Abstract
In the paper, we define the $q$-Fibonacci bicomplex quaternions and the $q$-Lucas bicomplex quaternions, respectively. Then, we give some algebraic properties of $q$-Fibonacci bicomplex quaternions and the $q$-Lucas bicomplex quaternions.

Keywords: Bicomplex number; $q$-integer; Fibonacci number; Bicomplex Fibonacci quaternion; $q$-quaternion; $q$-Fibonacci quaternion.

1. Introduction

The real quaternions were first described by Irish mathematician William Rowan Hamilton in 1843. The real quaternions constitute an extension of complex numbers into a four-dimensional space and can be considered as four-dimensional vectors, in the same way that complex numbers are considered as two-dimensional vectors. Hamilton [1] introduced the set of quaternions which can be represented as

$$H = \{ q = q_0 + i q_1 + j q_2 + k q_3 \mid q_0, q_1, q_2, q_3 \in \mathbb{R} \}$$  \hspace{1cm} (1)

where

$$i^2 = j^2 = k^2 = -1, \quad i j = -j i = k, \quad j k = -k j = i, \quad k i = -i k = j.$$ \hspace{1cm} (2)

Horadam [2, 3] defined complex Fibonacci and Lucas quaternions as follows

$$Q_n = F_n + F_{n+1} i + F_{n+2} j + F_{n+3} k$$ \hspace{1cm} (3)
and
\[ K_n = L_n + L_{n+1} + L_{n+2} j + L_{n+3} k \]  
where \( F_n \) and \( L_n \) denote the \( n \)-th Fibonacci and Lucas numbers, respectively. Also, the imaginary quaternion units \( i, j, k \) have the following rules
\[ i^2 = j^2 = k^2 = -1, \quad i j = -j i = k, \quad j k = -k j = i, \quad k i = -i k = j \]

There are several studies on quaternions as the Fibonacci and Lucas quaternions and their generalizations, for example, [4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14]. Bicomplex numbers were introduced by Corrado Segre in 1892 [15]. In 1991, G. Baley Price, the bicomplex numbers are given in his book based on multicomplex spaces and functions [16]. In recent years, fractal structures of these numbers have also been studied [17, 18]. The set of bicomplex numbers can be expressed by the basis \( \{1, i, j, i j\} \) (Table 1) as,

\[ C_2 = \{ q = q_1 + i q_2 + j q_3 + i j q_4 \mid q_1, q_2, q_3, q_4 \in \mathbb{R} \} \]  
where \( i, j \) and \( i j \) satisfy the conditions
\[ i^2 = -1, \quad j^2 = -1, \quad i j = j i. \]  

In 2018, the bicomplex Fibonacci quaternions defined by Aydı̇n Torunbalcı [19] as follows
\[ \mathbb{BF}_n = F_n + i F_{n+1} + j F_{n+2} + i j F_{n+3} \]
\[ = (F_n + i F_{n+1}) + (F_{n+2} + i F_{n+3}) j \]  
where \( i, j \) and \( i j \) satisfy the conditions [6].

The theory of the quantum \( q \)-calculus has been extensively studied in many branches of mathematics as well as in other areas in biology, physics, electrochemistry, economics, probability theory, and statistics [20, 21]. For \( n \in \mathbb{N}_0 \), the \( q \)-integer \ [n]_q \ is defined as follows
\[ [n]_q = \frac{1 - q^n}{1 - q} = 1 + q + q^2 + \ldots + q^{n-1}. \]  

By (8), for all \( m, n \in \mathbb{Z} \), can be easily obtained \([m + n]_q = [m]_q + q^m [n]_q\). For more details related to the quantum \( q \)-calculus, we refer to [22, 23].
In 2019, $q$-Fibonacci hybrid and $q$-Lucas hybrid numbers defined by Kızılateş [24] as follows

$$HF_n(\alpha; q) = \alpha^{n-1}[n]_q + \alpha^n[n+1]_q i + \alpha^{n+1}[n+2]_q \varepsilon + \alpha^{n+2}[n+3]_q h$$

and

$$HL_n(\alpha; q) = \alpha^n[2n]_q + \alpha^{n+1}[2n+2]_q i + \alpha^{n+2}[2n+4]_q \varepsilon + \alpha^{n+3}[2n+6]_q h$$

where $i$, $\varepsilon$ and $h$ satisfy the conditions

$$i^2 = -1, \quad \varepsilon^2 = 0, \quad h^2 = 1, \quad i h = h i = \varepsilon + i.$$  

Also, Kızılateş derived several interesting properties of these numbers such as Binet-Like formulas, exponential generating functions, summation formulas, Cassini-like identities, Catalan-like identities and d’Ocagne-like identities [24].

2. $q$-Fibonacci bicomplex quaternions

In this section, we define $q$-Fibonacci bicomplex quaternions and $q$-Lucas bicomplex quaternions by using the basis \{1, $i$, $j$, $i j$\}, where $i$, $j$ and $i j$ satisfy the conditions (6) as follows

$$\mathbb{BF}_n(\alpha; q) = \alpha^{n-1}[n]_q + \alpha^n[n+1]_q i + \alpha^{n+1}[n+2]_q j + \alpha^{n+2}[n+3]_q i j$$

$$= \alpha^n \left( \frac{1-q^n}{\alpha - \alpha q} \right) i + \alpha^{n+1} \left( \frac{1-q^{n+1}}{\alpha - \alpha q} \right) j$$

$$+ \alpha^{n+2} \left( \frac{1-q^{n+2}}{\alpha - \alpha q} \right) i j + \alpha^{n+3} \left( \frac{1-q^{n+3}}{\alpha - \alpha q} \right) i j$$

$$= \frac{\alpha^n}{\alpha - (\alpha q)} \left[ 1 + \alpha i + \alpha^2 j + \alpha^3 i j \right]$$

$$- \frac{(\alpha q)^n}{\alpha - (\alpha q)} \left[ 1 + (\alpha q) i + (\alpha q)^2 j + (\alpha q)^3 i j \right].$$

(12)
bicomplex quaternions are defined by the bicomplex Fibonacci quaternions $BF$

Then, the addition, subtraction and multiplication by scalar of $q$

The multiplication of $q$

For $\alpha = \frac{1+\sqrt{5}}{2}$ and $(\alpha q) = \frac{-1}{\alpha}$, q-Fibonacci bicomplex quaternion $BF_n(\alpha; q)$ become the bicomplex Fibonacci quaternions $BF_n$.

The addition, subtraction and multiplication by real scalars of two q-Fibonacci bicomplex quaternions gives q-Fibonacci bicomplex quaternions. Then, the addition, subtraction and multiplication by scalar of q-Fibonacci bicomplex quaternions are defined by

\[
BF_n(\alpha; q) \pm BF_m(\alpha; q) = (\alpha^{n-1}[n]_q + \alpha^n[n + 1]_q i + \alpha^{n+1}[n + 2]_q j + \alpha^{n+2}[n + 3]_q i j)
\]

\[
BF_n(\alpha; q) \cdot BF_m(\alpha; q) = \lambda \alpha^n(1 + \alpha i + \alpha^2 j + \alpha^3 i j) + \lambda (\alpha q)^n (1 + (\alpha q) i + (\alpha q)^2 j + (\alpha q)^3 i j).
\]
The scalar and the vector part of $BF_n(\alpha; q)$ which is the $n - th$ term of the $q$-Fibonacci bicomplex quaternion are denoted by

$$S_{BF_n(\alpha; q)} = \alpha^{n-1}[n]_q, \quad V_{BF_n(\alpha; q)} = \alpha^n[n+1]_q i + \alpha^{n+1}[n+2]_q j + \alpha^{n+2}[n+3]_q i j.$$  \hspace{1cm} (16)

Thus, the $q$-Fibonacci bicomplex quaternion $BF_n(\alpha; q)$ is given by

$$BF_n(\alpha; q) = S_{BF_n(\alpha; q)} + V_{BF_n(\alpha; q)}.$$  

The multiplication of two $q$-Fibonacci bicomplex quaternions is defined by

$$BF_n(\alpha; q) \times BF_m(\alpha; q) = (\alpha^{n-1}[n]_q + \alpha^n[n+1]_q i + \alpha^{n+1}[n+2]_q j + \alpha^{n+2}[n+3]_q i j) \times (\alpha^{m-1}[m]_q + \alpha^m[m+1]_q i + \alpha^{m+1}[m+2]_q j + \alpha^{m+2}[m+3]_q i j)$$

$$= \frac{1}{\alpha^2 - \alpha^4 + \alpha^6} \left\{ \alpha^{n+m} \{ (1 - \alpha^2 - \alpha^4 + \alpha^6) + 2 i (\alpha - \alpha^3) + 2 j (\alpha^2 - \alpha^4) + 4 i j (\alpha^3) \} - q^n \{ (1 - \alpha^2 - \alpha^4 + \alpha^6) + 2 i (\alpha + \alpha q) - 2 (\alpha^2 q) - \alpha^3 (\alpha q)^2 \} + j (\alpha^2 + (\alpha q)^2 - \alpha (\alpha q)^3 - \alpha^3 (\alpha q)) \} + j (\alpha^2 + (\alpha q)^2 - \alpha (\alpha q)^3 - \alpha^3 (\alpha q)) \} - q^n \{ (1 - \alpha^2 - \alpha^4 + \alpha^6) + 2 i (\alpha + \alpha q) - 2 (\alpha^2 q) - \alpha^3 (\alpha q)^2 \} + j (\alpha^2 + (\alpha q)^2 - \alpha (\alpha q)^3 - \alpha^3 (\alpha q)) \} + j (\alpha^2 + (\alpha q)^2 - \alpha (\alpha q)^3 - \alpha^3 (\alpha q)) \} + q^{n+m} \{ (1 - \alpha^2 - \alpha^4 + \alpha^6) + 2 i (\alpha q - (\alpha q)^5) + 2 j ((\alpha q)^2 - (\alpha q)^4) + 4 i j ((\alpha q)^3) \} \right\}.$$  \hspace{1cm} (17)

Here, quaternion multiplication is done using bicomplex quaternionic units (table 1), and this product is commutative.

Also, the $q$-Fibonacci bicomplex quaternion product may be obtained as follows
Table 1: Multiplication scheme of bicomplex units

<table>
<thead>

\[ \mathbb{BF}_n(\alpha; q) \times \mathbb{BF}_m(\alpha; q) = \]

\[
\begin{pmatrix}
\alpha^{n-1}[n]_q & -\alpha^n[n+1]_q & -\alpha^{n+1}[n+2]_q & \alpha^{n+2}[n+3]_q \\
\alpha^n[n+1]_q & -\alpha^{n-1}[n]_q & -\alpha^{n+2}[n+3]_q & \alpha^{n+1}[n+2]_q \\
\alpha^{n+1}[n+2]_q & -\alpha^{n+2}[n+3]_q & \alpha^{n-1}[n+1]_q & -\alpha^n[n+1]_q \\
\alpha^{n+2}[n+3]_q & \alpha^{n+1}[n+2]_q & \alpha^n[n+1]_q & \alpha^{n-1}[n+1]_q
\end{pmatrix} \times
\begin{pmatrix}
\alpha^{m-1}[m]_q \\
\alpha^m[m+1]_q \\
\alpha^{m+1}[m+2]_q \\
\alpha^{m+2}[m+3]_q
\end{pmatrix}
\]

(18)

Three kinds of conjugation can be defined for bicomplex numbers \[17, 18\]. Therefore, conjugation of the \(q\)-Fibonacci bicomplex quaternion is defined in three different ways as follows

\[(\mathbb{BF}_n(\alpha; q))^{*1} = (\alpha^{n-1}[n]_q - i \alpha^n[n+1]_q + j \alpha^{n+1}[n+2]_q - i j \alpha^{n+2}[n+3]_q),\]  
(19)

\[(\mathbb{BF}_n(\alpha; q))^{*2} = (\alpha^{n-1}[n]_q + i \alpha^n[n+1]_q - j \alpha^{n+1}[n+2]_q - i j \alpha^{n+2}[n+3]_q),\]  
(20)

\[(\mathbb{BF}_n(\alpha; q))^{*3} = (\alpha^{n-1}[n]_q - i \alpha^n[n+1]_q - j \alpha^{n+1}[n+2]_q + i j \alpha^{n+2}[n+3]_q).\]  
(21)

Therefore, the norm of the \(q\)-Fibonacci bicomplex quaternion \(\mathbb{BF}_n(\alpha; q)\) is defined in three different ways as follows

\[N(\mathbb{BF}_n(\alpha; q))^{*1} = \|(\mathbb{BF}_n(\alpha; q)) \times (\mathbb{BF}_n(\alpha; q))^{*1}\|^2,\]  
(22)

\[N(\mathbb{BF}_n(\alpha; q))^{*2} = \|(\mathbb{BF}_n(\alpha; q)) \times (\mathbb{BF}_n(\alpha; q))^{*2}\|^2,\]  
(23)

\[N(\mathbb{BF}_n(\alpha; q))^{*3} = \|(\mathbb{BF}_n(\alpha; q)) \times (\mathbb{BF}_n(\alpha; q))^{*3}\|^2.\]  
(24)
Theorem 2.1. *(Binet’s Formula).* Let $\mathbb{BF}_n(\alpha; q)$ and $\mathbb{BL}_n(\alpha; q)$ be the $q$-Fibonacci bicomplex quaternion and the $q$-Lucas bicomplex quaternion. For $n \geq 1$, Binet’s formula for these quaternions respectively, is as follows:

\[
\mathbb{BF}_n(\alpha; q) = \frac{\alpha^n \hat{\gamma} - (\alpha q)^n \hat{\delta}}{\alpha - \alpha q}, \tag{25}
\]

and

\[
\mathbb{BL}_n(\alpha; q) = \alpha^n \hat{\gamma} + (\alpha q)^n \hat{\delta} \tag{26}
\]

where

\[
\hat{\gamma} = 1 + \alpha i + \alpha^2 j + \alpha^3 i j, \quad \alpha = \frac{1 + \sqrt{5}}{2}
\]

and

\[
\hat{\delta} = 1 + (\alpha q) i + (\alpha q)^2 j + (\alpha q)^3 i j, \quad \alpha q = -\frac{1}{\alpha}.
\]

**Proof.** *(25):* Using *(8)* and *(12)*, we find that

\[
\mathbb{BF}_n(\alpha; q) = \alpha^{n-1}[n]_q + \alpha^n [n + 1]_q i + \alpha^{n+1}[n + 2]_q j + \alpha^{n+2}[n + 3]_q i j
\]

\[
= \alpha^n \frac{1 - q^n}{\alpha - \alpha q} + \alpha^{n+1} \frac{1 - q^{n+1}}{\alpha - \alpha q} i + \alpha^{n+2} \frac{1 - q^{n+2}}{\alpha - \alpha q} j + \alpha^{n+3} \frac{1 - q^{n+3}}{\alpha - \alpha q} i j
\]

\[
= \frac{\alpha^n [1 + \alpha i + \alpha^2 j + \alpha^3 i j] - (\alpha q)^n [1 + (\alpha q) i + (\alpha q)^2 j + (\alpha q)^3 i j]}{\alpha - (\alpha q)}
\]

\[
= \frac{\alpha^n \hat{\gamma} - (\alpha q)^n \hat{\delta}}{\alpha - \alpha q}
\]

In a similar way, equality *(26)* can be derived as follows

\[
\mathbb{BL}_n(\alpha; q) = \alpha^{n-2}[n]_q + \alpha^{n-1} \frac{2[n+1]_q}{[n+2]_q} i + \alpha^n \frac{2[n+2]_q}{[n+3]_q} j + \alpha^{n+1} \frac{2[n+3]_q}{[n+4]_q} i j
\]

\[
= \alpha^{2n} \frac{1 - q^{2n}}{\alpha^n - (\alpha q)^n} + \alpha^{2n+2} \frac{1 - q^{2n+2}}{\alpha^{n+1} - (\alpha q)^{n+1}} i
\]

\[
+ \alpha^{2n+4} \frac{1 - q^{2n+4}}{\alpha^{n+2} - (\alpha q)^{n+2}} j + \alpha^{2n+6} \frac{1 - q^{2n+6}}{\alpha^{n+3} - (\alpha q)^{n+3}} i j
\]

\[
= \frac{\alpha^{2n}}{\alpha^n} (1 + \alpha i + \alpha^2 j + \alpha^3 i j)
\]

\[
- \frac{(\alpha q)^{2n}}{(\alpha q)^n} (1 + (\alpha q) i + (\alpha q)^2 j + (\alpha q)^3 i j)
\]

\[
= \alpha^n \hat{\gamma} - (\alpha q)^n \hat{\delta}.
\]
where \( \hat{\gamma} = 1 + \alpha i + \alpha^2 j + \alpha^3 k \), \( \hat{\delta} = 1 + (\alpha q) i + (\alpha q)^2 j + (\alpha q)^3 k \) and \( \hat{\gamma} \hat{\delta} = \hat{\delta} \hat{\gamma} \).

**Theorem 2.2. (Exponential generating function)**

Let \( BF_n(\alpha; q) \) be the \( q \)-Fibonacci bicomplex quaternion. For the exponential generating function for these quaternions is as follows:

\[
g_{BF_n(\alpha; q)} \left( \frac{t^n}{n!} \right) = \sum_{n=0}^{\infty} BF_n(\alpha; q) \frac{t^n}{n!} = \frac{\hat{\gamma} e^{\alpha t} - \hat{\delta} e^{(\alpha q) t}}{\alpha - \alpha q} \tag{27}
\]

**Proof.** Using the definition of exponential generating function, we obtain

\[
\sum_{n=0}^{\infty} BF_n(\alpha; q) \frac{t^n}{n!} = \sum_{n=0}^{\infty} \left( \frac{\hat{\gamma} e^{\alpha t} - \hat{\delta} e^{(\alpha q) t}}{\alpha - \alpha q} \right) \frac{t^n}{n!} = \frac{\hat{\gamma} e^{\alpha t} - \hat{\delta} e^{(\alpha q) t}}{\alpha - \alpha q} \tag{28}
\]

Thus, the proof is completed.

**Theorem 2.3. (Honsberger identity)**

For \( n, m \geq 0 \) the Honsberger identity for the \( q \)-Fibonacci bicomplex quaternions \( BF_n(\alpha; q) \) and \( BF_m(\alpha; q) \) is given by

\[
BF_n(\alpha; q) BF_m(\alpha; q) + BF_{n+1}(\alpha; q) BF_{m+1}(\alpha; q) = \frac{\alpha^{n+m}}{\alpha - \alpha q} \left\{ (1 + \alpha^2 \hat{\gamma} - \hat{\gamma} \delta (1 + \alpha(\alpha q))(q^n + q^m) + (1 + (\alpha q)^2 q^{n+m} \hat{\delta}^2) \right\}. \tag{29}
\]

**Proof.** (29): By using (12) and (25) we get,

\[
BF_n(\alpha; q) BF_m(\alpha; q) + BF_{n+1}(\alpha; q) BF_{m+1}(\alpha; q) = \left( \frac{\alpha^n \hat{\gamma} - (\alpha q)^n \hat{\delta}}{\alpha - \alpha q} \right) \left( \frac{\alpha^m \hat{\gamma} - (\alpha q)^m \hat{\delta}}{\alpha - \alpha q} \right) + \left( \frac{\alpha^{n+1} \hat{\gamma} - (\alpha q)^{n+1} \hat{\delta}}{\alpha - \alpha q} \right) \left( \frac{\alpha^{m+1} \hat{\gamma} - (\alpha q)^{m+1} \hat{\delta}}{\alpha - \alpha q} \right)
\]

\[
= \frac{\alpha^{n+m}}{(\alpha - \alpha q)^2} \left\{ (\hat{\gamma} - q^n \hat{\delta})(\hat{\gamma} - q^m \hat{\delta}) \right\} + \frac{\alpha^{n+m+2}}{(\alpha - \alpha q)^2} \left\{ (\hat{\gamma} - q^{n+1} \hat{\delta})(\hat{\gamma} - q^{m+1} \hat{\delta}) \right\}
\]

\[
= \frac{\alpha^{n+m}}{(\alpha - \alpha q)^2} \left\{ (1 + \alpha^2 \hat{\gamma}^2 - \hat{\gamma} \delta (1 + \alpha(\alpha q))(q^n + q^m) + (1 + (\alpha q)^2 q^{n+m} \hat{\delta}^2) \right\},
\]

where \( \hat{\gamma} \hat{\delta} = \hat{\delta} \hat{\gamma} \).
Theorem 2.4. \textit{(d'Ocagne's identity)}
For \( n, m \geq 0 \) the d'Ocagne's identity for the \( q \)-Fibonacci bicomplex quaternions \( BF_n(\alpha; q) \) and \( BF_m(\alpha; q) \) is given by

\[
BF_m(\alpha; q) BF_{n+1}(\alpha; q) - BF_{m+1}(\alpha; q) BF_n(\alpha; q) = \frac{\alpha^{n+m-1}(q^n - q^m)\hat{\gamma}\hat{\delta}}{(1-q)}. \tag{30}
\]

\textbf{Proof.} (30): By using (12) and (25) we get,

\[
BF_m(\alpha; q) BF_{n+1}(\alpha; q) - BF_{m+1}(\alpha; q) BF_n(\alpha; q)
= \left( \frac{\alpha^n \hat{\gamma} - (\alpha q)^n \hat{\delta}}{\alpha - \alpha q} \right) \left( \frac{\alpha^{n+1} \hat{\gamma} - (\alpha q)^{n+1} \hat{\delta}}{\alpha - \alpha q} \right)
- \left( \frac{\alpha^{m+1} \hat{\gamma} - (\alpha q)^{m+1} \hat{\delta}}{\alpha - \alpha q} \right) \left( \frac{\alpha^n \hat{\gamma} - (\alpha q)^n \hat{\delta}}{\alpha - \alpha q} \right)
= \frac{\alpha^{n+m+1}(q^n - q^m)\hat{\gamma}\hat{\delta}}{(1-q)} \{ (1 - q) (q^n - q^m) \hat{\gamma}\hat{\delta} \}
= \frac{\alpha^{n+m-1}(q^n - q^m)\hat{\gamma}\hat{\delta}}{(1-q)}. \]

Here, \( \hat{\gamma}\hat{\delta} = \hat{\delta}\hat{\gamma} \) is used.

Theorem 2.5. \textit{(Cassini Identity)}
Let \( BF_n(\alpha; q) \) be the \( q \)-Fibonacci bicomplex quaternion. For \( n \geq 1 \), Cassini’s identity for \( BF_n(\alpha; q) \) is as follows:

\[
BF_{n+1}(\alpha; q) BF_{n-1}(\alpha; q) - BF_n(\alpha; q)^2 = \frac{\alpha^{2n-2} q^n (1 - q^{-1}) \hat{\gamma}\hat{\delta}}{(1-q)}. \tag{31}
\]

\textbf{Proof.} (31): By using (12) and (25) we get

\[
BF_{n+1}(\alpha; q) BF_{n-1}(\alpha; q) - BF_n(\alpha; q)^2 = \left( \frac{\alpha^{n+1} \hat{\gamma} - (\alpha q)^{n+1} \hat{\delta}}{\alpha - \alpha q} \right) \left( \frac{\alpha^{n-1} \hat{\gamma} - (\alpha q)^{n-1} \hat{\delta}}{\alpha - \alpha q} \right)
- \left( \frac{\alpha^n \hat{\gamma} - (\alpha q)^n \hat{\delta}}{\alpha - \alpha q} \right)^2
= \frac{\alpha^{2n} q^n (1-q)(1-q^{-1}) \hat{\gamma}\hat{\delta}}{(\alpha - \alpha q)^2}
= \frac{\alpha^{2n-2} q^n (1-q^{-1}) \hat{\gamma}\hat{\delta}}{(1-q)}. \]

Here, \( \hat{\gamma}\hat{\delta} = \hat{\delta}\hat{\gamma} \) is used.
Theorem 2.6. (Catalan’s Identity)

Let $BF\n\n(\alpha; q)$ be the $q$-Fibonacci bicomplex quaternion. For $n \geq 1$, Catalan’s identity for $BF\n\n(\alpha; q)$ is as follows:

$$BF\n\n(\alpha; q) BF\n\n(\alpha; q)^2 = \frac{\alpha^{2n-2} q^n (1 - q^r)(1 - q^{-r}) \hat{\gamma} \hat{\delta}}{(1 - q)^2}. \quad (32)$$

Proof. (32): By using (12) and (25) we get

$$BF\n\n(\alpha; q) BF\n\n(\alpha; q)^2 = \frac{(a^{n+r} - (a q)^{n+r} q^{-r}) (a^{n-r} - (a q)^{n-r} q^r)}{(a - \alpha q)^2}$$

$$= \frac{a^{2n} q^n \hat{\gamma} \hat{\delta} - a^{2n} q^n \hat{\gamma} \hat{\delta} + 2 a^{2n} q^n \hat{\gamma} \hat{\delta}}{(a - \alpha q)^2}$$

$$= \frac{a^{2n} q^n \hat{\gamma} \hat{\delta} [(q^{-r} - 1) + (q^r - 1)]}{(a - \alpha q)^2}$$

$$= \frac{a^{2n} q^n \hat{\gamma} \hat{\delta} (1 - q^{-r})(1 - q^r)}{(1 - q)^2}.$$

Here, $\hat{\gamma} \hat{\delta} = \hat{\delta} \hat{\gamma}$ is used.

3. Conclusion

In this paper, algebraic and analytic properties of the $q$-Fibonacci bicomplex quaternions are investigated.
