The Projection onto the Cross

Heinz H. Bauschke, Manish Krishan Lal, and Xianfu Wang

August 9, 2021

Abstract

We consider the set of pairs of orthogonal vectors in Hilbert space, which is also called the cross because it is the union of the horizontal and vertical axes in the Euclidean plane when the underlying space is the real line. Crosses, which are nonconvex sets, play a significant role in various branches of nonsmooth analysis such as feasibility problems and optimization problems.

In this work, we study crosses and show that in infinite-dimensional settings, they are never weakly (sequentially) closed. Nonetheless, crosses do turn out to be proximinal (i.e., they always admit projections) and we provide explicit formulas for the projection onto the cross in all cases.

2020 Mathematics Subject Classification: Primary 41A50, 90C26; Secondary 46C05, 90C33.

Keywords: bilinear constraint, complementarity set, cross, Hilbert space, projection, switching cone.

1 Introduction

Throughout this paper, we assume that

\[ X \text{ is a real Hilbert space with inner product } \langle \cdot, \cdot \rangle : X \times X \to \mathbb{R}, \]  (1)
and induced norm $\| \cdot \|$. Consider the set $C$ defined by

$$C := \{(x, y) \in X \times X \mid \langle x, y \rangle = 0\}. \tag{2}$$

This set plays a role in optimization although it does not seem to have a name that is universally used. We follow Kruger, Luke, and Thao’s convention and refer to $C$ as cross (see [6, Example 2(a) on page 291]). Here is a selection of situations in which crosses are used.

- When $X = \mathbb{R}$, then
  $$C = \{(x, y) \in \mathbb{R}^2 \mid xy = 0\} \tag{3}$$
  is of interest in the study of set regularity and feasibility problems; see, e.g., Kruger et al.’s [6, Example 2(a) on page 291].

- When $X = \mathbb{R}$, then $C$ is also known as the switching cone in the study of mathematical programs by Liang and Ye; see, e.g., [7, equation (20) in Section 4].

- When $X = \mathbb{R}$ and one considers the (rectangular) hyperbola defined by
  $$xy = \alpha, \tag{4}$$
  where $\alpha > 0$, then $C$ arises as the asymptotic case when $\alpha \to 0^+$. 

- The set $C$ is a special case of the more general set $C_\gamma := \{(x, y) \in X \times X \mid \langle x, y \rangle = \gamma\}$, where $X$ is finite-dimensional and $\gamma \in \mathbb{R}$ is fixed: indeed, $C = C_0$. Sets of the form $C_\gamma$ are considered in nonnegative matrix factorization and also in deep learning — see [5, Sections 4.1–4.2 and Appendix B]. In that paper, Elser discusses also certain (but not all) cases of projecting onto $C_\gamma$ and computing projections numerically. He refers to $C_\gamma$ as a bilinear constraint set.

- The study of conic optimization problems may lead to the set $C$. If $K$ is a nonempty closed cone in $X$ and $K^\oplus$ is its dual cone, then the set
  $$C \cap (K \times K^\oplus) \tag{5}$$
  is called the conic complementarity set; see, e.g., Busseti, Moursi, and Boyd’s [4, Section 2].

In [5], the author is particularly interested in the projection (nearest point mapping) associated with the cross in the context of algorithms.

Classically, the most famous condition sufficient for uniqueness of the projection for a closed set is convexity. Unfortunately, the cross $C$ is far from being convex:
Lemma 1.1 (convex hull of C). We have \( \text{conv } C = X \times X \).

Proof. Clearly, \( X \times \{0\} \subseteq C \) and \( \{0\} \times X \subseteq C \). Let \((x, y) \in X \times X \). Then \((2x, 0) \in C\) and \((0, 2y) \in C\); hence, \((x, y) = \frac{1}{2}(2x, 0) + \frac{1}{2}(0, 2y) \in \text{conv } C\) and we are done. \( \blacksquare \)

Because C is not convex, the question arises whether C at least admits projections everywhere, i.e., whether C is proximinal.

An often employed condition sufficient for the existence of projections is weak closedness of the set (see, e.g., [1, Proposition 3.14]). When X is finite-dimensional, weak closedness characterizes proximality and is of course also equivalent to ordinary closedness (see, e.g., [1, Corollary 3.15]). Unfortunately, when X is infinite-dimensional, then C is far from being weakly closed as the next result illustrates:

Lemma 1.2 (weak (sequential) closure of C). The set C is closed. If X is finite-dimensional, then C is proximinal. If X is infinite-dimensional, then C is not weakly (sequentially) closed; in fact, the weak (sequential) closure of C is equal to \( X \times X \).

Proof. The continuity of the inner product immediately yields the closedness of C. So we assume that X is infinite-dimensional and we let \((u_i)_{i \in I}\) be an orthonormal family in X such that \( \text{span } \{e_i\}_{i \in I} = X \). Next, let \((i_n)_{n \in \mathbb{N}}\) be a sequence in I with pairwise distinct terms, and set \((\forall n \in \mathbb{N}) e_n := u_{i_n}\). Then \(e_n \to 0\). Set \( S := \text{span}\{e_i\}_{i \in I}\), and let \((x, y) \in S \times S\). Now set \( \zeta := \langle x, y \rangle\), and \((\forall n \in \mathbb{N}) (x_n, y_n) := (x + \zeta e_n, y - e_n)\). Then there exists \( N \in \mathbb{N}\) such that for all \( n \geq N\), we have \( e_n \in \{x, y\}^\perp\) and thus

\[
\langle x_n, y_n \rangle = \langle x + \zeta e_n, y - e_n \rangle = \langle x, y \rangle - \zeta \langle e_n, e_n \rangle = 0. \tag{6}
\]

Consequently, the sequence \((x_n, y_n)_{n \geq N}\) lies in C. On the other hand, \((x_n, y_n) \rightharpoonup (x, y)\). Altogether, \( S \times S \) lies in the weak sequential closure of C. Because \( S \times S \) is convex, it follows that its weak sequential closure, which is \( X \times X \), is also contained in the weak sequential closure of C. Therefore, the weak (sequential) closure of C is equal to \( X \times X \). In particular, C is neither weakly sequentially closed nor weakly closed. \( \blacksquare \)

After these explanations, we are now ready to state the main contribution of this paper: We will show that C is in fact proximinal and we will also provide an explicit formula for the projection onto C.

The remainder of the paper is organized as follows. In Section 2, we collect a few results that are known but will help in subsequent sections. Various auxiliary results are obtained in Section 3 to make the proof of the main result painless. The main result (Theorem 4.4) is proved in Section 4. The notation we employ is standard and follows largely [1].
2 Known results

In this section, we record some results which will make the proofs given in subsequent sections more clear.

**Fact 2.1.** Let $f : X \to \mathbb{R}$ and $h : X \to \mathbb{R}$ be continuously Fréchet differentiable. Consider the problem that asks to minimize $f(x)$ subject to $h(x) = 0$.

If $x^* \in X$ is a local minimizer of (7) and $\nabla h(x^*) \neq 0$, then there exists a unique $\lambda^* \in \mathbb{R}$ such that

$$\nabla f(x^*) + \lambda \nabla h(x^*) = 0. \quad (8)$$

**Proof.** When $X$ is finite-dimensional, then this follows from [2, Proposition 4.1.1]. If $X$ is infinite-dimensional, then use [8, Theorem 9.3.1 on page 243]. ■

**Lemma 2.2.** If $\lambda \in \mathbb{R} \setminus \{-1, 1\}$, then

$$\begin{pmatrix} \text{Id} & \lambda \text{Id} \\ \lambda \text{Id} & \text{Id} \end{pmatrix}^{-1} = \frac{1}{1 - \lambda^2} \begin{pmatrix} \text{Id} & -\lambda \text{Id} \\ -\lambda \text{Id} & \text{Id} \end{pmatrix}, \quad (9)$$

where the block matrices are interpreted as linear operators on $X \times X$.

**Proof.** The result follows by a direct verification. ■

We denote by

$$S := \{ x \in X \mid \|x\| = 1 \} \quad (10)$$

the unit sphere in $X$. The next result provides a parametrization of the unit sphere in $\mathbb{R}^n$ (See also [3].)

**Fact 2.3 (parametrization of the sphere).** Suppose that $X = \mathbb{R}^n$, where $n \geq 2$, and let $\rho > 0$. Then every point

$$x = (x_1, x_2, \ldots, x_n) \in S \subseteq \mathbb{R}^n \quad (11)$$

is uniquely described by its spherical coordinates $\theta_1, \ldots, \theta_{n-2}$ in $[0, \pi]$ and $\theta_{n-1} \in [0, 2\pi]$ via

$$\begin{align*}
& (\forall i \in \{1, 2, \ldots, n\} ) \quad x_i = \begin{cases}
\rho \cos(\theta_i) \prod_{j=1}^{i-1} \sin(\theta_j), & \text{if } i \leq n - 2; \\
\rho \cos(\theta_{n-1}) \prod_{j=1}^{n-2} \sin(\theta_j), & \text{if } i = n - 1; \\
\rho \sin(\theta_{n-1}) \prod_{j=1}^{n-2} \sin(\theta_j), & \text{if } i = n.
\end{cases} \quad (12)
\end{align*}$$

\footnote{Recall the empty product convention which sets such products equal to 1.}
3 Auxiliary results

This section lays out the preparatory work for our main result.

We consider a point \((x_0, y_0) \in X \times X\). Recall our aim, which is to compute \(P_C(x_0, y_0)\). The following result is clear; but it is nonetheless useful in our analysis as we shall see later.

**Lemma 3.1.** We have

\[
C = \bigcup_{U \text{ is a closed linear subspace of } X} U \times U^\perp; \quad (13)
\]

moreover,

\[
C = \bigcup_{U \text{ is a linear subspace of } X \text{ with } \dim U \leq 1} U \times U^\perp. \quad (14)
\]

Consequently, if \((x_0, y_0) \in X \times X\), then

\[
P_C(x_0, y_0) \subseteq \bigcup_{U \text{ is a closed linear subspace of } X} \{(P_U x_0, P_{U^\perp} y_0)\}. \quad (15)
\]

We also note that when \((x_0, y_0) \in C\), then \(P_C(x_0, y_0) = (x_0, y_0)\). Thus, for the remainder of this section, we focus on the case when \((x_0, y_0) \notin C\), i.e.,

\[
\langle x_0, y_0 \rangle \neq 0; \text{ consequently, } x_0 \neq 0 \text{ and } y_0 \neq 0. \quad (16)
\]

To determine \(P_C(x_0, y_0)\), we introduce the objective and constraint functions

\[
f(x, y) := \frac{1}{2}\|x - x_0\|^2 + \frac{1}{2}\|y - y_0\|^2 \quad \text{and} \quad h(x, y) := \langle x, y \rangle, \quad (17)
\]

which are obviously continuously Fréchet differentiable on \(X \times X\). Indeed, for every \((x, y) \in X \times X\), we have

\[
\nabla f(x, y) = (x - x_0, y - y_0) \quad \text{and} \quad \nabla h(x, y) = (y, x). \quad (18)
\]

Moreover, the points in \(P_C(x_0, y_0)\) are precisely the solutions to the following optimization problem:

\[
\text{minimize } f(x, y) \text{ subject to } h(x, y) = 0. \quad (19)
\]

Indeed, \(C = \{(x, y) \in X \times X \mid h(x, y) = 0\}\) while the optimal value of (19) is

\[
\frac{1}{2}d_C^2(x_0, y_0) = \inf_{(x, y) \in C} \frac{1}{2}\|h(x, y) - (x_0, y_0)\|^2.
\]

\(^2\text{We should technically write } P_C(x_0, y_0) = \{(x_0, y_0)\}; \text{ however, for convenience and readability, we will identify singleton sets with the vectors they contain.}\)
Proposition 3.2. \((0, 0)\) is never a solution to (19). Consequently, \(P^{-1}_C(0, 0) = \{(0, 0)\} \).

Proof. Suppose to the contrary that \((0, 0)\) solves (19). Then the optimal value of (19) is \(\frac{1}{2}\|x_0\|^2 + \frac{1}{2}\|y_0\|^2\) and both terms in this sum are positive (by (16)). Note that \((x_0, 0) \in C\). But \(f(x_0, 0) = \frac{1}{2}\|x_0\|^2 < \frac{1}{2}\|x_0\|^2 + \frac{1}{2}\|y_0\|^2 = f(0, 0)\) because \(y_0 \neq 0\). But this contradicts the minimality of \(f(0, 0)\) Hence \((0, 0)\) cannot be optimal. The “Consequently” part follows.

Corollary 3.3. Suppose that \((x, y) \in X \times X\) solves (19). Then \(\nabla h(x, y) \neq (0, 0)\).

Proof. By hypothesis, \((x, y) \in P_C(x_0, y_0)\). Suppose to the contrary that \(\nabla h(x, y) = (0, 0)\). Then, by (18), \((x, y) = (0, 0)\). Now Proposition 3.2 shows that \((x, y)\) cannot be a solution to (19) which is absurd.

Theorem 3.4. Suppose that \((x, y) \in X \times X\) solves (19). Then there exists a unique \(\lambda \in \mathbb{R}\) such that
\[
\begin{align*}
x + \lambda y &= x_0 \quad \text{and} \quad y + \lambda x = y_0.
\end{align*}
\]

Proof. By Fact 2.1, there exists a unique \(\lambda \in \mathbb{R}\) such that \(\nabla f(x, y) + \lambda \nabla h(x, y) = (0, 0)\). Using (18), this turns into \((x - x_0, y - y_0) + \lambda (y, x) = (0, 0)\), i.e., (20).

Proposition 3.5. Suppose that \((x, y) \in X \times X\) and \(\lambda \in \mathbb{R}\) satisfy
\[
\begin{align*}
x + \lambda y &= x_0 \quad \text{and} \quad y + \lambda x = y_0.
\end{align*}
\]
Then the following hold:

(i) If \(x_0 \neq y_0\), then \(\lambda \neq 1\).
(ii) If \(x_0 \neq -y_0\), then \(\lambda \neq -1\).
(iii) If \(x_0 \neq \pm y_0\), then \(\lambda \neq \pm 1\).

Proof. (i): We prove the contrapositive and thus assume that \(\lambda = 1\). Then, by (21), \(x_0 = x + (1)y = x + y = y + x = y + (1)x = y_0\). (ii): Argue similarly to the proof of (i). (iii): Combine (i) and (ii).

Proposition 3.6. Suppose that \((x, y) \in X \times X\) and \(\lambda \in \mathbb{R} \setminus \{-1, 1\}\) satisfy
\[
\begin{align*}
x + \lambda y &= x_0 \quad \text{and} \quad y + \lambda x = y_0.
\end{align*}
\]
Then
\[
\begin{align*}
x &= \frac{1}{1 - \lambda^2}(x_0 - \lambda y_0) \quad \text{and} \quad y = \frac{1}{1 - \lambda^2}(y_0 - \lambda x_0).
\end{align*}
\]

Proof. Combine (22) with Lemma 2.2.
Corollary 3.7. Suppose that $x_0 \neq \pm y_0$ and $(x, y) \in X \times X$ solves (19). Then there exists a unique $\lambda \in \mathbb{R} \setminus \{-1, 1\}$ such that $x + \lambda y = x_0$, $y + \lambda x = y_0$, and

$$x = \frac{1}{1 - \lambda^2} (x_0 - \lambda y_0) \quad \text{and} \quad y = \frac{1}{1 - \lambda^2} (y_0 - \lambda x_0). \quad (24)$$

**Proof.** The existence and uniqueness of $\lambda \in \mathbb{R}$ such that $x + \lambda y = x_0$ and $y + \lambda x = y_0$ follows from Theorem 3.4. Next, by Proposition 3.5(iii), $\lambda \neq \pm 1$. Finally, apply Proposition 3.6.

**Proposition 3.8.** Suppose $\lambda \in \mathbb{R} \setminus \{ \pm 1 \}$, and set

$$x := \frac{1}{1 - \lambda^2} (x_0 - \lambda y_0) \quad \text{and} \quad y := \frac{1}{1 - \lambda^2} (y_0 - \lambda x_0). \quad (25)$$

Then the following hold for $(x, y)$ defined in (25):

(i) $x + \lambda y = x_0$ and $y + \lambda x = y_0$.

(ii) The objective function $f$ defined in (17) evaluated at $(x, y)$ is

$$f(x, y) = \frac{\lambda^2}{2(1 - \lambda^2)^2} \left( (1 + \lambda^2)(\|x_0\|^2 + \|y_0\|^2) - 4\lambda \langle x_0, y_0 \rangle \right). \quad (26)$$

(iii) $\langle x, y \rangle = 0$ if and only if $(1 + \lambda^2) \langle x_0, y_0 \rangle = \lambda (\|x_0\|^2 + \|y_0\|^2)$.

(iv) If $\langle x, y \rangle = 0$, then

$$f(x, y) = \frac{1}{2} \lambda \langle x_0, y_0 \rangle. \quad (27)$$

**Proof.**

(i): This is an easy algebraic verification.

(ii): For convenience, set

$$\tau := \|x_0 - \lambda y_0\|^2 + \|y_0 - \lambda x_0\|^2 = (1 - \lambda^2)^2 (\|x\|^2 + \|y\|^2). \quad (28)$$

Then

$$\tau = \|x_0 - \lambda y_0\|^2 + \|y_0 - \lambda x_0\|^2 \quad (29a)$$

$$= \|x_0\|^2 - 2\lambda \langle x_0, y_0 \rangle + \lambda^2 \|y_0\|^2 + \|y_0\|^2 - 2\lambda \langle y_0, x_0 \rangle + \lambda^2 \|x_0\|^2 \quad (29b)$$

$$= (1 + \lambda^2)(\|x_0\|^2 + \|y_0\|^2) - 4\lambda \langle x_0, y_0 \rangle. \quad (29c)$$

Using (17), (25), (28), and (29), we obtain

$$f(x, y) = \frac{1}{2} \|x - x_0\|^2 + \frac{1}{2} \|y - y_0\|^2 \quad (30a)$$

$$= \frac{1}{2} \left( \frac{x_0 - \lambda y_0}{1 - \lambda^2} - x_0 \right)^2 + \frac{1}{2} \left( \frac{y_0 - \lambda x_0}{1 - \lambda^2} - y_0 \right)^2 \quad (30b)$$
\[ = \frac{1}{2(1-\lambda^2)^2} (\|x_0 - \lambda y_0 - (1-\lambda^2)x_0\|^2 + \|y_0 - \lambda x_0 - (1-\lambda^2)y_0\|^2) \quad (30c) \]
\[ = \frac{\lambda^2}{2(1-\lambda^2)^2} (\|\lambda x_0 - y_0\|^2 + \|\lambda y_0 - x_0\|^2) \quad (30d) \]
\[ = \frac{\lambda^2}{2(1-\lambda^2)^2} \tau \quad (30e) \]
\[ = \frac{\lambda^2}{2(1-\lambda^2)^2} ((1+\lambda^2)(\|x_0\|^2 + \|y_0\|^2) - 4\lambda \langle x_0, y_0 \rangle). \quad (30f) \]

(iii): Because \(1-\lambda^2 \neq 0\) and using (25), we have the following equivalences:
\[ \langle x, y \rangle = 0 \iff \langle x_0 - \lambda y_0, y_0 - \lambda x_0 \rangle = 0 \quad (31a) \]
\[ \iff \langle x_0, y_0 \rangle - \lambda \|x_0\|^2 - \lambda \|y_0\|^2 + \lambda^2 \langle x_0, y_0 \rangle = 0 \quad (31b) \]
\[ \iff (1+\lambda^2) \langle x_0, y_0 \rangle = \lambda (\|x_0\|^2 + \|y_0\|^2). \quad (31c) \]

(iv): Suppose that \(\langle x, y \rangle = 0\). By (iii),
\[ \lambda \langle x_0, y_0 \rangle = \frac{\lambda^2}{1+\lambda^2} (\|x_0\|^2 + \|y_0\|^2). \quad (32) \]

It thus follows from (32) that
\[ (1+\lambda^2) (\|x_0\|^2 + \|y_0\|^2) - 4\lambda \langle x_0, y_0 \rangle \quad (33a) \]
\[ = (1+\lambda^2) (\|x_0\|^2 + \|y_0\|^2) - 4 \frac{\lambda^2}{1+\lambda^2} (\|x_0\|^2 + \|y_0\|^2) \quad (33b) \]
\[ = \frac{\|x_0\|^2 + \|y_0\|^2}{1+\lambda^2} ((1+\lambda^2)^2 - 4\lambda^2) \quad (33c) \]
\[ = \frac{\|x_0\|^2 + \|y_0\|^2}{1+\lambda^2} (1 + \lambda^4 + 2\lambda^2 - 4\lambda^2) \quad (33d) \]
\[ = \frac{\|x_0\|^2 + \|y_0\|^2}{1+\lambda^2} (1 + \lambda^4 - 2\lambda^2) \quad (33e) \]
\[ = \frac{\|x_0\|^2 + \|y_0\|^2}{1+\lambda^2} (1 - \lambda^2)^2. \quad (33f) \]

Using (ii), (33), and (32), we conclude that
\[ f(x, y) = \frac{\lambda^2}{2(1-\lambda^2)^2} \frac{\|x_0\|^2 + \|y_0\|^2}{1+\lambda^2} (1 - \lambda^2)^2 \quad (34a) \]
\[ = \frac{\lambda^2}{1+\lambda^2} \frac{\|x_0\|^2 + \|y_0\|^2}{2} \quad (34b) \]
\[ \frac{1}{2} \lambda \langle x_0, y_0 \rangle. \]  

The proof is complete. \hfill ■

**Proposition 3.9.** Consider the equation

\[ \langle x_0, y_0 \rangle \lambda^2 - (\|x_0\|^2 + \|y_0\|^2)\lambda + \langle x_0, y_0 \rangle = 0, \]  

which is a quadratic polynomial with respect to the variable \( \lambda \). Then (35) has (possibly distinct) real roots

\[ \lambda_{\pm} := \frac{\|x_0\|^2 + \|y_0\|^2 \pm \sqrt{(\|x_0\|^2 + \|y_0\|^2)^2 - 4 \langle x_0, y_0 \rangle^2}}{2 \langle x_0, y_0 \rangle} \]  

which satisfy \( \lambda_+ \lambda_- = 1 \). Moreover, \( \lambda_+ \neq \lambda_- \iff x_0 \neq \pm y_0 \),

\[ \lambda_+ \langle x_0, y_0 \rangle \geq \lambda_- \langle x_0, y_0 \rangle > 0, \]  

and the left inequality is strict if and only if \( x_0 \neq \pm y_0 \).

**Proof.** First note that \( \|x_0 + y_0\|^2 \geq 0 \iff \|x_0\|^2 + \|y_0\|^2 \geq \pm 2 \langle x_0, y_0 \rangle \iff \|x_0\|^2 + \|y_0\|^2 \geq 2|\langle x_0, y_0 \rangle| \) which makes the discriminant of (35) nonnegative, and equal to 0 \( \iff x_0 = \pm y_0 \). Hence, the roots of (35) are real, and distinct if and only if \( x_0 \neq \pm y_0 \). Second, Vieta’s formulas give \( \lambda_+ \lambda_- = \langle x_0, y_0 \rangle / \langle x_0, y_0 \rangle = 1 \), so both \( \lambda_+ \) and \( \lambda_- \) are nonzero and they have the same sign. Next, the quadratic formula yields

\[ \lambda_{\pm} = \frac{\|x_0\|^2 + \|y_0\|^2 \pm \sqrt{(\|x_0\|^2 + \|y_0\|^2)^2 - 4 \langle x_0, y_0 \rangle^2}}{2 \langle x_0, y_0 \rangle} \]  

which yields (36). Clearly, \( \lambda_+ \langle x_0, y_0 \rangle > 0 \) and \( \lambda_+ \langle x_0, y_0 \rangle \geq \lambda_- \langle x_0, y_0 \rangle \). Finally, as observed above, \( \lambda_+ \) and \( \lambda_- \) have the same sign; hence, \( \lambda_- \langle x_0, y_0 \rangle \) is positive as well. \hfill ■
4 Main result

In this section, we derive formulas for $P_C$ in all possible cases. We start with the trivial case.

**Proposition 4.1.** Suppose that $(x_0, y_0) \in X \times X$ satisfies $\langle x_0, y_0 \rangle = 0$. Then

$$P_C(x_0, y_0) = (x_0, y_0). \quad (39)$$

**Proof.** This is clear because $(x_0, y_0) \in C$ by definition of $C$ (see (2)). ■

We now turn to a much more involved case the proof of which won’t be too complicated because of our preparatory work in Section 3.

**Proposition 4.2.** Suppose that $(x_0, y_0) \in X \times X$ satisfies $\langle x_0, y_0 \rangle \neq 0$ and $x_0 \neq \pm y_0$. Then

$$\lambda := \frac{\|x_0\|^2 + \|y_0\|^2 - \|x_0 + y_0\|\|x_0 - y_0\|}{2 \langle x_0, y_0 \rangle} \neq \pm 1, \quad (40)$$

$$P_C(x_0, y_0) = \frac{1}{1 - \lambda^2} (x_0 - \lambda y_0, y_0 - \lambda x_0) \quad (41)$$

is a singleton, and

$$\frac{1}{2} d_C^2(x_0, y_0) = \frac{1}{2} \lambda \langle x_0, y_0 \rangle = \frac{\|x_0\|^2 + \|y_0\|^2 - \|x_0 + y_0\|\|x_0 - y_0\|}{4}. \quad (42)$$

**Proof.** Assume that

$$(x, y) \in P_C(x_0, y_0). \quad (43)$$

(We will show that $P_C(x_0, y_0) \neq \emptyset$ later in this proof.) Then $(x, y)$ solves (19). From Corollary 3.7, there exists a unique $\lambda \in \mathbb{R} \setminus \{\pm 1\}$ such that $x + \lambda y = x_0$, $y + \lambda x = y_0$, and

$$x = \frac{1}{1 - \lambda^2} (x_0 - \lambda y_0) \quad \text{and} \quad y = \frac{1}{1 - \lambda^2} (y_0 - \lambda x_0). \quad (44)$$

Because $(x, y) \in C$, Proposition 3.8(iii) shows that of the quadratic equation

$$\lambda \text{ is a solution of } (1 + \mu^2) \langle x_0, y_0 \rangle = \mu (\|x_0\|^2 + \|y_0\|^2), \quad (45)$$

which is a quadratic equation in the real variable $\mu$. Set

$$\lambda_\pm := \frac{\|x_0\|^2 + \|y_0\|^2 \pm \|x_0 + y_0\|\|x_0 - y_0\|}{2 \langle x_0, y_0 \rangle}. \quad (46)$$
which are the two (possibly distinct) roots of the quadratic equation in \((45)\). By \((45)\) and Proposition 3.9, we deduce that \(\lambda \in \{\lambda_-, \lambda_+\}\) and that \(\lambda_+ \lambda_- = 1\). Because \(x_0 \neq \pm y_0\), Proposition 3.9 also yields \(\lambda_+ \neq \lambda_-\) and
\[
\lambda_+ \langle x_0, y_0 \rangle > \lambda_- \langle x_0, y_0 \rangle. \tag{47}
\]
Hence neither \(\lambda_+\) nor \(\lambda_-\) is equal to \(\pm 1\). Now we (well) define
\[
x_\pm = \frac{1}{1 - \lambda_\pm^2} (x_0 - \lambda \pm y_0) \quad \text{and} \quad y_\pm = \frac{1}{1 - \lambda_\pm^2} (y_0 - \lambda \pm x_0). \tag{48}
\]
In view of \((44)\), \(x \in \{x_-, x_+\}\). Because \(\lambda_\pm\) solve the quadratic equation in \((45)\), we deduce from Proposition 3.8(iii) that \(\langle x_+, y_+ \rangle = \langle x_-, y_- \rangle = 0\), i.e., \((x_+, y_+)\) and \((x_-, y_-)\) both belong to \(C\). Recalling the definition of \(f\) from \((17)\), we note that Proposition 3.8(iv) and \((47)\) result in \(f(x_+, y_+) > f(x_-, y_-)\). On the other hand, we know that \((x, y)\) is either \((x_+, y_+)\) or \((x_-, y_-)\). Altogether, because we’ve assumed at the beginning of the proof in \((43)\) that \((x, y)\) is a minimizer of \(f\), we conclude that \((x, y) = (x_-, y_-)\). This yields \((41)\). Moreover, \((42)\) follows because
\[
f(x, y) = f(x_-, y_-) = \frac{\lambda_- \langle x_0, y_0 \rangle}{2} = \frac{\|x_0\|^2 + \|y_0\|^2 - \|x_0 + y_0\| \|x_0 - y_0\|}{4} \tag{49}
\]
by \((46)\).

It remains now to show that \(P_C(x_0, y_0) \neq \emptyset\). Let \(U\) be a closed linear subspace of \(X\). In view of \((15)\), \((49)\), and \((17)\) it suffices to show that \(f(x, y) \leq f(P_U x_0, P_U y_0)\), i.e.,
\[
\frac{\|x_0\|^2 + \|y_0\|^2 - \|x_0 + y_0\| \|x_0 - y_0\|}{4} \leq \frac{1}{2} \|P_U x_0 - x_0\|^2 + \frac{1}{2} \|P_U y_0 - y_0\|^2. \tag{50}
\]
To this end, recall that the reflector \(R_U := P_U - P_{U^\perp}\) is a linear isometry. Using Cauchy-Schwarz, we thus estimate
\[
\|x_0 + y_0\| \|x_0 - y_0\| \tag{51a}
\]
\[
= \|x_0 + y_0\| \|R_U(x_0 - y_0)\| \tag{51b}
\]
\[
\geq \langle x_0 + y_0, R_U(x_0 - y_0) \rangle \tag{51c}
\]
\[
= \langle x_0 + y_0, P_U(x_0 - y_0) - P_{U^\perp}(x_0 - y_0) \rangle \tag{51d}
\]
\[
= \langle x_0 + y_0, P_U(x_0 - y_0) \rangle + \langle x_0 + y_0, P_{U^\perp}(y_0 - x_0) \rangle \tag{51e}
\]
\[
= \langle P_U(x_0 + y_0), P_U(x_0 - y_0) \rangle + \langle P_{U^\perp}(x_0 + y_0), P_{U^\perp}(y_0 - x_0) \rangle \tag{51f}
\]
\[
= \langle P_U x_0 + P_{U^\perp} y_0, P_U x_0 - P_{U^\perp} y_0 \rangle + \langle P_{U^\perp} x_0 + P_{U^\perp} y_0, P_{U^\perp} y_0 - P_{U^\perp} x_0 \rangle \tag{51g}
\]
\[
= \|P_U x_0\|^2 - \|P_{U^\perp} y_0\|^2 + \|P_{U^\perp} y_0\|^2 - \|P_{U^\perp} x_0\|^2. \tag{51h}
\]
This implies
\[ \|P_U x_0\|^2 + \|P_{U^\perp} y_0\|^2 - \|x_0 + y_0\| \|x_0 - y_0\| \leq \|P_U y_0\|^2 + \|P_{U^\perp} x_0\|^2. \]  
(52)
Adding to this \(\|P_{U^\perp} x_0\|^2 + \|P_U y_0\|^2\) yields
\[ \|x_0\|^2 + \|y_0\|^2 - \|x_0 + y_0\| \|x_0 - y_0\| \leq 2\|P_U y_0\|^2 + 2\|P_{U^\perp} x_0\|^2. \]  
(53)
Finally, dividing (53) by 4 gives (50) and we are done. □

**Proposition 4.3.** Suppose that \((x_0, y_0) \in X \times X\) satisfies \(x_0 = \pm y_0\). Then
\[ P_C(x_0, y_0) = \bigcup \{ (P_U x_0, P_{U^\perp} y_0) \mid U \text{ is a closed subspace of } X \}; \]  
(54)
this can also be written as
\[ P_C(x_0, y_0) = \{(0, y_0)\} \cup \left\{ (0, y_0) + \left( \langle u, x_0 \rangle u, -\langle u, y_0 \rangle u \right) \mid u \in S \right\}, \]  
(55)
where \(S = \{ z \in X \mid \|z\| = 1 \}\) is the unit sphere of \(X\).

**Proof.** In view of Lemma 3.1, let \(U\) be an arbitrary closed subspace of \(X\). Then
\[ P_{U \times U^\perp}(x_0, y_0) = (P_U x_0, P_{U^\perp} y_0). \]  
(56)
Let \(f\) be defined as in (17). Using the assumption that \(x_0 = \pm y_0\) in (57c), we see that
\[ f(P_U x_0, P_{U^\perp} y_0) = \frac{1}{2} \|x_0 - P_U x_0\|^2 + \frac{1}{2} \|y_0 - P_{U^\perp} y_0\|^2 \]  
(57a)
\[ = \frac{1}{2} \|P_{U^\perp} x_0\|^2 + \frac{1}{2} \|P_U y_0\|^2 \]  
(57b)
\[ = \frac{1}{2} \|P_{U^\perp} x_0\|^2 + \frac{1}{2} \|P_U x_0\|^2 \]  
(57c)
\[ = \frac{1}{2} \|x_0\|^2 \]  
(57d)
\[ = \frac{1}{4} \|x_0\|^2 + \frac{1}{4} \|y_0\|^2 \]  
(57e)
is independent of \(U\)! This proves (54).

We now tackle (55) via (14). So let \(U\) be a linear subspace of \(X\) with \(\dim U \leq 1\).

If \(U = \{0\}\), then \(U^\perp = X\) and \((P_U x_0, P_{U^\perp} y_0) = (0, y_0)\) which is the first term on the right side of (55).

Now assume that \(\dim U = 1\), say \(U = \mathbb{R} u\), where \(u \in S\). Then \(\|u\| = 1\), \(P_U x_0 = \langle u, x_0 \rangle u\) and \(P_{U^\perp} y_0 = y_0 - \langle u, y_0 \rangle u\). Hence
\[ (P_U x_0, P_{U^\perp} y_0) = (0, y_0) + \left( \langle u, x_0 \rangle u, -\langle u, y_0 \rangle u \right) \]  
(58)
which yields the second term on the right side of (55). □

Let us summarize our work in one convenient theorem.
Theorem 4.4 (main result). The set \( C \) defined in (2) is proximinal. Let \((x_0, y_0) \in X \times X\). Then exactly one of the following three cases occurs.

(i) \( \langle x_0, y_0 \rangle = 0, \frac{1}{2} d^2_C(x_0, y_0) = 0, \) and

\[ P_C(x_0, y_0) = (x_0, y_0). \] (59)

(ii) \( \langle x_0, y_0 \rangle \neq 0, x_0 \neq \pm y_0, \)

\[ P_C(x_0, y_0) = \frac{1}{1 - \lambda^2} (x_0 - \lambda y_0, y_0 - \lambda x_0), \] (60)

and

\[ \frac{1}{2} d^2_C(x_0, y_0) = \frac{1}{2} \lambda \langle x_0, y_0 \rangle = \frac{\|x_0\|^2 + \|y_0\|^2 - \|x_0 + y_0\| \|x_0 - y_0\|}{4}, \] (61)

where

\[ \lambda := \frac{\|x_0\|^2 + \|y_0\|^2 - \|x_0 + y_0\| \|x_0 - y_0\|}{2 \langle x_0, y_0 \rangle} \neq \pm 1. \] (62)

(iii) \( \langle x_0, y_0 \rangle \neq 0, x_0 = \pm y_0, \frac{1}{2} d^2_C(x_0, y_0) = \frac{1}{4} (\|x_0\|^2 + \|y_0\|^2), \) and

\[ P_C(x_0, y_0) = \left\{ (0, y_0) \bigcup \left\{ (0, y_0) + (\langle u, x_0 \rangle u, -\langle u, y_0 \rangle u) \right\} \mid u \in S \right\} \] (63)

is not a singleton, where \( S = \{ z \in X \mid \|z\| = 1 \} \) is the unit sphere of \( X \).

Remark 4.5. Several results regarding Theorem 4.4 are in order.

(i) (relationship to Elser’s work) Case (ii) was considered by Elser who obtained the basic structure of (60) in a more general setting; see [5, equation (19)]. However, his analysis is carried out in the finite-dimensional setting. And neither was the explicit formula for \( \lambda \) in (62) presented nor the case (iii) discussed.

(ii) A convenient selection of \( P_C \) in case (iii) is \((0, y_0)\) or \((x_0, 0)\).

(iii) If we work in \( X = \mathbb{R}^n \) and we require the complete projection in case (iii), then we may invoke Fact 2.3.

(iv) It is possible to subsume case (i) into case (ii) by setting \( \lambda = 0 \) and using (60) to obtain (59).

(v) A tight injective parametrization in case (iii) is

\[ P_C(x_0, y_0) = \left\{ (0, y_0) \bigcup \left\{ (0, y_0) + (\langle u, x_0 \rangle u, -\langle u, y_0 \rangle u) \right\} \right\} \] (64)

where “\( \bigcup \)” denotes disjoint union. Hence the cardinality of \( P_C(x_0, y_0) \) is the same as the cardinality of \( S \).
When $X = \mathbb{R}$, then the reader may confirm that Theorem 4.4 simplifies to the following:

**Example 4.6.** Suppose that $X = \mathbb{R}$. Then

$$C = \{(x, y) \in \mathbb{R}^2 \mid xy = 0\} = (\mathbb{R} \times \{0\}) \cup (\{0\} \times \mathbb{R}).$$

Let $(x_0, y_0) \in \mathbb{R}^2$. Then exactly one of the following cases holds.

(i) $|x_0| \neq |y_0|$ and

$$P_C(x_0, y_0) = \begin{cases} 
(0, y_0), & \text{if } |x_0| < |y_0|; \\
(x_0, 0), & \text{if } |x_0| > |y_0|. 
\end{cases}$$

(ii) $|x_0| = |y_0|$ and

$$P_C(x_0, y_0) = \{(x_0, 0), (0, y_0)\}.$$  

For an illustration, see Figure 1.

Figure 1: Projecting onto the cross $C$ when $X = \mathbb{R}$ (see Example 4.6).
