beta]_l \nabla u \cdot t = [\beta]_l \nabla u \cdot t.
\]

The following lemma gives an estimate on interface edges.

**Lemma 4.3.** Let \( u \) be the solution of the problem (2.2). Assume the triangulation near the interface is quasi-uniform, i.e., \( h_T^{-1} \leq C h_l^{-1} \) for all \( T \in \mathcal{T}^\text{int}_h \). Then it holds that

\[
\sum_{e \in \mathcal{E}^\text{int}_h} \| \beta \nabla u \cdot n_e - P^T_0(\beta \nabla u \cdot n_e) \|_{L^2(e)}^2 \leq C h T \sum_{T \in \mathcal{T}^\text{int}_h} |u|_{H^2(T^+ \cup T^-)}^2 + C |\| \beta \nabla u \cdot t \|_{H^1/2}^2. \tag{4.10}
\]

**Proof.** Define a function \( z|_{\Omega^s} = z^s \), \( s = +, - \), such that

\[
- \Delta z^s + z^s = 0 \quad \text{in} \quad \Omega^s, \quad s = +, -
\]

\[
z^s = [\beta]_l \nabla u \cdot t \quad \text{on} \quad \Gamma, \quad \frac{\partial z^s}{\partial \nu} = 0 \quad \text{on} \quad \partial \Omega, \quad s = +, -
\]

where \( \nu \) is the outward unit normal vector to \( \partial \Omega \). Since \( [\beta]_l \nabla u \cdot t \in H^{1/2}(\Gamma) \), the function \( z \) exists and satisfies

\[
z|_l = [\beta]_l \nabla u \cdot t \quad \text{and} \quad \| z \|_{H^1/2}^2 \leq \| [\beta]_l \nabla u \cdot t \|_{H^1/2}^2. \tag{4.11}
\]

For an edge \( e \in \mathcal{E}^\text{int}_h \), let \( w = \beta \nabla u \cdot n_e \) and \( T \) be an element that has \( e \) as one of its edges. Define

\[
\tilde{w}(x) = z(x) t(x) \cdot n_e \quad \forall x \in T \quad \text{and} \quad \tilde{w}(x) = \begin{cases}
\tilde{w} & \text{if } x \in T^+, \\
0 & \text{if } x \in T^-.
\end{cases}
\]

From (4.9) and (4.11), we have \( [w - \tilde{w}]|_{\Gamma \cap T} = 0 \). Thus, \( w - \tilde{w} \in H^1(T) \). By the property of the \( L^2 \) projection operator \( P^T_0 \) and the standard trace inequality, we derive

\[
\| w - P^T_0(w) \|_{L^2(T)}^2 \leq \| w - P^T_0(w - \tilde{w}) \|_{L^2(T)}^2 + \| w - \tilde{w} - P^T_0(w - \tilde{w}) \|_{L^2(T)}^2 \\
\leq 2 \| w - \tilde{w} - P^T_0(w - \tilde{w}) \|_{L^2(T)}^2 + 2 \| \tilde{w} \|_{L^2(T)}^2 \\
\leq C (h_T^{-1} || w - \tilde{w} - P^T_0(w - \tilde{w}) ||_{L^2(T)}^2 + h_T |w - \tilde{w}|_{H^1(T)}^2) + 2 \| z \|_{L^2(T)}^2 \\
\leq C (h_T |w - \tilde{w}|_{H^1(T)}^2 + h_T^{-1} || z ||_{L^2(T)}^2 + h_T |z|_{H^1(T)}^2) \\
\leq C (h_T |w|^2_{H^1(T)} + h_T^{-1} || z ||_{L^2(T)}^2 + h_T |z|_{H^1(T)}^2).
\]
Summing over all interface edges and using Lemma 2.4, we get
\[ \sum_{e \in E_h^i} \| \beta \nabla u \cdot n_e - P_0^e (\beta \nabla u \cdot n_e) \|_{L^2(e)}^2 \leq \sum_{T \in T_h^i} C(h_T |u|_{H^2(T^+ \cup T^-)}^2 + h_T^{-1} |u|_{L^2(T)}^2 + h_T |z|_{H^1(T)}^2) \]
\[ \leq C h_T \sum_{T \in T_h^i} |u|_{H^2(T^+ \cup T^-)}^2 + C h_T^{-1} |u|_{L^2(T)}^2 + C h_T |z|_{H^1(T)}^2 \]
\[ \leq C h_T \sum_{T \in T_h^i} |u|_{H^2(T^+ \cup T^-)}^2 + C |z|_{H^1(\Omega)}^2, \]
which together with (4.11) yields this lemma.

\[ \sum_{e \in E_h^i} \| \beta \nabla u \cdot n_e - P_0^e (\beta \nabla u \cdot n_e) \|_{L^2(e)}^2 = \sum_{T \in T_h^i} C(h_T |u|_{H^2(T^+ \cup T^-)}^2 + h_T^{-1} |u|_{L^2(T)}^2 + h_T |z|_{H^1(T)}^2) \]

\[ \leq C h_T \sum_{T \in T_h^i} |u|_{H^2(T^+ \cup T^-)}^2 + C h_T^{-1} |u|_{L^2(T)}^2 + C h_T |z|_{H^1(T)}^2 \]

\[ \leq C h_T \sum_{T \in T_h^i} |u|_{H^2(T^+ \cup T^-)}^2 + C |z|_{H^1(\Omega)}^2, \]

which together with (4.11) yields this lemma.

**Remark 4.4.** The estimate (4.11) is sharp, i.e., we cannot find a better upper bound for the approximation error than \( O(1) \) when \( |\beta|_T \nabla u \cdot t \neq 0 \) on \( \Gamma \). We explain it by a concrete example as illustrated in Figure 3. The domain \( \Omega \) contains a region \( \Lambda \) such that \( \Lambda = (0, 1)^2 \), \( \Lambda^+ = \{ x = (x_1, x_2) \in \Lambda : x_1 > x_2 \} \), \( \Lambda^- = \{ x = (x_1, x_2) \in \Lambda : x_1 < x_2 \} \). The interface contained in the region is \( \Gamma \cap \Lambda = \{ x = (x_1, x_2) \in \Lambda : x_1 = x_2 \} \). We use uniform triangulations constructed by connecting the midpoints of edges (see Figure 3) and only consider these interface edges which are contained in the region \( \Lambda \). Obviously, \( n_e = t = (\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}})^T \) and \( n = (\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}})^T \). Let \( \beta^+ = 2, \beta^- = 1 \) and the exact solution \( u(x_1, x_2) \) be a piecewise linear function on \( \Lambda^+, \Lambda^- \) such that
\[ \beta^+ \nabla u^+ \cdot n = \beta^- \nabla u^- \cdot n = 1 \quad \text{and} \quad u|_{\Gamma \cap \Lambda} = \frac{1}{\sqrt{2}} (x_1 + x_2). \]

Thus, \( \nabla u \cdot t = 1 \) and \( (\beta \nabla u \cdot n_e)|_e = 2, (\beta \nabla u \cdot n_e)|_e = 1 \) for all \( e \subset \Lambda \) and \( e \subset \epsilon^i \). Therefore,
\[ \| \beta \nabla u \cdot n_e - P_0^e (\beta \nabla u \cdot n_e) \|_{L^2(e)}^2 = \inf_{c_e \in \mathbb{R}} \| \beta \nabla u \cdot n_e - c_e \|_{L^2(e)}^2 \]
\[ = \inf_{c_e \in \mathbb{R}} \left( \frac{|e|}{2} (2 - c_e)^2 + \frac{|e|}{2} (1 - c_e)^2 \right) \geq \frac{|e|}{4} \geq Ch. \]

Using the fact that the number of interface edges contained in \( \Lambda \) is \( O(h^{-1}) \), we observe that
\[ \sum_{e \in E_h^i} \| \beta \nabla u \cdot n_e - P_0^e (\beta \nabla u \cdot n_e) \|_{L^2(e)}^2 \geq \sum_{e \in E_h^i, e \subset \Lambda} Ch \geq C. \]

With the above discussions, we have the following error estimate for the existing nonconforming IFE method.

**Theorem 4.5.** Let \( u \) and \( u_h \) be the solutions of the problems (2.2) and (4.1), respectively. Under the assumption of Lemma 4.3, the following discretization error estimate holds
\[ \| u - u_h \|_{H^1} \leq Ch \| u \|_{H^2(\Omega)} + Ch^{1/2} \| |\beta|_\Gamma \nabla u \cdot t \|_{H^{1/2}(\Gamma)}. \]
Proof. It follows from (4.8) and (4.10) that
\[
\sum_{e \in \mathcal{E}_h} \| \beta \nabla u \cdot n_e - P_0^h(\beta \nabla u \cdot n_e) \|_{L^2(e)}^2 \leq C h \| u \|_{H^2(\Omega + \bigcup \Omega^-)}^2 + C \| [\beta]_T \nabla u \cdot t \|_{H^{1/2}(\Gamma)}^2,
\] (4.13)
which together with (4.4) and (4.5) yields
\[
|a_h(u - u_h, w_h)| \leq Ch^{1/2} \| w_h \|_{\mathcal{A}_h} \left( h^{1/2} \| u \|_{H^2(\Omega + \bigcup \Omega^-)} + \| [\beta]_T \nabla u \cdot t \|_{H^{1/2}(\Gamma)} \right).
\] (4.14)
Combining (4.12), (4.2) and (4.14), we complete the proof. \(\square\)

Remark 4.6. The estimate (4.12) in Theorem 4.3 suggests that the solution of the nonconforming IFE method (4.4) only converges with a suboptimal convergence rate \(O(h^{1/2})\) in the energy norm if \([\beta]_T \nabla u \cdot t \neq 0\) on \(\Gamma\). Applying global trace inequalities on \(\Omega^+\) and \(\Omega^-\) to the second term on the right-hand side of (4.12), we get
\[
\| u - u_h \|_{\mathcal{A}_h} \leq Ch^{1/2} \| u \|_{H^2(\Omega + \bigcup \Omega^-)}.
\] Using the standard duality argument (see [4], p. 284), we can also derive the following suboptimal \(L^2\) error estimate
\[
\| u - u_h \|_{L^2(\Omega)} \leq Ch \| u \|_{H^2(\Omega + \bigcup \Omega^-)}.
\] (5.1)

5 A new nonconforming IFE method and error estimates

To recover the optimal convergence rates, we propose a new nonconforming IFE method. On each interface element \(T \in \mathcal{T}_h^T\), define
\[
W_h(T) := \{ w_h \in (L^2(T))^2 : w_h = \nabla v_h \quad \forall v_h \in \mathcal{S}_h(T) \}.
\] (5.1)
We also define a space associated with an edge \(e \in \mathcal{E}_h^T\) as
\[
W_e := \{ w_h \in (L^2(\Omega))^2 : w_h|_{T^i} \in W_h(T^i), w_h|_{T^2} \in W_h(T^2), w_h|_{\Omega \setminus (T^1 \cup T^2)} = 0 \}.
\] (5.2)
For simplicity of the implementation, the coefficient \(\beta(x)\) is approximated by
\[
\beta_h(x) = \begin{cases} 
\beta^+(x) & \text{if } x \in \Omega^+_h, \\
\beta^-(x) & \text{if } x \in \Omega^-_h.
\end{cases}
\]
Define a local lifting operator \(r_e : L^2(e) \rightarrow W_e\) such that
\[
\int_{\Omega} \beta_h(x) r_e(\varphi) \cdot w_h \, dx = \int_e \{ \beta_h w_h \cdot n_e \} \varphi \, ds \quad \forall w_h \in W_e,
\] (5.3)
where \(\{ v \}_e = \frac{1}{2}(v|_{T^1} + v|_{T^2})\). Obviously, the support of \(r_e(\varphi)\) is \(T^1 \cup T^2\).

The new nonconforming IFE method is to find \(u_h \in V_{h,0}^{IFE}\) such that
\[
A_h(u_h, v_h) := \widetilde{a}_h(u_h, v_h) + b_h(u_h, v_h) + s_h(u_h, v_h) = \int_\Omega f v_h \, dx \quad \forall v_h \in V_{h,0}^{IFE},
\] (5.4)
where
\[
\widetilde{a}_h(u_h, v_h) = \sum_{T \in \mathcal{T}_h} \int_T \beta_h(x) \nabla u_h \cdot \nabla v_h \, dx,
\]
\[
b_h(u_h, v_h) = - \sum_{e \in \mathcal{E}_h^T} \int_e \left( \{ \beta_h \nabla u_h \cdot n_e \} v_h \right)_e + \{ \beta_h \nabla v_h \cdot n_e \} u_h \, ds,
\] (5.5)
\[
s_h(u_h, v_h) = 4 \sum_{e \in \mathcal{E}_h^T} \int_{T^1 \cup T^2} \beta_h(x) r_e(\{ u_h \}) \cdot r_e(\{ v_h \}) \, dx.
\]
Note that the new nonconforming IFE method is symmetric and does not require a manually chosen stabilization parameter. Now we analyze the new method. For all \( v \in H^1_0(\Omega) \cap \bar{H}^2(\Omega) + V^{IFE}_{h,0} \), define the following mesh-dependent norms

\[
\|v\|_{\tilde{a}_h} := \sqrt{\tilde{a}_h(v, v)}
\]

and

\[
\|v\|_h := \left( \|v\|_{\tilde{a}_h}^2 + \sum_{e \in E_h^I} |e| \|\{\beta_h \nabla v\}_e\|_{L^2(e)}^2 + \sum_{e \in E_h^I} |e|^{-1} \|v\|_{L^2(e)}^2 + s_h(v, v) \right)^{1/2}.
\] (5.6)

The continuity of the bilinear form \( A(\cdot, \cdot) \) is verified directly from the Cauchy-Schwarz inequality

\[
|A_h(w, v)| \leq \|w\|_h \|v\|_h \quad \forall w, v \in H^1_0(\Omega) \cap \bar{H}^2(\Omega) + V^{IFE}_{h,0}.
\] (5.7)

The following lemma demonstrates the coercivity of the bilinear form \( A(\cdot, \cdot) \) on the IFE space \( V^{IFE}_{h,0} \) with respect to the norm \( \|\cdot\|_{\tilde{a}_h} \).

**Lemma 5.1.** It holds that

\[
A_h(v_h, v_h) \geq \frac{1}{2} \|v_h\|_{\tilde{a}_h}^2 \quad \forall v_h \in V^{IFE}_{h,0}.
\] (5.8)

**Proof.** For all \( v_h \in V^{IFE}_{h,0} \), choosing \( w_h|_{T^I \cup T^2} = \nabla v_h, \ w_h|_{\Omega \setminus (T^I \cup T^2)} = 0 \) in (5.3) and using the fact that the support of \( r_e(\varphi) \) is \( T^I \cup T^2 \), we have

\[
\int_{T^I \cup T^2} \beta_h(x) r_e(\varphi) \cdot \nabla v_h dx = \int_{\Omega} \beta_h(x) r_e(\varphi) \cdot \nabla v_h dx = \int_{e} \{\beta_h \nabla v_h \cdot \mathbf{n}_e\}_e \varphi ds.
\]

It follows from the Cauchy-Schwarz inequality that

\[
|b_h(v_h, v_h)| = 2 \sum_{e \in E_h^I} \int_{e} \{\beta_h \nabla v_h \cdot \mathbf{n}_e\}_e [v_h]_e ds
\]

\[
\leq \left( \sum_{e \in E_h^I} \int_{\Omega} \beta_h r_e([v_h]_e) \cdot r_e([v_h]_e) ds \right)^{1/2} \left( \sum_{e \in E_h^I} \int_{T^I \cup T^2} \beta_h \nabla v_h \cdot \nabla v_h dx \right)^{1/2}
\] (5.9)

Since each interface element has at most two interface edges from Assumption 2.2, each element is calculated at most twice. Therefore,

\[
\sum_{e \in E_h^I} \int_{T^I \cup T^2} \beta_h \nabla v_h \cdot \nabla v_h dx \leq 2 \sum_{T \in T_h} \int_{T} \beta_h(x) \nabla v_h \cdot \nabla v_h dx.
\] (5.10)

Combining (5.5), (5.9) and (5.10), we have

\[
|b_h(v_h, v_h)| \leq (s_h(v_h, v_h))^{1/2} \left( \sum_{T \in T_h} \int_{T} \beta_h(x) \nabla v_h \cdot \nabla v_h dx \right)^{1/2}
\]

\[
\leq s_h(v_h, v_h) + \frac{1}{2} \sum_{T \in T_h} \int_{T} \beta_h(x) \nabla v_h \cdot \nabla v_h dx,
\]

which together with (5.3) yields the result

\[
A(v_h, v_h) = \tilde{a}_h(v_h, v_h) + b_h(v_h, v_h) + s_h(v_h, v_h) \geq \frac{1}{2} \sum_{T \in T_h} \int_{T} \beta_h(x) \nabla v_h \cdot \nabla v_h dx = \frac{1}{2} \|v_h\|_{\tilde{a}_h}^2.
\]

\[\blacksquare\]
Next, we show the equivalence of the two norms \( \| \cdot \|_{\tilde{a}} \) and \( \| \cdot \|_{h} \) on the IFE space \( \mathcal{V}_{h,0}^{IFE} \). To begin with, we need the following trace inequality for the IFE shape functions in \( S_h(T) \) which can be verified via straightforward calculations. We also refer readers to [23] Theorem 2.7.1.

**Lemma 5.2.** There exists a constant \( C \) independent of \( h \) and the interface location relative to the mesh such that
\[
\| \nabla v_h \|_{L^2(\partial T)} \leq C h^{-1/2} \| \nabla v_h \|_{L^2(T)} \quad \forall v_h \in S_h(T) \quad \forall T \in T^h_0.
\] (5.11)

We also need the following stability estimate for the local lifting operator \( r_e \).

**Lemma 5.3.** There exists a constant \( C \) independent of \( h \) and the interface location relative to the mesh such that
\[
\| r_e(\varphi) \|_{L^2(\Omega)} \leq C \| \varphi \|_{L^2(e)} \quad \forall \varphi \in L^2(e) \quad \forall e \in E^*_h.
\] (5.12)

**Proof.** Since the support of \( r_e(\varphi) \) is \( T^+_1 \cup T^-_2 \), choosing \( w_h = r_e(\varphi) \) in (5.3) yields
\[
\| r_e(\varphi) \|_{L^2(\Omega)} \leq C \| \beta^1_{r_e}(T^-_1 \cup T^-_2) \| \nabla \varphi \|_{L^2(e)} = C \int_{\Omega} \{ \beta_{r_e}(\varphi) \cdot n_e \} \varphi ds
\]
\[
\leq C \| \{ \beta_{r_e}(\varphi) \}_e \|_{L^2(e)} \| \varphi \|_{L^2(e)} \leq C \| \varphi \|_{L^2(e)} \sum_{i=1,2} \| r_e(\varphi) \|_{T^+_i} \| \varphi \|_{L^2(e)}.
\] (5.12)

Note \( r_e(\varphi)|_{T^+_1} \in W_h(T^+_1) \), we know from (5.11) that there exists a function \( v_h \in S_h(T^+_1) \) such that \( r_e(\varphi)|_{T^+_1} = \nabla v_h \). By the trace inequality (5.11) for the IFE shape functions, we have
\[
\| r_e(\varphi)|_{T^+_1} \|_{L^2(e)} = \| \nabla v_h \|_{L^2(e)} \leq C h^{-1/2} \| \nabla v_h \|_{L^2(T^+_1)} = C h^{-1/2} \| r_e(\varphi) \|_{L^2(T^+_1)},
\]
which, together with (5.12) and a similar estimate on \( T^-_2 \), completes the proof of this lemma. \( \square \)

We now prove the norm-equivalence in the following lemma.

**Lemma 5.4.** There exists a constant \( C \) independent of \( h \) and the interface location relative to the mesh such that
\[
\| v_h \|_{\tilde{a}} \leq \| v_h \|_{h} \leq C \| v_h \|_{\tilde{a}} \quad \forall v_h \in \mathcal{V}_{h,0}^{IFE}.
\] (5.13)

**Proof.** We just need to prove the second inequality since the first inequality is obvious. By the trace inequality (5.11) for the IFE shape functions, it holds
\[
\sum_{e \in E^*_h} \| \beta_{r_e}(v_h) \|_{L^2(e)} \leq C \sum_{e \in E^*_h} \sum_{i=1,2} \| \nabla v_h \|_{L^2(T^+_i)} \leq C \| v_h \|_{\tilde{a}}^2.
\] (5.14)

From Lemma 4.2, we have
\[
\sum_{e \in E^*_h} \| \beta_{r_e}(v_h) \|_{L^2(e)} \leq C \sum_{e \in E^*_h} \sum_{i=1,2} \| \nabla v_h \|_{L^2(T^+_i)} \leq C \| v_h \|_{\tilde{a}}^2,
\] (5.15)

which, together with Lemma 5.3 for the local lifting operator, leads to
\[
\| r_e(\varphi) \|_{L^2(\Omega)} \leq C \sum_{e \in E^*_h} \| \varphi \|_{L^2(e)} \leq C \sum_{e \in E^*_h} \| e \|_{L^2(\Omega)} \| \varphi \|_{L^2(e)} \leq C \| v_h \|_{\tilde{a}}^2.
\] (5.16)

Combining (5.10), (5.14) - (5.16), we get the second inequality in (5.13). \( \square \)

The following lemma provides an optimal estimate for the interpolation error in terms of the norm \( \| \cdot \|_{h} \).
Lemma 5.5. Suppose \( v \in \tilde{H}^2(\Omega) \), then there exists a constant \( C \) independent of \( h \) and the interface location relative to the mesh such that
\[
\|v - I_h^{IFE}v\|_h \leq Ch\|v\|_{H^2(\Omega^+ \cup \Omega^-)}.
\]

Proof. The first term in the norm \( \| \cdot \| \) can be bounded by Theorem 3.8
\[
\|v - I_h^{IFE}v\|_{\mathcal{A}_h} \leq Ch\|v\|_{H^2(\Omega^+ \cup \Omega^-)}. \tag{5.17}
\]
Since \((v - I_h^{IFE}v)|_T \in H^1(T)\) for all \( T \in \mathcal{T}_h \), by the standard trace inequality and Theorem 3.8 we have
\[
\sum_{e \in \mathcal{E}_h} |e|^{-1}\|v - I_h^{IFE}v\|_{L^2(e)}^2 \leq C \sum_{e \in \mathcal{E}_h} \sum_{i=1,2} \left( h_{e,T}^{-2}\|v - I_h^{IFE}v\|_{L^2(T)}^2 + \|v - I_h^{IFE}v\|_{H^1(T)}^2 \right)
\leq C \sum_{T \in \mathcal{T}_h} \left( h_{T}^{-2}\|v - I_h^{IFE}v\|_{L^2(T)}^2 + \|v - I_h^{IFE}v\|_{H^1(T)}^2 \right) \leq Ch^2\|v\|_{H^2(\Omega^+ \cup \Omega^-)}^2, \tag{5.18}
\]
which, together with Lemma 5.3 implies
\[
s_h(v - I_h^{IFE}v, v - I_h^{IFE}v) \leq C \sum_{e \in \mathcal{E}_h} \max_{i=1,2} \|v - I_h^{IFE}v\|_{L^2(e)}^2 \leq Ch^2\|v\|_{H^2(\Omega^+ \cup \Omega^-)}^2. \tag{5.19}
\]

Let \( e^s = e \cap \Omega^s, s = +, - \). Recalling the notations in (3.19)-(3.20), it holds
\[
\|\{ \beta_h \nabla(v - I_h^{IFE}v)\}e\|_{L^2(e)} = \|\{ \beta_h \nabla(v - I_h^{IFE}v)\}e\|_{L^2(e)}^2 \leq C\|\{ \nabla(v^E - (I_h^{IFE}v)^E)\}e\|_{L^2(e)}^2 + C\|\{ \nabla(v^E - (I_h^{IFE}v)^E)\}e\|_{L^2(e)}^2
\]
Then using the standard trace inequality and Theorem 3.7 we can derive
\[
\sum_{e \in \mathcal{E}_h} \max_{i=1,2} \|\{ \beta_h \nabla(v - I_h^{IFE}v)\}e\|_{L^2(e)}^2 \leq Ch^2\|v\|_{H^2(\Omega^+ \cup \Omega^-)}. \tag{5.20}
\]
The lemma follows from (5.6), (5.17)-(5.20). \( \square \)

The following lemma concerns the errors caused by replacing \( \beta(x) \) by \( \beta_h(x) \).

Lemma 5.6. Let \( v \in \tilde{H}^2(\Omega) \) and \( w \in V_h^{IFE} + H^1(\Omega) \). Then there exists a constant \( C \) independent of \( h \) and the interface location relative to the mesh such that
\[
|a_h(v, w) - \bar{a}_h(v, w)| \leq Ch\|v\|_{H^2(\Omega^+ \cup \Omega^-)} \left( \sum_{T \in \mathcal{T}_h} \|\nabla w\|_{L^2(T)}^2 \right)^{1/2}. \tag{5.21}
\]

Furthermore, if \( w \in H^2(\Omega) \), then holds
\[
|a_h(v, w) - \bar{a}_h(v, w)| \leq Ch^2\|v\|_{H^2(\Omega^+ \cup \Omega^-)}\|w\|_{H^2(\Omega^+ \cup \Omega^-)}. \tag{5.22}
\]

Proof. The Cauchy-Schwarz inequality gives
\[
|a_h(v, w) - \bar{a}_h(v, w)| = \left| \sum_{T \in \mathcal{T}_h} \int_{T^\triangle} (\beta - \beta_h)\nabla v \cdot \nabla w \ dx \right| 
\leq C \left( \sum_{T \in \mathcal{T}_h} \|\nabla v\|_{L^2(T^\triangle)}^2 \right)^{1/2} \left( \sum_{T \in \mathcal{T}_h} \|\nabla w\|_{L^2(T^\triangle)}^2 \right)^{1/2}. \tag{5.23}
\]
Using Lemma 2.5 and the global trace inequalities on $\Omega^+$ and $\Omega^-$, we derive

$$\sum_{T \in T_h^I} \| \nabla v \|^2_{L^2(T^\Delta)} = \sum_{T \in T_h^I \subset \partial \Omega} \| \nabla v^* \|^2_{L^2(T^\Delta \cap T^\Delta)} \leq \sum_{T \in T_h^I \subset \partial \Omega} \| \nabla v^* \|^2_{L^2(T^\Delta)}$$

$$\leq C \sum_{T \in T_h^I \subset \partial \Omega} \left( h_T^2 \| \nabla v^* \|^2_{L^2(T \supset T^\Delta)} + h_T^2 \| v_e^* \|^2_{H^2(T^\Delta)} \right)$$

$$\leq Ch_T^2 \sum_{s=+,-} \| v^* \|^2_{H^2(\Gamma)} + Ch_T^4 \sum_{s=+,-} |v_e^*|^2_{H^2(\Omega)}$$

$$\leq Ch_T^2 \sum_{s=+,-} \| v \|^2_{H^2(\Omega)} = Ch_T^2 \| v \|^2_{H^2(\Omega^+ \cup \Omega^-)}.$$ (5.24)

The estimate (5.21) follows from (5.23) and (5.24). If $w \in H^2(\Omega)$, then similar to (5.24),

$$\sum_{T \in T_h^I} \| \nabla w \|^2_{L^2(T^\Delta)} \leq Ch_T^2 \| w \|^2_{H^2(\Omega^+ \cup \Omega^-)}.$$ (5.25)

The estimate (5.22) then follows from (5.21) and (5.25).

With these preparations, we are ready to derive the $H^1$ error estimate for the new nonconforming IFE method.

**Theorem 5.7.** Let $u$ and $u_h$ be the solutions of the problems (2.2) and (7.4), respectively. Then there exists a constant $C$ independent of $h$ and the interface location relative to the mesh such that

$$\| u - u_h \|_h \leq C h \| u \|_{H^2(\Omega^+ \cup \Omega^-)}.$$ (5.26)

**Proof.** From Lemma 5.1 and Lemma 5.4 we know that the bilinear form $A_h(\cdot, \cdot)$ is also coercive on $V_h^{IFE}$ with respect to the norm $\| \cdot \|_h$. Thus, the second Strang lemma implies

$$\| u - u_h \|_h \leq C \left\{ \inf_{v_h \in V_h^{IFE}} \| u - v_h \|_h + \sup_{w_h \in V_h^{IFE} \setminus \{0\}} \frac{|A_h(u - w_h, w_h)|}{\| w_h \|_h} \right\}.$$ (5.27)

The first term of the right-hand side of (5.27) can be bounded by Lemma 5.5

$$\inf_{v_h \in V_h^{IFE}} \| u - v_h \|_h \leq \| u - I_h^{IFE} u \|_h \leq C h \| u \|_{H^2(\Omega^+ \cup \Omega^-)}.$$ (5.28)

Multiplying (1.1) by $w_h \in V_{h,0}^{IFE}$ and integrating by parts, we obtain

$$\int_{\Omega} f w_h dx = a_h(u, w_h) + s_h(u, w_h) - \sum_{e \in \mathcal{E}^I} \int_{e} \{\beta \nabla u \cdot n_e\} [w_h]_e + \{\beta \nabla w_h \cdot n_e\} [u]_e ds$$

$$= A_h(u, w_h) - \sum_{e \in \mathcal{E}^I} \int_{e} \{\beta \nabla u \cdot n_e\} [w_h]_e ds + \tilde{a}_h(u, w_h).$$ (5.29)

where $\beta_h(x) = \beta(x)$ on edges, $[u]_e = 0$, $[\beta \nabla u \cdot n_e]_e = 0$ and $r_e([u]_e) = 0$ are used. It follows from (5.29) and (5.4) that

$$A_h(u - u_h, w_h) = \sum_{e \in \mathcal{E}^{I,0}} \int_{e} \{\beta \nabla u \cdot n_e\} [w_h]_e ds + \tilde{a}_h(u, w_h) - a_h(u, w_h).$$ (5.30)

Hence, by (4.4), (4.5), (4.8), and Lemma 5.6, we have

$$|A_h(u - u_h, w_h)| \leq C h \| u \|_{H^2(\Omega^+ \cup \Omega^-)} \| w_h \|,$$

which, together with (5.27) and (5.28), completes the proof of the theorem. \qed
The optimal $L^2$ error estimate is also derived by using the standard duality argument below.

**Theorem 5.8.** Let $u$ and $u_h$ be the solutions of the problems (2.2) and (5.4), respectively. Then there exists a constant $C$ independent of $h$ and the interface location relative to the mesh such that

$$
\|u - u_h\|_{L^2(\Omega)} \leq C h^2 \|u\|_{H^2(\Omega^{++} \cup \Omega^{-})}.
$$

(5.31)

**Proof.** Let $z \in H_0^1(\Omega)$ be the solution of the following auxiliary problem

$$
a(v, z) = \int_\Omega (u - u_h)v \, dx \quad \forall v \in H_0^1(\Omega).
$$

(5.32)

Since $u - u_h \in L^2(\Omega)$, it follows from Theorem 2.1 that

$$
z \in H^2(\Omega) \quad \text{and} \quad \|z\|_{H^2(\Omega^{++} \cup \Omega^{-})} \leq C \|u - u_h\|_{L^2(\Omega)}.
$$

(5.33)

Let $z_h \in V_{h,0}^{\text{IFE}}$ be the solution of the new nonconforming IFE method applied to the auxiliary problem (5.35), i.e.,

$$
A_h(v_h, z_h) = \int_\Omega (u - u_h)v_h \, dx \quad \forall v_h \in V_{h,0}^{\text{IFE}}.
$$

(5.34)

Recalling that $a_h(\cdot, \cdot) = a(\cdot, \cdot)$ on $H_0^1(\Omega)$, and applying (5.32) and (5.34), we have

$$
\|u - u_h\|_{L^2(\Omega)}^2 = a(u, z) - A_h(u, z_h) = A_h(u, z) - A_h(u_h, z_h) + \tilde{a}_h(u, z) - a_h(u, z)
$$

(5.35)

$$
= A_h(u - u_h, z - z_h) + A_h(u - u_h, z_h) + (a_h(u, z) - a_h(u, z)),
$$

where the relation $b_h(u, z) = s_h(u, z) = 0$ is used in the second identity since $[u]_e = [v]_e = 0$ for all edges. Lemma 5.6 provides the estimate for the last term

$$
\tilde{a}_h(u, z) - a_h(u, z) \leq C h^2 \|u\|_{H^2(\Omega^{++} \cup \Omega^{-})} \|z\|_{H^2(\Omega^{++} \cup \Omega^{-})}.
$$

(5.36)

The first terms on the right-hand side of (5.35) can be estimated using Theorem 5.7

$$
A_h(u - u_h, z - z_h) \leq \|u - u_h\|_h \|z - z_h\|_h \leq C h^2 \|u\|_{H^2(\Omega^{++} \cup \Omega^{-})} \|z\|_{H^2(\Omega^{++} \cup \Omega^{-})}.
$$

(5.37)

We rewrite the second term on the right-hand side of (5.35) as

$$
A_h(u - u_h, z_h) = A_h(u - u_h, z_h - I_h^{\text{IFE}}z) + A_h(u - u_h, I_h^{\text{IFE}}z_h).
$$

(5.38)

It is easy to see that

$$
A_h(u - u_h, z_h - I_h^{\text{IFE}}z) \leq \|u - u_h\|_h \|z_h - I_h^{\text{IFE}}z\|_h \leq C h^2 \|u\|_{H^2(\Omega^{++} \cup \Omega^{-})} \|z\|_{H^2(\Omega^{++} \cup \Omega^{-})}.
$$

(5.39)

From (5.38), we have

$$
A_h(u - u_h, I_h^{\text{IFE}}z_h) = \sum_{e \in E_{\text{non}}} \int_e \beta \nabla u \cdot n_e [I_h^{\text{IFE}}z_h]_e \, ds + \tilde{a}_h(u, I_h^{\text{IFE}}z_h) - a_h(u, I_h^{\text{IFE}}z_h).
$$

(5.40)

Since $[I_h^{\text{IFE}}z_h]_e = [z]_e = 0$, we can derive

$$
\sum_{e \in E_{\text{non}}} \int_e \beta \nabla u \cdot n_e [I_h^{\text{IFE}}z_h]_e \, ds = \sum_{e \in E_{\text{non}}} \int_e (\beta \nabla u \cdot n_e - P_0^e(\beta \nabla u \cdot n_e)) [I_h^{\text{IFE}}z_h - z]_e \, ds \leq C h^2 \|u\|_{H^2(\Omega^{++} \cup \Omega^{-})} \|z\|_{H^2(\Omega^{++} \cup \Omega^{-})},
$$

(5.41)
The Cauchy-Schwarz inequality, the standard trace inequality and Theorem 3.8 are used. Applying Lemma 5.6 and Theorem 3.8 again we obtain
\[
|a_h(u, I_{h}^{IE} z_h) - a_h(u, I_{h}^{IE} z_h)| \leq |\tilde{a}_h(u, z) - a_h(u, z)| + |\tilde{a}_h(u, I_{h}^{IE} z_h - z) - a_h(u, I_{h}^{IE} z_h - z)| \leq C h^2 \|u\|_{H^2(\Omega+\cup\Omega-)} \|z\|_{H^2(\Omega+\cup\Omega-)}.
\]
Combining (5.38)-(5.42), we find
\[
A_h(u - u_h, z_h) \leq C h^2 \|u\|_{H^2(\Omega+\cup\Omega-)} \|z\|_{H^2(\Omega+\cup\Omega-)},
\]
and similarly,
\[
A_h(u_h, z - z_h) \leq C h^2 \|u\|_{H^2(\Omega+\cup\Omega-)} \|z\|_{H^2(\Omega+\cup\Omega-)}.
\]
Applying (5.38)-(5.47), we arrive at the estimate
\[
\|u - u_h\|_{L^2(\Omega)}^2 \leq C h^2 \|u\|_{H^2(\Omega+\cup\Omega-)} \|z\|_{H^2(\Omega+\cup\Omega-)},
\]
which together with the regularity result (5.33) implies the estimate (5.31).

6 Numerical examples

In this section, we present some numerical examples to validate the theoretical analysis. To avoid redundancy, we only report numerical results of IFE methods based on the Crouzeix-Raviart element since the results of IFE methods based on the rotated-$Q_1$ element are almost the same.

For simplicity, we take $\Omega = (-1,1) \times (-1,1)$ as the computational domain and use uniform triangulations constructed as follows. We first partition the domain into $N \times N$ congruent rectangles, and then obtain the triangulation by cutting the rectangles along one of diagonals in the same direction. We examine the convergence rate of IFE solutions using the following norms
\[
|e_h|_{H^1} := \left( \sum_{T \in \mathcal{T}_h} \|\sqrt{\beta_h} \nabla (u - u_h)\|_{L^2(T)}^2 \right)^{1/2} \quad \text{and} \quad \|e_h\|_{L^2} := \|u - u_h\|_{L^2(\Omega)}.
\]

For comparison, we replace $\beta(x)$ by $\beta_h(x)$ in the existing nonconforming IFE method (4.11) in our computation. Thus, the difference of the existing nonconforming IFE method and our new nonconforming IFE method (5.4) is the terms $b_h(\cdot, \cdot)$ and $s_h(\cdot, \cdot)$. In view of the analysis for our new method, the error resulting from replacing $\beta(x)$ by $\beta_h(x)$ does not affect the error estimates in Theorem 1.1 for the existing nonconforming IFE method.

6.1 A counter example with $\nabla u \cdot t \neq 0$ on $\Gamma$

We use this example to show that the existing nonconforming IFE method using integral values as degrees of freedom does not have the optimal convergence rates.

Example 6.1. The interface is $\Gamma = \{(x_1, x_2) \in \mathbb{R}^2 : x_1^2 + x_2^2 = r_0^2\}$ such that $\Omega^- = \{(x_1, x_2) \in \mathbb{R}^2 : x_1^2 + x_2^2 < r_0^2\}$. Let $(r, \theta)$ be the polar coordinate of $x = (x_1, x_2)$. The exact solution is chosen as $u(x) = j(x) v(x) \omega(x)$, where $\omega(x) = \sin(\theta)$,
\[
j(x) = \begin{cases} 
\exp \left( -\frac{1}{1 - (r - r_0)^2/\eta^2} \right) & \text{if } |r - r_0| < \eta, \\
0 & \text{if } |r - r_0| \geq \eta,
\end{cases}
\]
and

\[
v(x) = \begin{cases} 
1 + (r^2 - r_0^2)/\beta^+(x) & \text{if } x \in \Omega^+,

1 + (r^2 - r_0^2)/\beta^-(x) & \text{if } x \in \Omega^-.
\end{cases}
\]

Let \( r_0 = 0.5, \eta = 0.45, \beta^+(x) \) and \( \beta^-(x) \) be positive constants. It is easy to verify that the jump condition (1.2)-(1.3) is satisfied and \( \nabla u \cdot t \neq 0 \) on \( \Gamma \). We test two cases: \( (\beta^+, \beta^-) = (10, 1000) \) and \( (\beta^+, \beta^-) = (1000, 10) \). The exact solutions of these two cases are plotted in Figure 4.

![Figure 4: Exact solutions of Example 6.1. Left: (\( \beta^+, \beta^- \)) = (10, 1000); Right: (\( \beta^+, \beta^- \)) = (1000, 10)](image)

We report numerical results in Tables 1-2 which clearly confirm our theoretical analysis. The second and third columns in Tables 1-2 indicate suboptimal convergence rates: \( \| e_h \|_{L^2} \approx O(h) \), \( | e_h |_{H^1} \approx O(h^{1/2}) \) for the existing nonconforming IFE method (4.1). When the terms \( b_h(\cdot, \cdot) \) and \( s_h(\cdot, \cdot) \) are added to the scheme, i.e., the new nonconforming IFE method (5.4), we observe the optimal convergence rates (see last two columns in Tables 1-2).

6.2 An example with variable coefficients and a non-convex interface

Example 6.2. The interface is the zero level set of the function,

\[ \varphi(x) = (3(x_1^2 + x_2^2) - x_1)^2 - x_1^2 - x_2^2 + 0.02. \]

The exact solution is chosen as \(u(x) = \varphi(x)/\beta(x)\), where

\[ \beta(x) = \begin{cases} 
\beta^+(x) = 300(2 + \sin(6x_1 + 6x_2)) & \text{if } \varphi(x) > 0, \\
\beta^-(x) = 2 + \cos(6x_1 + 6x_2) & \text{if } \varphi(x) < 0.
\end{cases} \]

It is easy to verify that the jump condition (1.2)-(1.3) is satisfied and \(\nabla u \cdot t = 0\) on \(\Gamma\). The exact solution and the interface are plotted in Figure 5.

For the problem with variable coefficients, we choose \(\beta^+_c = \beta^+(x_m), \beta^-_c = \beta^-(x_m)\) on each interface element \(T \in \mathcal{T}_h\), where \(x_m\) is the midpoint of \(\Gamma_h \cap T\). Since \(\nabla u \cdot t = 0\) on \(\Gamma\), our theoretical analysis suggests the optimal convergence rates for both the existing and the new IFE methods, which are confirmed by the results listed in Table 3.

In view of the requirement (3.4), we also test another choice: \(\beta^\pm_c = \beta^+(A_i) + C^\pm h\), i.e., using the value at one vertex \(A_i\) of \(T\) and random constants \(C^\pm\) in \([0,1]\). The numerical results are almost the same and thus are not presented to avoid redundancy.

7 Conclusions

In this paper, we have shown that the nonconforming IFE methods using integral-value degrees of freedom cannot achieve optimal convergence rates although the continuity of IFE shape functions is weakly enforced through average values over edges. The suboptimal convergence rates have been confirmed by a counter numerical example where the tangential derivative of the exact solution is not zero on the interface. We think there is similar issue for nonconforming IFE methods using integral-value degrees of freedom for solving elasticity and Stokes interface problems, which is an interesting topic in our future research.

To recover the optimal convergence rates, we have developed a new nonconforming IFE method with additional terms at interface edges. The new nonconforming IFE method is symmetric and the coercivity is ensured by a local lifting operator without a sufficient large penalty parameter. We have also proved that IFE basis functions based on the Crouzeix-Raviart elements are unisolvent on arbitrary triangles which is one of advantages compared with the IFEs using nodal values as degrees of freedom. The optimal approximation capabilities of nonconforming IFE spaces based on the Crouzeix-Raviart and the rotated-$Q_1$ elements have been derived via a novel approach where the problem with variable coefficients are also considered. The optimal error estimates for the IFE solutions in the $H^1$- and $L^2$- norms have been derived and confirmed by some numerical examples.
