Abstract

We investigate symmetric equilibria of mutual reinforcement learning when both players alternately learn the optimal memory-two strategies against the opponent in the repeated prisoner’s dilemma game. We provide the necessary condition for memory-two deterministic strategies to form symmetric equilibria. We then provide two examples of memory-two deterministic strategies which form symmetric mutual reinforcement learning equilibria. We also prove that mutual reinforcement learning equilibria formed by memory-two strategies are also mutual reinforcement learning equilibria when both players use reinforcement learning of memory-\(n\) strategies with \(n > 2\).

Keywords: Repeated prisoner’s dilemma game; Reinforcement learning; Memory-two strategies

1. Introduction

Learning in game theory has been attracted much attention \[1, 2, 3, 4, 5\]. Because rationality of human beings is bounded \[6\], modeling of human beings as learning agents has been used in game theory and theoretical economics. One of the most popular learning methods is reinforcement learning \[7\]. In reinforcement learning, an agent gradually learns the optimal policy against a stationary environment. Mutual reinforcement learning in game theory is a more difficult problem since the existence of multiple agents makes an environment nonstationary \[8, 9, 10, 11, 12\]. Several methods have been proposed for reinforcement learning with multiple agents \[13\].

Here, we investigate mutual reinforcement learning in the repeated prisoner’s dilemma game \[14\]. More explicitly, we investigate properties of equilibria formed by learning agents when the two agents alternately learn their optimal strategies against the opponent. In the previous study \[15\], it was
found that, among all deterministic memory-one strategies, only the Grim trigger strategy, the Win-Stay Lose-Shift strategy, and the All-D strategy can form symmetric equilibrium of mutual reinforcement learning. Recently, memory-n strategies with \( n > 1 \) attract much attention in game theory because longer memory enables more complicated behavior [16, 17, 18, 19, 20, 21]. However, even whether the above equilibria formed by memory-one strategies are still equilibria in memory-n settings or not has not been known.

In this paper, we extend the analysis of Ref. [15] to memory-two strategies. First, we provide the necessary condition for memory-two deterministic strategies to form symmetric equilibria. Then we provide two non-trivial examples of memory-two deterministic strategies which form symmetric mutual reinforcement learning equilibria. Furthermore, we also prove that mutual reinforcement learning equilibria formed by memory-n strategies are also mutual reinforcement learning equilibria when both players use reinforcement learning of memory-n strategies with \( n > n' \).

This paper is organized as follows. In Section 2 we introduce the repeated prisoner’s dilemma game with memory-n strategies, and players using reinforcement learning. In Section 3 we show that the structure of the optimal strategies is constrained by the Bellman optimality equation. In Section 4 we introduce the concepts of mutual reinforcement learning equilibrium and symmetric equilibrium. We then provide the necessary condition for memory-two deterministic strategies to form symmetric equilibria. In Section 5 we provide two examples of memory-two deterministic strategies which form symmetric mutual reinforcement learning equilibria. In Section 6 we show that mutual reinforcement learning equilibria formed by memory-n’ strategies are also mutual reinforcement learning equilibria when both players use reinforcement learning of memory-n strategies with \( n > n' \). Section 7 is devoted to conclusion.

2. Model

We introduce the repeated prisoner’s dilemma game [8]. There are two players (1 and 2) in the game. Each player chooses cooperation (C) or defection (D) on every round. The action of player \( a \) is written as \( \sigma_a \in \{C, D\} \). We collectively write \( \sigma := (\sigma_1, \sigma_2) \), and call \( \sigma \) a state. We also write the space of all possible states as \( \Omega := \{C, D\}^2 \). The payoff of player \( a \in \{1, 2\} \) when the state is \( \sigma \) is described as \( r_a(\sigma) \). The payoffs in the prisoner’s dilemma game are given by

\[
\begin{align*}
(r_1(C, C), r_1(C, D), r_1(D, C), r_1(D, D)) &= (R, S, T, P) \\
(r_2(C, C), r_2(C, D), r_2(D, C), r_2(D, D)) &= (R, T, S, P)
\end{align*}
\]

with \( T > R > P > S \) and \( 2R > T + S \). The memory-n strategy (\( n \geq 1 \)) of player \( a \) is described as the conditional probability \( T_a(\sigma_a| [\sigma^{(-m)}]^n_{m=1}) \) of taking action \( \sigma_a \) when the states in the previous \( n \) rounds are \( [\sigma^{(-m)}]^n_{m=1} \), where we have introduced the notation \( [\sigma^{(-m)}]^n_{m=1} := (\sigma^{(-1)}, \ldots, \sigma^{(-n)}) \) [21].
We write the length of memory of player $a$ as $n_a$ and define $n := \max \{n_1, n_2\}$. In this paper, we assume that $n$ is finite. Below we introduce the notation $-a := \{1, 2\} \setminus a$.

We consider the situation that both players learn their optimal strategies against the strategy of the opponent by reinforcement learning. In reinforcement learning, each player learns mapping (called policy) from the states $[\sigma^{(-m)}]_{m=1}^n$ in the previous $n$ rounds to his/her action $\sigma$ so as to maximize his/her expected future reward. We write the action of player $a$ at round $t$ as $\sigma_a(t)$. In addition, we write $r_a(t) := r_a(\sigma(t))$. We define the action-value function of player $a$ as

$$Q_a(\sigma, [\sigma^{(-m)}]_{m=1}^n) := \mathbb{E} \left[ \sum_{k=0}^{\infty} \gamma^k r_a(t+k) \bigg| \sigma_a(t) = \sigma, [\sigma(s)]_{s=t-1}^{t-n} = [\sigma^{(-m)}]_{m=1}^n \right],$$

(3)

where $\gamma$ is a discounting factor satisfying $0 < \gamma < 1$. The action-value function $Q_a(\sigma, [\sigma^{(-m)}]_{m=1}^n)$ represents the expected future payoffs of player $a$ by taking action $\sigma_a$ when states in the previous $n$ rounds are $[\sigma^{(-m)}]_{m=1}^n$. It should be noted that the right-hand side does not depend on $t$. Due to the property of memory-$n$ strategies, the action-value function $Q_a$ obeys the Bellman equation against a fixed strategy $T_{-a}$ of the opponent:

$$Q_a(\sigma_a, [\sigma^{(-m)}]_{m=1}^n) = \sum_{\sigma_a} r_a(\sigma) T_{-a}(\sigma_a | [\sigma^{(-m)}]_{m=1}^n) + \gamma \sum_{\sigma_a} \sum_{\sigma_a} T_a(\sigma_a' | \sigma_a, [\sigma^{(-m)}]_{m=1}^{n-1}) T_{-a}(\sigma_{-a} | [\sigma^{(-m)}]_{m=1}^n) Q_a(\sigma_a', \sigma, [\sigma^{(-m)}]_{m=1}^{n-1}).$$

(4)

See Appendix A for the derivation of Eq. (4). It has been known that the optimal policy $T_{a\ast}$ and the optimal action-value function $Q_{a\ast}$ obeys the following Bellman optimality equation:

$$Q_{a\ast}(\sigma_a, [\sigma^{(-m)}]_{m=1}^n) = \sum_{\sigma_a} r_a(\sigma) T_{-a}(\sigma_a | [\sigma^{(-m)}]_{m=1}^n) + \gamma \sum_{\sigma_a} T_a(\sigma_a | [\sigma^{(-m)}]_{m=1}^n) \max_{\hat{\sigma}} Q_{a\ast}(\hat{\sigma}, \sigma, [\sigma^{(-m)}]_{m=1}^{n-1}),$$

(5)

with the support

$$\text{supp} T_{a\ast}(\cdot | [\sigma^{(-m)}]_{m=1}^n) = \arg \max_{\sigma} Q_{a\ast}(\sigma, [\sigma^{(-m)}]_{m=1}^n).$$

(6)
increases rapidly as $n$ for $n$ with tic memory—only one action, that is, strategies are deterministic. The general properties of optimal strategies.

We investigate the situation that players infinitely repeat the infinitely-repeated games and players alternately learn their optimal strategies in each game, as in Ref. [15]. We write the optimal strategy and the corresponding optimal action-value function of player $a$ at $d$-th game as $T^{s(d)}_a$ and $Q^{s(d)}_a$, respectively. Given an initial strategy $T^{(0)}_2$ of player 2, in the $(2l - 1)$-th game $(l \in \mathbb{N})$, player 1 learns $T^{s(2l-1)}_1$ against $T^{s(2l-2)}_2$ by calculating $Q^{s(2l-1)}_1$. In the $2l$-th game, player 2 learns $T^{s(2l)}_2$ against $T^{s(2l-1)}_1$ by calculating $Q^{s(2l)}_2$. We are interested in the fixed points of the dynamics, that is, $T^{s(\infty)}_a$ and $Q^{s(\infty)}_a$.

In this paper, we mainly investigate situations that the support [6] contains only one action, that is, strategies are deterministic. The number of deterministic memory-$n$ strategies in the repeated prisoner’s dilemma game is $2^{2m}$, which increases rapidly as $n$ increases.

3. Structure of optimal strategies

Below we consider only the case $n = 2$. The Bellman optimality equation [5] for $n = 2$ is

$$Q^*_a \left( \sigma_a, [\sigma^{(-m)}^n]_{m=1} \right)$$

$$= \sum_{\sigma_{-a}} r^a(\sigma) T_{-a} \left( \sigma_{-a}, [\sigma^{(-1)}], [\sigma^{(-2)}] \right)$$

$$+ \gamma \sum_{\sigma_{-a}} T_{-a} \left( \sigma_{-a}, [\sigma^{(-1)}], [\sigma^{(-2)}] \right) \max_{\hat{\sigma}} Q^*_a \left( \hat{\sigma}, \sigma, [\sigma^{(-1)}] \right)$$

with

$$\text{supp} T^{s(\infty)}_a \left( \cdot | [\sigma^{(-1)}], [\sigma^{(-2)}] \right) = \arg \max_{\sigma} Q^*_a \left( \sigma, [\sigma^{(-1)}], [\sigma^{(-2)}] \right).$$

The number of memory-two deterministic strategies is $2^{16}$, which is quite large, and therefore we cannot investigate all memory-two deterministic strategies as in the case of memory-one deterministic strategies [15]. Instead, we first investigate general properties of optimal strategies.

We introduce the matrix representation of a strategy:

$$T_a(\sigma) := \begin{pmatrix}
T_a(\sigma | (C, C), (C, C)) & T_a(\sigma | (C, C), (C, D)) & T_a(\sigma | (C, C), (D, C)) & T_a(\sigma | (C, C), (D, D)) \\
T_a(\sigma | (C, D), (C, C)) & T_a(\sigma | (C, D), (C, D)) & T_a(\sigma | (C, D), (D, C)) & T_a(\sigma | (C, D), (D, D)) \\
T_a(\sigma | (D, C), (C, C)) & T_a(\sigma | (D, C), (C, D)) & T_a(\sigma | (D, C), (D, C)) & T_a(\sigma | (D, C), (D, D)) \\
T_a(\sigma | (D, D), (C, C)) & T_a(\sigma | (D, D), (C, D)) & T_a(\sigma | (D, D), (D, C)) & T_a(\sigma | (D, D), (D, D))
\end{pmatrix}.$$
For deterministic strategies, each component in the matrix is 0 or 1.

We now prove the following proposition:

**Proposition 1.** For two different states \( \sigma^{(-2)} \) and \( \sigma^{(-2)'} \), if

\[
T_{-a}(\sigma|\sigma^{(-1)},\sigma^{(-2)}) = T_{-a}(\sigma|\sigma^{(-1)},\sigma^{(-2)'}), \quad (\forall \sigma)
\]

(10)

holds for some \( \sigma^{(-1)} \), then

\[
T_a^*(\sigma|\sigma^{(-1)},\sigma^{(-2)}) = T_a^*(\sigma|\sigma^{(-1)},\sigma^{(-2)'}), \quad (\forall \sigma)
\]

(11)

also holds.

**Proof.** For such \( \sigma^{(-1)} \), because of Eq. (7), we find

\[
Q_a^*(\sigma_a, \sigma^{(-1)}, \sigma^{(-2)}) = \sum_{\sigma_{-a}} r_a(\sigma) T_{-a}(\sigma_{-a}|\sigma^{(-1)}, \sigma^{(-2)})
\]

\[
+ \gamma \sum_{\sigma_{-a}} T_{-a}(\sigma_{-a}|\sigma^{(-1)}, \sigma^{(-2)'}). \max_{\hat{\sigma}} Q_a^*(\hat{\sigma}, \sigma, \sigma^{(-1)})
\]

\[
= \sum_{\sigma_{-a}} r_a(\sigma) T_{-a}(\sigma_{-a}|\sigma^{(-1)}, \sigma^{(-2)'}). \max_{\hat{\sigma}} Q_a^*(\hat{\sigma}, \sigma, \sigma^{(-1)})
\]

\[
= Q_a^*(\sigma_a, \sigma^{(-1)}, \sigma^{(-2)'}),
\]

(12)

for all \( \sigma_a \). Since \( T_a^* \) is determined by Eq. (8), we obtain Eq. (11).

This proposition implies that the structure of the matrix \( T_a^*(\sigma) \) is the same as that of \( T_{-a}(\sigma) \). For deterministic strategies, in order to see this in more detail, we introduce the following sets for \( a \in \{1, 2\} \) and \( \sigma^{(-1)} \in \Omega \):

\[
N_x^a(\sigma^{(-1)}) := \left\{ \sigma^{(-2)} \in \Omega \left| T_a(C|\sigma^{(-1)}, \sigma^{(-2)}) = x \right. \right\},
\]

(13)

where \( x \in \{0, 1\} \). We remark that \( N_0^a(\sigma^{(-1)}) \cup N_1^a(\sigma^{(-1)}) = \Omega \) for all \( a \) and \( \sigma^{(-1)} \). Then, Proposition 1 leads the following corollary:

**Corollary 1.** For a deterministic strategy \( T_{-a} \) of player \(-a\), if the optimal strategy \( T_a^* \) of player \( a \) against \( T_{-a} \) is also deterministic, then one of the following four relations holds for each \( \sigma^{(-1)} \in \Omega \):

(a) \( N_x^a(\sigma^{(-1)}) = N_x^a(\sigma^{(-1)}) \) for all \( x \)
(b) \( N_x^a(\sigma^{(-1)}) = N_x^a(\sigma^{(-1)}) \) for all \( x \)
(c) \( N_0^a(\sigma^{(-1)}) = N_0^a(\sigma^{(-1)}) \cup N_1^a(\sigma^{(-1)}) = \Omega \) and \( N_1^a(\sigma^{(-1)}) = \emptyset \)
(d) \( N_1^a(\sigma^{(-1)}) = N_0^a(\sigma^{(-1)}) \cup N_1^a(\sigma^{(-1)}) = \Omega \) and \( N_0^a(\sigma^{(-1)}) = \emptyset \).
4. Symmetric equilibrium

In this section, we investigate symmetric equilibrium of mutual reinforcement learning.

First, we introduce the notation $C := D, D := C$, and $\pi (\sigma_1, \sigma_2) := (\sigma_2, \sigma_1)$. We define the word same strategy.

**Definition 1.** A strategy $T_a$ of player $a$ is the same strategy as that of player $-a$ iff

$$
T_a \left( \sigma | \sigma^{(-1)}, \sigma^{(-2)} \right) = T_{-a} \left( \sigma | \pi \left( \sigma^{(-1)} \right), \pi \left( \sigma^{(-2)} \right) \right)
$$

for all $\sigma, \sigma^{(-1)}$, and $\sigma^{(-2)}$.

Next, we introduce equilibria achieved by mutual reinforcement learning.

**Definition 2.** A pair of strategy $T_1$ and $T_2$ is a mutual reinforcement learning equilibrium iff $T_a$ is the optimal strategy against $T_{-a}$ for $a = 1, 2$.

For deterministic mutual reinforcement learning equilibria, the following proposition is the direct consequence of Corollary 1.

**Proposition 2.** For mutual reinforcement learning equilibria formed by deterministic strategies, one of the following two relations holds for each $\sigma^{(-1)} \in \Omega$:

(a) $N_2^{(1)} (\sigma^{(-1)}) = N_2^{(2)} (\sigma^{(-1)})$ for all $x$
(b) $N_2^{(1)} (\sigma^{(-1)}) = N_1^{(2)} (\sigma^{(-1)})$ for all $x$.

**Proof.** According to Corollary 1, one of the four situations (a)-(d) holds for the optimal strategy $T_1$ against $T_2$. However, because $T_2$ is also the optimal strategy against $T_1$, the cases (c) and (d) are excluded or integrated into the case (a) or (b).

Furthermore, we introduce symmetric equilibria of mutual reinforcement learning.

**Definition 3.** A pair of strategy $T_1$ and $T_2$ is a symmetric mutual reinforcement learning equilibrium iff $T_a$ is the optimal strategy against $T_{-a}$ and $T_a$ is the same strategy as $T_{-a}$ for $a = 1, 2$.

It should be noted that the deterministic optimal strategies can be written as

$$
T_a^* \left( \sigma | \sigma^{(-1)}, \sigma^{(-2)} \right) = \mathbb{I} \left( Q_a^* \left( \sigma, \sigma^{(-1)}, \sigma^{(-2)} \right) > Q_a^* \left( \pi, \sigma^{(-1)}, \sigma^{(-2)} \right) \right),
$$

where $\mathbb{I}(\cdots)$ is the indicator function that returns 1 when $\cdots$ holds and 0 otherwise. We also introduce the following sets for $a \in \{1, 2\}$ and $\sigma^{(-1)} \in \Omega$:

$$
\tilde{N}_2^{(a)} (\sigma^{(-1)}) := \left\{ \sigma^{(-2)} \in \Omega \left| T_a \left( C | \sigma^{(-1)}, \pi \left( \sigma^{(-2)} \right) \right) = x \right\},
$$

where $x \in \{0, 1\}$. We now prove the first main result of this paper.
\textbf{Theorem 1}. For symmetric mutual reinforcement learning equilibria formed by deterministic strategies, the following relations must hold:

(a) For $\sigma^{(-1)} \in \{(C, C), (D, D)\}$,

$$T_a \left( C \middle| \sigma^{(-1)} \right) = T_a \left( C \middle| \sigma^{(-1)} \right) \quad (17)$$

for all $a$.

(b) For $\sigma^{(-1)} \in \{(C, D), (D, C)\}$,

$$N_x^{(a)} \left( \pi \left( \sigma^{(-1)} \right) \right) = \tilde{N}_x^{(a)} \left( \sigma^{(-1)} \right) \quad (\forall x) \quad (18)$$

or

$$N_x^{(a)} \left( \pi \left( \sigma^{(-1)} \right) \right) = \tilde{N}_{1-x}^{(a)} \left( \sigma^{(-1)} \right) \quad (\forall x) \quad (19)$$

holds.

\textit{Proof.} For $\sigma^{(-1)} \in \{(C, C), (D, D)\}$, $\pi \left( \sigma^{(-1)} \right) = \sigma^{(-1)}$ holds. Because $T_1$ and $T_2$ are the same strategies as each other,

$$T_1 \left( C \middle| \sigma^{(-1)} \right) = T_2 \left( C \middle| \sigma^{(-1)} \right) \quad (\sigma^{(-2)} \in \{(C, C), (D, D)\}) \quad (20)$$

holds. This and Proposition 2 imply that $N_x^{(1)} \left( \sigma^{(-1)} \right) = N_x^{(2)} \left( \sigma^{(-1)} \right) \quad (\forall x \in \{0, 1\})$ must hold. On the other hand, due to Eq. (14),

$$T_1 \left( C \middle| \sigma^{(-1)} \right) = T_2 \left( C \middle| \sigma^{(-1)} \right) \quad (21)$$

and

$$T_1 \left( C \middle| \sigma^{(-1)} \right) = T_2 \left( C \middle| \sigma^{(-1)} \right) \quad (22)$$

also hold. This means that, if $(C, D) \in N_x^{(1)} \left( \sigma^{(-1)} \right)$, then $(D, C) \in N_x^{(2)} \left( \pi \left( \sigma^{(-1)} \right) \right) = N_x^{(2)} \left( \sigma^{(-1)} \right) = N_x^{(1)} \left( \sigma^{(-1)} \right)$, leading to Eq. (17).

For $\sigma^{(-1)} \in \{(C, D), (D, C)\}$, because $T_1$ and $T_2$ are the same strategies as each other,

$$T_2 \left( C \middle| \pi \left( \sigma^{(-1)} \right) \right) = T_1 \left( C \middle| \sigma^{(-1)} \right) \quad (\sigma^{(-2)}) \quad (23)$$

holds for $\forall \sigma^{(-2)} \in \Omega$. This means that

$$N_x^{(2)} \left( \pi \left( \sigma^{(-1)} \right) \right) = \tilde{N}_x^{(1)} \left( \sigma^{(-1)} \right) \quad (\forall x \in \{0, 1\}) \quad (24)$$

holds. On the other hand, Proposition 2 implies that

$$N_x^{(1)} \left( \pi \left( \sigma^{(-1)} \right) \right) = N_x^{(2)} \left( \pi \left( \sigma^{(-1)} \right) \right) \quad (\forall x \in \{0, 1\}) \quad (25)$$

or

$$N_x^{(1)} \left( \pi \left( \sigma^{(-1)} \right) \right) = \tilde{N}_{1-x}^{(2)} \left( \pi \left( \sigma^{(-1)} \right) \right) \quad (\forall x \in \{0, 1\}) \quad (26)$$

must hold. By combining Eq. (24) and Eq. (25) or (26), we obtain Eq. (18) or (19). 

\[\square\]
Theorem 1 provides a necessary condition for a deterministic strategy to form a symmetric mutual reinforcement learning equilibrium. In particular, Eqs. (18) and (19) imply that the second row and the third row of $T_a$ cannot be independent of each other. For example, the Tit-for-Tat-anti-Tit-for-Tat (TFT-ATFT) strategy [17] does not satisfy the condition of Theorem 1, and therefore it cannot form a symmetric mutual reinforcement learning equilibrium. However, there are still many memory-two strategies which satisfy the necessary condition, and further refinement will be needed.

5. Examples of deterministic strategies forming symmetric equilibrium

In this section, we provide two examples of memory-two deterministic strategies forming symmetric mutual reinforcement learning equilibrium. For convenience, we define the following sixteen quantities:

\[
\begin{align*}
q_1 & := R + \gamma \max_{\sigma} Q_1^* (\sigma, (C, C), (C, C)) \\
q_2 & := T + \gamma \max_{\sigma} Q_1^* (\sigma, (D, C), (C, C)) \\
q_3 & := S + \gamma \max_{\sigma} Q_1^* (\sigma, (C, D), (C, C)) \\
q_4 & := P + \gamma \max_{\sigma} Q_1^* (\sigma, (D, D), (C, C)) \\
q_5 & := R + \gamma \max_{\sigma} Q_1^* (\sigma, (C, C), (D, C)) \\
q_6 & := T + \gamma \max_{\sigma} Q_1^* (\sigma, (D, C), (C, D)) \\
q_7 & := S + \gamma \max_{\sigma} Q_1^* (\sigma, (C, D), (C, D)) \\
q_8 & := P + \gamma \max_{\sigma} Q_1^* (\sigma, (D, D), (C, D)) \\
q_9 & := R + \gamma \max_{\sigma} Q_1^* (\sigma, (C, C), (D, C)) \\
q_{10} & := T + \gamma \max_{\sigma} Q_1^* (\sigma, (D, C), (D, C)) \\
q_{11} & := S + \gamma \max_{\sigma} Q_1^* (\sigma, (C, D), (D, C)) \\
q_{12} & := P + \gamma \max_{\sigma} Q_1^* (\sigma, (D, D), (D, C)) \\
\end{align*}
\]
The Bellman optimality equation for symmetric equilibrium is

\[ Q_1^* \left( \sigma_1, \sigma^{(-1)}, \sigma^{(-2)} \right) = \sum_{\sigma_2} \left\{ r_1(\sigma) + \max_{\hat{\sigma}} Q_1^* \left( \hat{\sigma}, \sigma, \sigma^{(-1)} \right) \right\} \times 1 \left( Q_1^* \left( \sigma_2, \pi(\sigma^{(-1)}), \pi(\sigma^{(-2)}) \right) > Q_1^* \left( \sigma_2, \pi(\sigma^{(-1)}), \pi(\sigma^{(-2)}) \right) \right). \] (44)

We want to find solutions of this equation.

The first candidate of the solution of Eq. (44) is

\[ T_1(C) = T_2(C) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}. \] (45)

Because this strategy is a variant of the Grim trigger strategy \[22\]

\[ T_1(C) = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \] (46)

but uses only information at the second last state, the strategy (45) can be called as retarded Grim strategy.

**Theorem 2.** A pair of the strategy (45) forms a symmetric mutual reinforcement learning equilibrium if \( \gamma > \sqrt{\frac{P}{T-R}} \).

**Proof.** The Bellman optimality equation against the strategy (45) is

\[ Q_1^* (C, (C, C), (C, C)) = q_1 \] (47)
\[ Q_1^* (D, (C, C), (C, C)) = q_2 \] (48)
\[ Q_1^* (C, (C, C), \sigma^{(-2)}) = q_3 \left( \sigma^{(-2)} \neq (C, C) \right) \] (49)
\[ Q_1^* (D, (C, C), \sigma^{(-2)}) = q_4 \left( \sigma^{(-2)} \neq (C, C) \right) \] (50)
\[ Q_1^* (C, (C, D), (C, C)) = q_5 \] \hspace{1cm} (51)
\[ Q_1^* (D, (C, D), (C, C)) = q_6 \] \hspace{1cm} (52)
\[ Q_1^* (C, (C, D), \sigma^{(-2)}) = q_7 \left( \sigma^{(-2)} \neq (C, C) \right) \] \hspace{1cm} (53)
\[ Q_1^* (D, (C, D), \sigma^{(-2)}) = q_8 \left( \sigma^{(-2)} \neq (C, C) \right) \] \hspace{1cm} (54)
\[ Q_1^* (C, (D, C), (C, C)) = q_9 \] \hspace{1cm} (55)
\[ Q_1^* (D, (D, C), (C, C)) = q_{10} \] \hspace{1cm} (56)
\[ Q_1^* (C, (D, C), \sigma^{(-2)}) = q_{11} \left( \sigma^{(-2)} \neq (C, C) \right) \] \hspace{1cm} (57)
\[ Q_1^* (D, (D, C), \sigma^{(-2)}) = q_{12} \left( \sigma^{(-2)} \neq (C, C) \right) \] \hspace{1cm} (58)
\[ Q_1^* (C, (D, D), (C, C)) = q_{13} \] \hspace{1cm} (59)
\[ Q_1^* (D, (D, D), (C, C)) = q_{14} \] \hspace{1cm} (60)
\[ Q_1^* (C, (D, D), \sigma^{(-2)}) = q_{15} \left( \sigma^{(-2)} \neq (C, C) \right) \] \hspace{1cm} (61)
\[ Q_1^* (D, (D, D), \sigma^{(-2)}) = q_{16} \left( \sigma^{(-2)} \neq (C, C) \right) \] \hspace{1cm} (62)

with the self-consistency condition

\[ q_1 > q_2 \]
\[ q_3 < q_4 \]
\[ q_5 > q_6 \]
\[ q_7 < q_8 \]
\[ q_9 > q_{10} \]
\[ q_{11} < q_{12} \]
\[ q_{13} > q_{14} \]
\[ q_{15} < q_{16} \] \hspace{1cm} (63)
The solution is
\begin{align*}
q_1 &= \frac{1}{1 - \gamma} R \\
q_2 &= T + \frac{\gamma}{1 - \gamma^2} R + \frac{\gamma^2}{1 - \gamma^2} P \\
q_3 &= S + \frac{\gamma}{1 - \gamma^2} R + \frac{\gamma^2}{1 - \gamma^2} P \\
q_4 &= \frac{1}{1 - \gamma^2} P + \frac{\gamma}{1 - \gamma^2} R \\
q_5 &= q_9 = q_{13} = \frac{1}{1 - \gamma^2} R + \frac{\gamma}{1 - \gamma^2} P \\
q_6 &= q_{10} = q_{14} = T + \frac{\gamma}{1 - \gamma} P \\
q_7 &= q_{11} = q_{15} = S + \frac{\gamma}{1 - \gamma} P \\
q_8 &= q_{12} = q_{16} = \frac{1}{1 - \gamma} P.
\end{align*}

For these solution, the inequalities (63) are satisfied if
\begin{equation}
\gamma > \sqrt{\frac{T - R}{T - P}}.
\end{equation}

We remark that the condition (72) is more strict than the condition that Grim forms a symmetric equilibrium [15]: \( \gamma > \frac{T - R}{T - P} \).

The second candidate of the solution of Eq. (44) is
\begin{equation}
T_1 (C) = T_2 (C) = \begin{pmatrix}
1 & 0 & 0 & 1 \\
1 & 0 & 0 & 1 \\
1 & 0 & 0 & 1 \\
1 & 0 & 0 & 1
\end{pmatrix}.
\end{equation}

Because this strategy is a variant of the Win-Stay Lose-Shift (WSLS) strategy [23]
\begin{equation}
T_1 (C) = \begin{pmatrix}
1 & 1 & 1 & 1 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
1 & 1 & 1 & 1
\end{pmatrix}
\end{equation}
but uses only information at the second last state, the strategy (73) can be called as retarded WSLS strategy.

**Theorem 3.** A pair of the strategy (73) forms a symmetric mutual reinforcement learning equilibrium if \( \gamma > \sqrt{\frac{T - R}{T - P}} \).
Proof. The Bellman optimality equation against the strategy \( \sigma^+ \) is

\[
Q_1^* (C, (C, C), \sigma^{(-2)}) = q_1 \left( \sigma^{(-2)} \in \{(C, C), (D, D)\} \right) \quad (75)
\]

\[
Q_1^* (D, (C, C), \sigma^{(-2)}) = q_2 \left( \sigma^{(-2)} \in \{(C, C), (D, D)\} \right) \quad (76)
\]

\[
Q_1^* (C, (C, C), \sigma^{(-2)}) = q_3 \left( \sigma^{(-2)} \in \{(C, D), (D, C)\} \right) \quad (77)
\]

\[
Q_1^* (D, (C, C), \sigma^{(-2)}) = q_4 \left( \sigma^{(-2)} \in \{(C, D), (D, C)\} \right) \quad (78)
\]

\[
Q_1^* (C, (C, D), \sigma^{(-2)}) = q_5 \left( \sigma^{(-2)} \in \{(C, C), (D, D)\} \right) \quad (79)
\]

\[
Q_1^* (D, (C, D), \sigma^{(-2)}) = q_6 \left( \sigma^{(-2)} \in \{(C, C), (D, D)\} \right) \quad (80)
\]

\[
Q_1^* (C, (C, D), \sigma^{(-2)}) = q_7 \left( \sigma^{(-2)} \in \{(C, D), (D, C)\} \right) \quad (81)
\]

\[
Q_1^* (D, (C, D), \sigma^{(-2)}) = q_8 \left( \sigma^{(-2)} \in \{(C, D), (D, C)\} \right) \quad (82)
\]

\[
Q_1^* (C, (D, C), \sigma^{(-2)}) = q_9 \left( \sigma^{(-2)} \in \{(C, C), (D, D)\} \right) \quad (83)
\]

\[
Q_1^* (D, (D, C), \sigma^{(-2)}) = q_{10} \left( \sigma^{(-2)} \in \{(C, C), (D, D)\} \right) \quad (84)
\]

\[
Q_1^* (C, (D, C), \sigma^{(-2)}) = q_{11} \left( \sigma^{(-2)} \in \{(C, D), (D, C)\} \right) \quad (85)
\]

\[
Q_1^* (D, (D, C), \sigma^{(-2)}) = q_{12} \left( \sigma^{(-2)} \in \{(C, D), (D, C)\} \right) \quad (86)
\]

\[
Q_1^* (C, (D, D), \sigma^{(-2)}) = q_{13} \left( \sigma^{(-2)} \in \{(C, C), (D, D)\} \right) \quad (87)
\]

\[
Q_1^* (D, (D, D), \sigma^{(-2)}) = q_{14} \left( \sigma^{(-2)} \in \{(C, C), (D, D)\} \right) \quad (88)
\]

\[
Q_1^* (C, (D, D), \sigma^{(-2)}) = q_{15} \left( \sigma^{(-2)} \in \{(C, D), (D, C)\} \right) \quad (89)
\]

\[
Q_1^* (D, (D, D), \sigma^{(-2)}) = q_{16} \left( \sigma^{(-2)} \in \{(C, D), (D, C)\} \right) \quad (90)
\]

with the self-consistency condition

\[
q_1 > q_2 \\
q_3 < q_4 \\
q_5 > q_6 \\
q_7 < q_8 \\
q_9 > q_{10} \\
q_{11} < q_{12} \\
q_{13} > q_{14} \\
q_{15} < q_{16}.
\]

(91)
The solution is

\[ q_1 = q_{13} = \frac{1}{1 - \gamma} R \] (92)

\[ q_2 = q_{14} = T + \gamma R + \gamma^2 P + \frac{\gamma^3}{1 - \gamma} R \] (93)

\[ q_3 = q_{15} = S + \gamma R + \gamma^2 P + \frac{\gamma^3}{1 - \gamma} R \] (94)

\[ q_4 = q_{16} = P + \frac{\gamma}{1 - \gamma} R \] (95)

\[ q_5 = q_9 = R + \gamma P + \frac{\gamma^2}{1 - \gamma} R \] (96)

\[ q_6 = q_{10} = T + \gamma P + \gamma^2 P + \frac{\gamma^3}{1 - \gamma} R \] (97)

\[ q_7 = q_{11} = S + \gamma P + \gamma^2 P + \frac{\gamma^3}{1 - \gamma} R \] (98)

\[ q_8 = q_{12} = P + \gamma P + \frac{\gamma^2}{1 - \gamma} R. \] (99)

For these solution, the inequalities (91) are satisfied if

\[ \gamma > \sqrt{\frac{T - R}{R - P}}. \] (100)

We remark that the condition (100) is more strict than the condition that WSLS forms a symmetric equilibrium [13]: \( \gamma > \frac{T - R}{R - P} \).

6. Optimality in longer memory

In previous sections, we investigated symmetric equilibrium of mutual reinforcement learning when both players use memory-two strategies, and obtained two examples of deterministic strategies forming symmetric equilibrium. A natural question is “Do these strategies forming symmetric equilibrium in memory-two reinforcement learning also form symmetric equilibrium of mutual reinforcement learning of longer memory strategies?” In this section, we show that the answer to this question is “yes”.

We first prove the following theorem.

**Theorem 4.** Let \( T_{-a} \) be a memory-\( n' \) strategy of player \(-a\). Let \( T_{a}^* \) be the optimal strategy of player \( a \) against \( T_{-a} \) when player \( a \) use reinforcement learning of memory-\( n' \) strategies. When player \( a \) use reinforcement learning of memory-\( n \) strategies with \( n > n' \) to obtain the optimal strategy \( \hat{T}_{a}^* \) against \( T_{-a} \), then \( \hat{T}_{a}^* = T_{a}^* \).
Proof. When player \(-a\) use memory-\(n'\) strategy and player \(a\) use memory-\(n\) reinforcement learning with \(n > n'\), the Bellman optimality equation \(5\) becomes

\[
Q^*_a \left( \sigma_a, \left[ \sigma^{(-m)} \right]_{m=1}^n \right) = \sum_{\sigma_{-a}} r_a (\sigma) T_{-a} \left( \sigma_{-a} | \left[ \sigma^{(-m)} \right]_{m=1}^{n'} \right) + \gamma \sum_{\sigma_{-a}} T_{-a} \left( \sigma_{-a} | \left[ \sigma^{(-m)} \right]_{m=1}^{n'} \right) \max\sigma \ Q^*_a \left( \sigma, \sigma^{(-m)} \left[ \sigma^{(-m)} \right]_{m=1}^{n-1} \right) .
\]

(101)

Then, we find that the right-hand side does not depend on \(\sigma^{(-n)}\), and therefore

\[
Q^*_a \left( \sigma_a, \left[ \sigma^{(-m)} \right]_{m=1}^n \right) = Q^*_a \left( \sigma_a, \left[ \sigma^{(-m)} \right]_{m=1}^{n-1} \right) .
\]

(102)

Then, the Bellman optimality equation becomes

\[
Q^*_a \left( \sigma_a, \left[ \sigma^{(-m)} \right]_{m=1}^{n-1} \right) = \sum_{\sigma_{-a}} r_a (\sigma) T_{-a} \left( \sigma_{-a} | \left[ \sigma^{(-m)} \right]_{m=1}^{n'} \right) + \gamma \sum_{\sigma_{-a}} T_{-a} \left( \sigma_{-a} | \left[ \sigma^{(-m)} \right]_{m=1}^{n'} \right) \max\sigma \ Q^*_a \left( \sigma, \sigma^{(-m)} \left[ \sigma^{(-m)} \right]_{m=1}^{n-2} \right) .
\]

(103)

By repeating the same argument until the length of memory decreases to \(n'\), we find that

\[
Q^*_a \left( \sigma_a, \left[ \sigma^{(-m)} \right]_{m=1}^n \right) = Q^*_a \left( \sigma_a, \left[ \sigma^{(-m)} \right]_{m=1}^{n'} \right) ,
\]

(104)

which implies that \(\hat{T}^*_a = T^*_a\).

This theorem results in the following corollary.

**Corollary 2.** A mutual reinforcement learning equilibrium obtained by memory-\(n'\) reinforcement learning is also a mutual reinforcement learning equilibrium obtained by memory-\(n\) reinforcement learning with \(n > n'\).

Therefore, the strategies (15) and (73) in the previous section also form mutual reinforcement learning equilibria even if players use memory-\(n\) reinforcement learning with \(n > 2\). Similarly, the (memory-one) Grim strategy and the (memory-one) WSLS strategy still form mutual reinforcement learning equilibria even if players use memory-two reinforcement learning, since it has been known that Grim and WSLS form memory-one mutual reinforcement learning equilibria, respectively (15).
7. Conclusion

In this paper, we investigated symmetric equilibrium of mutual reinforcement learning when both players use memory-two deterministic strategies in the repeated prisoner’s dilemma game. First, we find that the structure of the optimal strategies is constrained by the Bellman optimality equation (Proposition 1). Then, we find the necessary condition for deterministic symmetric equilibrium of mutual reinforcement learning (Theorem 1). Furthermore, we provided two examples of memory-two deterministic strategies which form symmetric mutual reinforcement learning equilibrium, which can be regarded as variants of the Grim strategy and the WSLS strategy (Theorem 2 and Theorem 3). Finally, we proved that mutual reinforcement learning equilibria achieved by memory-two strategies are also mutual reinforcement learning equilibria when both players use reinforcement learning of memory-n strategies with \( n > 2 \) (Theorem 4).

We want to investigate whether other symmetric mutual reinforcement learning equilibria of deterministic memory-two strategies exist or not in future. Furthermore, extension of our analysis to mixed strategies is also a subject of future work.

Appendix A. Derivation of Eq. (4)

First we introduce the notation

\[
T \left( \sigma \left| \sigma^{(-m)} \right|_{m=1}^{n} \right) := \prod_{a=1}^{2} T_{a} \left( \sigma_{a} \left| \sigma^{(-m)} \right|_{m=1}^{n} \right). \quad (A.1)
\]

We remark that the joint probability distribution of the states \( \sigma^{(n)}, \ldots, \sigma^{(0)} \) given \( \sigma^{(-m)} \) is described as

\[
P \left( \sigma^{(n)}, \ldots, \sigma^{(0)} \left| \sigma^{(-m)} \right|_{m=1}^{n} \right) = \prod_{s=0}^{n} T \left( \sigma^{(s)} \left| \sigma^{(s-m)} \right|_{m=1}^{n} \right). \quad (A.2)
\]
The action-value function (3) is rewritten as

\[
Q_a \left( \sigma_a^{(0)}, \left[ \sigma^{(-m)} \right]_{m=1}^n \right) = \sum_{\sigma^{(s)}} \sum_{k=0}^{\infty} \gamma^k r_a \left( \sigma^{(k)} \right) \left\{ \prod_{s=1}^{\infty} T \left( \sigma^{(s)} \right) \left[ \sigma^{(s-m)} \right]_{m=1}^n \right\} \times T_a \left( \sigma^{(0)} \right) \left[ \sigma^{(-m)} \right]_{m=1}^n \]

\[
= \sum_{\sigma^{(s)}} \sum_{k=0}^{\infty} r_a \left( \sigma^{(0)} \right) + \gamma \sum_{k=0}^{\infty} \gamma^k r_a \left( \sigma^{(k+1)} \right) \left\{ \prod_{s=1}^{\infty} T \left( \sigma^{(s)} \right) \left[ \sigma^{(s-m)} \right]_{m=1}^n \right\} \times T_a \left( \sigma^{(0)} \right) \left[ \sigma^{(-m)} \right]_{m=1}^n \]

\[
= \sum_{\sigma^{(0)}-a} r_a \left( \sigma^{(0)} \right) T_a \left( \sigma^{(0)} \right) \left[ \sigma^{(-m)} \right]_{m=1}^n \]

\[
+ \gamma \sum_{\sigma^{(s)}} \sum_{k=0}^{\infty} \gamma^k r_a \left( \sigma^{(k+1)} \right) \left\{ \prod_{s=2}^{\infty} T \left( \sigma^{(s)} \right) \left[ \sigma^{(s-m)} \right]_{m=1}^n \right\} \times T_a \left( \sigma^{(1)} \right) \left[ \sigma^{(1-m)} \right]_{m=1}^n \]

\[
= \sum_{\sigma^{(0)}-a} r_a \left( \sigma^{(0)} \right) T_a \left( \sigma^{(0)} \right) \left[ \sigma^{(-m)} \right]_{m=1}^n \]

\[
+ \gamma \sum_{\sigma^{(1)}-a} Q_a \left( \sigma^{(1)} \right) T_a \left( \sigma^{(1)} \right) \left[ \sigma^{(1-m)} \right]_{m=1}^n \]  

(A.3)

which is Eq. (4).
Appendix B. Derivation of Eqs. (5) and (6)

We define $Q^*_a$ as the optimal value of $Q_a$, which is obtained by choosing optimal policy $T^*_a$. Then, $Q^*_a$ obeys

$$Q^*_a(\sigma_a, [\sigma^{(-m)}]_{m=1}^n) = \sum_{\sigma_a} r_a(\sigma) T_{-a}(\sigma_{-a}|[\sigma^{(-m)}]_{m=1}^n) + \gamma \sum_{\sigma_a} \sum_{\sigma_a} T^*_a(\sigma'|\sigma, [\sigma^{(-m)}]_{m=1}^{n-1}) T_{-a}(\sigma_{-a}|[\sigma^{(-m)}]_{m=1}^n) Q^*_a(\sigma', \sigma, [\sigma^{(-m)}]_{m=1}^{n-1}) \leq \sum_{\sigma_a} r_a(\sigma) T_{-a}(\sigma_{-a}|[\sigma^{(-m)}]_{m=1}^n) + \gamma \sum_{\sigma_a} \sum_{\sigma_a} T^*_a(\sigma'|\sigma, [\sigma^{(-m)}]_{m=1}^{n-1}) T_{-a}(\sigma_{-a}|[\sigma^{(-m)}]_{m=1}^n) \max_{\sigma} Q^*_a(\sigma, \sigma, [\sigma^{(-m)}]_{m=1}^{n-1})$$

The equality in the third line holds when

$$\text{supp} T^*_a(\cdot|[\sigma^{(-m)}]_{m=1}^n) = \arg \max_{\sigma} Q^*_a(\sigma, [\sigma^{(-m)}]_{m=1}^n), \quad \text{(B.1)}$$

which is Eq. (6).
