Abstract

A directed graph is semi-transitive if and only if it is acyclic and for any directed path \( u_1 \rightarrow u_2 \rightarrow \cdots \rightarrow u_t, \ t \geq 2 \), either there is no edge from \( u_1 \) to \( u_t \) or all edges \( u_i \rightarrow u_j \) exist for \( 1 \leq i < j \leq t \).

In this paper, we study semi-transitivity of families of directed split graphs obtained by iterations of morphisms applied to the adjacency matrices and giving in the limit infinite directed split graphs. A split graph is a graph in which the vertices can be partitioned into a clique and an independent set. We fully classify semi-transitive infinite directed split graphs when a morphism in question can involve any \( n \times m \) matrices over \( \{-1, 0, 1\} \) with a single natural condition.

1 Introduction

The notion of a semi-transitive orientation of a graph was introduced by Halldórsson et al. in [4] (also see [5]) as means to completely characterize so-called word-representable graphs [7, 8]: A graph is word-representable if and only if it admits a semi-transitive orientation. Word-representable graphs, and thus semi-transitive graphs (i.e. semi-transitively orientable graphs), generalize several important classes of graphs, e.g. circle graphs, 3-colorable graphs and comparability graphs. Semi-transitive orientations are also interesting in their own right as a generalization of transitive orientations.

Split graphs [3] are graphs in which the vertices can be partitioned into a clique and an independent set. The study of split graphs attracted much attention in the literature (e.g. see [2] and references

*Department of Mathematics and Statistics, University of Strathclyde, 26 Richmond Street Glasgow G1 1XH, United Kingdom
therein). Related to our context, the study of semi-transitive orientability of split graphs was initiated in \cite{1,9}, where certain subclasses of semi-transitive split graphs were characterized in terms of forbidden subgraphs. Also, split graphs were instrumental in \cite{1} to solve a 10 year old open problem in the theory of word-representable graphs.

In a recent work \cite{6}, the first author of this paper extended the studies in \cite{1,9} by characterizing semi-transitive split graphs in terms of permutations of columns of the adjacency matrices. Moreover, \cite{6} studies semi-transitivity of split graphs obtained by iterations of morphisms applied to the adjacency matrices, and thus giving yet another link to combinatorics on words \cite{10} (the original link comes from the definition of a word-representable graph). A number of general theorems and a complete classification of semi-transitive orientability in the case of morphisms defined by $2 \times 2$ matrices are given in \cite{6}.

In this paper, we study families of directed split graphs obtained by iterations of morphisms (involving three matrices $A, B, C$) applied to the adjacency matrices and giving as the limit infinite directed split graphs. For each of such a family we ask the question on whether all graphs in the family are oriented semi-transitively (i.e. are semi-transitive) or a finite iteration $k$ of the morphism produces a non-semi-transitive orientation (which will stay non-semi-transitive for all iterations $> k$). In the former case, we say that the infinite split graph’s index of semi-transitivity is $\infty$ (denoted $\text{IST}(A, B, C) = \infty$), and in the latter case it is $k$ (assuming $k$ is minimal possible).

The novelty of our paper is in the study of directed graphs in connection to semi-transitive orientations (as opposed to undirected graphs in the long list of relevant research papers cited in \cite{7,8}), and in that we offer a way to generate interesting (from semi-transitivity point of view) families of directed split graphs using adjacency matrices and iterations of morphisms. Our research will contribute to improving further known algorithms to recognise semi-transitive orientations (on directed split graphs and beyond). It comes somewhat as a surprise that we were able to completely classify infinite directed split graphs with the index of semi-transitivity $\infty$, where morphisms in question involve almost arbitrary $n \times m$ matrices over $\{-1, 0, 1\}$ as opposed to, say, $2 \times 2$ matrices in \cite{6} (in a different context though); the only natural condition, to ensure that our definitions work, is that $A$ has a 0. Our classification is done via several results depending on the structures of matrices $A, B, C$ in question, and it is summarised in the diagram in Figure \cite{1}. Following the diagram, one can easily determine whether $\text{IST}(A, B, C) = \infty$ for any given $A, B, C$. 

2
Figure 1: A guide to the classification results where $A$ is assumed to have a 0 (a natural condition to ensure that our definitions work). For example, if none of $A, B, C$ is a layered matrix then Theorem 29 is to be applied.

2 Preliminaries

2.1 Semi-transitive orientations and split graphs

Graphs in this paper have no loops or multiple edges. Any split graph $S_n$ on $n$ vertices can be partitioned into a maximal clique $K_m$ and an independent set $E_{n-m}$, and we write $S_n = (E_{n-m}, K_m)$.

A directed graph is oriented semi-transitively if and only if it is acyclic and for any directed path $u_1 \rightarrow u_2 \rightarrow \cdots \rightarrow u_t$, $t \geq 2$, either there is no edge from $u_1$ to $u_t$ or all edges $u_i \rightarrow u_j$ exist for $1 \leq i < j \leq t$. Graphs admitting semi-transitive orientations are semi-transitive.

In this paper, we will need the following results on semi-transitive orientations and split graphs, where a source (resp., sink) is a vertex of in-degree (resp., out-degree) 0.

**Lemma 1** ([9]). Let $K_m$ be a clique in a graph $G$. Then any acyclic orientation of $G$ induces a transitive orientation on $K_m$ (where the presence of edges $u \rightarrow v$ and $v \rightarrow z$ implies the presence of the edge $u \rightarrow z$). In particular, any semi-transitive orientation of $G$ induces a transitive orientation on $K_m$. In either case, the orientation induced on $K_m$ contains a single source and a single sink.
Figure 2: Three types of vertices in $E_{n-m}$ in a semi-transitive orientation of $(E_{n-m}, K_m)$. The vertical oriented paths are a schematic way to show (parts of) $\vec{P}$.

**Theorem 2** ([9]). Any semi-transitive orientation of a split graph $S_n = (E_{n-m}, K_m)$ subdivides the set of all vertices in $E_{n-m}$ into three, possibly empty, groups corresponding to each of the following types (also shown schematically in Figure 2), where $\vec{P} = p_1 \to \cdots \to p_m$ is the longest directed path in $K_m$:

- A vertex in $E_{n-m}$ is of type A if it is a source and is connected to all vertices in $\{p_i, p_{i+1}, \ldots, p_j\}$ for some $1 \leq i \leq j \leq m$;
- A vertex in $E_{n-m}$ is of type B if it is a sink and is connected to all vertices in $\{p_i, p_{i+1}, \ldots, p_j\}$ for some $1 \leq i \leq j \leq m$;
- A vertex $v \in E_{n-m}$ is of type C if there is an edge $x \to v$ for each $x \in I_v = \{p_1, p_2, \ldots, p_i\}$ and there is an edge $v \to y$ for each $y \in O_v = \{p_j, p_{j+1}, \ldots, p_m\}$ for some $1 \leq i < j \leq m$.

**Theorem 3** ([9]). Let $S_n = (E_{n-m}, K_m)$ be oriented semi-transitively with $\vec{P} = p_1 \to \cdots \to p_m$. For a vertex $x \in E_{n-m}$ of type C, there is no vertex $y \in E_{n-m}$ of type A or B, which is connected to both $p_{|I_x|}$ and $p_{m-|O_y|+1}$. Also, there is no vertex $y \in E_{n-m}$ of type C such that either $I_y$, or $O_y$ contains both $p_{|I_x|}$ and $p_{m-|O_y|+1}$.

**Theorem 4** ([9]). An orientation of a split graph $S_n = (E_{n-m}, K_m)$ is semi-transitive if and only if

(i) $K_m$ is oriented transitively;

(ii) each vertex in $E_{n-m}$ is of one of the three types in Theorem 2;

(iii) the restrictions in Theorem 3 are satisfied.

2.2 Directed split graphs

A directed graph is *semi-transitive* if its orientation is semi-transitive. The *adjacency matrix* $A = [a_{ij}]$ of a directed graph on $n$ vertices is
a binary matrix such that \( a_{ij} = 1 \) if \( j \rightarrow i \) is an edge, and \( a_{ij} = 0 \) otherwise. Let \( L(A) = [\ell_{ij}] \) be the \( n \times n \) lower triangular matrix such that, for any \( i > j \),

\[
\ell_{ij} = \begin{cases} 
1 & \text{if } a_{ij} = 1, \\
-1 & \text{if } a_{ji} = 1, \\
0 & \text{otherwise}
\end{cases}
\]

and \( \ell_{ij} = 0 \) for any \( i \leq j \).

Clearly, there is a one-to-one correspondence between directed graphs of order \( n \) and \( n \times n \) lower triangular matrices over \( \{-1, 0, 1\} \) with the diagonal elements equal \( 0 \). Thus, \( L(A) \) can play the role of the adjacency matrix of a directed graph. For \( i > j \), the connectivity between vertices \( i \) and \( j \) is \( j \rightarrow i \) if \( \ell_{ij} = 1 \), and is \( i \rightarrow j \) if \( \ell_{ij} = -1 \), and there is no edge if \( \ell_{ij} = 0 \).

**Example 5.** If \( A = \begin{bmatrix} 0 & 0 & 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 \end{bmatrix} \) is an adjacency matrix of a directed graph \( G \), then \( L(A) = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & -1 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & -1 & 1 & 0 \end{bmatrix} \) and the set of edges of \( G \) (on 6 vertices) is \( \{1 \rightarrow 2, 2 \rightarrow 4, 1 \rightarrow 6, 5 \rightarrow 6, 3 \rightarrow 1, 5 \rightarrow 1, 4 \rightarrow 3, 6 \rightarrow 4\} \).

Our interest is in acyclically (without directed cycles) oriented split graphs since only such graphs have a chance to be semi-transitive. For any acyclically oriented split graph \( G \), by Lemma 4, we know that the induced orientation of the maximal clique in \( G \) is transitive, so the following notion can be introduced.

**Definition 6.** An acyclically oriented split graph \( G \) with a maximal clique of order \( n \) is well-labelled if the vertex set of \( G \) is \( V(G) = \{1, 2, \ldots, |V(G)|\} \) and the longest directed path in the maximal clique is \( 1 \rightarrow 2 \rightarrow \cdots \rightarrow n \).

Since we can relabel graphs, throughout the paper, W.L.O.G. we can assume that any given acyclically oriented split graph is well-labelled. If \( A \) is the adjacency matrix for \( S = (E_m, K_n) \) (where \( K_n \) is maximal) of order \( m + n \), then

\[
L(A) = \begin{bmatrix} L_n & O_{n,m} \\ M & O_m \end{bmatrix}
\]
for some $m \times n$ matrix $M$, where $O_{n,m}$ and $O_{m}$ are $n \times m$ and $m \times m$ zero matrices, respectively, and $L_n$ is the $n \times n$ matrix such that all entries strictly below the main diagonal are 1’s, and all other entries are 0’s. Hence, every directed split graph with maximal clique of order $n$ and independent set of order $m$ can be represented by an $m \times n$ matrix $M$ appearing in $L(A)$ and recording directed edges between $K_n$ and $E_m$. Thus, generating a matrix $M$ with entries in $\{-1,0,1\}$, we generate an acyclically oriented split graph.

**Definition 7.** Let $M = [m_{ij}]$ be an $m \times n$ matrix such that $m_{ij} \in \{-1,0,1\}$ for $1 \leq i \leq m$ and $1 \leq j \leq n$. Define

$$S_o(M) = \begin{bmatrix} L_n & O_{n,m} \\ M & O_m \end{bmatrix}$$

where the subscript $o$ stands for “oriented” and $S$ stands for “split”. We denote the directed split graph corresponding to $S_o(M)$ by $G_o(M)$.

**Example 8.** If $M = \begin{bmatrix} 0 & 1 & 0 & 1 \\ -1 & 0 & -1 & -1 \\ 0 & 0 & 0 & 1 \end{bmatrix}$ then

$$S_o(M) = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 & 0 \\ -1 & 0 & -1 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \end{bmatrix}$$

is the adjacency matrix of the directed graph $G_o(M)$ shown in Figure 3.

For convenience, we will represent rows of an $m \times n$ matrix $M$ by strings of length $n$. For example, we will represent the three rows of \( \begin{bmatrix} 1 & -1 & 0 & 1 \\ 0 & 1 & -1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \) by $1(-1)01$, $01(-1)0$ and $0001$.

Note that in Definition 7, the maximal clique of $G_o(M)$ is of order $n + 1$ if there is a row of the form $11 \cdots 1$ or $(-1)(-1)\cdots(-1)$ in $M$, and
the maximal clique is of order \( n \) otherwise. In the former case, \( G_o(M) \)
may not be well-labelled. In the case of \( n = 1 \), the graph \( G_o(M) \) is a
tree which is always semi-transitive. Thus, throughout this paper, we
can assume that \( n \geq 2 \).

**Remark 9.** If \( M \) is a zero matrix, then \( G_o(M) \) is semi-transitive as it
is a disjoint union of a transitively oriented clique and isolated vertices.

In what follows, \( x^r \) denotes \( xx \cdots x \), where \( x \in \{ -1, 0, 1 \} \) is
repeated \( r \) times.

**Lemma 10.** Let \( M := [m_{ij}]_{m \times n} \) be an \( m \times n \) matrix over \( \{ -1, 0, 1 \} \)
such that \( m_{p1} = m_{p2} = \cdots = m_{pr} = 1 \) and \( m_{p(r+1)} = m_{p(r+2)} = \cdots = m_{pn} = -1 \) for every \( p \in \{ 1, 2, \ldots, m \} \) and \( r \in \{ 0, 1, \ldots, n \} \). If

\[
N = \begin{bmatrix}
    m_{11} & m_{12} & \cdots & m_{1r} & 0 & m_{1(r+1)} & \cdots & m_{1n} \\
    m_{21} & m_{22} & \cdots & m_{2r} & 0 & m_{2(r+1)} & \cdots & m_{2n} \\
    \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \cdots & \vdots \\
    m_{(p-1)1} & m_{(p-1)2} & \cdots & m_{(p-1)r} & 0 & m_{(p-1)(r+1)} & \cdots & m_{(p-1)n} \\
    m_{(p+1)1} & m_{(p+1)2} & \cdots & m_{(p+1)r} & 0 & m_{(p+1)(r+1)} & \cdots & m_{(p+1)n} \\
    \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \cdots & \vdots \\
    m_{m1} & m_{m2} & \cdots & m_{mr} & 0 & m_{m(r+1)} & \cdots & m_{mn}
\end{bmatrix}
\]

is an \((m - 1) \times (n + 1)\) matrix, then \( G_o(M) \) is isomorphic to \( G_o(N) \).

**Proof.** The \( p \)-th row in \( M \), which is \( 1'(-1)^{n-r} \), represents the
vertex \( n + p \) in the independent set connected to all vertices in \( K_n = \{ 1, 2, \ldots, n \} \). So \( K_n \) is not the maximal clique in \( G_o(M) \), but \( K_n \cup \{ n + p \} \) is the maximal clique. Note that \( \ell \to n + p \) for every vertex \( \ell \in \{ 1, 2, \ldots, r \} \) and \( n + p \to \ell \) for every vertex \( \ell \in \{ r + 1, r + 2, \ldots, n \} \). We relabel the vertex \( n + p \) to be \( r + 1 \) and relabel a vertex \( \ell \) to be
\( \ell + 1 \) for each \( \ell \in \{ r + 1, r + 2, \ldots, n + p - 1 \} \). The relabelling gives the
graph that can be represented by the matrix \( S_o(N) \). Hence, \( G_o(M) \) is
isomorphic to \( G_o(N) \). \( \square \)

**Remark 11.** Let \( M \) be an \( m \times n \) matrix over \( \{ -1, 0, 1 \} \). If \( a_1a_2 \cdots a_n \)
is the \( p \)-th row in \( M \) such that \( a_q = -1 \) and \( a_r = 1 \) for some \( 1 \leq q < r \leq n \), then \( q \to r \to n + p \to q \) forms a cycle in \( G_o(M) \). Hence, \( G_o(M) \) is not semi-transitive if there is a \( 1 \) occurring to the right of
\( a \) in a row in \( M \). Consequently, if there is a row in \( M \) such that
it has no \( 0 \) and it is not of the form \( 11 \cdots 1(-1)(1)(-1) \cdots (-1) \), then
\( G_o(M) \) is not semi-transitive.

Let \( M \) be an \( m \times n \) matrix over \( \{ -1, 0, 1 \} \). We can see that the
maximal clique of \( G_o(M) \) is of order \( n \) or \( n + 1 \). Moreover, the maximal
clique of \( G_o(M) \) is the clique of order \( n + 1 \) if there is a row in \( M \) containing
no \( 0 \). In this case, the matrix \( M \) does not represent only edges
between vertices in the maximal clique and vertices in the independent set, but also a vertex in the maximal clique. By Remark 11, we can assume that $M$ does not contain a row which has no 0 and is not of the form $1^r(-1)^{n-r}$ for some $0 \leq r \leq n$. Hence, if a row of $M$ has no 0, it must be $1^r(-1)^{n-r}$ for some $1 \leq r \leq n$ for graph $G_o(M)$ to have a chance to be semi-transitive. Further, if $1^r(-1)^{n-r}$ is a row of $M$ for some $0 \leq r \leq n$, by Lemma 10, we can consider the $(m-1) \times (n+1)$ matrix $N$ in the statement of the lemma instead of $M$, and every row of $N$ has a 0.

**Theorem 12.** Let $M$ be an $m \times n$ matrix over $\{-1, 0, 1\}$ such that every row of $M$ has a 0. The directed split graph $G_o(M)$ is semi-transitive if and only if $M$ satisfies the following conditions:

(i) every row of $M$ is of the form $0^r1^s0^t$ or $0^r(-1)^s0^t$ or $1^r0^s(-1)^t$ for $r, s, t \geq 0$, and

(ii) for each row of $M$ of the form $1^a0^b(-1)^c$ where $a, b, c > 0$, there is no other row distinct from $1^a0^b(-1)^c$ such that its entries in positions $a$ and $a+b+1$ are not 0’s.

**Proof.** “$\Rightarrow$” Note that the vertices in the independent set will then be of types A, B and C, and taking into account condition (ii), Theorem 4 can be applied to see that $G_o(M)$ is semi-transitive.

“$\Rightarrow$” One can see that $G_o(M)$ is well-labelled, so the clique is oriented transitively and its longest path is $1 \rightarrow 2 \rightarrow \cdots \rightarrow n$. Moreover, conditions (ii) and (iii) in Theorem 4 give conditions (i) and (ii) in this theorem.

**Corollary 13.** Let $M$ be an $m \times n$ matrix over $\{-1, 0, 1\}$. The directed split graph $G_o(M)$ is semi-transitive if $M$ satisfies the following conditions:

(i) every row of $M$ is of the form $0^r1^s0^t$ or $0^r(-1)^s0^t$ or $1^r0^s(-1)^t$ for $r, s, t \geq 0$, and

(ii) for each row of $M$ of the form $1^a0^b(-1)^c$ where $a, b, c > 0$ and $b \geq 0$, there is no other row distinct from $1^a0^b(-1)^c$ such that its entries in positions $a$ and $a+b+1$ are not 0’s.

**Proof.** The intersection of row $i$ and column $j$ in $G_o(M)$ represents connection between vertices $i$ and $j$ in $G_o(M)$. Assume that $M$ satisfies the conditions (i) and (ii). If every row of $M$ has a 0, then the result follows from Theorem 12. Suppose that there is a row $p$ of $M$ of the form $1^r(-1)^{n-r}$ where $1 \leq p \leq m$ and $0 \leq r \leq n$. Then, $\{1, 2, \ldots, n, n+p\}$ is the maximal clique in the directed graph $G_o(M)$. By Lemma 10, we have that $G_o(M)$ is isomorphic to $G_o(N)$, where $N$
Corollary 14. Let $M$ be an $m \times n$ matrix over $\{-1, 0, 1\}$. If the split graph $G_o(M)$ is semi-transitive, then every row of $M$ is of the form $0^r1^s0^t(−1)^{r+s+t}$ for $r, s, t \geq 0$.

Proof. Assume that $G_o(M)$ is semi-transitive. If every row of $M$ has a 0, then the result follows from Theorem 12. Suppose that there is a row $p$ in $M$ such that $m_{p,1}m_{p,2} \cdots m_{p,n}$ is semi-transitive and its longest path is $1 \to 2 \to \cdots \to \ell \to (n+p) \to (\ell+1) \to \cdots \to n$. Let $N$ be the matrix

$$
\begin{bmatrix}
m_{11} & m_{12} & \cdots & m_{1\ell} & 0 & m_{1(\ell+1)} & \cdots & m_{1n} \\
m_{21} & m_{22} & \cdots & m_{2\ell} & 0 & m_{2(\ell+1)} & \cdots & m_{2n} \\
\vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\
m_{(p-1)1} & m_{(p-1)2} & \cdots & m_{(p-1)\ell} & 0 & m_{(p-1)(\ell+1)} & \cdots & m_{(p-1)n} \\
m_{(p+1)1} & m_{(p+1)2} & \cdots & m_{(p+1)\ell} & 0 & m_{(p+1)(\ell+1)} & \cdots & m_{(p+1)n} \\
\vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\
m_{m1} & m_{m2} & \cdots & m_{m\ell} & 0 & m_{m(\ell+1)} & \cdots & m_{mn}
\end{bmatrix}
$$

By Lemma 10, we have that $G_o(M)$ is isomorphic to $G_o(N)$, and hence $G_o(N)$ is semi-transitive. Further, by Theorem 12 we have that $m_{i1}m_{i2} \cdots m_{i\ell}0m_{i(\ell+1)} \cdots m_{in}$ is of the form $0^r1^s0^t(−1)^{r+s+t}$ or $1^s0^t(−1)^{r+s+t}$ for any $i \in \{1, 2, \ldots, p-1, p+1, \ldots, m\}$. Note that $m_{i1}m_{i2} \cdots m_{in}$ is also of the form $0^r1^s0^t(−1)^{r+s+t}$ or $1^s0^t(−1)^{r+s+t}$ for any $i \in \{1, 2, \ldots, p-1, p+1, \ldots, m\}$. Hence, every row of $M$ is of the form $0^r1^s0^t(−1)^{r+s+t}$ for $r, s, t \geq 0$. □

Corollary 15. Let $M$ be an $m \times n$ matrix over $\{-1, 0, 1\}$. If every row of $M$ is of the form $0^r1^s0^t(−1)^{r+s+t}$ for $r, s, t \geq 0$, then the graph $G_o(M)$ is semi-transitive.
Proof. If every row of $M$ has a 0, then by Theorem 12, $G_o(M)$ is semi-transitive. Suppose there is an all 1’s or all $(−1)$’s row in $M$. By Lemma 11, we obtain a matrix $N$ such that every row has a 0 and $G_o(M)$ is isomorphic to $G_o(N)$. Note that every row of $N$ is also of the form $0^x 1^y 0^z$ or $0^x(−1)^y 0^z$ for $x, y, z \geq 0$. Thus, both $G_o(N)$ and $G_o(M)$ are semi-transitive.

Corollary 16. If $M$ is a matrix over $\{-1, 0, 1\}$ containing a row of the form $11 \cdots 1$ and a row of the form $1^r 0^s (−1)^t$ for some non-negative integers $r, s, t$ such that $r, t \neq 0$, then $G_o(M)$ is not semi-transitive.

Proof. By Lemma 10, the directed graph $G_o(M)$ is isomorphic to the graph $G_o(N)$, where $N$ is a matrix such that every row of $N$ has a 0 and $N$ contains a row of the form $1^r 0^s (−1)^t 0$. By Corollary 14, $G_o(N)$ is not semi-transitive, and so is $G_o(M)$.

Corollary 17. If $M$ is a matrix over $\{-1, 0, 1\}$ containing a row of the form $−1(−1)\cdots (−1)$ and a row of the form $1^r 0^s (−1)^t$ for some non-negative integers $r, s, t$ such that $r, t \neq 0$, then $G_o(M)$ is not semi-transitive.

Proof. By Lemma 10, the directed graph $G_o(M)$ is isomorphic to the graph $G_o(N)$, where $N$ is a matrix without all 1’s or all $(−1)$’s row and $N$ contains a row of the form $01 0^s (−1)^t$. By Corollary 14, $G_o(N)$ is not semi-transitive, and so is $G_o(M)$.

Definition 18. A matrix $M$ is said to be a layered matrix if all entries in the same row of $M$ are identical.

The next result is a straightforward corollary of Corollary 15.

Corollary 19. Let $M$ be an $m \times n$ matrix over $\{-1, 0, 1\}$. If $M$ is a layered matrix, then $G_o(M)$ is semi-transitive.

3 Directed split graphs generated by iterations of morphisms

Definition 20. Let $A, B, C$ be $m \times n$ matrices over $\{-1, 0, 1\}$. The matrix $M^k(A, B, C)$ is the $k^{th}$-iteration of the 2-dimensional morphism applied to the $1 \times 1$ matrix $[0]$ which maps $[0] \rightarrow A$, $[1] \rightarrow B$ and $[−1] \rightarrow C$. Moreover, we write $S^k_o(A, B, C)$ for the matrix $S_o(M^k(A, B, C))$ and $G^k_o(A, B, C)$ for the graph with the adjacency matrix $S^k_o(A, B, C)$. 

10
Figure 4: The directed split graph $G_2^2(A, B, C)$ corresponding to the adjacency matrix $S_2^2(A, B, C)$ in Example 21.

**Example 21.** Let $A = \begin{bmatrix} 0 & 1 \\ 0 & -1 \end{bmatrix}$, $B = \begin{bmatrix} -1 & -1 \\ 1 & 0 \end{bmatrix}$ and $C = \begin{bmatrix} 1 & 1 \\ -1 & -1 \end{bmatrix}$.

Then we have $M^0(A, B, C) = \begin{bmatrix} 0 \end{bmatrix}$, $M^1(A, B, C) = \begin{bmatrix} 0 & 1 \\ 0 & -1 \end{bmatrix}$ and $M^2(A, B, C) = \begin{bmatrix} 0 & 1 & -1 & -1 \\ 0 & -1 & 1 & 0 \\ 0 & 1 & 1 & 1 \\ 0 & -1 & -1 & -1 \end{bmatrix}$. Hence, $S_2^2(A, B, C)$ is the matrix

\[
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & -1 & -1 & 0 & 0 & 0 & 0 \\
0 & -1 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 \\
0 & -1 & -1 & -1 & 0 & 0 & 0 & 0
\end{bmatrix}
\]

and $G_2^2(A, B, C)$ is shown in Figure 4.

**Remark 22.** If $A$ is a zero matrix, then $M^k(A, B, C)$ is always a zero matrix for any $m \times n$ matrices $B$ and $C$ and $k \geq 0$. Thus, by Remark 9, $G_0^k(A, B, C)$ is semi-transitive in this case.

**Proposition 23.** If $A$, $B$ and $C$ are layered matrices over $\{-1, 0, 1\}$, then $G_0^k(A, B, C)$ is semi-transitive for any $k \geq 0$.

**Proof.** Let $A$, $B$ and $C$ be $m \times n$ matrices. Since every row in $A$, $B$ and $C$ is either $0^n$ or $1^n$ or $(-1)^n$, we have that every row in $M^k(A, B, C)$ is either $0^n$ or $1^n$ or $(-1)^n$, so by Corollary 19, $G_0^k(A, B, C)$ is semi-transitive. \qed
If $A = [a_{ij}]_{m \times n}$ contains at least one 0, say $a_{ij} = 0$, then the entry in row $i$ and column $j$ of $M^1(A, B, C)$ is 0. By mapping this 0 to $A$ in the next iteration of morphism, we obtain $A = M^1(A, B, C)$ as the $m \times n$ submatrix of $M^2(A, B, C)$ given by intersection of rows $(i-1)n+1, (i-1)n+2, \ldots, in$ and columns $(j-1)m+1, (j-1)m+2, \ldots, jm$. More generally, the $m^k - 1 \times n^k - 1$ submatrix of $M^k(A, B, C)$ given by intersection of rows $(i-1)n^{k-1}+1, (i-1)n^{k-1}+2, \ldots, in^{k-1}$ and columns $(j-1)m^{k-1}+1, (j-1)m^{k-1}+2, \ldots, jm^{k-1}$ is $M^{k-1}(A, B, C)$. So, we can consider the bottommost, then leftmost zero in $A$ as the start of a chain of induced subgraphs generated by the morphism. Thus, the limit $\lim_{k \to \infty} M^k(A, B, C)$, called a fixed point of the morphism, is well-defined. So, we have that $G_o^k(A, B, C)$ is not semi-transitive for given $A, B$ and $C$ (then $G_o^k(A, B)$ is not semi-transitive for $i \geq \ell$).

**Definition 24.** Let $A, B, C$ be $m \times n$ matrices such that $A$ has a 0 as an entry. The index of semi-transitivity $\text{IST}(A, B, C)$ of an infinite directed split graph $G_o(A, B, C)$ is the smallest integer $\ell$ such that $G_o^\ell(A, B, C)$ is not semi-transitive. If such an $\ell$ does not exist, that is, if $G_o^\ell(A, B, C)$ is semi-transitive for all $\ell$, then $\ell := \infty$.

Note that since $G_o^0(A, B, C)$ is a graph with one vertex for any $A, B, C$, we have $\text{IST}(A, B, C) \geq 1$.

**Remark 25.** It follows from Proposition 23 that $\text{IST}(A, B, C) = \infty$ if $A, B$ and $C$ are layered matrices.

The following three lemmas give sufficient conditions for $A, B$ and $C$ to have $\text{IST}(A, B, C) = \infty$.

**Lemma 26.** Let $A, B$ and $C$ be $m \times n$ matrices over $\{-1, 0, 1\}$ such that $A$ has a 0 and $\text{IST}(A, B, C) = \infty$. Then,

- If $A$ is not a layered matrix, then there is no row in $M^k(A, B, C)$ containing two 0’s for any $k \geq 0$.
- If $B$ is not a layered matrix, then there is no row in $M^k(A, B, C)$ containing two 1’s for any $k \geq 0$.
- If $C$ is not a layered matrix, then there is no row in $M^k(A, B, C)$ containing two ($-1$)’s for any $k \geq 0$.

**Proof.** We will prove the first bullet point; the other bullet points can be proved analogously.
Similarly, the submatrix of $A$ is $\mu$ and $C$ has one 0 and one 1 in each row of $M$. Since every row of $C$ has 4 columns with every row having more than one 0 or more than one 1, $A$ is a matrix because $\mu(a, b) = 0$. Thus, the submatrix of $M^{k+1}(A,B,C)$ contains at least two 0’s for some $k$, say $\mu^{k+1}(a, (b-1) \pm 1) = 0$ where $b < c$. Consider the intersection of rows $(a-1)m + 1, (a-1)m + 2, \ldots, am$ and columns $(b-1)n + 1, (b-1)n + 2, \ldots, bn$ in $M^{k+1}(A,B,C)$, which is the matrix $A$ because $\mu^{k}(a, b) = 0$.

Similarly, the submatrix of $M^{k+1}(A,B,C)$ formed by rows $(a-1)m + 1, (a-1)m + 2, \ldots, am$ and columns $(c-1)n + 1, (c-1)n + 2, \ldots, cn$ is $A$. Hence, we have

$$\mu^{k+1}((a-1)m+i, (b-1)n+r) = \mu^{k+1}((a-1)m+i, (c-1)n+r) = a_{ir}$$

and

$$\mu^{k+1}((a-1)m_i, (b-1)n+s) = \mu^{k+1}((a-1)m+i, (c-1)n+s) = a_{is}.$$  

Thus, the submatrix of $M^{k+1}(A,B,C)$ formed by row $(a-1)m + i$ and columns $(b-1)n + r, (b-1)n + s, (c-1)n + r, (c-1)n + s$ is $[a_{ir}, a_{is}, a_{ir}, a_{is}]$. That is, row $(a-1)m + i$ of $M^{k+1}(A,B,C)$ cannot be of the form $0^t1^00^t$ or $0^t(-1)^00^t$ or $1^t0^0(-1)^t$. By Corollary 14, $G_n^{k+1}(A,B,C)$ is not semi-transitive, which is a contradiction with $\text{IST}(A,B,C) = \infty$.

\begin{lemma}
Let $A$, $B$ and $C$ be $m \times n$ matrices over $\{-1,0,1\}$ such that $A$ has a 0 and $\text{IST}(A,B,C) = \infty$. Then,

- If $A$ and $B$ are not layered matrices, then every entry of $C$ is $(-1)$.
- If $A$ and $C$ are not layered matrices, then every entry of $B$ is 1.

\end{lemma}

\begin{proof}
Both statements are proved by similar arguments, so we will prove here only the first one. Suppose both $A$ and $B$ are not layered matrices. By Lemma 26, every row of $M^{k}(A,B,C)$ contains at most one 0 and at most one 1 for any $k \geq 2$. Then, there are at least $n^k - 2$ copies of $(-1)$ in every row of $M^{k}(A,B,C)$. By Lemma 26, $C$ is a layered matrix.

Suppose that there is no $(-1)$ in $A$ and $B$. Since every row of $M^1(A,B,C) = A$ has at most one 0 and at most one 1 and no $(-1)$, then $n = 2$ (recall our assumption of $n \geq 2$). Therefore, $M^2(A,B,C)$ has 4 columns with every row having more than one 0 or more than one 1, which is a contradiction.

If $(-1)$ is an entry of $A$, then $M^1(A,B,C) = A$ has $(-1)$ as an entry. So $C$ is a submatrix of $M^2(A,B,C)$ as $(-1)$ is mapped to $C$. Since every row of $C$ has the same entries, and there is no more than one 0 and one 1 in each row of $M^2(A,B,C)$, we have that each entry of $C$ must be $(-1)$.

13
Finally, if there is no \((-1)\) in \(A\), but \(B\) contains \((-1)\) as an entry, then \(M^1(A, B, C) = A\) contains 1 as an entry. Since 1 maps to \(B\), \(M^2(A, B, C)\) contains \(B\) as a submatrix. So there is an entry \((-1)\) in \(M^2(A, B, C)\), and then \(C\) is a submatrix of \(M^3(A, B, C)\). Since every row of \(C\) has entries equal to each other, and there is no more than one 0 and one 1 in each row of \(M^2(A, B, C)\), then each entry of \(C\) is \((-1)\).

\[\text{Lemma 28.} \text{ Let } A, B \text{ and } C \text{ be } m \times n \text{ matrices over } \{-1, 0, 1\} \text{ such that } A \text{ has a 0 and } \text{IST}(A, B, C) = \infty. \text{ If } B \text{ and } C \text{ are not layered matrices, then all entries of } A \text{ are 0.}\]

**Proof.** Suppose \(B\) and \(C\) are not layered matrices. By Lemma 26, every row of \(M^k(A, B, C)\) contains at most one 1 and at most one \((-1)\) for any \(k \geq 2\). Then there are at least \(n^k - 2\) zeroes in every row of \(M^k(A, B, C)\). By Lemma 26, \(A\) is a layered matrix.

Assume that there is a row \(r\) in \(A := [a_{ij}] = M^1(A, B, C)\) of the form \(11 \cdots 1\). Also, suppose that a row \(s\) in \(B := [b_{ij}]\) has two distinct entries, say \(b_{sp} \neq b_{sq}\) for some \(1 \leq p < q \leq n\). Note that the intersection of rows \((r - 1)m + 1, (r - 1)m + 2, \ldots, rm\) and columns \((\ell - 1)n + 1, (\ell - 1)n + 2, \ldots, \ell n\) in \(M^2(A, B, C)\) is \(B\) for \(\ell = 1, 2, \ldots, m\). Then the submatrix of \(M^2(A, B, C)\) formed by row \((r - 1)m + s\) and columns \(p, q, n + p, n + q, 2n + p, 2n + q, \ldots, (m - 1)n + p, (m - 1)n + q\) is

\[
\begin{bmatrix}
  b_{sp} & b_{sq} & b_{sp} & b_{sq} & \cdots & b_{sp} & b_{sq}
\end{bmatrix}
\]

Since every row of \(M^k(A, B, C)\) has at most one 1 and at most one \((-1)\) for any \(k\), we have \(b_{sp} = b_{sq} = 0\), which is a contradiction. Thus, there is no row in \(A\) of the form \(11 \cdots 1\). Similarly, we can show that there is no row in \(A\) of the form \((-1)(-1) \cdots (-1)\). Hence, \(A\) is an all 0 matrix.

From Lemmas 27 and 28 we have the following theorem.

**Theorem 29.** Let \(A, B \text{ and } C \text{ be } m \times n \text{ matrices over } \{-1, 0, 1\} \text{ such that } A \text{ has a 0.} \text{ If } A, B \text{ and } C \text{ are not layered, then } \text{IST}(A, B, C) \text{ is finite.}\)

**Definition 30.** Let \(A, B, C \text{ be } m \times n \text{ matrices over } \{-1, 0, 1\}. \text{ The triple } (A, B, C) \text{ is said to be independent from } B \text{ if there are no 1’s in } A \text{ and } C. \text{ Similarly, the triple } (A, B, C) \text{ is said to be independent from } C \text{ if there are no } (-1)’s \text{ in } A \text{ and } B.\)

For convenience, we write \(R(M)\) for the set of strings representing rows of \(M\). Moreover, if \(A, B \text{ and } C \text{ are } m \times n \text{ matrices over } \{-1, 0, 1\}, \text{ then define } R^k(A, B, C) \text{ to be the set of strings representing rows of } M^k(A, B, C). \text{ So, every element of } R^k(A, B, C) \text{ is a string}
over \{-1,0,1\} of length \(n^k\). Each element of \(R^k(A,B,C)\) is called a row pattern of \(M^k(A,B,C)\).

**Theorem 31.** Let \(A,B\) and \(C\) be \(m \times n\) matrices over \{-1,0,1\} such that \(A\) has a 0 and \((A,B,C)\) is independent from \(C\). Then, \(\text{IST}(A,B,C) = \infty\) if and only if \(A\) and \(B\) satisfy one of the following conditions, where \(a_i \in \{0,1\}\):

(1) \(A\) and \(B\) are layered matrices, or

(2) \(A = \begin{bmatrix} a_1 & 1 & 1 & \cdots & 1 \\ a_2 & 1 & 1 & \cdots & 1 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_m & 1 & 1 & \cdots & 1 \end{bmatrix}\) and \(B = \begin{bmatrix} 1 & 1 & \cdots & 1 \\ 1 & 1 & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & \cdots & 1 \end{bmatrix}\), or

(3) \(A = \begin{bmatrix} 1 & 1 & \cdots & 1 & a_1 \\ 1 & 1 & \cdots & 1 & a_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 1 & 1 & \cdots & 1 & a_m \end{bmatrix}\) and \(B = \begin{bmatrix} 1 & 1 & \cdots & 1 \\ 1 & 1 & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & \cdots & 1 \end{bmatrix}\).

**Proof.** "\(\Rightarrow\)" There is no \(-1\) in \(A\) and \(B\), and row patterns of \(M^k(A,B,C)\) generated by \(A,B\) and \(C\) in (1), (2) and (3) are in the set

\(\{1^{nk}, 0^{nk}, 01^{nk-1}, 1^{nk-1}0\}\).

By Corollary 15, \(M^k(A,B,C)\) is semi-transitive for all \(k \geq 0\).

"\(\Leftarrow\)" Since \((A,B,C)\) is independent from \(C\), every entry of \(M^k(A,B,C)\) is either 0 or 1. Assume \(\text{IST}(A,B,C) = \infty\) and let \(R(B) = \{b_1, b_2, \ldots, b_p\}\) where \(b_i\) is a binary string of length \(n\). By Corollary 14, we have that every row of \(M^k(A,B,C)\) is of the form \(0^i1^00^f\). If \(A\) is a layered matrix, then \(R^1(A,B,C) \subseteq \{0^n, 1^n\}\) and

\(R^2(A,B,C) \subseteq \{0^{n^2}, 1^{n^2}, (b_1)^n, (b_2)^n, \ldots, (b_p)^n\}\).

So, \(R(B) \subseteq \{0^n, 1^n\}\) as otherwise, some strings in \(R^2(A,B,C)\) are not of the form \(0^i1^00^f\). Thus, \(B\) is a layered matrix. Suppose \(A\) is not a layered matrix. By Lemma 26, \(R^1(A,B,C) \subseteq \{0^{n-1}, 1^{n-1}0, 1^n\}\). If both \(0^{n-1}\) and \(1^{n-1}0\) are rows in \(A\), then \(1^{n-1}0(b_i)^{n-1}\) is a row pattern in \(R^2(A,B,C)\) for some \(i\). Since every row of \(M^k(A,B,C)\) contains at most one 0, \(b_i\) must be \(1^n\), which contradicts \(1^{n-1}0(b_i)^{n-1}\) not being of the form \(0^i1^00^f\). So, we have

\[A = \begin{bmatrix} a_1 & 1 & 1 & \cdots & 1 \\ a_2 & 1 & 1 & \cdots & 1 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_m & 1 & 1 & \cdots & 1 \end{bmatrix}\] \(\text{or}\) \[A = \begin{bmatrix} 1 & 1 & \cdots & 1 & a_1 \\ 1 & 1 & \cdots & 1 & a_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 1 & 1 & \cdots & 1 & a_m \end{bmatrix}\].

15
where \( a_i \in \{0, 1\} \). Note that each row of \( A \) is \( 1^n \), \( 01^{n-1} \) or \( 1^{n-1}0 \). If row \( i \) in \( A \) is \( 1^n \), then row \( ((i-1)m + i) \) in \( M^2(A, B, C) \) is \( x^n \), where \( x \) is row \( i \) in \( B \). Since \( x^n \) cannot contain more than one 0, we have \( x = 1^n \). If row \( i \) in \( A \) is \( 01^{n-1} \), then row \( ((i-1)m + i) \) in \( M^2(A, B, C) \) is \( 01^{n-1}x^{n-1} \), where \( x \) is row \( i \) in \( B \). So, \( x = 1^n \) because \( 01^{n-1}x^{n-1} \) contains at most one 0. Similarly, if row \( i \) in \( A \) is \( 1^{n-1}0 \), then row \( i \) in \( B \) is \( 1^n \). Hence, \( B \) is an all 1 matrix. \( \square \)

Next theorem can be proved similarly to Theorem [31]

**Theorem 32.** Let \( A, B \) and \( C \) be \( m \times n \) matrices over \( \{-1, 0, 1\} \) such that \( A \) has a 0 and \( (A, B, C) \) is independent from \( B \). Then, \( \text{IST}(A, B, C) = \infty \) if and only if \( A \) and \( C \) satisfy one of the following conditions, where \( a_i \in \{0, 1\} \):

1. \( A \) and \( C \) are layered matrices, or
   
   \[
   A = \begin{bmatrix}
   a_1 & -1 & -1 & \cdots & -1 \\
   a_2 & -1 & -1 & \cdots & -1 \\
   \vdots & \vdots & \vdots & \ddots & \vdots \\
   a_m & -1 & -1 & \cdots & -1 \\
   \end{bmatrix} \quad \text{and} \quad C = \begin{bmatrix}
   -1 & -1 & \cdots & -1 \\
   -1 & -1 & \cdots & -1 \\
   \vdots & \vdots & \ddots & \vdots \\
   -1 & -1 & \cdots & -1 \\
   \end{bmatrix}
   
   or
   
   \[
   A = \begin{bmatrix}
   -1 & -1 & \cdots & -1 & a_1 \\
   -1 & -1 & \cdots & -1 & a_2 \\
   \vdots & \vdots & \ddots & \vdots & \vdots \\
   -1 & -1 & \cdots & -1 & a_m \\
   \end{bmatrix} \quad \text{and} \quad C = \begin{bmatrix}
   -1 & -1 & \cdots & -1 \\
   -1 & -1 & \cdots & -1 \\
   \vdots & \vdots & \ddots & \vdots \\
   -1 & -1 & \cdots & -1 \\
   \end{bmatrix}
   
   (2)

2. \( A \) and \( C \) are layered matrices, or
   
   \[
   A = \begin{bmatrix}
   a_1 & -1 & -1 & \cdots & -1 \\
   a_2 & -1 & -1 & \cdots & -1 \\
   \vdots & \vdots & \vdots & \ddots & \vdots \\
   a_m & -1 & -1 & \cdots & -1 \\
   \end{bmatrix} \quad \text{and} \quad C = \begin{bmatrix}
   -1 & -1 & \cdots & -1 \\
   -1 & -1 & \cdots & -1 \\
   \vdots & \vdots & \ddots & \vdots \\
   -1 & -1 & \cdots & -1 \\
   \end{bmatrix}
   
   (3)

**Theorem 33.** Let \( A, B \) and \( C \) be \( m \times n \) matrices over \( \{-1, 0, 1\} \) such that \( A \) has a 0 and \( (A, B, C) \) is not independent from \( B \) and \( C \). Suppose \( A \) is a layered matrix. Then, \( \text{IST}(A, B, C) = \infty \) if and only if \( B \) and \( C \) are layered matrices.

**Proof.** Suppose \( \text{IST}(A, B, C) = \infty \). The case when \( A \) is a zero matrix is trivial. Thus, assume that \( 1^n \) or \( -1^n \) is a row in \( A \). W.L.O.G., we suppose that \( 1^n \) is a row in \( A = M^1(A, B, C) \). By Lemma 26, we have \( B \) is a layered matrix. If \( A \) also contains a row \( -1^n \), then \( C \) is a layered matrix with the same reason. If \( A \) does not contain a row \( -1^n \), then \( -1^n \) must be a row of \( B \) because \( (A, B, C) \) is not independent from \( B \) and \( C \). Since \( 1^n \) is a row of \( A \), we have \( BB \cdots B \) are \( m \) consecutive rows in \( M^2(A, B, C) \). As \( -1^n \) is a row in \( B \), we have that \( -1^n \) is a row in \( M^2(A, B, C) \). By Lemma 26, \( C \) is a layered matrix.

For the converse direction, it is clear from Proposition 23 that if \( A, B \) and \( C \) are layered matrices, then \( \text{IST}(A, B, C) = \infty \). \( \square \)

**Definition 34.** Let \( A, B, C \) be \( m \times n \) matrices over \( \{-1, 0, 1\} \). The triple \((A, B, C)\) is said to be
• an all-but-leftmost-negative triple if \( R(A), R(B) \subseteq \{0(-1)^{n-1}, 1(-1)^{n-1}\} \)
  and \( C \) is an all \((-1)\) matrix,
• an all-but-rightmost-negative triple if \( R(A), R(B) \subseteq \{(-1)^{n-1}0, (-1)^{n-1}1\} \)
  and \( C \) is an all \((-1)\) matrix,
• an all-but-leftmost-positive triple if \( R(A), R(B) \subseteq \{01^{n-1}, (-1)1^{n-1}\} \)
  and \( C \) is an all \(1\) matrix,
• an all-but-rightmost-positive triple if \( R(A), R(B) \subseteq \{1^{n-1}0, 1^{n-1}(-1)\} \)
  and \( C \) is an all \(1\) matrix.

From Definition \[34\] we can easily see that
• If \((A, B, C)\) is all-but-leftmost-negative, then
  \[
  R^k(A, B, C) \subseteq \{0(-1)^{k-1}, 1(-1)^{k-1}\},
  \]
• If \((A, B, C)\) is all-but-rightmost-negative, then
  \[
  R^k(A, B, C) \subseteq \{(-1)^{k-1}0, (-1)^{k-1}1\},
  \]
• If \((A, B, C)\) is all-but-leftmost-positive, then
  \[
  R^k(A, B, C) \subseteq \{01^{k-1}, (-1)1^{k-1}\},
  \]
• If \((A, B, C)\) is all-but-rightmost-positive, then
  \[
  R^k(A, B, C) \subseteq \{1^{k-1}0, 1^{k-1}(-1)\}.
  \]

With this observation, we can prove the following theorem.

**Theorem 35.** Let \(A, B, C\) be \(m \times n\) matrices over \((-1, 0, 1)\) such that \(A\) has a 0 and \((A, B, C)\) is not independent from \(B\) and \(C\). Suppose \(A\) and \(B\) are not layered matrices and \(C\) is a layered matrix. Then, \(\text{IST}(A, B, C) = \infty\) if and only if \((A, B, C)\) is an all-but-leftmost-negative triple.

**Proof.** “\(\Leftarrow\)” Let \((A, B, C)\) be all-but-leftmost-negative. Then, for any \(k \geq 1\),

\[
M^k(A, B, C) = \begin{bmatrix}
x_1 & -1 & -1 & \cdots & -1 \\
x_2 & -1 & -1 & \cdots & -1 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
x_{mk} & -1 & -1 & \cdots & -1
\end{bmatrix}
\]

where \(x_i \in \{0, 1\}\). So \(M^k(A, B, C)\) satisfies both conditions in Corollary \[13\] and hence \(\text{IST}(A, B, C) = \infty\).

“\(\Rightarrow\)” Suppose \(\text{IST}(A, B, C) = \infty\). From Lemma \[27\] we have that \(C\) is an all \((-1)\) matrix. By Lemma \[26\] every row of \(M^k(A, B, C)\) does not contain more than one 0 and more than one 1. Note that every row of \(A\) must be of the form \(0^r1^s0^t, 0^r(-1)^s0^t\) or \(1^s0^r(-1)^t\), where \(r, s, t \geq 0\). So, all possible row patterns of \(A\) are in

\[\{01, 00, 0(-1)^{n-1}, (-1)^{n-1}0, (-1)^{n}, 1(-1)^{n-1}, 10(-1)^{n-2}\}\] .

Suppose that \(n = 2\) and row \(i\) in \(A\) is 01. Then, the submatrix of \(M^2(A, B, C)\) formed by rows \((i-1)m+1, (i-1)m+2, \ldots, im\) and
columns 1, 2, 3, 4 is $AB$. So, row $(i - 1)m + i$ in $M^2(A, B, C)$ is $01x$, where $x$ is row $i$ in $B$. Note that $01x$ must be of the form $0^r1^s0^t$, where $r, s, t \geq 0$. Therefore, $x$ is 11 because $M^2(A, B, C)$ contains at most one 0. So, $01x$ contains more than one 1, which contradicts Lemma 26. Hence, 01 cannot be a row in $A$. Similarly, we obtain that 10 is also not a row in $A$. Hence, we have that 01 and 10 cannot be a row in $A$.

Suppose row $i$ in $A$ is $10(-1)^{n-2}$. Then there is $m$ consecutive rows in $M^2(A, B, C)$ built by $BACC \cdots C$. Note that row $i$ in $BACC \cdots C$ is $y10(-1)^{n-2}zz \cdots z$, where $y$ and $z$ are rows in $B$ and $C$, respectively. Since $\text{IST}(A, B, C) = \infty$, $y10(-1)^{n-2}zz \cdots z$ must be of the form $1^r0^s(-1)^t$, where $r, s, t \geq 0$. Thus, $y = 1^n$ and $z = (-1)^n$. This contradicts to the fact that any row in $M^2(A, B, C)$ has at most one 1. Hence, $10(-1)^{n-2}$ cannot be a row in $A$.

Now, all possible row patterns of $A$ are in

$$\{0(-1)^{n-1}, (-1)^{n-1}0, (-1)^n, 1(-1)^{n-1}\}.$$ 

If $1(-1)^{n-1}$ is not a row in $A$, then $(A, B, C)$ is independent from $C$. Then $1(-1)^{n-1}$ must be a row in $A$. By Lemma 10, we have $G_1(A, B, C)$ is isomorphic to $G_o(A^*)$ where $A^*$ is the matrix obtained by deleting row $1(-1)^{n-1}$ from $A$ and after that adding a zero column between the first and the second columns. If $(-1)^{n-1}0$ or $(-1)^{n-1}$ is a row in $A$, then $(-1)0(-1)^{n-3}0$ or $(-1)0(-1)^{n-2}$ is a row in $A^*$, respectively. By Corollary 14, $G_o(A^*)$ and $G_2(A, B, C)$ are not semi-transitive. Therefore $(-1)^{n-1}0$ and $(-1)^n$ are not rows in $A$ and we have

$$A = \begin{bmatrix} a_1 & -1 & -1 & \cdots & -1 \\ a_2 & -1 & -1 & \cdots & -1 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_m & -1 & -1 & \cdots & -1 \end{bmatrix} \quad \text{where } a_i \in \{0, 1\}. $$

Since both $0(-1)^{n-1}$ and $1(-1)^{n-1}$ are rows in $A$, there are $m$ consecutive rows of $M^2(A, B, C)$ built by $ACC \cdots C$ and $BCC \cdots C$. Then $1(-1)^{n-1}$ is a row in $M^2(A, B, C)$. By Lemma 10, we have $G_2(A, B, C)$ is isomorphic to $G_o(N)$ where $N$ is a matrix obtained by deleting row $1(-1)^{n-1}$ from $M^2(A, B, C)$ and after that adding a zero column between the first and the second columns. Note that a row $i$ of $BCC \cdots C$ is $b_{i1}b_{i2} \cdots b_{in}(-1)^{n^2-n}$ where $b_{i1}b_{i2} \cdots b_{in}$ is the row $i$ of $B$. Since $G_o(N)$ is semi-transitive and $b_{i1}b_{i2} \cdots b_{in}(-1)^{n^2-n}$ is a row of $N$, we have $b_{i1}b_{i2} \cdots b_{in}$ is $0^r+1(-1)^{n+1-r}$ or $0^r(-1)^{n-r}$ for some $1 \leq r \leq n$. As $M^2(A, B, C)$ contains at most one 0, we obtain that $b_{i1}b_{i2} \cdots b_{in}$ must be $10(-1)^{n-1}$ or $0^2(-1)^{n-1}$ for any $1 \leq i \leq m$.  

\[18\]
Proof.

That is,

\[ B = \begin{bmatrix}
  b_1 & -1 & -1 & \cdots & -1 \\
  b_2 & -1 & -1 & \cdots & -1 \\
  \vdots & \vdots & \vdots & \ddots & \vdots \\
  b_m & -1 & -1 & \cdots & -1 \\
\end{bmatrix} \quad \text{where } b_i \in \{0, 1\}. \]

Using similar arguments, we can prove the following theorem.

**Theorem 36.** Let \( A, B, C \) be \( m \times n \) matrices over \( \{-1, 0, 1\} \) such that \( A \) has a 0 and \( (A, B, C) \) is not independent from \( B \) and \( C \). Suppose \( A \) and \( C \) are not layered matrices and \( B \) is a layered matrix. Then, IST\((A, B, C) = \infty \) if and only if \( (A, B, C) \) is all-but-rightmost-positive.

By now, we already have classification for triples \((A, B, C)\) with the index of semi-transitivity infinity except for the case when \( A \) is not a layered matrix and \( B \) and \( C \) are layered matrices and \((A, B, C)\) is not independent from \( B, C \). To solve the remaining cases, we need the following four lemmas.

**Lemma 37.** Let \( A, B, C \) be \( m \times n \) matrices over \( \{-1, 0, 1\} \) such that \( A \) has a 0 and \( (A, B, C) \) is not independent from \( B \) and \( C \). Then,

1. if \( 01^{n-1} \) and \( 1^{n-1}0 \) are rows in \( A \), then IST\((A, B, C)\) is finite;
2. if \( 0(-1)^{n-1} \) and \((-1)^{n-1}0\) are rows in \( A \), then IST\((A, B, C)\) is finite;
3. if \( 01^{n-1} \) and \((-1)^{n-1}0\) are rows in \( A \), then IST\((A, B, C)\) is finite;
4. if \( 0(-1)^{n-1} \) and \( 1^{n-1}0 \) are rows in \( A \), then IST\((A, B, C)\) is finite;
5. if \( 1p0(-1)^{n-p-1} \) and \( 1q0(-1)^{n-q-1} \) are rows in \( A \), where \( 0 \leq p < q \leq n - 1 \), then IST\((A, B, C)\) is finite.

**Proof.**

1. Suppose that IST\((A, B, C) = \infty \) and row \( i \) and row \( j \) in \( A \) are \( 01^{n-1} \) and \( 1^{n-1}0 \), respectively. Note that \( B^{n-1} \) gives \( m \) consecutive rows in \( M^2(A, B, C) \) obtained by applying the morphism to \( 1^{n-1}0 \). Row \( i \) in \( B^{n-1} \) is \( x^{n-1}01^{n-1} \), where \( x \) is row \( i \) in \( B \). Since \( A \) is not a layered matrix, by Lemma 20, there is no 0 in \( x \). So \( x^{n-1}01^{n-1} \) cannot be of the form \( 0^t1^0 \), \( 0^t(-1)^0 \) or \( 1^t0^t(-1)^t \). This contradicts to Corollary 14.

2. Suppose that IST\((A, B, C) = \infty \) and row \( i \) and row \( j \) in \( A \) are \( 0(-1)^{n-1} \) and \( (-1)^{n-1}0 \), respectively. Note that \( AC^{n-1} \) gives \( m \) consecutive rows in \( M^2(A, B, C) \) obtained by applying the morphism to \( 0(-1)^{n-1} \). Row \( j \) in \( AC^{n-1} \) is \( (-1)^{n-1}0x^{n-1} \), where \( x \) is row \( j \) in \( B \). Since \( A \) is not a layered matrix, by Lemma 20.
there is no 0 in \(x\). So \((-1)^{n-1}t^{n-1}z^{n-1}\) cannot be of the form \(0^r1^s0^t\), \(0^r(-1)^s0^t\) or \(1^r0^s(-1)^t\). This contradicts to Corollary 14.

(3) Suppose that \(\text{IST}(A,B,C) = \infty\) and row \(i\) and row \(j\) in \(A\) are \(01^{n-1}\) and \((-1)^{n-1}0\), respectively. Note that \(AB^{n-1}\) gives \(m\) consecutive rows in \(M^2(A,B,C)\) obtained by applying the morphism to \(01^{n-1}\). Row \(j\) in \(AB^{n-1}\) is \((-1)^{n-1}t^{n-1}\), where \(x\) is row \(j\) in \(B\). Note that \((-1)^{n-1}t^{n-1}x^{n-1}\) must be of the form \(0^r(-1)^s0^t\), and so \(x = 0^n\). Thus, \((-1)^{n-1}t^{n-1}(0^{n-1})^{(n^2-n-1)}\) is a row in \(M^2(A,B,C)\) having more than one 0, which contradicts to Lemma 26.

(4) Suppose that \(\text{IST}(A,B,C) = \infty\) and row \(i\) and row \(j\) in \(A\) are \(0(1-n)^{n-1}\) and \(1-n^{n-1}\), respectively. Note that \(AC^{n-1}\) gives \(m\) consecutive rows in \(M^2(A,B,C)\) obtained by applying the morphism to \(0(1-n)^{n-1}\). Row \(j\) in \(AC^{n-1}\) is \(1-n^{n-1}t^{n-1}\), where \(x\) is row \(j\) in \(C\). Since \(A\) is not a layered matrix, by Lemma 26 there is no 0 in \(x\). Therefore, \((-1)^{n-1}t^{n-1}\) is of the form \(1^s0^r(-1)^t\). So \(x = (-1)^{n-1}t^{n-1}\) and \((-1)^{n-1}t^{n-1}(0^{n-1})^{(n^2-n)}\) is a row in \(M^2(A,B,C)\). Note that \(B^{n-1}A\) gives \(m\) consecutive rows in \(M^2(A,B,C)\) obtained by application of the morphism to \(1-n^{n-1}\). Row \(j\) in \(B^{n-1}A\) is \(y^{n-1}t^{n-1}\), where \(y\) is row \(j\) in \(B\). Since \(A\) is not a layered matrix, by Lemma 26 there is no 0 in \(y\). Therefore, \(y^{n-1}t^{n-1}\) is of the form \(0^r1^s0^t\). So \(y = 1^n\) and \(y^{n-1}t^{n-1}(0^{n-1})^{(n^2-n)}\) is a row in \(M^2(A,B,C)\). If every row of \(M^2(A,B,C)\) has a 0, then \(1-n^{n-1}(0^{n-1})^{(n^2-n-1)}\) and \(1-n^{n-1}(0^{n-1})^{(n^2-n)}\) break the second condition of Theorem 12. Hence, \(G_2(A,B,C)\) is not semi-transitive and this leads to a contradiction. Suppose that \(1^\ell(-1)^{n^2-\ell}\) is a row of \(M^2(A,B,C)\) for some \(0 \leq \ell \leq n^2\). By Lemma 10 we have \(G_2(A,B,C)\) is isomorphic to \(G_0(N)\) where \(N\) is a matrix obtained by deleting row \(1^\ell(-1)^{n^2-\ell}\) from \(M^2(A,B,C)\) and after that adding a zero column between the \(\ell\)-th and the \((\ell+1)\)-th columns. So, \(G_0(N)\) is semi-transitive. Note that \(\ell\) must be \(n - 1\) or \(n\), otherwise the row of \(N\) obtained by adding a zero to \(1-n^{n-1}(0^{n-1})^{(n^2-n)}\) is not of the form \(1^n0^p(-1)^q\). Then row of \(N\) obtained by adding a zero to \(1-n^{n-1}(0^{n-1})^{(n^2-n)}\) in between the \(\ell\)-th and the \((\ell+1)\)-th positions is not of the form \(0^r1^s0^t\) or \(0^r(-1)^s0^t\) or \(1^r0^s(-1)^t\). Hence, by Corollary 14 \(G_0(N)\) is not semi-transitive, which is a contradiction.

(5) Suppose that \(\text{IST}(A,B,C) = \infty\) and row \(i\) and row \(j\) in \(A\) are \(1^p0(-1)^{n-p-1}\) and \(1^q0(-1)^{n-q-1}\), respectively, where \(0 \leq p < q \leq n - 1\). Note that \(B^pAC^{n-p-1}\) gives \(m\) consecutive rows in \(M^2(A,B,C)\) obtained by applying the morphism to \(1^p0(-1)^{n-p-1}\). Row \(i\) in \(B^pAC^{n-p-1}\) is \(x^{p}1^{p}0(-1)^{n-p-1}y^{n-p-1}\) where \(x\) is row \(i\) in \(B\) and \(y\) is row \(i\) in \(C\). Since \(A\) is not a layered matrix, by Lemma 26 there is no more than one 0 in any row of
Lemma 38. Let $A, B, C$ be $m \times n$ matrices over $\{-1, 0, 1\}$ such that $A$ has a 0 and $(A, B, C)$ is not independent from $B$ and $C$. Then,

1. if $1^p0(-1)^{n-p-1}$ and $01^{n-1}$ are rows in $A$, where $1 \leq p \leq n - 2$, then IST$(A, B, C)$ is finite;
2. if $1^p0(-1)^{n-p-1}$ and $0(-1)^{n-1}$ are rows in $A$, where $1 \leq p \leq n - 2$, then IST$(A, B, C)$ is finite;
3. if $1^p0(-1)^{n-p-1}$ and $1^{n-1}0$ are rows in $A$, where $1 \leq p \leq n - 2$, then IST$(A, B, C)$ is finite;
4. if $1^p0(-1)^{n-p-1}$ and $(-1)^{n-1}0$ are rows in $A$, where $1 \leq p \leq n - 2$, then IST$(A, B, C)$ is finite.

Proof.

1. Suppose that $1^p0(-1)^{n-p-1}$ and $01^{n-1}$ are rows $i$ and $j$ in $A$, respectively, and IST$(A, B, C) = \infty$. Note that $B^pAC^{n-p-1}$ gives $m$ consecutive rows in $M^2(A, B, C)$ obtained by applying the morphism to $1^p0(-1)^{n-p-1}$ in $M^1(A, B, C)$. Row $j$ in $B^pAC^{n-p-1}$ is $b^p01^{n-1}c^{n-p-1}$, where $b$ and $c$ are row $j$ in $B$ and $C$, respectively. So $b^p01^{n-1}c^{n-p-1}$ must be $0^t1^s0^t$ for some
\( r, s, t \geq 0 \). Hence, \( b = 0^n \) and \( c = 1^n \). As \( A \) is not a layered matrix, every row in \( M^2(A, B, C) \) contains at most one 0, which is a contradiction. Therefore, \( \text{IST}(A, B, C) < \infty \).

(2) This is given by (5) in Lemma \ref{lem:37}.

(3) This is given by (5) in Lemma \ref{lem:37}.

(4) Suppose that \( 1^p0((-1)^{n-p-1} and \((-1)^{n-1}0 \) are rows \( i \) and \( j \) in \( A \), respectively, and \( \text{IST}(A, B, C) = \infty \). Note that \( B^pAC^{n-p-1} \) gives \( m \) consecutive rows in \( M^2(A, B, C) \) obtained by applying the morphism to \( 1^p0((-1)^{n-p-1} in \( M^1(A, B, C) \). Row \( j \) in \( B^pAC^{n-p-1} \) is \( b^p(1)^{n-1}0c^{n-p-1} \), where \( b \) and \( c \) are row \( j \) in \( B \) and \( C \), respectively. So, \( b^p(1)^{n-1}0c^{n-p-1} \) must be \( 0^r((-1)^{s}0 \) for some \( r, s, t \geq 0 \). Hence, \( b = (-1)^n \) and \( c = 0^n \). As \( A \) is not a layered matrix, every row in \( M^2(A, B, C) \) contains at most one 0, which is a contradiction. Therefore, \( \text{IST}(A, B, C) < \infty \).

\( \square \)

**Definition 39.** Let \( A, B, C \) be \( m \times n \) matrices over \( \{-1, 0, 1\} \). A triple \( (A, B, C) \) is left-0-invariant if \( A, B, C \) satisfy the following properties:

- every row in \( A \) is in \( \{01^{n-1}, 1^n, 0(-1)^{n-1}, (-1)^n\} \);
- every row in \( B \) and \( C \) is in \( \{1^n, (-1)^n\} \);
- if \( 01^{n-1} \) appears as a row in \( A \), then
  - row \( i \) in \( A \) is \( 01^{n-1} \) implies row \( i \) in \( B \) is \( 1^n \);
  - row \( i \) in \( A \) is \( 1^n \) implies row \( i \) in \( B \) is \( 1^n \);
  - row \( i \) in \( A \) is \( 0(-1)^{n-1} \) implies row \( i \) in \( B \) is \( (-1)^n \);
  - row \( i \) in \( A \) is \( (-1)^n \) implies row \( i \) in \( B \) is \( (-1)^n \);
- if \( 0(-1)^{n-1} \) appears as a row in \( A \), then
  - row \( i \) in \( A \) is \( 01^{n-1} \) implies row \( i \) in \( C \) is \( 1^n \);
  - row \( i \) in \( A \) is \( 1^n \) implies row \( i \) in \( C \) is \( 1^n \);
  - row \( i \) in \( A \) is \( 0(-1)^{n-1} \) implies row \( i \) in \( C \) is \( (-1)^n \);
  - row \( i \) in \( A \) is \( (-1)^n \) implies row \( i \) in \( C \) is \( (-1)^n \).

**Definition 40.** Let \( A, B, C \) be \( m \times n \) matrices over \( \{-1, 0, 1\} \). A triple \( (A, B, C) \) is right-0-invariant if \( A, B, C \) satisfy the following properties:

- every row in \( A \) is in \( \{1^n-10, 1^n, (-1)^{n-1}0, (-1)^n\} \);
- every row of \( B \) and \( C \) is in \( \{1^n, (-1)^n\} \);
- if \( 1^n-10 \) appears as a row in \( A \), then
  - row \( i \) in \( A \) is \( 1^n-10 \) implies row \( i \) in \( B \) is \( 1^n \);
  - row \( i \) in \( A \) is \( 1^n \) implies row \( i \) in \( B \) is \( 1^n \);
  - row \( i \) in \( A \) is \( (-1)^{n-1}0 \) implies row \( i \) in \( B \) is \( (-1)^n \);
  - row \( i \) in \( A \) is \( (-1)^n \) implies row \( i \) in \( B \) is \( (-1)^n \);
• if \((-1)^{n-1}0\) appears as a row in \(A\), then
  - row \(i\) in \(A\) is \(1^{n-1}0\) implies row \(i\) in \(C\) is \(1^n\);
  - row \(i\) in \(A\) is \(1^n\) implies row \(i\) in \(C\) is \(1^n\);
  - row \(i\) in \(A\) is \((-1)^{n-1}0\) implies row \(i\) in \(C\) is \((-1)^n\);
  - row \(i\) in \(A\) is \((-1)^n\) implies row \(i\) in \(C\) is \((-1)^n\).

**Lemma 41.** Let \(A, B, C\) be \(m \times n\) matrices over \([-1, 0, 1]\) such that \(A\) has a 0. Then,

1. If \((A, B, C)\) is left-0-invariant and \(01^{n-1} \notin R(A)\), then \(01^{n-1} \notin R^k(A, B, C)\) for any \(k \geq 0\).
2. If \((A, B, C)\) is left-0-invariant and \(0(-1)^{n-1} \notin R(A)\), then \(0(-1)^{n-1} \notin R^k(A, B, C)\) for any \(k > 0\).
3. If \((A, B, C)\) is right-0-invariant and \(1^{n-1}0 \notin R(A)\), then \(1^{n-1}0 \notin R^k(A, B, C)\) for any \(k > 0\).
4. If \((A, B, C)\) is right-0-invariant and \((-1)^{n-1}0 \notin R(A)\), then \((-1)^{n-1}0 \notin R^k(A, B, C)\) for any \(k > 0\).

**Proof.** As all of the statements are proved in similar ways, we will only prove (1). Assume \((A, B, C)\) is left-0-invariant and \(01^{n-1} \notin R(A)\). For \(k = 1\), it is obvious that \(M^1(A, B, C) = A\) and then \(01^{n-1} \notin R^1(A, B, C)\). Suppose \(k \geq 2\) and \(01^{n-1} \in R^k(A, B, C)\). Let \(0x_1x_2\cdots x_{n-1}1\) be a row in \(M^{k-1}(A, B, C)\) such that applying to it the morphism creates row \(01^{n-1}\). That is, \(01^{n-1}\) is a row in the matrix \(AX_1X_2\cdots X_{n-1}\), where \(X_i \in \{A, B, C\}\), obtained from \(0x_1x_2\cdots x_{n-1}1\) by application of the morphism. This is a contradiction because \(01^{n-1} \notin R(A)\). Hence, \(01^{n-1} \notin R^k(A, B, C)\). \(\square\)

**Lemma 42.** Let \(A, B, C\) be \(m \times n\) matrices over \([-1, 0, 1]\) such that \(A\) has a 0. If \((A, B, C)\) is left-0-invariant (resp., right-0-invariant), then \(\text{IST}(A, B, C) = \infty\).

**Proof.** Suppose that \((A, B, C)\) is left-0-invariant. We will prove that for any \(k > 0\), \(R^k(A, B, C) \subseteq \{01^{n-1}, 1^{n-k}, 0(-1)^{n-k}, (-1)^n\}\) by induction on \(k\). From the definition of a left-0-invariant triple, we have that \(R^1(A, B, C) = R(A) \subseteq \{01^{n-1}, 1^n, 0(-1)^{n-1}, (-1)^n\}\). Suppose \(R^k(A, B, C) \subseteq \{01^{n-1}, 1^n, 0(-1)^{n-k}, (-1)^n\}\) for some \(k\). If \(01^{n-1} \notin R(A)\), then \(0(-1)^{n-1} \in R(A)\) and, by Lemma 41, \(01^{n-1} \notin R^k(A, B, C)\). So, every row in \(M^k(A, B, C)\) is \(1^n\), \(0(-1)^{n-k}\) or \((-1)^n\). As every row in \(M^{k+1}(A, B, C)\) is a row in an \(m \times n^{k+1}\) matrix obtained by applying the morphism to a row in \(M^k(A, B, C)\), we have that

\[
R^{k+1}(A, B, C) = R(B^{n^k}) \cup R(AC^{n^k-1}) \cup R(C^{n^k}).
\]
We can see that $R(B^n)$ and $R(C^n)$ are subset of $\{1^{n+1}, (-1)^{n+1}\}$. Row $i$ in $AC^{n-1}$ is $1^{n+1}$, $(-1)^{n+1}$ and $0(-1)^{n+1-1}$ if row $i$ in $A$ is $1^n$, $(-1)^n$ and $0(-1)^n$, respectively. Hence, $R^{k+1}(A, B, C) \subseteq \{1^{k+1}, 0(-1)^{k+1-1}, (-1)^{k+1}\}$ in the case of $01^{n-1} \notin R(A)$. For the case of $0(-1)^{n-1} \notin R(A)$, we can follow similar arguments to see that $R^{k+1}(A, B, C) \subseteq \{01^{n+1-1}, 1^{n+1}, (-1)^{k+1}\}$. Assume both $01^{n-1}$ and $0(-1)^{n-1}$ are in $R(A)$. So, every row in $M^k(A, B, C)$ is $01^{n-1}$, $1^n$, $0(-1)^{n-1}$ or $(1)^n$ and

$$R^{k+1}(A, B, C) = R(AB^{n-1}) \cup R(B^n) \cup R(AC^{n-1}) \cup R(C^n).$$

Note that $R(B^n)$, $R(C^n) \subseteq \{1^{n+1}, (-1)^{n+1}\}$. Row $i$ in $AC^{n-1}$ is $1^{n+1}$, $(-1)^{n+1}$, $01^{n+1-1}$ and $0(-1)^{n+1-1}$ if row $i$ in $A$ is $1^n$, $(-1)^n$, $01^n$ and $0(-1)^n$, respectively. Row $i$ in $AB^{n-1}$ is $1^{n+1}$, $(-1)^{n+1}$, $01^{n+1-1}$ and $0(-1)^{n+1-1}$ if row $i$ in $A$ is $1^n$, $(-1)^n$, $01^n$ and $0(-1)^n$, respectively. Hence, $R^{k+1}(A, B, C) \subseteq \{1^{n+1}, 0(-1)^{n+1-1}, (-1)^{k+1}\}$. Thus, we have shown that, for any $k > 0$,

$$R^k(A, B, C) \subseteq \{01^{n-1}, 1^n, 0(-1)^{n-1}, (-1)^n\}.$$ 

By Corollary 15, $G^k_a(A, B, C)$ is semi-transitive for any $k > 0$, which means that IST($A, B, C$) $= \infty$. \hfill $\Box$

**Theorem 43.** Let $A, B, C$ be $m \times n$ matrices over $\{-1, 0, 1\}$ such that $A$ has a 0 and $(A, B, C)$ is not independent from $B$ and $C$. Suppose $A$ is not a layered matrix but $B$ and $C$ are layered matrices. Then, IST($A, B, C$) $= \infty$ if and only if one of the following conditions holds:

- $(A, B, C)$ is left-0-invariant.
- $(A, B, C)$ is right-0-invariant.
- $R(A) = \{1^p01^{n-p-1}\}$ for some $p \in \{1, 2, \ldots, n-2\}$, and $B$ and $C$ are all 1 and $(-1)$ matrices, respectively.

**Proof.** Assume IST($A, B, C$) $= \infty$. Since $A$ is not a layered matrix, by Lemma 26, every row of $M^1(A, B, C) = A$ contains at most one 0. Then, every row in $A$ is $01^{n-1}$, $1^n$,$0(-1)^{n-1}$, $(-1)^{n-10}$, $(-1)^n$, $1^p0(-1)^{n-p-1}$ or $1^q(-1)^{n-q}$ for some $p \in \{1, 2, \ldots, n-2\}$ and $q \in \{1, 2, \ldots, n-1\}$. Since $(A, B, C)$ is not independent from $B$ and $C$, and $B$ and $C$ are layered matrices, we have every row of $B$ and $C$ must be $1^n$ or $(-1)^n$, otherwise there is a row in $M^k(A, B, C)$ having more than one 0 for some $k$.

If $1^q(-1)^{n-q}$ is row $i$ in $A$ for $q \in \{1, 2, \ldots, n-1\}$, then $G^k_a(A, B, C)$ is isomorphic to $G(N_1)$ where $N_1$ is an $(m-1) \times (n+1)$ matrix obtained by deleting row $i$ and then adding a zero column between the $q$-th and $(q+1)$-th columns. Note that $G(N_1)$ is semi-transitive. By
Corollary 14 every row of $N_1$ is of the form $0^r1^s0^t$ or $0^r(-1)^s0^t$ for some non-negative integers $r, s, t$. So every row of $A$ except row $i$ is $1^q(-1)^{n-q}$, $1^q0(-1)^{n-q}$ or $1^0(-1)^{n-q}$. By (5) in Lemma 37 we have that $A$ cannot contain both $1^q0(-1)^{n-q}$ and $1^0(-1)^{n-q}$ as its rows. If $1^q0(-1)^{n-q} \not\in R(A)$, then

$$A = \begin{bmatrix} 1^q & a_1 & (-1)^{n-q-1} \\ 1^q & a_2 & (-1)^{n-q-1} \\ \vdots & \vdots & \vdots \\ 1^q & a_m & (-1)^{n-q-1} \end{bmatrix}$$

for $a_i \in \{0, 1\}$. Since $A$ has a 0, there is row $j$ in $A$ of the form $1^q0(-1)^{n-q-1}$. Let $b$ and $c$ be row $j$ in $B$ and $C$, respectively. Note that $B^qAC^{n-q-1}$ is $m$ consecutive rows of $M^2$ obtained by applying the morphism to $1^q0(-1)^{n-q-1}$. Then, $b^q1^q0(-1)^{n-q-1}c^{n-q-1}$ is row $j$ in $M^2(A, B, C)$ and it must be of the form $1^r0(-1)^t$ for some $r, s, t \geq 0$. So, we obtain $b = 1^n$ and $c = (-1)^n$ and $1^q0(-1)^{n-q-1}$ is a row of $M^2(A, B, C)$. Note that $B^qC^{n-q}$ is $m$ consecutive rows of $M^2$ obtained by applying the morphism to $1^q(-1)^{n-q}$, and $1^q(-1)^{n(n-q)}$ is row $j$ in $B^qC^{n-q}$. Then, $B^qC^{n-q}$ is isomorphic to $G(N_2)$ where $N_2$ is a matrix obtained by deleting the row $1^q(-1)^{n(n-q)}$ and then adding a zero column between the $(nq)$-th and $(nq+1)$-th columns. So, $1^q01^q0(-1)^{n^2-nq-1}$ is a row in $N_2$. Therefore, by Corollary 14, we have $N_2$ is not semi-transitive which contradicts to semi-transitivity of $G^2(A, B, C)$. By the same argument, we also obtain a contradiction in the case of $1^q-1(-1)^{n-q} \not\in R(A)$. Hence $1^q(-1)^{n-q}$ cannot be a row in $A$.

Suppose that $1^q0(-1)^{n-p-1}$ is row $i$ in $A$. By Corollaries 16 and 17 we have that $1^q$ and $(-1)^{n}$ are not rows in $M^1(A, B, C)$. By Lemma 38 we have that $01^n-1$, $1^n-10$, $0(-1)^{n-1}$ and $(-1)^{n-1}0$ are not rows in $M^1(A, B, C)$. If there is a row in $A$ of the form $1^q0(-1)^{n-u-1}$, where $1 \leq u \leq n-2$, by (5) in Lemma 37 we have $p = u$. Hence, we obtain

$$A = \begin{bmatrix} 1^p & 0 & (-1)^{n-p-1} \\ 1^p & 0 & (-1)^{n-p-1} \\ \vdots & \vdots & \vdots \\ 1^p & 0 & (-1)^{n-p-1} \end{bmatrix} \quad \text{where} \quad 1 \leq p < n-2.$$  

Let $b$ and $c$ be row $j$ in $B$ and $C$, respectively, for any $1 \leq j \leq m$. Note that $B^pAC^{n-p-1}$ is $m$ consecutive rows of $M^2$ obtained by applying the morphism to $1^p0(-1)^{n-p-1}$. Then, $b^p1^p0(-1)^{n-p-1}c^{n-p-1}$ is row $j$ in $M^2(A, B, C)$ and it must be of the form $1^r0(-1)^t$ for some $r, s, t \geq 0$. So, we obtain $b = 1^n$ and $c = (-1)^n$. Hence, we see that $B$ and $C$ are all 1 matrix and all $(-1)$ matrix, respectively.

25
Assume that $1 p 0 \left(-1\right)^{n-p-1}$ is not a row in $A$ for any $1 \leq p \leq n - 2$. That is, every row in $A$ is $01^{n-1}$, $1^n-10$, $1^n$, $0(-1)^{n-1}$, $(-1)^{n-1}0$ or $(-1)^n$. By Lemma 37, we need to consider the following two cases.

**Case 1:** $01^{n-1}, 0(-1)^{n-1} \in R(A)$ and $1^n-10, (-1)^{n-1}0 \notin R(A)$. That is, every row in $A$ is $01^{n-1}$, $1^n$, $0(-1)^{n-1}$ or $(-1)^n$. Suppose that $01^{n-1}$ is a row in $A$. Then, $AB^{n-1}$ is $m$ consecutive rows in $M^2(A, B, C)$. Let row $i$ in $B$ be $b$. Consider the following subcases:

- If row $i$ in $A$ is $01^{n-1}$, then $01^{n-1}b^{n-1}$ is a row in $M^2(A, B, C)$. Since $b \neq 0^n$, we have $b = 1^n$.
- If row $i$ in $A$ is $1^n$, then $1^n_b^{n-1}$ is a row in $M^2(A, B, C)$. Since $b \neq 0^n$, we have $b = 1^n$.
- If row $i$ in $A$ is $0(-1)^{n-1}$, then $0(-1)^{n-1}b^{n-1}$ is a row in $M^2(A, B, C)$. Since $b \neq 0^n$, we have $b = (-1)^n$.
- If row $i$ in $A$ is $(-1)^n$, then $(-1)^n_b^{n-1}$ is a row in $M^2(A, B, C)$. Since $b \neq 0^n$, we have $b = (-1)^n$.

Suppose that $0(-1)^{n-1}$ is a row in $A$. Then, $A^Cn^{-1}$ is $m$ consecutive rows in $M^2(A, B, C)$. Let row $i$ in $C$ be $c$. Consider the following subcases:

- If row $i$ in $A$ is $01^{n-1}$, then $0(-1)^{n-1}c^{n-1}$ is a row in $M^2(A, B, C)$. Since $c \neq 0^n$, we have $c = 1^n$.
- If row $i$ in $A$ is $1^n$, then $1^n_c^{n-1}$ is a row in $M^2(A, B, C)$. Since $c \neq 0^n$, we have $c = 1^n$.
- If row $i$ in $A$ is $0(-1)^{n-1}$, then $0(-1)^{n-1}c^{n-1}$ is a row in $M^2(A, B, C)$. Since $c \neq 0^n$, we have $c = (-1)^n$.
- If row $i$ in $A$ is $(-1)^n$, then $(-1)^n_c^{n-1}$ is a row in $M^2(A, B, C)$. Since $c \neq 0^n$, we have $c = (-1)^n$.

Thus, we see that $(A, B, C)$ is left-0-invariant.

**Case 2:** $1^n-10, (-1)^{n-1}0 \in R(A)$ and $01^{n-1}, 0(-1)^{n-1} \notin R(A)$. With the same way of the case 1, we can prove that $(A, B, C)$ is right-0-invariant.

Thus, “$\Rightarrow$” has been proved. Lemma 42 gives us the converse.

### 4 Direction of further research

In this paper, we fully classified semi-transitivity of infinite families of directed split graphs generated by iterations of morphisms in the cases when the matrix $A$ has a 0. This research is a first step towards a classification of semi-transitive directed graphs in terms of positions of
0s and 1s (and \((-1)\)s in the lower-triangular case) in the adjacency matrices. An application of such a classification could be in finding more efficient algorithms to recognize semi-transitivity of a directed graph, which is a problem solvable in polynomial time \[8\]. More importantly, a classification of semi-transitive directed graphs via adjacency matrices may lead to a better understanding of which (undirected) graphs admit semi-transitive orientations; this is an NP-complete problem \[7, 8\]. Should the general problem resist attempts to solve it, one could shift their attention to classification of semi-transitivity of naturally defined (infinite) families of directed graphs. Such a shift should allow discovering new methods to deal with semi-transitivity of oriented graphs, and hence bring us closer to solving the general problem.

For yet another direction of research, note that Definition 24 of the index of semi-transitivity IST\((A, B, C)\) makes sense in many situations when \(A\) has no 0’s. For example, if \(A, B\) and \(C\) contain only 1’s, we still can apply Definition 24 to see that IST\((A, B, C) = \infty\). On the other hand, Definition 24 does not work, for example, in the case when \(A\) is any matrix without 0’s while \(B\) and \(C\) contain only 0’s, as the infinite graph \(G_o(A, B, C)\) is then not well-defined. Indeed, in the later case we see that \(G_o^i(A, B, C)\) is not an induced subgraph of \(G_o^{i+1}(A, B, C)\) while \(G_o^i(A, B, C)\) is an induced subgraph of \(G_o^{i+2}(A, B, C)\) for any \(i \geq 0\), so that we have two infinite chains of induced subgraphs leading to two different infinite graphs as the limits (one of which is with no edges between the clique and the independent set). For another example, letting \(A\) be an all one matrix, \(B\) be an all \((-1)\) matrix, and \(C\) be an all zero matrix, we witness the situation of three infinite chains of induced subgraphs with three infinite graphs as the limits.

In any case, the problem we solved in this paper can be extended to the case of matrices \(A\) with no 0’s in the situations when the limiting infinite graph is uniquely defined, and the goal then is to classify such triples \((A, B, C)\) with IST\((A, B, C) = \infty\). Of course, extra care should be taken about Definition 24 as it still may not work. For example, \(A\) without 0’s can easily be chosen so that \(G_o^k(A, B, C)\) has directed cycles and thus is not semi-transitive, while then choosing \(B\) and \(C\) be all one matrices, we see that \(G_o^k(A, B, C)\) is semi-transitive for \(k > 1\), so that the limiting graph is also semi-transitive and it is natural to assume that IST\((A, B, C) = \infty\), while by Definition 24, IST\((A, B, C) = 1\). However, natural adjustments to Definition 24 could be introduced. For example, we can define IST\((A, B, C) := \infty\) if there exists a natural number \(k\) such that \(G_o^k(A, B, C)\) is semi-transitive for every \(i \geq k\).
