1. Introduction. The Borrvall–Petersson problem is the first model in literature for the topology optimization of fluid flow [12]. Given a restriction on the proportion of a design domain that a Stokes fluid can occupy, the problem attempts to find the optimal channels from the inlets to the outlets that minimize the power dissipation of the flow. No prior assumptions are required for the shape or topology of the solution resulting in a flexible optimization process [3, 10]. This flexibility comes at the cost of a nonconvex optimization problem with PDE, box, and inequality constraints that often supports multiple minimizers.

The topology of the solution is encoded in the material distribution, $\rho: \Omega \to [0, 1]$; a function that maps from the coordinates of the domain to the unit interval. Regions where $\{\rho = 1\} \subset \Omega$ are physically interpreted as the channels in which the fluid flows through. Whereas the regions $\{\rho = 0\} \subset \Omega$ are highly impermeable and thus there is negligible fluid flow in these areas. Intermediate values $\{0 < \rho < 1\} \subset \Omega$ are difficult to interpret. However, these regions are penalized in the Borrvall–Petersson model via an inverse permeability function $\alpha$.

Since Borrvall and Petersson’s seminal work, there have been numerous extensions. Evgrafov [23], Olesen et al. [43], and Gersborg-Hansen et al. [33] extended the model to fluids satisfying the steady-state Navier–Stokes flow. Kreissl et al. [39] and Deng et al. [19] were the first to consider unsteady Navier–Stokes flow and Deng et al. [18] later included body forces. Alonso et al. extended the model to rotating bodies in cylindrical coordinates [4, 5]. For a detailed review on the literature of the topology optimization of fluids, we refer to the work of Alexandersen and Andreasen [2].

Due to the nonlinear nature of the problem, analytical solutions are often difficult
to find. Hence, the problem is typically discretized with the finite element method and the minimizers are computed numerically. Until recently, the only known results for the convergence of any finite element method were found in the original paper by Borrvall and Petersson [12]. They showed that a conforming and inf-sup stable finite element discretization for the velocity-pressure pair together with a piece-wise constant discretization for the material distribution weakly(-\ast) converges to an unspecified minimizer of the problem. Recently this result was improved and extended by Papadopoulos and Süli [46] for conforming and inf-sup stable finite element discretizations for the velocity-pressure pair and conforming discretizations for the material distribution. They showed that for every isolated minimizer of the problem, there exists a sequence of finite element solutions, to the first-order optimality conditions, that strongly converges to the minimizer. Their analysis resolved a number of outstanding issues; namely the lack of checkerboarding in material distribution approximation as the mesh size tends to zero and whether every minimizer of the problem could be well approximated by a finite element method. The difficulty in the analysis is primarily due to the nonconvexity of problem. In order to account for the possibility of multiple minimizers, the authors fix an analytical minimizer and construct a modified optimization problem with the fixed analytical minimizer as its unique minimizer. Then, strong convergence of the finite element minimizers to the modified optimization problem is proven. The modified optimization problem is then related back to the original optimization problem by showing that a subsequence of the finite element minimizers also satisfy the first-order optimality conditions of the original optimization problem.

Both the analysis by Borrvall and Petersson [12] and Papadopoulos and Süli [46] heavily relied on the use of an $H^1$-conforming finite element discretization for the velocity. In the past couple of decades, discontinuous Galerkin (DG) methods for fluid flow have become increasingly popular [17, 16, 31, 37, 38]. This is in part due to the existence of divergence-free DG finite element methods. Some stable finite element methods for fluid flow, such as the Taylor–Hood finite element pair, only weakly satisfy the incompressibility constraint $\text{div}(u) = 0$. This manifests as a dependence of the error in the velocity on the best approximation error in the pressure. In some problems, only weakly satisfying the incompressibility constraint has been observed to support instabilities that result in nonphysical solutions [35, 40]. In divergence-free finite element methods, the incompressibility constraint is satisfied pointwise which is useful for ensuring pressure robustness [52] and deriving error bounds on the velocity that are independent of the error of the pressure.

In Borrvall–Petersson topology optimization problems, a natural mesh refinement to obtain sharper solutions is in regions where $0 < \rho < 1$ a.e. It can be empirically checked that mesh refinement in these regions does little to improve the error in the pressure. If the convergence for the velocity and material distribution rely heavily on the convergence of the pressure, then only doing mesh refinement in those areas caps the improvement in the errors for the velocity and material distribution. This motivates the need for discretizations that decouple the dependence of errors of the velocity and material distribution with the approximation error of the pressure. Divergence-free finite element discretizations also allow for an easier characterization of the kernel of the discretized grad-div term. This characterization has applications in preconditioners for systems arising in incompressible fluid flow [27, 28, 34, 51]. $H^1$-conforming divergence-free finite element methods exist, for example the Scott–Vogelius finite element [52]. To ensure inf-sup stability for a general mesh in a $k$-th order Scott–Vogelius finite element method, the polynomial order for the velocity
space must be \( k \geq 2d \) where \( d \in \{2, 3\} \) is the dimension of the problem [52, 55]. The expense of the high order method is normally justified by the accompanying high convergence rate. However, the material distribution \( \rho \) is often discretized with piecewise constant or continuous piecewise linear finite elements due to the box constraints on the material distribution. The box constraints not only cause algorithmic restrictions but also reduce the regularity of \( \rho \). The relatively low order approximation of the material distribution then caps the order of convergence of the velocity and pressure [46, Sec. 5.1] which negates the advantage of the high order method. Inf-sup stability can be achieved for \( k \geq d \) if the mesh is barycentrically refined [47]. This was successfully implemented for the double-pipe problem [45, Sec. 4.1], an example of the Borrvall–Petersson problem with a local and global minimizer. However, barycentrically refined meshes can be difficult to align with jumps in the analytical material distribution, which can lead to poorly resolved solutions. Moreover, barycentrically refined meshes complicate the generation of a mesh hierarchy for robust multigrid cycles [27]. In contrast, there exist low-order divergence-free DG finite element methods that are inf-sup stable on general meshes.

In this paper, we extend the results of Papadopoulos and S"uli [46] to divergence-free DG finite element methods. A standard interior penalty method is used to control the jumps across the facets. Our main result is to show that for every isolated minimizer of the Borrvall–Petersson optimization problem, there exists a sequence of DG finite element solutions to the discretized first-order optimality conditions that strongly converges in the appropriate norms to the minimizer. In particular, if \((u, \rho)\) is an isolated velocity-material distribution minimizer to the Borrvall–Petersson problem, and \( p \) is the associated pressure, then there exists a sequence of strongly converging finite element solutions \((u_h, p_h, \rho_h)\) such that \( \|u - u_h\|_{H^1_g(T_h)} \to 0 \), \( \|p - p_h\|_{L^2(\Omega)} \to 0 \), and \( \|\rho - \rho_h\|_{L^1(\Omega)} \to 0 \), \( s \in [1, \infty) \), where \( \| \cdot \|_{H^s_g(T_h)} \) is the broken \( H^s_g \)-norm as defined in (3.6). This analysis ensures that every isolated minimizer is well approximated by the divergence-free DG finite element method as the mesh size tends to zero. Our results may have implications for a number of finite volume schemes implemented in the topology optimization literature [20, 21, 32, 36, 41, 53, 54].

2. Topology optimization of Stokes flow. Given a volume constraint on a fluid in a fixed Lipschitz domain \( \Omega \subset \mathbb{R}^d \), \( d \in \{2, 3\} \), the Borrvall–Petersson model attempts to minimize the energy lost by the flow due to viscous dissipation, whilst maximizing the flow velocities at the applied body force. More precisely, the objective is to find \((u, \rho) \in H^1_{v, \text{div}}(\Omega)^d \times C_\gamma\) that minimizes

\[
J(u, \rho) := \frac{1}{2} \int_\Omega \left( \alpha(\rho)|u|^2 + \nu|\nabla u|^2 - 2f \cdot u \right) \, dx,
\]

where \( u : \Omega \to \mathbb{R}^d \) denotes the velocity of the fluid, \( \rho : \Omega \to [0, 1] \) is the material distribution of the fluid and

\[
H^1_{v, \text{div}}(\Omega)^d := \{ v \in H^1(\Omega)^d : v = g \text{ on } \partial \Omega \},
\]

\[
C_\gamma := \left\{ \eta \in L^\infty(\Omega) : 0 \leq \eta \leq 1 \text{ a.e.}, \int_\Omega \eta \, dx \leq \gamma |\Omega| \right\}.
\]

Here, \( H^1(\Omega) \) denotes the Sobolev space \( W^{1,2}(\Omega) \) and \( L^\infty(\Omega) \) denotes the vector space of essentially bounded measurable functions equipped with the essential supremum
norm. Furthermore, $f \in L^2(\Omega)^d$ is a body force, $\nu > 0$ is the (constant) viscosity, and $\gamma \in (0, 1)$ is the volume fraction. The equality $u = g$ on $\partial \Omega$ is to be understood in the boundary trace sense [22, Sec. 5.5]. Moreover, the boundary data $g \in H^{1/2}(\partial \Omega)^d$ and $g = 0$ on $\Gamma \subset \partial \Omega$, with $H^{d-1}(\Gamma) > 0$, i.e. $\Gamma$ has nonzero Hausdorff measure on the boundary. Borrvall and Petersson introduced the inverse permeability term, $\alpha$, which models the influence of the material distribution on the flow. For values of $\rho$ close to one, $\alpha(\rho)$ is small, permitting fluid flow; for values of $\rho$ close to zero, $\alpha(\rho)$ is very large, restricting fluid flow. The function $\alpha$ satisfies the following properties:

(A1) $\alpha : [0, 1] \to [\underline{\alpha}, \bar{\alpha}]$ with $0 \leq \underline{\alpha} < \alpha < \bar{\alpha} < \infty$;
(A2) $\alpha$ is strongly convex and monotonically decreasing;
(A3) $\alpha(0) = \bar{\alpha}$ and $\alpha(1) = \underline{\alpha}$;
(A4) $\alpha$ is twice continuously differentiable, generating an operator also denoted $\alpha : C_\gamma \to L^\infty(\Omega; [\underline{\alpha}, \bar{\alpha}])$.

Typically, in the literature $\alpha$ takes the form [12, 24]

$$\alpha(\rho) = \bar{\alpha}(1 - \rho) \quad (2.1)$$

where $q > 0$ is a penalty parameter, so that $\lim_{q \to \infty} \alpha(\rho) = \bar{\alpha}(1 - \rho)$. Borrvall and Petersson [12, Sec. 3.2] remark that as $q \to \infty$ the material distribution tends to a 0-1 solution.

The following existence theorem is due to Borrvall and Petersson [12, Th. 3.1].

**Theorem 2.1.** Suppose that $\Omega \subset \mathbb{R}^d$ is a Lipschitz domain, with $d \in \{2, 3\}$ and $\alpha$ satisfies properties (A1)–(A3). Then, there exists a pair $(u, \rho) \in H^1_{g, \text{div}}(\Omega)^d \times C_\gamma$ that minimizes $J$ (as defined in (BP)).

Although we are guaranteed the existence of the minimizer from Theorem 2.1, the lack of convexity in the functional $J$ means that (BP) can support multiple minimizers.

We define the following spaces as:

$$L^2_0(\Omega) := \left\{ q \in L^2(\Omega) : \int_\Omega q \, dx = 0 \right\},$$

$$H^1_0(\Omega)^d := \{ v \in H^1(\Omega)^d : v = 0 \text{ on } \partial \Omega \},$$

$$H(\text{div}; \Omega) := \{ v \in L^2(\Omega)^d : \text{div}(v) \in L^2(\Omega) \},$$

$$H_0(\text{div}; \Omega) := \{ v \in H(\text{div}; \Omega) : v \cdot n = 0 \text{ on } \partial \Omega \},$$

$$H_g(\text{div}; \Omega) := \{ v \in H(\text{div}; \Omega) : (v - g) \cdot n = 0 \text{ on } \partial \Omega \},$$

$$H_{g, \text{div}}(\Omega) := \{ v \in H_g(\text{div}; \Omega) : \text{div}(v) = 0 \text{ a.e. in } \Omega \}. $$

We note that $v \cdot n$ on $\partial \Omega$ is well-defined for all $v \in H(\text{div}; \Omega)$ [7, Th. 3.12]. Moreover, $H(\text{div}; \Omega)$ is a Hilbert space when equipped with the inner product

$$ (u, v)_{H(\text{div}; \Omega)} := \int_\Omega u \cdot v + \text{div}(u) \text{div}(v) \, dx. $$

We extend the definition of $J$ in (BP) to functions $v \notin H^1_g(\Omega)^d$ by

$$J(v, \eta) = +\infty \quad \text{for all } v \notin H^1_g(\Omega)^d, \eta \in C_\gamma. $$

We now define the following forms:

\begin{align}
(2.10) \quad a(u, v; \rho) &:= \int_\Omega \alpha(\rho) u \cdot v + v \nabla u : \nabla v \, dx, \quad l(v) := \int_\Omega f \cdot v \, dx, \\
(2.11) \quad c(\rho, \eta; u) &:= \frac{1}{2} \int_\Omega \alpha'(\rho) |u|^2 \eta \, dx, \\
(2.12) \quad b(u, p) &:= -\int_\Omega p \operatorname{div}(u) \, dx.
\end{align}

**DEFINITION 2.2 (Isolated minimizer).** Let \( Z \) be a Banach space and suppose that the function \( z_0 \in Z \) is a local or global minimizer of the functional \( J : Z \to \mathbb{R} \). Then \( z_0 \) is an isolated minimizer if there exists an open neighborhood \( E \) of \( z_0 \) such that there are no other minimizers contained in \( E \).

The proof of the following proposition on first-order optimality conditions for isolated minimizers of (BP) can be found in Papadopoulos and Suli [46, Prop. 2].

**PROPOSITION 2.3.** Suppose that \( \Omega \subset \mathbb{R}^d \) is a Lipschitz domain, with \( d \in \{2, 3\} \) and \( \alpha \) satisfies properties (A1)–(A4). By Theorem 2.1 there exists a local minimizer \( (u, \rho) \in H^1_{\text{div}}(\Omega)^d \times C_\gamma \). If the local minimizer is also an isolated local minimizer, then there exists a unique Lagrange multiplier \( p \in L^2_0(\Omega) \) such that the following necessary first-order optimality conditions hold:

\begin{align}
(FOC1) \quad a(u, v; \rho) + b(v, p) &= l(v) \quad \text{for all } v \in H^1_0(\Omega)^d, \\
(FOC2) \quad b(u, q) &= 0 \quad \text{for all } q \in L^2_0(\Omega), \\
(FOC3) \quad c(\rho, \eta; u) &\geq 0 \quad \text{for all } \eta \in C_\gamma.
\end{align}

3. Discretization. In this section we fix our choice of discretization. We denote the finite element spaces for the velocity, pressure, and material distribution by \( X_h \subset H(\text{div}; \Omega), \text{ and } M_h \subset L^2_0(\Omega) \) and \( C_{\gamma,h} \subset C_{\gamma} \), respectively. In the following we introduce the notation that is required to define the discretized optimization problem.

Let \( (T_h)_{h \in (0, 1]} \) denote a family of triangulations of the domain \( \Omega \subset \mathbb{R}^d \), \( d \in \{2, 3\} \), characterized by the mesh size \( h := \max_{K \in T_h} h_K \), where \( h_K \) is the diameter of the element \( K \in T_h \). We assume that \( (T_h)_{h \in (0, 1]} \) satisfies:

(M1) (Shape regularity). There exist constants \( c_1, c_2 > 0 \) such that

\[ c_1 h^d_K \leq |K| \leq c_2 h^d_K \quad \text{for all } K \in T_h. \]

Moreover, \( (T_h)_{h \in (0, 1]} \) satisfies a submesh condition as found in Buffa and Ortner [15, Assumption 2.1]. For a given \( h \), let the set \( \mathcal{F}_h \) denote the set of all facets of the triangulation \( T_h \) and \( h_F \) represent the diameter of each facet \( F \in \mathcal{F}_h \). We split the set of facets into the union \( \mathcal{F}_h = \mathcal{F}^i_h \cup \mathcal{F}^d_h \) where \( \mathcal{F}^i_h \) is the subset of interior facets and \( \mathcal{F}^d_h \) collects all Dirichlet boundary facets \( F \subset \partial \Omega \). We assume the following:

(M2) (Contact regularity). There exists a constant \( c_1 > 0 \) such that

\[ c_1 h^{d-1}_K \leq h^{d-1}(F) \quad \text{for all } F \in \mathcal{F}_h, K \in T_h \quad \text{such that } F \subset K; \]

(M3) (Boundary regularity). There exists a constant \( c_1 > 0 \) such that:

\[ c_1 h \leq h_F \quad \text{for all } F \in \mathcal{F}^d_h. \]
If \( F \in \mathcal{F}_h^1 \), then \( F = \partial K^+ \cap \partial K^- \) for two elements \( K^-, K^+ \in \mathcal{T}_h \). We write \( n_F^+ \) and \( n_F^- \) to denote the outward normal unit vectors to the boundaries \( \partial K^+ \) and \( \partial K^- \), respectively. If \( F \in \mathcal{F}_h^2 \), then \( n_F \) is the outer unit normal vector \( n \). We denote the space of discontinuous finite element functions with degree no higher than \( k \) by

\[
X_{DG,k} := \{ v \in L^1(\Omega) : v|_K \in \mathcal{P}_k \text{ for all } K \in \mathcal{T}_h \},
\]

where \( \mathcal{P}_k \) denotes the set of polynomials of order no higher than \( k \). Let \( \phi \in (X_{DG,k})^d \) and \( \Phi \in (X_{DG,k})^{d \times d} \) be any piecewise vector or matrix-valued function, respectively with traces from within the interior of \( K^\pm \), denoted by \( \phi^\pm \) and \( \Phi^\pm \), respectively. We define the jump \( [\cdot] \) and the average \( \langle \cdot \rangle \) operators across interior facets \( F \in \mathcal{F}_h^2 \) by

\[
[\phi]_F := \phi^+ \otimes n_F^+ - \phi^- \otimes n_F^- \quad \text{and} \quad \langle \Phi \rangle_F = \frac{1}{2} (\Phi^+ + \Phi^-).
\]

If \( F \in \mathcal{F}_h^2 \), we set \( [\phi]_F = \phi \otimes n_F \) and \( \langle \Phi \rangle_F = \Phi \). We note that, for any \( F \in \mathcal{F}_h^2 \),

\[
\int_F [\phi]_F^2 \, ds = \int_F |\phi|^2 \, ds.
\]

A function, \( v \in X_{DG,k} \), only has a well-defined weak derivative on each element on the mesh. Hence, we define the broken Sobolev space \( H^1(\mathcal{T}_h) \) as:

\[
H^1(\mathcal{T}_h) := \{ v \in L^1(\Omega) : v \in H^1(K) \text{ for all } K \in \mathcal{T}_h \}.
\]

Moreover, for a function \( \mathbf{v} \in H^1(\mathcal{T}_h)^d \), we define the broken \( H^1 \)-seminorm and norms as:

\[
|\mathbf{v}|^2_{H^1(\mathcal{T}_h)} := \sum_{K \in \mathcal{T}_h} \| \nabla v \|^2_{L^2(K)} + \sum_{F \in \mathcal{F}_h^2} h_F^{-1} |[\mathbf{v}]_F|^2 \, ds,
\]

\[
\| \mathbf{v} \|^2_{H^1(\mathcal{T}_h)} := \| \mathbf{v} \|^2_{L^2(\Omega)} + |\mathbf{v}|^2_{H^1(\mathcal{T}_h)},
\]

\[
\| \mathbf{v} \|^2_{H^1(\mathcal{T}_h)} := \| \mathbf{v} \|^2_{L^2(\Omega)} + \sum_{F \in \mathcal{F}_h^2} h_F^{-1} |[\mathbf{v} - \mathbf{g}]_F|^2 \, ds.
\]

The two families of DG finite elements of interest for the velocity are the Brezzi–Douglas–Marini (BDM) finite element [13, 14] and the Raviart–Thomas (RT) finite element [49, 14]. The \( k \)-th order BDM finite element is defined for \( d = 2 \) in [14, Sec. 2] and for \( d = 3 \) in [13, Sec. 2]. Similarly the \( k \)-th order RT finite element is defined in [49, Sec. 3] and [42, Sec. 2] for \( d = 2 \) and \( d = 3 \), respectively. The finite element spaces induced by the \( k \)-th order BDM and RT finite elements are denoted by \( X_{\text{BDM}_k} \) and \( X_{\text{RT}_k} \), respectively. We note that \( X_{\text{RT}_k} \subset X_{\text{BDM}_k} \subset Z_h \) where, for a given \( k \geq 1 \),

\[
Z_h := \{ \mathbf{v} \in (X_{DG,k})^d : \text{div}(\mathbf{v}) \in X_{DG,k-1} \cap L^2(\Omega) \}.
\]

We note that \( Z_h \subset H(\text{div}; \Omega) \) and \( Z_h \subset H^1(\mathcal{T}_h)^d \).

We define the following subspaces of \( X_h \):

\[
X_{h,0} := \{ \mathbf{v} \in X_h : \mathbf{v} \cdot \mathbf{n} = 0 \text{ on } \partial \Omega \},
\]

\[
X_{h,g} := \{ \mathbf{v} \in X_h : (\mathbf{v} - g) \cdot \mathbf{n} = 0 \text{ on } \partial \Omega \}.
\]

In general the boundary data \( g \) cannot be represented in the finite element space. Hence we instead approximate the boundary data with a finite element function \( g_h \) (which can be represented) and assume that

\[
(F1) \quad h^{-1}\|g - g_h\|_{L^2(\partial \Omega)} \to 0 \text{ as } h \to 0.
\]
We also assume that:

(F2) \( X_{h,0} \) and \( M_h \) satisfy the following inf-sup condition for some \( c_h > 0 \),

\[
\tag{3.10} \inf_{q_h \in M_h \setminus \{0\}} \sup_{v_h \in X_{h,0} \setminus \{0\}} \frac{b(v_h, q_h)}{\|v_h\|_{H^1(\Omega)} \|q_h\|_{L^2(\Omega)}}.
\]

(F3) The finite element spaces are dense in their respective function spaces, i.e., for any \( (v, \eta, q) \in H^1(\Gamma_h)^d \times C_{\gamma} \times L^2(\Omega) \),

\[
\lim_{h \to 0} \inf_{w_h \in X_h} \|v - w_h\|_{H^1(\Gamma_h)} = \lim_{h \to 0} \inf_{\zeta_h \in C_{\gamma,h}} \|\eta - \zeta_h\|_{L^2(\Omega)}
= \lim_{h \to 0} \inf_{r_h \in M_h} \|q - r_h\|_{L^2(\Omega)} = 0.
\]

**Remark 3.1.** The inf-sup (F2) and density (F3) conditions are satisfied by either \( X_h = X_{BDM_k} \) or \( X_h = X_{RT_k} \) with the choice of the pressure finite element space \( M_h = X_{DG_{k-1}} \) [16].

We now define the discrete Borrvall–Petersson power dissipation functional for a DG finite element discretization. Consider the functions \( u_h \in X_h \subset Z_h \) and \( \rho_h \in C_{\gamma,h} \). We note that, in general, \( J(u_h, \rho_h) \) is ill-defined as \( \nabla u_h \) is not defined on all of \( \Omega \). Hence, given a penalization parameter \( \sigma > 0 \), we define the discrete analogue \( J_h \) as

\[
J_h(u_h, \rho_h) := \frac{1}{2} \int_{\Omega} (\alpha(\rho_h)|u_h|^2 - 2f \cdot u_h) \, dx + \frac{\nu}{2} \sum_{K \in T_h} \int_K |\nabla u_h|^2 \, dx
+ \frac{1}{2} \sum_{F \in \mathcal{F}_h} \sigma h_F^{-1} \int_F \|u_h\|_F^2 \, ds - \sum_{F \in \mathcal{F}_h} \int_F \nabla u_h : [u_h]_F \, ds
+ \frac{1}{2} \sum_{F \in \mathcal{F}_h^{\partial}} \sigma h_F^{-1} \int_F \|u_h - g_h\|_F^2 \, ds
- \sum_{F \in \mathcal{F}_h^{\partial}} \int_F \nabla u_h : [u_h - g_h]_F \, ds.
\]

**Remark 3.2.** This particular choice \( J_h \) as the discrete analogue of \( J \) is motivated by an interior penalty approach for DG formulations. In Proposition 4.5 we prove that velocity minimizers of \( J_h \) are well-defined and there can be no jumps in \( v \) across elements. Hence, for all \( F \in \mathcal{F}_h \), integrals involving \( \|v\|_F \) are equal to zero. Moreover \( v = g \) on \( \partial \Omega \) and, therefore, \( \int_F \|v - g\|_F^2 \, ds = 0 \) for all \( F \in \mathcal{F}_h^{\partial} \).

**Proposition 3.4 (Consistency of \( J_h \)).** Consider any \( (v, \eta) \in H^1_b(\Omega)^d \times C_{\gamma} \) such that \( v \in H^r(\Omega)^d \) for some \( r > 3/2 \). Then, \( J_h, h > 0 \) is consistent, i.e.

\[
\tag{3.12} J_h(v, \eta) = J(v, \eta).
\]

**Proof.** Since \( v \in H^r(\Omega)^d \), for \( r > 3/2 \), we note that \( J_h(v, \eta) \) is well-defined and there can be no jumps in \( v \) across elements. Hence, for all \( F \in \mathcal{F}_h \), integrals involving \( \|v\|_F \) are equal to zero. Moreover \( v = g \) on \( \partial \Omega \) and, therefore, \( \int_F \|v - g\|_F^2 \, ds = 0 \) for all \( F \in \mathcal{F}_h^{\partial} \). Hence, \n
\[
\tag{3.13} J_h(v, \eta) = \frac{1}{2} \int_{\Omega} (\alpha(\eta)|v|^2 - 2f \cdot v) \, dx + \frac{\nu}{2} \sum_{K \in T_h} \int_K |\nabla v|^2 \, dx = J(v, \eta).
\]
For a sufficiently large penalization parameter $\sigma > 0$, we define the broken form $a_h(u, v; \rho)$ by

$$a_h(u, v; \rho) := \sum_{K \in T_h} \int_K \alpha(\rho) u \cdot v + \nabla u : \nabla v \, dx + \sum_{F \in F_h} \sigma h_F^{-1} \int_{F} \|u\|_F : \|v\|_F \, ds$$

$$- \sum_{F \in F_h} \int_F \|\nabla u\|_F : \|v\|_F \, ds - \sum_{F \in F_h} \int_F [u]_F : \|\nabla v\|_F \, ds,$$

and the linear functional $l_h(v; g)$ as

$$l_h(v; g) := \int_{\Omega} f \cdot v \, dx$$

$$+ \sum_{F \in F_h} \sigma h_F^{-1} \int_{F} \|g\|_F : \|v\|_F \, ds - \sum_{F \in F_h} \int_{F} [g]_F : \|\nabla v\|_F \, ds.$$

**Proposition 3.5** (Consistency of $a_h$). Suppose that $(u, \rho) \in H^1_{0, \text{div}}(\Omega)^d \times C_\rho$ is an isolated local minimizer of (BP) and let $p \in L^2(\Omega)$ denote the Lagrange multiplier such that $(u, \rho, p)$ satisfy (FOC1)–(FOC3). Moreover, assume that $u \in H^r(\Omega)^d$ for some $r > 3/2$. Then, for all $v_h \in H^1(\Omega)^d \cap H_0(\text{div}; \Omega)$, we have that

$$a_h(u, v_h; \rho) + b(v_h, p) = l_h(v_h; g).$$

*Proof.* By (FOC1), we have that, for all $w_h \in H^1_0(\Omega)^d$,

$$a(u, w_h; \rho) + b(w_h, p) = l(w_h).$$

Since, by assumption, $f \in L^2(\Omega)^d$, then, by an integration by parts, we see that

$$\alpha(\rho) u - \nu \Delta u + \nabla p = f \quad \text{a.e. in } \Omega.$$

Therefore, as the set of smooth functions is dense in $L^2(\Omega)$, we can test (3.18) against any $v_h \in H^1(\Omega)^d \cap H_0(\text{div}; \Omega) \subset L^2(\Omega)^d$. Thus, by performing a second integration by parts, we have that

$$\sum_{K \in T_h} \int_K \alpha(\rho) u \cdot v_h + \nu \nabla u : \nabla v_h - p \text{div}(v_h) \, dx$$

$$- \sum_{F \in F_h} \int_F \|\nabla u\|_F : \|v_h\|_F \, ds = \int_{\Omega} f \cdot v_h \, dx.$$

The element-wise surface integrals arising by the integration by parts of the $\nabla p$ term drop out due to the continuity of $v_h \cdot n$ across elements for all $v_h \in H_0(\text{div}; \Omega)$. Similarly the boundary surface integrals drop out since $v_h \cdot n = 0$ on $\partial \Omega$. As $u \in H^1_{0, \text{div}}(\Omega)^d$, for all $F \in F_h$, we have that $[u]_F = 0$ and for all $F \in F_h$, $[u]_F = [g]_F$. As $u \in H^r(\Omega)^d$ for some $r > 3/2$ the traces of $\nabla u$ on $F \in F_h$ are well-defined. We conclude that (3.16) holds. \(\square\)

**Proposition 3.6** (Coercivity and boundedness of $a_h$). There exists a $\sigma_0 > 0$, such that for all $\sigma \geq \sigma_0$, $w_h, u_h \in X_h$ and $\eta \in C_\rho$, there exists constants $c_a, C_a > 0$ such that

$$c_a \|w_h\|_{H^1(\Omega)}^2 \leq a_h(w_h, w_h; \eta),$$

$$a_h(w_h, u_h; \eta) \leq C_a \|w_h\|_{H^1(\Omega)} \|u_h\|_{H^1(\Omega)}.$$
Hence, there exists a \( v \in U \) such approximations of the velocity and material distribution (\( U \) is a polygonal domain in two dimensions or a polyhedral Lipschitz domain in three dimensions, \( H \) velocity finite element space was finite element approximation of the velocity and the pressure. In particular their Borrvall and Petersson [12, Sec. 3.3] considered a piecewise constant finite element \( X \) of sequences in \( U \) that minimize \( \| \text{div}(v_h) \|_{L^2(\Omega)}^2 = 0 \), which implies that \( \text{div}(v_h) = 0 \) a.e. in \( \Omega \).

Proof. We note that, by assumption (A1), \( 0 \leq \alpha(\eta) \leq \bar{\alpha} \) for all \( \eta \in C_\gamma \). Hence, the result follows from classical coercivity and boundedness results for DG discretizations for interior penalty methods [8, Sec. 4.1–4.2].

**Definition 3.7.** We define the spaces \( U_{h,g_h} \) and \( U_{h,0} \) as:

\[
U_{h,g_h} := \{ u \in X_{h,g_h} : b(u_h, q_h) = 0 \text{ for all } q_h \in X_{DG_{k-1}} \}
\]

\[
U_{h,0} := \{ u \in X_{h,0} : b(u_h, q_h) = 0 \text{ for all } q_h \in X_{DG_{k-1}} \}.
\]

In the following lemma we provide the proof that functions \( v_h \in U_{h,0} \) and \( v_h \in U_{g_h,0} \) are pointwise divergence-free.

**Lemma 3.8 (Pointwise divergence-free).** Suppose that \( X_h \subset Z_h \). Consider a function \( v_h \in U_{h,0} \) or \( v_h \in U_{h,g_h} \). Then, \( \text{div}(v_h) = 0 \) a.e. in \( \Omega \).

Proof. Since \( U_{h,0} \subset X_h \subset Z_h \) then, by definition, \( \text{div}(v_h) \in X_{DG_{k-1}} \). Hence, there exists a \( q_h \in X_{DG_{k-1}} \) such that \( q_h = \text{div}(v_h) \). Therefore,

\[
b(v_h, q_h) = \| \text{div}(v_h) \|_{L^2(\Omega)}^2 = 0,
\]

which implies that \( \text{div}(v_h) = 0 \) a.e. in \( \Omega \).

To prove the convergence of a DG finite element method, we require the existence of sequences in \( U_{h,g_h} \) that converge strongly to \( u \).

**Lemma 3.9 (Strongly converging sequences).** Suppose that (F1)–(F3) hold and \( X_h \subset Z_h \). Consider any isolated minimizer \( (u, \rho) \in H^1(\div; \Omega)^d \times C_\gamma \) of (BP). Then, there exists a sequence of functions \( (\tilde{u}_h, \tilde{p}_h) \in U_{g_h,h} \times M_h \) such that \( \| u - \tilde{u}_h \|_{H^1(\Omega)} \to 0 \) and \( \| p - \tilde{p}_h \|_{L^2(\Omega)} \to 0 \).

Proof. For sufficient large \( \sigma \geq 0 \) and fixed \( \rho \in C_\gamma \), consider the problem, find \( (\tilde{u}_h, \tilde{p}_h) \in U_{g_h,h} \times M_h \) that satisfies

\[
a_h(\tilde{u}_h, v_h ; \rho) + b(v_h, \tilde{p}_h) = l_h(v_h) \quad \text{for all } v_h \in X_{h,0},
\]

\[
b(\tilde{u}_h, q_h) = 0 \quad \text{for all } q_h \in M_h.
\]

Then, under assumptions (F1)–(F3), by standard results for \( H(\div; \Omega) \) finite element discretizations of the Stokes and Stokes–Brinkman equations with an interior penalty [17, 37, 38], the pair \( (\tilde{u}_h, \tilde{p}_h) \) exists, is unique, and \( \| u - \tilde{u}_h \|_{H^1(\Omega)} \to 0 \), \( \| p - \tilde{p}_h \|_{L^2(\Omega)} \to 0 \) as \( h \to 0 \).

4. Convergence of a DG finite element method. In their original paper Borrvall and Petersson [12, Sec. 3.3] considered a piecewise constant finite element approximation of the material distribution coupled with an inf-sup stable quadrilateral finite element approximation of the velocity and the pressure. In particular their velocity finite element space was \( H^1 \)-conforming. They showed that if the domain \( \Omega \) is a polygonal domain in two dimensions or a polyhedral Lipschitz domain in three dimensions, such approximations of the velocity and material distribution \( (u_h, \rho_h) \) that minimize \( J(u_h, \rho_h) \) converge to an unspecified solution \( (u, \rho) \) of (BP) in the following sense [12, Th. 3.2]:

\[
u_h \rightharpoonup u \text{ weakly in } H^1(\Omega)^d,
\]

\[
\rho_h \rightharpoonup^\ast \rho \text{ weakly-* in } L^\infty(\Omega),
\]

\[
\rho_h \rightarrow \rho \text{ strongly in } L^s(\Omega), \quad s \in [1, \infty),
\]
where $\Omega_h$ is any measurable subset of $\Omega$ where $\rho$ is equal to zero or one a.e. Their analysis suggests that a finite element method is a suitable discretization, but it left a number of open problems:

(P1) It is not clear which minimizer the sequence is converging to as the nonconvexity of the problem provides multiple candidates for the limits;

(P2) The convergence is weak-* in the material distribution in regions where $\{0 < \rho < 1\} \subset \Omega$ which permits the presence of checkerboard patterns as $h \to 0$;

(P3) There are no convergence results for the finite element approximation of the pressure, $p$.

In general (P1) means that their result does not imply that there exists a sequence of finite element solutions that converges to the global minimizer.

Recently Borrvall and Petersson’s result was extended and refined by Papadopoulos and Süli [46, Th. 4]. They considered conforming discretizations of the material distribution and conforming inf-sup stable finite element discretizations for the velocity-pressure pair. Once again, the velocity finite element space $X_h$ was assumed to be $H^1$-conforming. They showed that, for any isolated minimizer $(u, \rho)$ of (BP), there exists a sequence of solutions $(u_h, \rho_h, p_h) \in X_{h,g_h} \times C_{\gamma,h} \times M_h$ satisfying the discretized first-order optimality conditions, for all $(v_h, \eta_h, q_h) \in X_{h,0} \times C_{\gamma,h} \times M_h$:

(4.1) \[ a(u_h, v_h; \rho_h) + b(v_h, \rho_h) = l(v_h), \]
(4.2) \[ b(u_h, q_h) = 0, \]
(4.3) \[ c(\rho_h, \eta_h - \rho_h; u_h) \geq 0, \]

such that

$u_h \to u$ strongly in $H^1(\Omega)^d$, 
$\rho_h \to \rho$ strongly in $L^s(\Omega)$, $s \in [1, \infty)$, 
$p_h \to p$ strongly in $L^2(\Omega)$.

Their analysis resolved the open issues (P1)–(P3). The assumption that $X_{h,g_h} \subset H^1(\Omega)^d$ was crucial for the compactness results utilized in their proof.

Our goal in this section is to prove a similar result for when $X_{h,g_h} \not\subset H^1(\Omega)^d$ but $X_{h,g_h} \subset Z_h \subset H(\text{div}; \Omega)$. The following theorem is the main result of this work.

**Theorem 4.1 (Convergence of the DG finite element method).** Let $\Omega \subset \mathbb{R}^d$ be a polygonal domain in two dimensions or a polyhedral Lipschitz domain in three dimensions. Suppose that the inverse permeability $\alpha$ satisfies (A1)–(A4) and there exists an isolated local minimizer $(u, \rho) \in H_{g,\text{div}}^1(\Omega)^d \times C_{\gamma}$ of (BP) that has the additional regularity $u \in H^r(\Omega)^d$ for some $r > 3/2$. Moreover, assume that, for $\theta > 0$, $U_\theta$ is the subset of $\Omega$ where $|u|^2 \geq \theta$ a.e. in $U_\theta$ and suppose that there exists a $\theta'$ such that $U_\theta$ is closed and has non-empty interior for all $\theta \leq \theta'$. Let $p$ denote the unique Lagrange multiplier associated with $(u, \rho)$ such that $(u, \rho, p)$ satisfy the first-order optimality conditions (FOC1)–(FOC3).

Consider the finite element spaces $X_h \subset Z_h$, $C_{\gamma,h} \subset C_{\gamma}$, and $M_h \subset L_0^2(\Omega)$ and suppose that the assumptions (F1)–(F3) hold.

Then, there exists an $\bar{h} > 0$ such that, for $h \leq \bar{h}$, $h \to 0$, there is a sequence of solutions $(u_h, \rho_h, p_h) \in X_{h,g_h} \times C_{\gamma,h} \times M_h$ to the following discretized first-order
where

(FOC1-h) \quad a_h(u_h, v_h; \rho_h) + b(v_h, p_h) = l_h(v_h; g_h) \quad \text{for all } v_h \in X_{h,0},
(FOC2-h) \quad b(u_h, q_h) = 0 \quad \text{for all } q_h \in M_h,
(FOC3-h) \quad c(\rho_h, \eta_h - \rho_h; u_h) \geq 0 \quad \text{for all } \eta_h \in C_{\gamma,h},

such that, \( \|u - u_h\|_{H^1_g(T_h)} \to 0 \), \( p_h \to p \) strongly in \( L^s(\Omega) \), \( s \in [1, \infty) \), and \( p_h \to p \)

strongly in \( L^2(\Omega) \) as \( h \to 0 \).

We now fix an isolated local minimizer \((u, \rho) \in H^1_g(\Omega)^d \times C_{\gamma} \) of \((BP)\). We also

fix an \( r > 0 \) such that \((u, \rho)\) is the unique local minimizer of \((BP)\) in

\[ B_r, H(\text{div}; \Omega) \times L^2(\Omega) \](u, \rho) \cap (H^g, \text{div}(\Omega) \times C_{\gamma}), \]

where

\[
(4.4) \quad B_r, H(\text{div}; \Omega) \times L^2(\Omega) (u, \rho) := \{v \in H(\text{div}; \Omega), \eta \in C_{\gamma} : \|u - v\|_{H(\text{div}; \Omega)} + \|\rho - \eta\|_{L^2(\Omega)} \leq r \}.
\]

Such an \( r \) is guaranteed to exist by the definition of an isolated minimizer and the

extension of \( J \) in (2.9) to functions \( v \in H^g, \text{div}(\Omega) \) such that \( v \notin H^1_g(\Omega)^d \). We also define

\[ B_r, H(\text{div}; \Omega)(u) \quad \text{and} \quad B_r, L^2(\Omega)(\rho) \]

by

\[
(4.5) \quad B_r, H(\text{div}; \Omega)(u) := \{v \in H(\text{div}; \Omega) : \|u - v\|_{H(\text{div}; \Omega)} \leq r \},
(4.6) \quad B_r, L^2(\Omega)(\rho) := \{\eta \in C_{\gamma} : \|\rho - \eta\|_{L^2(\Omega)} \leq r \}.
\]

We note that

\[ (H^g, \text{div}(\Omega) \cap B_r/2, H(\text{div}; \Omega)(u)) \times (C_{\gamma} \cap B_r/2, L^2(\Omega)(\rho)) \]

and hence \((u, \rho)\) is also the unique minimizer in \((H^g, \text{div}(\Omega) \cap B_r/2, H(\text{div}; \Omega)(u)) \times

\(C_{\gamma} \cap B_r/2, L^2(\Omega)(\rho))\).

**Proposition 4.2** (Weak convergence of \((u_h, \rho_h)\) in \( H(\text{div}; \Omega) \times L^2(\Omega) \)). Suppose

that the conditions of Theorem 4.1 hold. Fix an isolated minimizer \((u, \rho)\) of \((BP)\). For

a given \( h > 0 \), consider the finite-dimensional optimization problem: find \((u_h, \rho_h) \in

\(U_h, g_h \cap B_r/2, H(\text{div}; \Omega)(u)) \times (C_{\gamma,h} \cap B_r/2, L^2(\Omega)(\rho))\) that minimizes

\((BP-h)\)

\[ J_h(u_h, \rho_h). \]

Then, a global minimizer \((u_h, \rho_h)\) of \((BP-h)\) exists and there exist subsequences (up
to relabeling) such that as \( h \to 0 \):

\[
(4.7) \quad u_h \rightharpoonup u \text{ weakly in } H(\text{div}; \Omega),
(4.8) \quad u_h \rightharpoonup u \text{ strongly in } L^q(\Omega)^d,
(4.9) \quad u_h \rightharpoonup u \text{ strongly in } L^r(\partial \Omega)^d,
(4.10) \quad \rho_h \rightharpoonup^* \rho \text{ weakly-* in } L^\infty(\Omega),
(4.11) \quad \rho_h \rightharpoonup^* \rho \text{ weakly in } L^s(\Omega), \ s \in [1, \infty),
\]

where \( 1 \leq q, r < \infty \) in two dimensions and \( 1 \leq q < 6, 1 \leq r < 4 \) in three dimensions.

**Proof.** The functional \( J_h \) is continuous and

\[
(4.12) \quad (U_h, g_h \cap B_r/2, H(\text{div}; \Omega)(u)) \times (C_{\gamma,h} \cap B_r/2, L^2(\Omega)(\rho)) \]
is a finite-dimensional, closed and bounded set and, therefore, sequentially compact by the Heine–Borel theorem [29, Th. 11.18]. Hence, \( J_h \) obtains its infimum in \( (U_{g_{h,h}} \cap B_{r/2,H}^{(\text{div};\Omega)}(u)) \times (C_{\gamma,h} \cap B_{r/2,L^2(\Omega)}(\rho)) \) and, therefore, a global minimizer \( (u_h,\rho_h) \) exists for all \( h > 0 \).

By a corollary of Kakutani’s Theorem [30, Th. A.65], if a Banach space is reflexive then every norm-closed, bounded and convex subset of the Banach space is weakly sequentially compact. It can be checked that \( H^{(\text{div};\Omega)} \) is weakly sequentially compact. Hence, \( H^{(\text{div};\Omega)} \cap B_{r/2,H}^{(\text{div};\Omega)}(u) \) is norm-closed, bounded and convex subsets of the reflexive Banach spaces \( H^{(\text{div};\Omega)} \) and \( L^2(\Omega) \), respectively. Therefore, \( H^{(\text{div};\Omega)} \cap B_{r/2,H}^{(\text{div};\Omega)}(u) \) is weakly sequentially compact in \( H^{(\text{div};\Omega)} \) and \( C_{\gamma} \cap B_{r/2,L^2(\Omega)}(\rho) \) is weakly sequentially compact in \( L^2(\Omega) \).

Hence we extract subsequences (up to relabeling), \( (u_h) \) and \( (\rho_h) \) of the sequence generated by the global minimizers of \((\text{BP-}h)\) such that

\[
\begin{align*}
(4.13) & \quad u_h \rightharpoonup \hat{u} \in H^{(\text{div};\Omega)} \cap B_{r/2,H}^{(\text{div};\Omega)}(u) \text{ weakly in } H^{(\text{div};\Omega)}, \\
(4.14) & \quad \rho_h \rightharpoonup \hat{\rho} \in C_{\gamma} \cap B_{r/2,L^2(\Omega)}(\rho) \text{ weakly in } L^2(\Omega).
\end{align*}
\]

By assumption (F3), there exists a sequence of finite element functions \( \tilde{\rho}_h \in C_{\gamma,h} \) that strongly converges to \( \rho \) in \( L^2(\Omega) \). Moreover, Lemma 3.9 implies the existence of a sequence \( (\tilde{u}_h) \in U_{g_{h,h}} \) that satisfies \( \| u - \tilde{u}_h \|_{H^2(T_h)} \to 0 \).

We now wish to identify the limits \( \hat{u} \) and \( \hat{\rho} \). Consider the following bound:

\[
2|J_h(\tilde{u}_h,\tilde{\rho}_h) - J(u,\rho)| \\
\leq \int_{\Omega} |(\alpha(\rho) - \alpha(\tilde{\rho}_h))|u|^2| + |\alpha(\tilde{\rho}_h)(|u|^2 - |\tilde{u}_h|^2)| + 2|f \cdot (u - \tilde{u}_h)| \, dx \\
+ \nu \sum_{K \in T_h} \int_K \| \nabla u^2 - |\nabla \tilde{u}_h|^2 \| \, dx \\
+ \sum_{F \in F_h} \int_F \sigma h_{F}^{-1} \| [\tilde{u}_h]_{F} \|^2 \, ds + \sum_{F \in F_h} \int_F \sigma h_{F}^{-1} \| [\tilde{u}_h - g_h]_{F} \|^2 \, ds \\
+ 2 \sum_{F \in F_h} \int_F \| [\nabla \tilde{u}_h]_{F} : [\tilde{u}_h]_{F} \| \, ds \\
+ 2 \sum_{F \in F_h} \int_F \| [\nabla \tilde{u}_h]_{F} : [\tilde{u}_h - g_h]_{F} \| \, ds.
\]

For all \( v \in H^1(T_h)^d \), \( \Phi \in (X_{\text{DG}_h})^{d \times d}, \) \( h > 0 \), we have that [15, Lem. 7]

\[
\sum_{F \in F_h} \int_F \| \Phi \|_{F} \cdot \| v \|_{F} \, ds \\
\leq C \left( \sum_{F \in F_h} \int_F h_{F}^{-1} \| v \|_{F}^2 \, ds \right)^{1/2} \left( \sum_{K \in T_h} \| \Phi \|_{L^2(K)}^2 \right)^{1/2},
\]
for a constant $C$ that only depends on the mesh quality. Hence, we see that

$$
2|J_h(\tilde{u}_h, \tilde{\rho}_h) - J(u, \rho)| \\
\leq L_\alpha ||u||_{L^2(\Omega)}^2 ||\tilde{\rho}_h - \rho||_{L^2(\Omega)} + 2||f||_{L^2(\Omega)} ||\tilde{u}_h - u||_{L^2(\Omega)} \\
+ \alpha ||\tilde{u}_h - u||_{L^2(\Omega)} + ||\tilde{u}_h - u||_{L^2(\Omega)} + 2||u||_{L^2(\Omega)} \\
+ \nu \sum_{K \in T_h} ||\nabla \tilde{u}_h - \nabla u||_{L^2(K)} ||\nabla \tilde{u}_h - \nabla u||_{L^2(K)} + 2||\nabla u||_{L^2(K)} \\
+ \sum_{F \in F_h^I} \int_F \sigma h_F^{-1} ||\tilde{u}_h||_{F}^2 \, ds + \sum_{F \in F_h^I} \int_F \sigma h_F^{-1} ||\tilde{u}_h - g_h||_{F}^2 \, ds \\
+ C \left( \sum_{F \in F_h^I} \int_F h_F^{-1} ||\tilde{u}_h||_{F}^2 \, ds \right)^{1/2} \left( \sum_{K \in T_h} ||\nabla \tilde{u}_h||_{L^2(K)}^2 \right)^{1/2} \\
+ C \left( \sum_{F \in F_h^I} \int_F h_F^{-1} ||\tilde{u}_h - g_h||_{F}^2 \, ds \right)^{1/2} \left( \sum_{K \in T_h} ||\nabla \tilde{u}_h||_{L^2(K)}^2 \right)^{1/2}.
$$

(4.17)

where $L_\alpha$ denotes the Lipschitz constant for $\alpha$. Thanks to the strong convergence of $\tilde{u}_h$ in the broken $H^1_g$ norm to $u$ and by assumption (F1), from (4.17) we deduce that

$$
J_h(\tilde{u}_h, \tilde{\rho}_h) \to J(u, \rho) \quad \text{as} \quad h \to 0.
$$

Furthermore, for sufficiently small $h > 0$ we note that

$$
(\tilde{u}_h, \tilde{\rho}_h) \in (U_{g_h,h} \cap B_{r/2, H(\text{div}; \Omega)}(u)) \times (C_{T_h} \cap B_{r/2, L^2(\Omega)}(\rho)).
$$

Therefore, since $(u_h, \rho_h)$ is a global minimizer of (BP-h) in $B_{r/2, H(\text{div}; \Omega)}(u) \times (C_{T_h} \cap B_{r/2, L^2(\Omega)}(\rho))$,

$$
J_h(u_h, \rho_h) \leq J_h(\tilde{u}_h, \tilde{\rho}_h).
$$

(4.18)

By taking the limit as $h \to 0$ and utilizing the strong convergence of $\tilde{u}_h$ and $\tilde{\rho}_h$ to $u$ and $\rho$, respectively, we see that

$$
\lim_{h \to 0} J_h(u_h, \rho_h) \leq J(u, \rho).
$$

(4.19)

By construction $\tilde{\rho} \in C_{T_h} \cap B_{r/2, L^2(\Omega)}(\rho)$. By assumption (F3), for every $q \in L^2_0(\Omega)$, there exists a sequence of $\tilde{q}_h \in M_h$ such that $\tilde{q}_h \to q$ strongly in $L^2(\Omega)$. Since $u_h \rightharpoonup \tilde{u}$ weakly in $H(\text{div}; \Omega)$ and $u_h \in U_{g_h,h}$, we see that

$$
b(\tilde{u}, q) = \lim_{h \to 0} b(u_h, \tilde{q}_h) + \lim_{h \to 0} b(u_h, q - \tilde{q}_h) = 0 \quad \text{for all} \quad q \in L^2_0(\Omega).
$$

(4.20)

Hence, $\tilde{u}$ is pointwise divergence-free. The final step to identify $\tilde{u}$ as $u$ is to show that $\tilde{u} \in H^1_g(\Omega)^d$. Now, the sequence $(u_h)$ also defines a bounded sequence in $H^1(T_h)^d$ such that

$$
\sup_{h > 0} \|u_h\|_{L^1(\Omega)} + \|u_h\|_{H^1(T_h)} < +\infty.
$$

Hence, by the compact embedding lemma, as found in Buffa and Ortner [15, Lem. 8], there exists a subsequence (up to relabeling) and a limit $\tilde{w} \in H^1(\Omega)^d$ such that

$$
u \to \tilde{w} \quad \text{strongly in} \quad L^2(\Omega)^d,
$$

(4.21)
where $1 \leq q < \infty$ in two dimensions and $1 \leq q < 6$ in three dimensions. By the uniqueness of limits $\hat{w} = \hat{u}$ a.e. in $\Omega$ and thus $\hat{u} \in H^1(\Omega)^d$. Moreover, the same compact embedding lemma implies that

$$u_h \to \hat{u} \text{ strongly in } L^r(\partial\Omega)^d,$$

where $1 \leq r < \infty$ in two dimensions and $1 \leq r < 4$ in three dimensions. If $\|u_h - g\|_{L^2(\partial\Omega)} \not\to 0$, then $J_h(u_h, \rho_h) \to +\infty$. Since $(u_h)$ is a bounded sequence, we must have that $\|u_h - g\|_{L^2(\partial\Omega)} \to 0$. Hence,

$$\|\hat{u} - g\|_{L^2(\partial\Omega)} \leq \|\hat{u} - u_h\|_{L^2(\partial\Omega)} + \|u_h - g\|_{L^2(\partial\Omega)} \to 0.$$  

Thus, (4.20), (4.21), and (4.23) imply that $\hat{u} \in H^1_{g,\text{div}}(\Omega) \cap B_{r/2,H(\text{div};\Omega)}(u)$. Since $(u, \rho)$ is the unique local minimizer of (BP) in

$$(H_{g,\text{div}}(\Omega) \cap B_{r/2,H(\text{div};\Omega)}(u)) \times (C_\gamma \cap B_{r/2,L^2(\Omega)}(\rho)),$$

from (4.19), we see that

$$\lim_{h \to 0} J_h(u_h, \rho_h) = J(u, \rho).$$

Since $(u, \rho)$ is the unique minimizer in the spaces we consider, we identify the limits $\hat{u}$ and $\hat{\rho}$ as $u$ and $\rho$, respectively, and state that $u_h \to u$ weakly in $H(\text{div};\Omega)$, $u_h \to u$ strongly in $L^q(\Omega)^d$, $u_h \to u$ strongly in $L^r(\partial\Omega)^d$ and $\rho_h \to \rho$ weakly in $L^2(\Omega)$, where $1 \leq q, r < \infty$ in two dimensions and $1 \leq q < 6$, $1 \leq r < 4$ in three dimensions.

We note that by the Banach–Alaoglu theorem [30, Th. A.52], the closed unit ball of the dual space of a normed vector space, (for example $L^1(\Omega)$), is compact in the weak-* topology. Hence we also find a subsequence such that $\rho_h \rightharpoonup \rho \in C_\gamma \cap \{\eta : \|\rho - \eta\|_{L^\infty(\Omega)} \leq r/2\}$ weakly-* in $L^\infty(\Omega)$. By the uniqueness of the weak limit, we identify $\rho = \rho$ a.e. in $\Omega$ and, thus, we deduce that $\rho_h \rightharpoonup \rho$ weakly-* in $L^\infty(\Omega)$. Consequently, $\rho_h \to \rho$ weakly in $L^s(\Omega)$ for all $s \in [1, \infty)$.

**Proposition 4.3** (Strong convergence of $\rho_h$ in $L^s(\Omega)$, $s \in [1, \infty)$). Suppose that the conditions stated in Theorem 4.1 hold. Fix an isolated minimizer $(u, \rho)$ of (BP). Then, there exists a subsequence of minimizers, $(\rho_h)$, of (BP-h) such that

$$\rho_h \to \rho \text{ strongly in } L^s(\Omega), \quad s \in [1, \infty).$$

The proof of Proposition 4.3, with some small modifications, can be found in [46, Prop. 5]. For the convenience of the reader, we reproduce the proof in Appendix A with the necessary changes.

**Proposition 4.4** (Strong convergence of $u_h$ in the $H^1_T(\Omega)$-norm). Suppose that the conditions stated in Theorem 4.1 hold. Fix an isolated minimizer $(u, \rho)$ of (BP). Then, there exists a subsequence of minimizers, $(u_h)$, of (BP-h) such that

$$\|u - u_h\|_{H^1_T(\Omega)} \to 0.$$  

**Proof.** We note that $U_{h,g,h} \cap B_{r/2,H(\text{div};\Omega)}(u)$ is a convex set, and hence for any $w_h \in U_{h,g,h} \cap B_{r/2,H(\text{div};\Omega)}(u)$, $t \in [0, 1]$, we have that $u_h + t(w_h - u_h) \in U_{h,g,h} \cap B_{r/2,H(\text{div};\Omega)}(u)$. Since $(u_h, \rho_h)$ is a global minimizer of (BP-h), we note that

$$\frac{1}{t} [J_h(u_h + t(w_h - u_h), \rho_h) - J_h(u_h, \rho_h)] \geq 0.$$
By taking the limit $t \to 0$, a calculation shows that, for all $w_h \in U_{h,g_R} \cap B_{r/2,H(\text{div};\Omega)}(u)$,

\begin{equation}
4.28 \quad a_h(u_h, w_h - u_h; \rho_h) \geq l_h(w_h - u_h; g_h).
\end{equation}

We note that $w_h - u_h \in U_{h,0}$. Hence, from Proposition 3.5 and Lemma 3.8, we deduce that

\begin{equation}
4.29 \quad a_h(u, w_h - u_h; \rho) = l_h(w_h - u_h; g).
\end{equation}

Therefore, from (4.28) and (4.29), we see that

\begin{equation}
4.30 \quad a_h(u_h, u_h - w_h; \rho_h) \leq a_h(u, u_h - w_h; \rho) + l_h(u_h - w_h; g_h) - l_h(u_h - w_h; g).
\end{equation}

Hence, by subtracting $a_h(w_h, u_h - w_h; \rho_h)$ from both sides of (4.30), and utilizing the coercivity of $a_h(\cdot, \cdot; \cdot)$ as stated in Proposition 3.6, we have that

\begin{equation}
4.31 \quad c_a \|u_h - w_h\|_{H^1(T)}^2 \leq a_h(u_h, u_h - w_h; \rho) - a_h(w_h, u_h - w_h; \rho_h) + l_h(u_h - w_h; g_h) - l_h(u_h - w_h; g).
\end{equation}

Now by assumption (M3), for all $F \in F_h^d$ there exists a $c > 0$ such that $h_F^{-1} \leq c h^{-1}$, where $c$ depends on the mesh regularity. By taking the absolute value of the right-hand side of (4.31), collecting terms, utilizing the inequality (4.16), and the boundedness of $a_h$ by $C_a$ as stated in Proposition 3.6, we have that

\begin{equation}
4.32 \quad c_a \|u_h - w_h\|_{H^1(T)}^2 \leq \bar{c} \|u - w\|_{L^2(\Omega)} \|u_h - w_h\|_{L^2(\Omega)} + \|(\alpha(\rho) - \alpha(\rho_h))\|_{L^2(\Omega)} \|u_h - w_h\|_{L^2(\Omega)} + C_a \|u - w\|_{H^1(\Omega)} \|u_h - w_h\|_{H^1(\Omega)} + Ch^{-1} \|g - g_h\|_{L^2(\partial\Omega)} \|u_h - w_h\|_{L^2(\partial\Omega)} + Ch^{-1} \|g - g_h\|_{L^2(\partial\Omega)} \|u_h - w_h\|_{H^1(\Omega)}
\end{equation}

for some constant $C = C(\sigma)$ that also depends on the mesh regularity.

We note that $\|u - w\|_{L^2(\Omega)} \leq \|u_h - w_h\|_{H^1(T)}$ by definition. Moreover, by the broken trace theorem as found in Buffa and Ortner [15, Th. 4.4], there exists a constant $C_{\text{BT}}$ such that, for all $v \in H^1(\Omega)^d$, $d \in \{2,3\}$ we have

\begin{equation}
4.33 \quad \|v\|_{L^2(\Omega)} \leq C_{\text{BT}} \|v\|_{H^1(\Omega)}.
\end{equation}

Therefore, by bounding the $L^2(\Omega)$ and $L^2(\partial\Omega)$-norms of $u_h - w_h$ above by the broken $H^1$-norm, and dividing through by $c_a \|u_h - w_h\|_{H^1(\Omega)}$ we see that

\begin{equation}
4.34 \quad \|u_h - w_h\|_{H^1(\Omega)} \leq C \|u - w\|_{L^2(\Omega)} + C \|\alpha(\rho) - \alpha(\rho_h)\|_{L^2(\Omega)} + C \|\alpha(\rho) - \alpha(\rho_h)\|_{L^2(\Omega)} + Ch^{-1} \|g - g_h\|_{L^2(\partial\Omega)},
\end{equation}

for some constant $C$ that depends on $c_a, C_a, C_{\text{BT}}, \bar{c}, \sigma$ and the mesh regularity.

For sufficiently small $h$, we note that $\tilde{u}_h \in U_{h,g_h} \cap B_{r/2,H(\text{div};\Omega)}(u)$ (where $\tilde{u}_h$ is defined in Lemma 3.9) and $\tilde{u}_h \to u$ strongly in $H^1(T)^d$. Fix $w_h = \tilde{u}_h$.

From Proposition 4.3, we know that there exists a subsequence (not indicated) such that $\rho_h \to \rho$ strongly in $L^1(\Omega)$. We now observe that

\begin{equation}
4.35 \quad \|\alpha(\rho) - \alpha(\rho_h)\|_{L^2(\Omega)} \leq L_{\alpha} \|\rho - \rho_h\|_{L^1(\Omega)} \|u\|_{L^1(\Omega)},
\end{equation}
Hence, there exists \( \overline{B} \) strongly in \( \gamma, h \) that solves the conditions stated in Theorem 4.1.\( \overline{B} \) satisfies the first-order optimality conditions (FOC1-h)–(FOC3-h).

**Proof.** From Proposition 4.4, we know that \( u_h \to u \) strongly in \( H^1(T_h) \). Hence by definition of strong convergence, there exists an \( h^1 > 0 \) such that, for all \( h \leq h^1, \) \( u - u_h \|_{H^1(T_h)} \leq \frac{r}{4}. \) Moreover, since \( u \in H^1_0, \) we have that \( \text{div}(u) = 0 \) a.e. in \( \Omega \) and by Lemma 3.8, we have that \( \text{div}(u_h) = 0 \) a.e. in \( \Omega. \) Therefore,

\[
\|u - u_h\|_{H^1(\Omega)}^2 = \|u - u_h\|_{L^2(\Omega)}^2 + \|\text{div}(u - u_h)\|_{L^2(\Omega)}^2.
\]

(4.36)

Hence, for each \( v_h \in U_{h,0}, \) if \( |t| < \frac{r}{4}\|v_h\|_{H^1(T_h)} \) then \( u_h + tv_h \in U_{h,0} \cap B_r(\text{div}(\Omega)\|u\)). \) From Proposition 4.3 we have that \( \rho_h \to \rho \) strongly in \( L^2(\Omega). \) Hence, there exists an \( \bar{h}_2 > 0 \) such that, for all \( h \leq \bar{h}_2, \) \( \|\rho - \rho_h\|_{L^2(\Omega)} \leq \frac{r}{4}. \) Therefore, for each \( \eta_h \in C_{\gamma, h}, \) if \( 0 < t < \frac{r}{4}\|\eta_h - \rho_h\|_{L^2(\Omega)} \) then \( \rho_h + t(\eta_h - \rho_h) \in C_{\gamma, h} \cap B_r(\text{div}(\Omega))\). Let \( \bar{h} = \min\{\bar{h}_1, \bar{h}_2\} \) and consider \( h \leq \bar{h}. \)

Since \( (u_h, \rho_h) \) is a global minimizer of (BP-h), then, for all \( v_h \in U_{h,0}, \) if \( |t| < \frac{r}{4}\|v_h\|_{H^1(T_h)} \)\( (4.37)\)

\[
\frac{1}{t} [J_h(u_h + tv_h, \rho_h) - J_h(u_h, \rho_h)] \geq 0.
\]

By considering the limits for \( t \to 0_+ \) and \( t \to 0_- \), we have that, for all \( v_h \in U_{h,0}, \)

\[
a_h(u_h, v_h; \rho_h) = l_h(v_h; g_h).
\]

(4.38)

From (4.38), the existence of a unique \( p_h \in M_h \) such that \( (u_h, \rho_h, p_h) \) satisfy (FOC1-h)–(FOC2-h) follows from the inf-sup condition (F2) and the argument can be found in [46, Prop. 2].

Similarly, since \( (u_h, \rho_h) \) is a global minimizer of (BP-h), then, for all \( \eta_h \in C_{\gamma, h}, \) if \( 0 < t < \frac{r}{4}\|\eta_h - \rho_h\|_{L^2(\Omega)} \)\( (4.39)\)

\[
\frac{1}{t} [J_h(u_h, \rho_h + t(\eta_h - \rho_h)) - J_h(u_h, \rho_h)] \geq 0.
\]

By taking the limit as \( t \to 0, \) we deduce that (FOC3-h) holds.

**Proposition 4.6.** Suppose that the conditions stated in Theorem 4.1 hold. Then, there is a subsequence of the unique \( p_h \in M_h \) defined in Proposition 4.5 that converges strongly in \( L^2(\Omega) \) to the \( p \in L^2(\Omega) \) that solves (FOC1)–(FOC3) for the given isolated local minimizer \( (u, \rho) \).
Proof. The inf-sup condition (F2) for $M_h$ and $X_{h,0}$ implies that, for any $q_h \in M_h$, 
\[
\|q_h - p_h\|_{L^2(\Omega)} \leq \sup_{w_h \in X_{h,0} \setminus \{0\}} \frac{b(w_h, q_h - p_h)}{\|w_h\|_{H^1(\mathcal{T}_h)}} \leq \sup_{w_h \in X_{h,0} \setminus \{0\}} \frac{b(w_h, p - p_h) + b(w_h, q_h - p)}{\|w_h\|_{H^1(\mathcal{T}_h)}} \leq \sup_{w_h \in X_{h,0} \setminus \{0\}} \frac{|b(w_h, p - p_h)| + |b(w_h, q_h - p)|}{\|w_h\|_{H^1(\mathcal{T}_h)}}.
\]  
From Proposition 3.5 and Proposition 4.5, it follows that 
\[
(4.40) \quad b(w_h, p - p_h) = a_h(u_h, w_h; \rho_h) - a_h(u, w_h; \rho) + l_h(w_h; g) - l_h(w_h; g_h).
\] 
Therefore, 
\[
(4.41) \quad c_b\|q_h - p_h\|_{L^2(\Omega)} \leq \sup_{w_h \in X_{h,0} \setminus \{0\}} \frac{|a_h(u_h, w_h; \rho_h) - a_h(u, w_h; \rho)|}{\|w_h\|_{H^1(\mathcal{T}_h)}} + \sup_{w_h \in X_{h,0} \setminus \{0\}} \frac{|l_h(w_h; g) - l_h(w_h; g_h)| + |b(w_h, q_h - p)|}{\|w_h\|_{H^1(\mathcal{T}_h)}}.
\] 
By using the same argument we used to bound (4.32) by (4.34), we see that (4.41) implies that 
\[
(4.42) \quad c_b\|q_h - p_h\|_{L^2(\Omega)} \leq C\|\alpha(\rho) - \alpha(\rho_h)\|_{L^2(\Omega)} + C\|u - u_h\|_{H^1(\mathcal{T}_h)} + Ch^{-1}\|g - g_h\|_{L^2(\partial\Omega)} + C_b\|p - q_h\|_{L^2(\Omega)},
\] 
where $C_b$ is the boundedness constant for $b(\cdot, \cdot)$ and $C$ is dependent on $C_\alpha$, $C_{BT}$, $\bar{\alpha}$, $L_\alpha$, $\nu$, $\sigma$ and the mesh regularity. Hence, by an application of the Cauchy–Schwarz inequality, 
\[
(4.43) \quad \|p - p_h\|_{L^2(\Omega)} \leq C\|\alpha(\rho) - \alpha(\rho_h)\|_{L^2(\Omega)} + C\|u - u_h\|_{H^1(\mathcal{T}_h)} + Ch^{-1}\|g - g_h\|_{L^2(\partial\Omega)} + C\|p - q_h\|_{L^2(\Omega)},
\] 
where $C$ is dependent on $c_b$, $C_b$, $C_\alpha$, $C_{BT}$, $\bar{\alpha}$, $L_\alpha$, $\nu$, $\sigma$ and the mesh regularity.

By assumption (F3), there exists a sequence of finite element functions, $\tilde{p}_h \in M_h$ that satisfies $\tilde{p}_h \to p$ strongly in $L^2(\Omega)$. Let $q_h = \tilde{p}_h$. We have already shown that $u_h \to u$ strongly in $H^1(\mathcal{T}_h)^d$ in Proposition 4.4. Similarly, in the proof of Proposition 4.4 we also showed that $\|\alpha(\rho) - \alpha(\rho_h)\|_{L^2(\Omega)} \to 0$. By assumption (F1), $h^{-1}\|g - g_h\|_{L^2(\partial\Omega)} \to 0$. Hence, we conclude that $p_h \to p$ strongly in $L^2(\Omega)$. \[\square\]

We now have the required results to prove Theorem 4.1.

Proof of Theorem 4.1. Fix an isolated minimizer $(u, \rho)$ of (BP) and its unique associated Lagrange multiplier $p$. By the results of Propositions 4.2, 4.3, 4.4, and 4.5, there exists a mesh size $\bar{h}$ such that for, $h < \bar{h}$, there exists a sequence of finite element solutions $(u_h, \rho_h, p_h) \in X_h, g_h \times C_{\gamma,h} \times M_h$ satisfying (FOC1-h)–(FOC3-h) that converges to $(u, \rho, p)$. By taking a subsequence if necessary (not indicated), Proposition 4.3, implies that $\rho_h \to \rho$ strongly in $L^s(\Omega)$, $s \in [1, \infty)$, Proposition 4.4 implies that $\|u - u_h\|_{H^1(\mathcal{T}_h)} \to 0$, and Proposition 4.6 implies that $p_h \to p$ strongly in $L^2(\Omega)$. \[\square\]
5. Numerical results. In this section we consider an example of a Borrvall–Petersson topology optimization problem that supports two minimizers. Our goal is to discretize the velocity-pressure pair with a Brezzi–Douglas–Marini BDM$_1 \times$ DG$_0$ discretization and numerically verify the existence of two sequences of solutions to (FOC1-h)–(FOC3-h) that converge to the two different minimizers. Moreover, we compare the violation of the incompressibility constraint, measured by $\|\text{div}(u_h)\|_{L^2(\Omega)}$, with the equivalent solution as computed via a Taylor–Hood (CG$_2$)$^2 \times$ CG$_1$ discretization on the same meshes.

The problem is implemented with the finite element software Firedrake [48] and the computational domains are triangulated with simplices. The solutions are computed using the deflated barrier method [45]. The deflated barrier method reformulates (FOC1-h)–(FOC3-h) into a mixed complementarity problem and solves the nonlinear system with a primal-dual active set solver [11]. The global nonlinear convergence is aided by the continuation of barrier terms. A key feature of the deflated barrier method is that it can systematically discover multiple solutions of topology optimization problems by utilizing the deflation technique [25, 26]. In the BDM discretization, the linear systems arising in the deflated barrier method are solved with FGMRES [50] preconditioned with block preconditioning techniques and the Schur complements are controlled with an augmented Lagrangian term [44]. The individual blocks are solved by a sparse LU factorization with MUMPS [6] and PETSc [9]. In the Taylor–Hood discretization, we invert the entire linear system directly with MUMPS. There are no known analytical solutions for choices of the inverse permeability, $\alpha$, used in practice. Hence, the errors are measured with respect to the most heavily-refined finite element solution where $h = 1.41 \times 10^{-3}$ resulting in 16,389,121 degrees of freedom for the first-order BDM discretization.

Although, for each isolated minimizer, Theorem 4.1 guarantees the existence of a converging sequence of solutions, it does not guarantee that the sequence is unique. In principle, there can be infinitely many different subsequences of finite element solutions that strongly converge to the same analytical minimizer at different convergence rates. Separate subsequences can appear in oscillations in the error and cause difficulty in the interpretation of the convergence plots [46, Sec. 5]. Here, we attempt to find solutions along the same sequence by first computing the solutions on a coarse mesh, uniformly refining the mesh, and successively interpolating the solutions onto the finer mesh as initial guesses for the deflated barrier method.

We now describe the double-pipe problem of Borrvall and Petersson [12, Sec. 4.5] with a modification to the boundary conditions that improves the guaranteed regularity of the solutions. The design domain is a rectangle $\Omega = (0, 3/2) \times (0, 1)$ with two inlets and two outlets. The volume fraction is chosen to be $\gamma = 1/3$ and the inverse permeability $\alpha$ is given by (2.1) with $q = 1/10$ and $\bar{\alpha} = 2.5 \times 10^4$. The boundary conditions are given by:

\begin{equation}
 g(x, y) = \begin{cases}
 (\exp(1 - \frac{1}{1-(12y-9)^2}), 0) & \text{if } 2/3 \leq y \leq 5/6, \ x = 0 \text{ or } 3/2, \\
 (\exp(1 - \frac{1}{1-(12y-3)^2}), 0) & \text{if } 1/6 \leq y \leq 1/3, \ x = 0 \text{ or } 3/2, \\
 (0, 0) & \text{elsewhere on } \partial\Omega.
\end{cases}
\end{equation}

This problem supports two isolated minimizers in form of a straight channels solution and double-ended wrench solution as shown in Figure 1.

It can be checked that the boundary datum $g$ can be expressed as the trace of a function $\hat{g} \in H^2(\Omega)^d$. Hence, since the domain is convex and the forcing term is
smooth, we have that, by regularity results for isolated minimizers of the Borrvall–Petersson problem [46, Lem. 5], $(u, p) \in H^2(\Omega)^d \times H^1(\Omega)$ for both minimizers. Hence, the trace of $\nabla u$ is well-defined on the faces of each element and the consistency result in Proposition 3.5 holds. All the conditions of Theorem 4.1 are satisfied and hence there exists a sequence of solutions to (FOC1-h)–(FOC3-h) that converges strongly to the straight channel solution and a different sequence of solutions that converges to the double-ended wrench. The existence of these sequences are numerically verified in Figure 2 for a DG$_0 \times$ BDM$_1 \times$ DG$_0$ discretization for $(\rho_h, u_h, p_h)$.
We report the values of $\|\text{div}(u_h)\|_{L^2(\Omega)}$ in Table 1 for the BDM discretization alongside the equivalent solutions computed with a Taylor–Hood $(CG_2)^2 \times CG_1$ discretization for the velocity-pressure pair and a DG$_0$ discretization for the material distribution on the same meshes. Even on coarse meshes, the $L^2$-norm of the divergence in the BDM discretization is small with values in the range of $10^{-6} \sim 10^{-9}$ for both minimizers. By contrast, the pointwise violation of the incompressibility constraint for the Taylor–Hood discretization manifests as relatively large values of $\|\text{div}(u_h)\|_{L^2(\Omega)}$. Even on the finest mesh, where $h = 2.82 \times 10^{-3}$ resulting in 4,512,004 degrees of freedom, the $L^2$-norm is still $O(10^{-3})$, 4 orders of magnitude larger than the equivalent BDM discretization.

Table 1: Reported values for $\|\text{div}(u_h)\|_{L^2(\Omega)}$ in a BDM and Taylor–Hood discretization for the double-pipe problem as measured on five meshes in a uniformly refined mesh hierarchy.

**Code availability:** For reproducibility, the implementation of the deflated barrier method used in this work, as well as scripts to generate the convergence plots and solutions can be found at https://github.com/ioannisPAPapadopoulos/lr3dab/. The version of the software used in this paper is archived on Zenodo [1].

**6. Conclusions.** In this work we studied the convergence of a divergence-free discontinuous Galerkin finite element discretization of the fluid topology optimization model of Borrvall and Petersson [12]. Our approach extends the techniques used by Papadopoulos and Stili [46] for $H^1$-conforming finite element approximations of the velocity. The nonconvexity of the optimization problem was handled by fixing any isolated minimizer and introducing a modified optimization problem with the chosen isolated local minimizer as its unique solution. We then showed that there exists a sequence of discretized solutions that converges to the minimizer in the appropriate norms. In particular, $\|u - u_h\|_{H^1(\Omega)} \to 0$, $\|\rho - \rho_h\|_{L^s(\Omega)} \to 0$, $s \in [1, \infty)$, and $\|p - p_h\|_{L^2(\Omega)} \to 0$. The modified optimization problem was related back to the original optimization problem by showing that a subsequence of the strongly converging minimizers also satisfy the first-order optimality conditions of the original problem. Moreover, these first-order optimality conditions can be solved numerically. Finally, we numerically verified that these sequences exist and compared the improvement in the $L^2$-norm of the incompressibility constraint in the discretized solutions.

**Appendix A. Proof of Proposition 4.3.** Here we reproduce a proof found in [46, Prop. 5], with some small modifications.

**Proof of Proposition 4.3.** We note that $C_{\gamma,h} \cap B_{r/2,L^2(\Omega)}(\rho)$ is a convex set, and hence for any $\eta_h \in C_{\gamma,h} \cap B_{r/L^2(\Omega)}(\rho)$, $t \in [0,1]$, we have that $\rho_h + t(\eta_h - \rho_h) \in C_{\gamma,h} \cap B_{r/L^2(\Omega)}(\rho)$. Since $(u_h, \rho_h)$ is a global minimizer of (BP-h), we note that

\[
\frac{1}{t} \left[ J_h(u_h, \rho_h + t(\eta_h - \rho_h)) - J_h(u_h, \rho_h) \right] \geq 0.
\]

(A.1)
By taking the limit $t \to 0$ and noting that by assumption (A4), $\alpha$ is continuously differentiable, we deduce that
\begin{equation}
\int_{\Omega} \alpha'(\rho_h) |u_h|^2 (\eta_h - \rho_h) \, dx \geq 0 \quad \text{for all } \eta_h \in C_{\gamma,h} \cap B_{r/2,L^2(\Omega)}(\rho).
\end{equation}

Hence, (FOC3) and (A.2) imply that for all $\eta \in C_{\gamma}$ and $\eta_h \in C_{\gamma,h} \cap B_{r/2,L^2(\Omega)}(\rho)$ we have that
\begin{equation}
\int_{\Omega} \alpha'(\rho) |u|^2 \rho \, dx \leq \int_{\Omega} \alpha'(\rho)|u|^2 \eta \, dx,
\end{equation}
\begin{equation}
\int_{\Omega} \alpha'(\rho_h)|u_h|^2 \rho_h \, dx \leq \int_{\Omega} \alpha'(\rho)|u_h|^2 \eta_h \, dx.
\end{equation}

By subtracting $\int_{\Omega} \alpha'(\rho)|u|^2 \rho_h \, dx$ from (A.3) and $\int_{\Omega} \alpha'(\rho_h)|u_h|^2 \rho \, dx$ from (A.4), we see that
\begin{equation}
\int_{\Omega} \alpha'(\rho)|u|^2 (\rho - \rho_h) \, dx \leq \int_{\Omega} \alpha'(\rho)|u|^2 (\eta - \rho_h) \, dx,
\end{equation}
\begin{equation}
\int_{\Omega} \alpha'(\rho_h)|u_h|^2 (\rho_h - \rho) \, dx \leq \int_{\Omega} \alpha'(\rho)|u_h|^2 (\eta_h - \rho) \, dx.
\end{equation}

Summing (A.5) and (A.6) and rearranging the left-hand side, we see that
\begin{equation}
\int_{\Omega} (\alpha'(\rho) - \alpha'(\rho_h))|u|^2 (\rho - \rho_h) \, dx + \int_{\Omega} \alpha'(\rho_h)|u|^2 (\rho - \rho_h) \, dx
\leq \int_{\Omega} \alpha'(\rho)|u|^2 (\eta - \rho_h) \, dx + \int_{\Omega} \alpha'(\rho)|u_h|^2 (\eta_h - \rho) \, dx.
\end{equation}

By fixing $\eta = \rho_h \in C_{\gamma}$ and subtracting the second term on the left-hand side of (A.7) from both sides we deduce that
\begin{equation}
\int_{\Omega} (\alpha'(\rho) - \alpha'(\rho_h))|u|^2 (\rho - \rho_h) \, dx
\leq \int_{\Omega} \alpha'(\rho_h)|u_h|^2 (\eta_h - \rho) \, dx + \int_{\Omega} \alpha'(\rho_h)|u|^2 (\rho - \rho_h) \, dx + \int_{\Omega} \alpha'(\rho_h)(|u_h|^2 - |u|^2)(\rho - \rho_h) \, dx.
\end{equation}

By applying the mean value theorem, we note that there exists a $c \in (0,1)$ such that
\begin{equation}
\int_{\Omega} (\alpha'(\rho) - \alpha'(\rho_h))|u|^2 (\rho - \rho_h) \, dx
= \int_{\Omega} \alpha''(\rho_h + c(\rho - \rho_h))|u|^2 (\rho - \rho_h)^2 \, dx.
\end{equation}

Since by assumption (A2), $\alpha$ is strongly convex and by (A4) it is twice continuously differentiable, there exists a constant $\alpha''_{\min} > 0$ such that
\begin{equation}
\alpha''_{\min} \leq \alpha''(y) \quad \text{for all } y \in [0,1].
\end{equation}

Therefore by (A.10) and the definition of $U_\theta$ (given in Theorem 4.1) we bound (A.9) from below:
\begin{equation}
\int_{\Omega} \alpha''(\rho_h + c(\rho - \rho_h))|u|^2 (\rho - \rho_h)^2 \, dx
\geq \int_{U_\theta} \alpha''(\rho_h + c(\rho - \rho_h))|u|^2 (\rho - \rho_h)^2 \, dx \geq \alpha''_{\min} \theta \|\rho - \rho_h\|_{L^2(U_\theta)}^2.
\end{equation}
Now we bound the right-hand side of (A.8) as follows,

\[
\int_{\Omega} \alpha'(\rho_h) |u_h|^2 (\eta_h - \rho) \, dx + \int_{\Omega} \alpha'(\rho_h) (|u_h|^2 - |u|^2) (\rho - \rho_h) \, dx
\]

(A.12)

\[
\leq 2\alpha'_{\text{max}}(\|u\|_{L^4(\Omega)}^2 + \|u - u_h\|_{L^4(\Omega)}^2)\|\rho - \eta_h\|_{L^4(\Omega)}
\]

\[
+ \alpha'_{\text{max}} \|\rho - \rho_h\|_{L^q(\Omega)} \|u + u_h\|_{L^q'(\Omega)} \|u - u_h\|_{L^q(\Omega)},
\]

where \(2 < q' < \infty\) in two dimensions, \(2 < q' \leq 6\) in three dimensions, and \(q = 2q'/(q' - 2)\). We note that

\[
\|u + u_h\|_{L^q'(\Omega)} \leq \|u\|_{L^q'(\Omega)} + \|u_h\|_{L^q'(\Omega)}
\]

(A.13)

\[
\leq \|u\|_{H^1(\Omega)} + \|u_h\|_{H^1(\Omega)} \leq \tilde{C} < \infty,
\]

where the second inequality holds thanks to the Sobolev embedding theorem and the broken Friedrichs-type inequality as found in Buffa and Ortner [15, Cor. 4.3]. Combining (A.8)–(A.13) we see that

\[
\|\rho - \rho_h\|_{L^2(U_\theta)}^2 \leq C \left( \|\rho - \eta_h\|_{L^2(\Omega)} + \|\rho - \rho_h\|_{L^q(\Omega)} \|u - u_h\|_{L^2(\Omega)} \right),
\]

(A.14)

where \(C = C'(\alpha'_{\text{max}}, \alpha''_{\text{min}}, \theta, \|u\|_{L^4(\Omega)}, \tilde{C})\). By assumption (F3), there exists a sequence of finite element functions \(\tilde{\rho}_h \in C_{\gamma,h}\) such that \(\tilde{\rho}_h \to \rho\) strongly in \(L^2(\Omega)\). Thanks to the strong convergence, we note that for sufficiently small \(h, \tilde{\rho}_h \in \mathcal{B}_{\gamma/2,L^2(\Omega)}(\rho)\). Hence we fix \(\eta_h = \tilde{\rho}_h\). By Proposition 4.2, we know that \(u_h \to u\) strongly in \(L^2(\Omega)^d\) and since \(\rho \in C_{\gamma}, \rho_h \in C_{\gamma,h} \subset C_{\gamma}\), then \(\|\rho - \rho_h\|_{L^\infty(\Omega)} \leq |\Omega|^{1/q} \|\rho - \rho_h\|_{L^\infty(\Omega)} \leq |\Omega|^{1/q}\).

Therefore, the right-hand side of (A.14) tends to zero as \(h \to 0\). Hence, we deduce that

\[
\rho_h \to \rho \quad \text{strongly in} \quad L^2(U_\theta), \quad \theta > 0.
\]

We define \(U\) as \(U := \text{supp}(u)\). Now we note that

\[
\|\rho - \rho_h\|_{L^2(\Omega)} = \|\rho - \rho_h\|_{L^2(U_\theta)} + \|\rho - \rho_h\|_{L^2(U \setminus U_\theta)} + \|\rho - \rho_h\|_{L^2(\Omega \setminus U)}.
\]

(A.16)

If \(U \setminus U_\theta\) or \(\Omega \setminus U\) are empty, we neglect the corresponding term in (A.16) with no loss of generality. Suppose \(\Omega \setminus U\) is non-empty. By definition of \(U, u = 0\) a.e. in \(\Omega \setminus U\). Proposition 3 in [46] implies that \(\rho = 0\) a.e. in \(\Omega \setminus U\). Therefore, Corollary 1 in [46] implies that

\[
\rho_h \to \rho \quad \text{strongly in} \quad L^2(\Omega \setminus U).
\]

(A.17)

Suppose \(U \setminus U_\theta\) is non-empty. Since, \(\rho, \rho_h \in C_{\gamma}\) we see that

\[
\|\rho - \rho_h\|_{L^2(U \setminus U_\theta)} \leq |U \setminus U_\theta|^{1/2} \to 0 \quad \text{as} \quad \theta \to 0.
\]

(A.18)

Therefore, by first taking the limit as \(h \to 0\) and then by taking the limit as \(\theta \to 0\), (A.15)–(A.18) imply that \(\rho_h \to \rho\) strongly in \(L^2(\Omega)\).

Since \(\|\rho - \rho_h\|_{L^1(\Omega)} \leq |\Omega|^{1/2} \|\rho - \rho_h\|_{L^2(\Omega)}\), we see that \(\rho_h \to \rho\) strongly in \(L^1(\Omega)\). Hence, for any \(s \in [1, \infty)\),

\[
\int_{\Omega} |\rho - \rho_h|^s \, dx = \int_{\Omega} |\rho - \rho_h|^{s-1} |\rho - \rho_h| \, dx \leq 1^{s-1} \|\rho - \rho_h\|_{L^1(\Omega)},
\]

(A.19)

which implies that \(\rho_h \to \rho\) strongly in \(L^s(\Omega)\).

\[\blacksquare\]
