Cellular-Connected UAV with Adaptive Air-to-Ground Interference Cancellation and Trajectory Optimization

Peiming Li, Lifeng Xie, Jianping Yao, and Jie Xu

Abstract

This letter studies a cellular-connected unmanned aerial vehicle (UAV) scenario, in which a UAV user communicates with ground base stations (GBSs) in cellular uplink by sharing the spectrum with ground users (GUs). To deal with the severe air-to-ground (A2G) co-channel interference, we consider an adaptive interference cancellation (IC) approach, in which each GBS can decode the GU’s messages by adaptively switching between the modes of IC (i.e., precancelling the UAV’s resultant interference) and treating interference as noise (TIN). By designing the GBSs’ decoding modes, jointly with the wireless resource allocation and the UAV’s trajectory control, we maximize the UAV’s data-rate throughput over a finite mission period, while ensuring the minimum data-rate requirements at individual GUs. We propose an efficient algorithm to solve the throughput maximization problem by using the techniques of alternating optimization and successive convex approximation (SCA). Numerical results show that our proposed design significantly improves the UAV’s throughput as compared to the benchmark schemes without the adaptive IC and/or trajectory optimization.

I. INTRODUCTION

Cellular-connected unmanned aerial vehicles (UAVs) have emerged as one of the key technologies for beyond fifth-generation (B5G) or sixth-generation (6G) cellular networks to enable secure and long-distance UAV applications [1]–[3]. UAVs can be connected with cellular networks as a new type of aerial users, which can share the scarce spectrum resources with conventional ground users (GUs). As the UAVs fly at a relatively high altitude and normally have strong line-of-sight (LoS) links with ground base stations (GBSs), the resultant severe air-to-ground (A2G) co-channel interference from UAVs to GBSs is becoming a key technical challenge faced in cellular uplink integrated with UAVs.

In the literature, there have been various interference mitigation approaches proposed to tackle the A2G interference issue (see, e.g., [4]). For instance, the authors in [5] proposed a new inter-cell interference coordination approach that is jointly designed with the UAV-GBS association. [6] investigated a local interference cancellation (IC) approach, in which the associated GBS can first decode the UAV’s messages and precancel the resultant interference to facilitate the decoding of GUs’ messages. Furthermore, [7]–[9] investigated a cooperative IC method, in which GBSs can decode the UAV’s messages and then send them to nearby GBSs to enable their cooperative IC, at the cost of data sharing over backhaul links. Despite their benefits, these prior works only considered one-shot resource allocation by considering UAVs staying at fixed locations, in which their controllable mobility was overlooked.

By exploiting the controllable mobility, the trajectory design has been recognized as a unique new design degree of freedom for optimizing the performance of UAV communications [2], [3]. For cellular-connected UAVs, the authors in [10] and [11] considered the UAV trajectory optimization to maximize the UAV user’s data-rate throughput over a certain mission period under different setups. However, only interference coordination with power control was considered in [10], [11], in which the A2G interference was treated as noise.

To unlock the full potential of cellular-connected UAV, this letter exploits both benefits of IC and trajectory design to maximize the UAV communication performance. In particular, we consider an uplink spectrum sharing scenario, in which a UAV user communicates with GBSs by sharing the scarce spectrum resources with GUs. We consider a new adaptive A2G IC approach, in which one or more GBSs are enabled to adaptively decode the UAV’s messages based on the channel conditions, such that they can precancel the resultant A2G interference to facilitate
the decoding of the GU’s messages. Different from the cooperative IC method in [7]–[9], this approach only requires local IC at multiple GBSs, thus avoiding the data sharing cost over backhauls. Under this setup, we consider a particular UAV mission period, and adaptively optimize each GBS’s decoding modes between IC and treating interference as noise (TIN), jointly with the wireless resource allocation and the UAV’s trajectory control. Our objective is to maximize the data-rate throughput of the UAV, while ensuring the minimum data-rate requirements at individual GUs. Although the formulated throughput maximization problem is highly non-convex, we propose an efficient algorithm to obtain a high-quality solution by using the techniques of alternating optimization and successive convex approximation (SCA). Numerical results show that our proposed joint design substantially improves the UAV’s throughput as compared to the benchmark schemes without the adaptive IC and/or trajectory optimization.

As shown in Fig. 1, we consider the uplink spectrum sharing scenario with one cellular-connected UAV user, where there are $K$ GBSs each serving one GU by using the same frequency band with the UAV. Let $\mathcal{K} \triangleq \{1, \ldots, K\}$ denote the set of GBSs or their associated GUs. Suppose that each GBS $k \in \mathcal{K}$ locates at a fixed location $(x_k, y_k, 0)$ on the ground in a three-dimensional (3D) coordinate system, where $\nu_k = (x_k, y_k) \in \mathbb{R}^{2\times1}$ denotes the horizontal location.

We focus on a particular mission period $\mathcal{T} \triangleq [0, T]$, with finite duration $T$ in second (s), in which the UAV flies horizontally at a fixed altitude $H \geq 0$. For ease of exposition, we discretize the whole period $\mathcal{T}$ into $N$ time slots each with a given duration $\delta_t = T/N$, where $\delta_t$ is
sufficiently small such that the UAV’s location is approximately unchanged during each slot. Let \((x[n], y[n], H)\) denote the time-varying location of the UAV at time slot \(n \in \mathcal{N} \triangleq \{1, \ldots, N\}\), where \(u[n] = (x[n], y[n])\) denotes the UAV’s horizontal location. Let \(u_I\) and \(u_F\) denote the UAV’s horizontal initial and final locations, respectively, which are predetermined based on the specific UAV mission. As a result, we have the following UAV flight constraints:

\[
\|u[n] - u[n-1]\| \leq V_{\text{max}} \delta_t, \forall n \in \mathcal{N},
\]

\[
u[n] = u_I, \quad u[N] = u_F,
\]

where \(\| \cdot \|\) denotes the Euclidean norm.

We consider a quasi-static channel model, in which the wireless channels remain unchanged over each time slot. In general, the A2G wireless links are mainly dominated by the LoS propagation due to the UAV’s high flight altitude. Therefore, we denote the channel power gain from the UAV to each GBS \(k \in K\) as

\[
h_k(u[n]) = \beta_0 d_k^{-\alpha}(u[n]) = \beta_0 / (H^2 + \|u[n] - \nu_k\|^2)^{\alpha/2},
\]

where \(\alpha \geq 2\) denotes the pathloss exponent, \(\beta_0\) denotes the channel power gain at the reference distance of \(d_0 = 1\) m, and \(d_k(u[n]) = \sqrt{H^2 + \|u[n] - \nu_k\|^2}\) denotes the distance from the UAV to GBS \(k \in K\) at time slot \(n \in \mathcal{N}\). Furthermore, we assume that the GU stays at slow-varying or fixed locations. Accordingly, we denote \(g_k\) as the channel power gain between GBS \(k \in K\) and its associated GU, which is assumed to remain unchanged over the mission period, and thus can be known by the GBSs \(a\)-priori to facilitate the adaptive IC and trajectory design. Furthermore, let \(q_k[n] \geq 0\) and \(p[n] \geq 0\) denote the transmit powers of GU \(k\) and the UAV at time slot \(n \in \mathcal{N}\), and \(P\) and \(Q_k\) denote their maximum transmit powers, respectively. Thus, we have \(p[n] \leq P\) and \(q_k[n] \leq Q_k, \forall k \in K, n \in \mathcal{N}\).

Next, we consider the cellular-connected UAV communication. As the UAV normally has strong LoS channels with multiple GBSs, we allow multiple GBSs to adaptively decode the UAV’s messages to enable IC for facilitating the GUs’ communications. Suppose that the UAV adopts the adaptive rate transmission, by setting the coding rate as \(r[n] \geq 0\), which is a variable to be optimized later. Accordingly, at each time slot \(n\), each GBS can determine whether to decode the UAV’s messages or treating them as noise. Let \(\tau_k[n] \in \{0, 1\}\) denote the decoding mode of GBS \(k \in K\) at time slot \(n \in \mathcal{N}\), where \(\tau_k[n] = 1\) means that GBS \(k\) needs to decode the UAV’s messages (with IC) and \(\tau_k[n] = 0\) otherwise (with TIN). To ensure the UAV’s communication,
at least one GBS should successfully decode the UAV’s messages at each time slot $n \in \mathcal{N}$, and thus we have $\sum_{k \in \mathcal{K}} \tau_k[n] \geq 1, \forall n \in \mathcal{N}$. Notice that the achievable rate from the UAV to GBS $k \in \mathcal{K}$ at time slot $n \in \mathcal{N}$ is given by

$$R_k(p[n], u[n], q_k[n]) = \log_2 \left( 1 + \frac{h_k(u[n])p[n]}{\sigma_k^2 + q_k[n]g_k} \right),$$

where $\sigma_k^2$ denotes the background noise power at GBS $k$ containing the potential terrestrial inter-cell interference from other GUs. Therefore, it must follow that

$$\tau_k[n]r[n] \leq R_k(p[n], u[n], q_k[n]), \forall k \in \mathcal{K}, n \in \mathcal{N}.$$ 

Then, we consider the decoding of the associated GU $k$’s messages at each GBS $k \in \mathcal{K}$. Consider a particular time slot $n \in \mathcal{N}$. If $\tau_k[n] = 1$ holds with the UAV’s messages successfully decoded, then GBS $k$ can adopt IC, i.e., GBS $k$ can first cancel the UAV’s resulting interference, and then decode the GU’s messages. In this case, the achievable rate of GU $k$ at time slot $n$ is

$$\bar{R}_{IC}^k(q_k[n]) = \log_2(1 + g_kq_k[n]/\sigma_k^2).$$

On the other hand, if $\tau_k[n] = 0$, then GBS $k$ needs to decode the messages of GU $k$ by TIN (i.e., treating the interference from the UAV as noise). As a result, its achievable rate is given by

$$\bar{R}_{TIN}^k(p[n], u[n], q_k[n]) = \log_2 \left( 1 + \frac{g_kq_k[n]}{\sigma_k^2 + h_k(u[n])p[n]} \right).$$

Our objective is to maximize the UAV’s average throughput (i.e., $\frac{1}{N} \sum_{n \in \mathcal{N}} r[n]$) over the mission period, while ensuring the GUs’ communication requirements. In particular, we suppose that at each time slot $n \in \mathcal{N}$, the achievable rate of each GU must be no less than a certain threshold $\Gamma_k \geq 0$. The decision variables include the UAV trajectory $\{u[n]\}$, the transmit power of the UAV $\{p[n]\}$ and GUs $\{q_k[n]\}$, the decoding modes of GBSs $\{\tau_k[n]\}$, as well as the UAV’s coding rate $\{r[n]\}$. Therefore, the throughput maximization problem of our interest is formulated
as

\[(P1): \max_{\{\tau_k[n]\},\{q_k[n]\},\{p[n]\},\{u[n]\},\{r[n]\} \geq 0} \frac{1}{N} \sum_{n \in \mathcal{N}} r[n] \]

s.t. \[\|u[n] - u[n-1]\| \leq V_{\text{max}} \delta_t, \forall n \in \mathcal{N} \]  
\[u[0] = u_I, \quad u[N] = u_F \]  
\[0 \leq p[n] \leq P, \quad 0 \leq q_k[n] \leq Q_k, \forall k \in \mathcal{K}, n \in \mathcal{N} \]  
\[\sum_{k \in \mathcal{K}} \tau_k[n] \geq 1, \quad \tau_k[n] \in \{0, 1\}, \forall k \in \mathcal{K}, n \in \mathcal{N} \]  
\[\tau_k[n] r[n] \leq R_k(p[n], u[n], q_k[n]), \forall k \in \mathcal{K}, n \in \mathcal{N} \]  
\[\tau_k[n] \bar{R}^{\text{IC}}_k(q_k[n]) + (1 - \tau_k[n]) \bar{R}^{\text{TIN}}_k(p[n], u[n], q_k[n]) \geq \Gamma_k, \forall k \in \mathcal{K}, n \in \mathcal{N}. \]

Here, (2) and (3) denote the UAV flight constraints, (4) denotes the power constraints for both the UAV and GUs, (5) denotes the decoding mode constraints for GBSs, (6) denotes the rate constraints for the UAV, and (7) denotes the minimum rate constraints for GUs. Note that problem (P1) is a mixed-integer non-convex problem, as the variable \(\{\tau_k[n]\}\) are binary, and the constraints in (6) and (7) are non-convex due to the coupling of variables.

Before proceeding, we check the feasibility of problem (P1). Notice that problem (P1) is feasible, as long as the mission duration \(T\) is sufficient for the UAV to fly from the initial location to the final location (i.e., \(\|u_F - u_I\| \leq V_{\text{max}}T\)) and the communication requirements of GUs can be met at their maximum powers under the IC mode (i.e., \(\bar{R}_k^{\text{IC}}(Q_k) \geq \Gamma_k, \forall k \in \mathcal{K}\)). Supposing that \(T\) and \(\{Q_k\}\) are sufficiently large, we focus on the case when problem (P1) is feasible in the sequel.

### III. Proposed Solution to Problem (P1)

In this section, we propose an efficient algorithm to solve problem (P1) iteratively by using the technique of alternating optimization. In particular, in each iteration we optimize the resource allocation (i.e., the decoding modes of GBSs \(\{\tau_k[n]\}\), and the power control of GUs \(\{q_k[n]\}\) and the UAV \(\{p[n]\}\)), as well as the UAV trajectory \(\{u[n]\}\), in an alternating manner, by assuming the other to be given.
A. Resource Allocation for (P1) Under Given UAV Trajectory

Under any given UAV trajectory \( \{u[n]\} \), problem (P1) is reduced to

\[
(P1.1): \quad \max_{\{\tau_k[n]\}, \{q_k[n]\}, \{p[n]\}, \{r[n]\} \geq 0} \quad \frac{1}{N} \sum_{n \in \mathcal{N}} r[n]
\]
\[\text{s.t. } (4), (5), (6), (7).\]

It is observed that problem (P1.1) can be decomposed into \( N \) subproblems in problem (P1.2), each corresponding to optimizing \( \{\tau_k[n]\}, \{q_k[n]\}, p[n], \) and \( r[n] \) at time slot \( n \in \mathcal{N} \) with a given UAV location \( u[n] \).

\[
(P1.2): \quad \max_{\{\tau_k[n]\}, \{q_k[n]\}, p[n], r[n] \geq 0} \quad r[n]
\]
\[\text{s.t. } 0 \leq p[n] \leq P, \quad 0 \leq q_k[n] \leq Q_k, \forall k \in \mathcal{K} \quad (8)
\]
\[\sum_{k \in \mathcal{K}} \tau_k[n] \geq 1, \quad \tau_k[n] \in \{0, 1\}, \forall k \in \mathcal{K} \quad (9)
\]
\[\tau_k[n]r[n] \leq R_k(p[n], u[n], q_k[n]), \forall k \in \mathcal{K} \quad (10)
\]
\[\tau_k[n]\tilde{R}_{IC}[q_k[n]] + (1 - \tau_k[n])\tilde{R}_{TIN}[p[n], u[n], q_k[n]] \geq \Gamma_k, \forall k \in \mathcal{K}. \quad (11)
\]

To solve problem (P1.2), we first solve for \( \{q_k[n]\}, p[n], \) and \( r[n] \) by considering the decoding modes \( \{\tau_k[n]\} \) to be fixed, and then compare the achieved objective values under different \( \{\tau_k[n]\} \) to obtain the optimal solution.

First, consider the case when \( \{\tau_k[n]\} \) are given. In this case, let \( \mathcal{K}^{IC} = \{k \in \mathcal{K}|\tau_k[n] = 1\} \) denote the set of GBSs adopting the IC mode and \( \mathcal{K}^{TIN} = \{k \in \mathcal{K}|\tau_k[n] = 0\} \) denote that adopting the TIN mode. If GBS \( k \in \mathcal{K}^{IC} \), based on constraints (10) and (11), the optimal power allocation of GU \( k \in \mathcal{K}^{IC} \) is

\[
q_k^*[n] = (2^{\Gamma_k} - 1)\sigma_k^2/g_k, \forall k \in \mathcal{K}^{IC}. \quad (12)
\]

In this case, constraints (10) and (11) respectively become

\[
r[n] \leq R_k(p[n], u[n], q_k^*[n]), \forall k \in \mathcal{K}^{IC}, \quad (13)
\]
\[
\tilde{R}_{TIN}[p[n], u[n], q_k[n]] \geq \Gamma_k, \forall k \in \mathcal{K}^{TIN}. \quad (14)
\]

As a result, problem (P1.2) under given \( \{\tau_k[n]\} \) is reduced as

\[
(P1.3): \quad \max_{\{q_k[n]\}, p[n], r[n] \geq 0} \quad r[n]
\]
\[\text{s.t. } (8), (13), (14).\]
It is easy to observe that at the optimality of problem (P1.3), the constraints in (14) must be met with strict equality, i.e.,
\[ \bar{R}_{k}^{\text{TIN}}(p[n], u[n], q_k[n]) = \Gamma_k, \forall k \in \mathcal{K}, \] (15)
and accordingly, we have
\[ p[n] = \frac{g_k q_k[n]}{(2^{\Gamma_k} - 1) h_k(u[n])} - \frac{\sigma_k^2}{h_k(u[n])}, \forall k \in \mathcal{K}. \] (16)
Furthermore, by combining (16) with constraint (8), we have the optimal power allocation of GU \( k \in \mathcal{K}^{\text{TIN}} \) as
\[ q_k^*[n] = Q_k, \forall k \in \mathcal{K}^{\text{TIN}}, \] (17)
and
\[ p[n] \leq \min_{k \in \mathcal{K}^{\text{TIN}}} \left( \frac{g_k Q_k}{(2^{\Gamma_k} - 1) h_k(u[n])} - \frac{\sigma_k^2}{h_k(u[n])} \right). \] (18)
Notice that the achievable rate of the UAV or the objective value of problem (P1.3) is monotonically increasing with respect to \( p[n] \). Therefore, based on (18) and \( p[n] \leq P \), we obtain the optimal solution of \( p[n] \) as
\[ p^*[n] = \min \left( \min_{k \in \mathcal{K}^{\text{TIN}}} \left( \frac{g_k Q_k}{(2^{\Gamma_k} - 1) h_k(u[n])} - \frac{\sigma_k^2}{h_k(u[n])} \right), P \right). \] (19)
Accordingly, based on (13), the optimal rate \( r^*[n] \) of the UAV is given as
\[ r^*[n] = \min_{k \in \mathcal{K}^{\text{TIN}}} \left( \frac{R_k(p^*[n], u[n], q_k^*[n])}{Q_k} \right). \] (20)
By combining (12), (17), (19), and (20), the optimal solution to problem (P1.2) with fixed \( \{\tau_k[n]\} \) is obtained.

Next, we compare the obtained achievable rate or optimal objective value in (20) of problem (P1.3) under different values of \( \{\tau_k[n]\} \). Notice that due to the constraints in (9), there are a total number of \( 2^K - 1 \) opinions with at least one of the \( \tau_k[n] \)'s must be one. By comparing the \( 2^K - 1 \) optimal values, we can get the optimal decoding mode solution to problem (P1.2) as \( \tau_k^*[n] \). Accordingly, the optimal solution \( \{q_k^*[n]\}, p^*[n] \), and \( r^*[n] \) in (12), (17), (19), and (20) under the optimal \( \tau_k^*[n] \) correspond to the optimal solution \( \{q_k^*[n]\}, p^*[n] \), and \( r^*[n] \) to problem (P1.2). As such, problem (P1.2) is optimally solved.

With the optimal resource allocation to problem (P1.2) for each time slot \( n \in \mathcal{N} \) at hand, we can obtain the optimal resource allocation during the whole UAV’s mission period \( T \) and obtain the corresponding average throughput. As such, problem (P1.1) is solved.
B. UAV Trajectory Optimization for (P1) Under Given Resource Allocation

Under any given resource allocation \( \{r_k[n]\}, \{q_k[n]\}, \text{ and } \{p[n]\} \), problem (P1) is reduced as the following trajectory optimization problem:

\[
\begin{align*}
\text{(P1.4):} & \quad \max_{\{u[n]\}, \{r[n]\} \geq 0} \frac{1}{N} \sum_{n \in \mathcal{N}} r[n] \\
\text{s.t.} & \quad (2), (3), (6), (7).
\end{align*}
\]

Notice that problem (P1.4) is still a non-convex optimization problem, as the constraints in (6) and (7) are non-convex with respect to \( \{u[n]\} \). Therefore, problem (P1.4) cannot be solved by standard convex optimization techniques. To tackle this difficulty, we adopt the SCA-based algorithm to obtain an efficient solution, which is implemented in an iterative manner as follows.

Consider each iteration \( j \geq 1 \), in which the local trajectory point is denoted as \( \{u^{(j)}[n]\} \). Accordingly, the non-convex constraints in (6) and (7) can be approximated into convex forms as follows. First, we consider constraint (6). Note that \( R_k(p[n], u[n], q_k[n]) \) in (1) is a convex function with respect to \( \|u[n] - \nu_k\|^2 \). As the first-order Taylor expansion of a convex function is a global underestimate of the function value, we have

\[
R_k(p[n], u[n], q_k[n]) \geq \hat{R}^{lb}(p[n], u[n], q_k[n]),
\]

with

\[
\hat{R}^{lb}(p[n], u[n], q_k[n]) \triangleq R_k(p[n], u^{(j)}[n], q_k[n]) - A^{(j)}_k[\|u[n] - \nu_k\|^2 - \|u^{(j)}[n] - \nu_k\|^2],
\]

where \( A^{(j)}_k[n] = \frac{1}{2} \alpha \beta p[n] \beta_0 / \ln 2(p[n] \beta_0 d_k(u^{(j)}[n]) + (\sigma_k^2 + g_k q_k[n]) d_k^{n+1}(u^{(j)}[n])) \). Therefore, the non-convex constraints in (6) can be approximated as the following convex constraints:

\[
\tau_k[n] r[n] \leq \hat{R}^{lb}(p[n], u[n], q_k[n]), \quad \forall k \in \mathcal{K}, n \in \mathcal{N}. \quad (21)
\]

Next, for constraint (7), we rewrite \( \bar{R}^{TIN}_k(p[n], u[n], q_k[n]) \) as

\[
\bar{R}^{TIN}_k(p[n], u[n], q_k[n]) = \log_2 \left( \sigma_k^2 + h_k(u[n]) + q_k[n] g_k \right) - \log_2 \left( \sigma_k^2 + h_k(u[n]) p[n] \right). \quad (22)
\]

Note that the first term at the right-hand-side (RHS) in (22) is a convex functions with respect to \( \|u[n] - \nu_k\|^2 \). Similarly, we have

\[
\begin{align*}
\log_2 & \left( \sigma_k^2 + h_k(u[n]) p[n] + g_k q_k[n] \right) \\
\geq & \log_2 \left( \sigma_k^2 + h_k(u^{(j)}[n]) p[n] + g_k q_k[n] \right) - B^{(j)}_k[n] \left( \|u[n] - \nu_k\|^2 - \|u^{(j)}[n] - \nu_k\|^2 \right) \\
\triangleq & \bar{R}^{lb}_k(p[n], u[n], q_k[n]),
\end{align*}
\]
where $B_k^{(j)}[n] = \frac{1}{2}\alpha p[n]h_0/\ln 2((\sigma_k^2 + p[n]h_0d_k^\alpha(u^{(j)}[n]) + q_k[n]g_k)d_k^{\alpha+1}(u^{(j)}[n]))$. Therefore, the non-convex constraints in (7) can be approximated as the following convex constraints:

$$
\tau_k[n]\bar{R}_k^{IC}(q_k[n]) + (1 - \tau_k[n])(\bar{R}_k^{lb}(p[n], u[n], q_k[n]) - \log_2(\sigma_k^2 + h_k(u[n])p[n])) \geq \Gamma_k,
$$

\(\forall k \in K, n \in N\). (23)

As a result, with given local point \(\{u^{(j)}[n]\}\), problem (P1.4) is approximated as the following convex optimization problem (P1.5), which can thus be solved optimally via standard convex optimization techniques such as CVX [13].

$$
\text{(P1.5):}\quad \max_{\{u[n]\}, \{r[n] \geq 0\}} \frac{1}{N} \sum_{n \in N} r[n]
$$

s.t. (2), (3), (21), (23).

The obtained optimal solution to problem (P1.5) under given local point \(\{u^{(j-1)}[n]\}\) is given as \(\{u^{(j)}[n]\}\), which is then used as the local point for the next iteration \(j + 1\). As the obtained objective value of problem (P1.4) is monotonically non-decreasing for each iteration and the optimal value is upper bounded, it is clear that the SCA-based update will lead to a converged solution to problem (P1.4).

C. Complete Algorithm for Solving (P1)

By combining the solutions in Sections III-A and III-B, we solve problem (P1) by updating the variables iteratively in an alternating manner. In each iteration, we first solve problem (P1.1) under given \(\{u[n]\}\) to obtain \(\{\tau_k[n]\}, \{q_k[n]\}, \{p[n]\}\) and \(\{r[n]\}\), and then solve problem (P1.4) under the obtained \(\{\tau_k[n]\}, \{q_k[n]\}, \{p[n]\}\) to update \(\{u[n]\}\) and \(\{r[n]\}\). For each iteration, the updated objective value of problem (P1) can be shown to be monotonically non-decreasing. As the optimal value of problem (P1) is upper bounded, the convergence of the SCA-based solution to problem (P1) can be ensured. Notice that the overall computation complexity for the proposed algorithm is \(O(2^KN/\varepsilon + K^2N^3/\varepsilon^2)\), where \(\varepsilon\) is the desired accuracy.

IV. Numerical Results

This section provides numerical results to validate the performance of the proposed joint design, as compared with the following three benchmark schemes.
• **Straight-fly scheme**: The UAV flies straight from the initial to the final locations at a constant speed $\|u_f - u_i\|/T$. This scheme corresponds to solving problem (P1.1) under a given UAV trajectory. This is also adopted as the initial UAV trajectory for the proposed design.

• **Egoistic decoding scheme**: In this scheme, only one GBS decodes the UAV’s messages at each time slot $n \in \mathcal{N}$. This scheme corresponds to solving problem (P1) by replacing constraint (5) as $\sum_{k \in \mathcal{K}} \tau_k[n] = 1$, $\forall n \in \mathcal{N}$.

• **Altruistic decoding scheme**: In this scheme, all GBSs are enabled to decode the UAV’s messages. This scheme corresponds to solving problem (P1) under fixed decoding modes with $\tau_k[n] = 1$, $\forall k \in \mathcal{N}, n \in \mathcal{N}$, where constraint (6) becomes

$$r[n] \leq \min_{k \in \mathcal{K}} R_k(p[n], u[n], q_k[n]), \forall n \in \mathcal{N}.$$

In the simulation, suppose that there are $K = 3$ GBSs and GUs distributed within a geographic area of size $1 \times 1$ km$^2$, as shown in Fig. 2. We set the flying altitude of the UAV as $H = 100$ m, the reference channel power gain as $\beta_0 = -30$ dB, the pathloss exponent as $\alpha = 2$, the noise power as $\sigma_k^2 = -50$ dBm, $\forall k \in \mathcal{K}$, the maximum UAV speed as $V_{\text{max}} = 50$ m/s, the maximum transmit power of the UAV as $P = 30$ dBm, the maximum transmit power of GUs as $Q_k = 30$ dBm $k \in \mathcal{K}$, and the minimum rate threshold of GUs as $\Gamma_k = 2 \text{ bps/Hz}, \forall k \in \mathcal{K}$. We consider a simplified path loss model for the ground wireless channels as $g_k = \theta_0(\Theta_k/d_0)^{-\epsilon}$, $\forall k \in \mathcal{K}$, where $\epsilon = 3$ is the pathloss exponent, $\theta_0 = -40$ dB corresponds to the pathloss at the reference distance.
of $d_0 = 1$ m, $\Theta_k$ denotes the corresponding distance from the GBS to its associated GU. The mission period $T$ is discretized into $N = 200$ time slots.

Fig. 2 shows the optimized UAV trajectory projected on the horizontal plane with $T = 150$ s, in which each trajectory is sampled every three seconds for illustration. It is observed that for the proposed design, the UAV first reaches a point between GBSs 1 and 2, then flies towards GBS 3, and hovers there for around 92 s. The UAV is observed to first connect with GBS 1 from 0 to 18.75 s, then with both GBSs 1 and 2 from 18.75 s to 24.75 s, and finally with GBS 3, thus maximizing the UAV communication performance while protecting the GUs’ communications. By contrast, for the egoistic decoding scheme, the UAV is observed to fly close to GBS 1 and GBS 3, as it needs to connect with them in time interval $[0, 27.75]$ s and $(27.75, 150]$ s, respectively. For the altruistic decoding scheme, the UAV is observed to fly among the three GBSs, as all the GBSs need to decode the messages of the UAV. For the straight-fly scheme, the UAV is observed to connect with GBSs 1 and 3 during the whole period $T$.

Fig. 3 shows the average throughput of the UAV versus the mission duration $T$. It is observed that as $T$ becomes larger, the UAV’s average throughput increases for all the four schemes as the UAV can better exploit the mobility via hovering at desired locations for longer durations. It is observed that the proposed design achieves the highest throughput among the four schemes over all regimes of $T$, by jointly exploiting both trajectory design and adaptive IC over time. The altruistic decoding scheme is observed to perform worst, which is due to the fact that the
UAV’s coding rate needs to be sufficiently low so that all GBSs can decode the UAV’s messages.

V. CONCLUSION

This letter studied an uplink spectrum sharing scenario for cellular-connected UAV, in which a UAV user communicates with GBSs by sharing the spectrum with GUs. We proposed a new approach that jointly exploits the trajectory optimization and adaptive IC to maximize the data-rate throughput of the UAV, while protecting the communication data-rate of each GU. How to extend the results to the cases with multiple UAVs, spectrum sharing of both uplink and downlink, or online designs are interesting directions worth pursuing in future research.
