WEYL SYMMETRY FOR CURVE COUNTING INVARIANTS VIA SPHERICAL TWISTS

TIM-HENRIK BUelles AND MIGUEL MOREIRA

Abstract. We study the curve counting invariants of Calabi–Yau threefolds via the Weyl reflection along a ruled divisor. We obtain a new rationality result and functional equation for the generating functions of Pandharipande–Thomas invariants. When the divisor arises as resolution of a curve of $A_1$-singularities, our results match the rationality of the associated Calabi–Yau orbifold.

The symmetry on generating functions descends from the action of an infinite dihedral group of derived auto-equivalences, which is generated by the derived dual and a composition of spherical twists. Our techniques involve wall-crossing formulas and generalized DT invariants for surface-like objects.

0. Introduction

0.1. Overview. Let $Y$ be a Calabi–Yau threefold containing a smooth ruled divisor $E$. Physical considerations for BPS state counts [17, 20] suggest that the curve counting invariants of $Y$ are constrained by this...
constellation. More precisely, let $B$ be the class of the rational curve of the ruling and consider the Weyl symmetry on $H_2(Y, \mathbb{Z})$ defined by

$$\beta \mapsto \beta' = \beta + (E \cdot \beta)B.$$ 

When $E \cdot B = -2$, this defines a reflection. The guiding example is that of an elliptic Calabi–Yau threefold

$$Y \to \mathbb{P}^1 \times \mathbb{P}^1$$

which is fibered in elliptic K3 surfaces over $\mathbb{P}^1$, see Section 0.6. For K3 curve classes $\beta$, the Weyl symmetry $\beta \leftrightarrow \beta'$ is exactly realized on the level of Gopakumar–Vafa invariants

$$n_{g, \beta}^{K3} = n_{g, \beta'}^{K3}.$$ 

The equality is reminiscent of the monodromy for quasi-polarized K3 surfaces. For arbitrary $\beta \in H_2(Y, \mathbb{Z})$ such an equality cannot hold, for example when $\beta \in H_2(E, \mathbb{Z})$ in which case the invariants are given by the local surface $K_E$. Instead, we find that the Weyl symmetry is realized as a functional equation. This symmetry is analogous to the rationality and the $q \leftrightarrow q^{-1}$ invariance for generating series of Pandharipande–Thomas stable pairs invariants.

The Pandharipande–Thomas (PT) [27] invariants $P_{n, \beta} \in \mathbb{Z}$ are curve counting invariants enumerating stable pairs in the derived category $D^b(Y)$ with curve class $\beta$ and Euler characteristic $n \in \mathbb{Z}$. Our results concern the 2-variable generating series

$$\text{PT}_\beta(q, Q) = \sum_{n,j \in \mathbb{Z}} P_{n, \beta+jB} (-q)^n Q^j.$$ 

The generating series $\text{PT}_0$ of multiples of $B$ is easily computed as

$$\text{PT}_0(q, Q) = \prod_{j \geq 1} (1-q^jQ)^{-2j}.$$ 

We consider the $\mathbb{Z}_2 \times \mathbb{Z}_2$-action on $\mathbb{Q}[[q^{\pm 1}, Q^{\pm 1}]]$ generated by the two involutions

(1) $D(f(q, Q)) = f(q^{-1}, Q),$

(2) $\rho_\beta(f(q, Q)) = Q^{E \cdot \beta} f(q^{-1}, Q^{-1}).$

\[1\]We use the non-standard sign $-q$ which simplifies some formulas.

\[2\]This calculation is for the geometry that we consider. It is fully determined by the single BPS number $c_1(\mathbb{P}^1) = 2$. 
For our main results we restrict to the following geometry:

(i) $E \to \mathbb{P}^1$ is a Hirzebruch surface with fiber class $B$,
(ii) $E$ is a weak del Pezzo surface, i.e. $-K_E$ is nef,
(iii) $Y$ admits a nef class which vanishes only on the extremal ray spanned by $B$.\(^3\)

We expect that conditions (i) and (ii) are not essential and can be weakened, see Section 0.3.

**Theorem 1.** Let $Y$ be a Calabi-Yau 3-fold containing a smooth divisor $E$ satisfying conditions (i)-(iii). Then

$$\frac{\text{PT}_\beta(q, Q)}{\text{PT}_0(q, Q)} \in \mathbb{Q}(q, Q)$$

is the expansion of a rational function $f_\beta(q, Q)$ which is invariant under $\mathbb{Z}_2 \times \mathbb{Z}_2$, in particular

$$f_\beta(q^{-1}, Q) = f_\beta(q, Q),$$
$$f_\beta(q, Q^{-1}) = Q^{-E \cdot \beta} f_\beta(q, Q).$$

The generating series $[\text{PT}_\beta]_Q$ for fixed $j \geq 0$ are known to be the expansion of rational functions invariant under $q \leftrightarrow q^{-1}$, i.e. invariant under (1) \([4, 27, 31, 34]\). The symmetry is induced by the action of the derived dual $\mathbb{D}$ on $D^b(Y)$. Analogously, we introduce a derived anti-equivalence $\rho$ of order two, which induces the Weyl symmetry on $H_2(Y, \mathbb{Z})$ and acts on generating series as symmetry (2). It is defined as

$$\rho = \text{ST} \circ \mathbb{D},$$

where ST is a derived equivalence of infinite order given as a composition of spherical twists.

As for the derived dual, the image of a stable pair under $\rho$ leads to complicated objects in the derived category and a symmetry on invariants is not easily deduced. Instead, we consider an abelian category

$$\mathcal{A} \subset D^{[-1,0]}(Y),$$

defined as a tilt of $\text{Coh}(Y)$ along a torsion pair. The action of $\rho$ on $\mathcal{A}$ is analogous to the action of $\mathbb{D}$ on $\text{Coh}(Y)$. In particular, we consider

\(^3\)We do not require the line bundle to be basepoint-free and we do not assume a contraction morphism. Such a nef class exists in many cases, e.g. for elliptic Calabi–Yau threefolds.
a notion of dimension which is preserved by $\rho$ (up to shift). Define the extension closure

$$A = \left\langle \mathcal{O}_Y[1], \mathcal{A}_{\leq 1} \right\rangle_{ex}.$$

The action of $\rho$ induces a symmetry for “perverse stable pairs” invariants $^pP_{n,\gamma}$ enumerating torsion-free objects in $A$. These objects are allowed to have non-trivial first Chern class a multiple of $[E]$. For a fixed first Chern class and curve class $\gamma = (l[E], \beta)$ define the generating series

$$^p\text{PT}_\gamma(q, Q) = \sum_{n,j \in \mathbb{Z}} ^pP_{n,\gamma+jB} (-q)^n Q^j \in \mathbb{Q}[[q^{\pm 1}, Q^{\pm 1}]].$$

The rationality and functional equation for $^p\text{PT}_\gamma$ is proved via Joyce’s wall-crossing formula [15]. The formula involves generalized DT invariants for surface-like objects supported on $E$ with non-trivial Euler pairings. To state the result we consider a generalization $\rho_\gamma$ of the action (2) for arbitrary $\gamma = (l[E], \beta)$ defined as

$$\rho_\gamma \left( f(q, Q) \right) = Q^{E \cdot \beta - 2l} f(q^{-1}, Q^{-1}).$$

Theorem 2.

$$^p\text{PT}_\gamma(q, Q) \in \mathbb{Q}(q, Q)$$

is the expansion of a rational function invariant under $\rho_\gamma$.

Theorem 1 is consequence of Theorem 2 in the special case $\gamma = (0, \beta)$ together with the $q \leftrightarrow q^{-1}$ symmetry. The comparison between stable pairs and perverse stable pairs is given by a second wall-crossing. The following formula holds as an equality of rational functions but not necessarily as generating series.

Theorem 3.

$$^p\text{PT}_{(0,\beta)}(q, Q) = \frac{\text{PT}_\beta(q, Q)}{\text{PT}_0(q, Q)}.$$

0.2. Crepant resolution. The results and techniques of this paper are strongly influenced by the recent proof of the crepant resolution conjecture [1] for Donaldson–Thomas (DT) invariants [29]. Consider a type III contraction $Y \to X$ with exceptional divisor $E$ and contracted curves in class $B$. Assume that $Y \to X$ is the distinguished

---

4Our notations and conventions largely agree with op. cit. .
crepant resolution of the (singular) coarse moduli space of a Calabi–Yau orbifold $\mathcal{X}$

$$\mathcal{X} \xrightarrow{\Phi} Y \xleftarrow{X}$$

The McKay correspondence [5] induces a derived equivalence

$$\Phi: D^b(Y) \sim \to D^b(\mathcal{X}),$$

which restricts to an equivalence [9, Thm. 1.4]

$$\mathcal{A} \sim \to \text{Coh}(\mathcal{X}).$$

The notion of perverse stable pairs on $Y$ coincides with the image of stable pairs on $\mathcal{X}$. The results of Theorems 1, 2 and 3 are the rationality and functional equation of $\text{PT}(\mathcal{X})$ and the wall-crossing between $\Phi^{-1}(\text{PT}(\mathcal{X}))$ and Bryan–Steinberg pairs of $Y \to X$ [1, 7, 9].

The nef class is given by the pullback of an ample class on $X$ and the derived anti-equivalence $\rho$ corresponds to the derived dual of $\mathcal{X}$

$$\rho = \Phi^{-1} \circ \mathbb{D}^X \circ \Phi.$$ 

0.3. Spherical twists. The derived equivalence $\text{ST} \in Aut(D^b(Y))$ is defined as a composition

$$\text{ST}_{\mathcal{O}_E(-C+kB)} \circ \text{ST}_{\mathcal{O}_E(-C+kB+B)}$$

of Seidel–Thomas spherical twists [28] associated to sheaves supported on $E$. Here, $C$ is a section of the projection $E \to \mathbb{P}^1$ and $k \in \mathbb{Z}$. The equivalence is independent of $k$ and it is of infinite order. The composition of the $\mathbb{Z}_2$-symmetries (1) and (2) is the symmetry induced by ST. Although the action of $\mathbb{D}$ and $\rho$ on generating series is commutative and factors through $\mathbb{Z}_2 \times \mathbb{Z}_2$, the action on the derived category is not. It generates an infinite dihedral group $\text{Dih}_\infty$. We do not know what the full group generated by the dual and all the twists is.

It is natural to consider a refinement of our results, i.e. constraints induced by each spherical twist (or more general spherical objects) and we hope to come back to this in the future. To generalize to $\mathbb{P}^1$-bundles over curves of higher genus it might be possible to identify $\text{ST}$ with a $EZ$-twist [11] associated to

$$E \hookrightarrow Y$$

$$\downarrow$$

$$Z$$
Under homological mirror symmetry, the spherical twists correspond to generalized Dehn twists along Lagrangian spheres. We do not at present know of a good interpretation of ST.

0.4. Gromov–Witten/ BPS invariants. The functional equation induced by symmetry (2) implies strong constraints for the enumerative invariants in curve class $\beta + jB$ for varying $j \mathbb{Z}$ and fixed genus. In particular, finitely many $j$ determine the full set of these invariants. Let $GW_{g,\beta}$ be the Gromov–Witten invariants of $Y$ and assume that the GW/ PT correspondence holds for $Y$.

**Corollary 4.** For all $(g, \beta) \neq (0, mB), (1, mB)$ the series

$$\sum_{j \in \mathbb{Z}} GW_{g,\beta + jB} Q^j$$

is the expansion of a rational function $f_{\beta}(Q)$ with functional equation

$$f_{\beta}(Q^{-1}) = Q^{-E \cdot \beta} f_{\beta}(Q).$$

The rational function is expected to have the particular form

$$f_{\beta}(Q) = \frac{p_{\beta}(Q)}{(1 - Q)^d}$$

which leads to polynomiality of $GW_{g,\beta + jB}$ and the limit behavior of BPS counts (as $j \to \infty$) discussed in the physics literature [16, Section 5]. For the local Hirzebruch surface $K_E$ we give full proofs in Appendix A.

0.5. Elliptic Calabi–Yau threefolds. Let $E$ be a Hirzebruch surface$^5$ and

$$f: Y \to E$$

an elliptic fibration with a section. Let $H \in H^2(E, \mathbb{Z})$ be the divisor class corresponding to $B$. A nef class vanishing only on the extremal ray spanned by $B$ is given by

$$E + f^*(H - K_E) \in H^2(Y, \mathbb{Z}).$$

For any $\beta \in H_2(E, \mathbb{Z})$ define

$$P_{\beta}(q, t) = \sum_{d \geq 0} \sum_{n \in \mathbb{Z}} P_{n, \beta + dF} (-q)^n t^d,$$

$^5$Assumption (i) is satisfied for Hirzebuch surfaces $\mathbb{P}_r$ with $r = 0, 1, 2.$
where $F \in H_2(Y, \mathbb{Z})$ is the class of an elliptic fiber. Recent considerations in topological string theory [12] predict that

$$Z_\beta(q, t) = \frac{P_\beta(q, t)}{P_0(q, t)}$$

is the expansion of a meromorphic Jacobi form. Theorem 1 implies non-trivial constraints among the Jacobi forms $\{Z_{\beta+jB}\}_{j \in \mathbb{Z}}$.

0.6. **STU.** Theorem 1 and Corollary 4 provide mathematical proofs of a heterotic mirror symmetry on BPS invariants as observed in [19]. The symmetry is discussed for type IIA duals of the STU model, e.g. the elliptic Calabi–Yau threefold

$$Y \to \mathbb{P}^1 \times \mathbb{P}^1$$

such that both projections to $\mathbb{P}^1$ define K3-fibrations with 528 singular fibers with exactly one double point as singularity. This geometry can be constructed as a hypersurface in a toric variety [18].

The symmetry on BPS invariants [19, 6.10.3] is realized by $\rho_\beta$ and we can identify the infinite order symmetry [19, 6.65] with the action of ST. The rationality and functional equation of Corollary 4 verifies [19, 6.67]. We obtain the precise form of the rational function for the local case $K_{\mathbb{P}^1 \times \mathbb{P}^1}$ in Appendix A.

As a special case of the rationality and functional equation, consider $\beta = h F$ a multiple of the elliptic fiber class. Then, the generating function is in fact a *Laurent polynomial* in $Q$ and the functional equation

$$f_\beta(q, Q^{-1}) = Q^{-E \cdot \beta} f_\beta(q, Q)$$

holds at the level of coefficients and recovers the symmetry

$$n_{g,mB+hF}^{K3} = n_{g,(h-m)B+hF}^{K3}$$

of BPS invariants for K3 surfaces. This symmetry is usually seen as a consequence of the monodromy for quasi-polarized K3 surfaces.

A related geometry, also called an STU model in the physics literature, may be useful towards a crepant resolution conjecture in the *non hard Lefschetz* case. We consider

$$Y \to \mathbb{F}_1$$

an elliptic Calabi–Yau threefold over the Hirzebruch surface $\mathbb{F}_1$. The fibration has a section $E$ and we obtain $Y \dashrightarrow Y'$ as the Atiyah flop along
the rational curve in $E$ of self-intersection $−1$. After this transformation we have a type II contraction $Y' \to X'$ with exceptional divisor $\mathbb{P}^2$, which is the crepant resolution of an isolated canonical singularity. After the flop formula for DT invariants [8, 32], the symmetry $\rho_\beta$ must induce a symmetry on $Y'$.

0.7. **Outline.** We briefly sketch the strategy of the paper. In Section 1 we recall some facts on Hall algebras and wall-crossing, and we set some notation for the rest of the paper.

The following diagram represents the different invariants we use in the paper and their relations:

$$
\begin{align*}
\text{PT} & \leftrightarrow \text{BS} \quad (\zeta, 0) \leftrightarrow \rho(\text{PT}) \\
\text{BS} & \mid \quad \rho(\text{PT})
\end{align*}
$$

The squiggly arrows represent wall-crossing formulas. In Section 2 we introduce invariants which resemble Bryan–Steinberg invariants [7] and we prove a wall-crossing formula between those and usual PT invariants. The wall-crossing formula shows a relation of the form

$$
\text{BS}_\beta = \frac{\text{PT}_\beta}{\text{PT}_0}
$$

and thus gives a natural interpretation to the quotient on the right hand side. In Section 3 we introduce the anti-equivalence $\rho$ and show several important properties that will be needed in the later parts. The rationality and symmetry for $\rho$PT invariants are proven in Section 4. Essentially, the result is obtained by comparing $\rho$PT invariants with $\rho(\text{PT})$ invariants in two ways: first using the anti-equivalence $\rho$, and then using wall-crossing. In Section 5 we describe a wall-crossing between the BS invariants and the perverse $\rho$PT invariants (which in the crepant case $Y \to X$ are the orbifold invariants). An important aspect is that while PT and BS invariants are defined using the integration map on the Hall algebra obtained from the heart $\text{Coh}(Y) \subseteq D^b(Y)$, the perverse $\rho$PT invariants are defined using the heart $\mathcal{A} \subseteq D^b(Y)$. The $\zeta$-wall-crossing of Section 5 takes place in $\mathcal{A}$. In Section 5.2 we identify BS-pairs as the pairs in the end of the $\zeta$-wall-crossing.

0.8. **Related work.** The following question was posed by Toda [33]
Question 1. How are stable pair invariants on a Calabi–Yau 3–fold constrained, due to the presence of non-trivial autoequivalences of the derived category?

The most famous instance is the rationality and functional equation induced by the derived dual. Similarly, the elliptic transformation law for $Z_β(q, t)$ is deduced from a derived involution [25]. Significant progress for abelian threefolds was made using Bridgeland stability conditions [24]. The Seidel–Thomas spherical twist for an embedded $\mathbb{P}^2$ was considered in [33] and certain polynomial relations for stable pairs invariants were obtained. Our results provide an answer to Question 1 for the involution $\rho$. The flop construction $Y \mapsto Y'$ of the previous section must connect our results with the ones obtained in [33, Theorem 1.2].

0.9. Conventions. We work over the complex numbers. The canonical bundle of a variety $E$ is denoted $K_E$. If $ι: E \hookrightarrow Y$ and $F \in D^b(E)$ we also write $F$ to denote the pushforward $ι_∗(F)$. Intersection products are denoted by a dot, e.g. $E \cdot β$. Stable pairs are considered in cohomological degree $-1$ and 0. This convention follows [1] and differs from [27].

0.10. Acknowledgements. We are grateful to Y. Bae, T. Beckmann, G. Oberdieck, R. Pandharipande, D. Nesterov, E. Scheidegger, R. Thomas for discussions on stable pairs in the derived category and curve counting on Calabi–Yau threefolds. Conversations with E. Scheidegger on the STU model were very helpful. We thank G. Oberdieck for pointing out the connection to the DT crepant resolution conjecture, and R. Thomas for discussions on spherical twists and wall-crossing. The first author thanks the IHES for hospitality during the final stage of this work. The authors were supported by ERC-2017-AdG-786580-MACI. The project received funding from the European Research Council (ERC) under the European Union Horizon 2020 research and innovation programme (grant agreement 786580).

1. Preliminaries

We define a heart of a bounded $t$-structure $\mathcal{A} \subset D^b(Y)$ which plays the central role for this paper. It is defined as the tilt along a torsion
pair of \( \text{Coh}(Y) \). Recall the surface \( \iota: E \to Y \) and the projection \( p: E \to \mathbb{P}^1 \). The torsion part is defined as

\[
T = \{ T \in \text{Coh}(Y) : R^1 p_* \iota^* T = 0 \}.
\]

**Lemma 5.** The category \( T \subseteq \text{Coh}(Y) \) is closed under extensions and quotients in \( \text{Coh}(Y) \).

**Proof.** Use the long exact sequence of higher pushforward sheaves and the fact that \( R^2 p_* = 0 \) since the fibers of \( p \) are 1 dimensional. \( \square \)

By the lemma we can find a complement \( \mathcal{F} \) such that

\[
\text{Coh}(Y) = \langle T, \mathcal{F} \rangle.
\]

Now we define the tilting

\[
\mathcal{A} = \langle \mathcal{F}[1], T \rangle.
\]

**Remark 6.** In the case that \( \pi: Y \to X \) is a crepant resolution the category \( \mathcal{A} \) coincides with the category of perverse sheaves \( [3, 35] \)

\[
\mathcal{A} = \text{Per}(Y/X).
\]

Let \( j: C \to X \) be the image of \( E \). Then, for any \( T \in \text{Coh}(Y) \) the higher pushforward \( R^1 \pi_* T \) is supported on \( C \), so \( R^1 \pi_* T = 0 \) if and only if

\[
0 = j^* R^1 \pi_* T = R^1 p_* \iota^* T.
\]

The equality used holds by the proper base change theorem.

### 1.1. Numerical Grothendieck groups.

The numerical Grothendieck group \( N(Y) \) is the Grothendieck group of \( D^b(Y) \) modulo the Euler paring. We will tacitly use the injection into the even cohomolgy via the Chern character. The class \([F] \in N(Y)\) is equivalently characterised by

\[
\left( \text{ch}_0(F), \text{ch}_1(F), \text{ch}_2(F), \chi(F) \right).
\]

The numerical Grothendieck group admits a dimension filtration \( N_{\leq i}(Y) \). For our purposes, we define

\[
N_0 = N_0(Y) \oplus \mathbb{Z}B \text{ and } N_{\leq 1} = N_{\leq 1}(Y) \oplus \mathbb{Z}E,
\]

where \( B \) and \( E \) are the classes of a fiber resp. the Hirzebruch surface as introduced in Section 0.1. The group \( N_0(Y) \cong \mathbb{Z} \) is spanned by the class \([pt]\) of a point. We also define \( N_1 = N_{\leq 1}/N_0 \) and we choose a splitting

\[
N_{\leq 1} = N_0 \oplus N_1.
\]
In Section 4 we define a natural notion of dimension on $\mathcal{A}$. The definitions given above then agree with the induced dimension filtration on $N(\mathcal{A})$.

An element $\alpha \in N_{\leq 1}$ can be written as

$$\alpha = (\gamma, c) = (lE, \beta + jB, n)$$

where $\gamma = (lE, \beta) \in N_1$ and $c = (jB, n) \in N_0$ (so $\beta \in N_1(Y)/\mathbb{Z}B$).

We will consider various generating series of DT invariants using the Novikov parameter $z$ of $Q[[N_{\leq 1}]]$ and we use the notation $Q = z^B$, $-q = z^{[pt]}$, $t = z^{[O_Y]}$.

In particular, for $\alpha$ as above $z^\alpha = z^\gamma Q^j (-q)^n$.

1.2. Hall algebra. We briefly recall the notion of Hall algebras following [34]. Let $C \subset D^b(Y)$ be the heart of a bounded $t$-structure. In our applications we’ll use two different hearts:

$$C = \langle \text{Coh}_{\geq 2}[1], \text{Coh}_{\leq 1} \rangle$$

and

$$C = \langle A_{\geq 2}[1], A_{\leq 1} \rangle.$$

The first is used to define PT and BS invariants and the latter will be used for $p$PT invariants. Both of these hearts are open by [1, Lemma 4.1] so they satisfy the technical hypothesis in [1, Appendix B], [2, Section 3].

The objects of $C$ form an algebraic stack which we still denote by $C$ and we assume that it is an open substack of the stack $\mathcal{M}$ of objects

$$\{ F \in D^b(Y) : \text{Ext}^{<0}(F, F) = 0 \}.$$

The Hall algebra $H(C)$ is the $\mathbb{Q}$-vector space generated by maps of algebraic stacks $[Z \to C]$, where $Z$ is an algebraic stack of finite type with affine stabilizers, modulo some motivic relations described in [34].

The Hall algebra $H(C)$ admits a product induced by extensions and, via cartesian products, is a module over $K(\text{St}/C)$, the Grothendieck ring of stacks with affine stabilizers. Equivalently,

$$K(\text{St}/C) = K(\text{Var}/\mathbb{C})[\mathbb{L}^{-1}, (\mathbb{L}^n - 1)^{-1}]$$

where $\mathbb{L} = [\mathbb{A}^1 \to \mathbb{C}]$. The decomposition

$$C = \coprod_{\alpha \in N(Y)} C_\alpha$$

into numerical classes induces a decomposition of the Hall algebra

$$H(C) = \bigoplus_{\alpha} H_\alpha(C).$$
The feature of most interest in the Hall algebra is the existence of the integration map. To state this we introduce two more definitions. We let $H_{\text{reg}}(C) \subseteq H(C)$ be the $K(\text{Var}/C)[L^{-1}]$-submodule spanned by $[Z \to C]$ so that $Z$ is a variety and

$$H^{\text{sc}}(C) = H^{\text{reg}}(C)/(L - 1)H^{\text{reg}}(C).$$

This has the structure of a Poisson algebra. The integration map maps $H^{\text{sc}}(C)$ to the Poisson torus $Q[N(Y)] = \bigoplus_{\alpha \in N(Y)} Q z^\alpha$.

The Poisson torus has the structure of a Poisson algebra as well; its bracket is defined by

$$\{z^\alpha, z^{\alpha'}\} = (-1)^{\chi(\alpha, \alpha')} \chi(\alpha, \alpha') z^{\alpha + \alpha'}.$$

**Theorem 7** ([34, Theorem 2.8]). There is a Poisson algebra homomorphism $I : H^{\text{sc}}(C) \to Q[N(Y)]$ such that if $Z$ is a variety and $f : Z \to C_{\alpha} \hookrightarrow C$ then

$$I([Z \overset{f}{\to} C]) = \left( \int_Z f^* \nu_C \right) z^\alpha$$

where $\nu_C$ is the Behrend function on the stack $C$.

The Hall algebra can be enlarged to the graded pre-algebra $H^{\text{gr}}(C)$ by defining its generators to be $[Z \to X]$ with $Z$ being an algebraic stack with affine stabilizers such that $Z_\alpha$ is of finite type for every $\alpha \in N(Y)$ (instead of asking that $Z$ is already of finite type). One can define analogous versions $H^{\text{gr,reg}}(C), H^{\text{gr,sc}}(C)$. The integration map extends to

$$I : H^{\text{gr,sc}}(C) \to \mathbb{Q}[N(Y)].$$

### 1.3. Pairs.

We consider various notions of stable objects in $D^b(Y)$ and their associated generating series. All of them are defined via torsion pairs $(T, F)$ of certain subcategories. The notion of BS and PT pairs, defined in Section 2, are instances of the following:

**Definition 8** ([1, Definition 3.9]). Let $\mathcal{T}$ and $\mathcal{F}$ be full subcategories of $\text{Coh}_{\leq 1}(Y)$. A $(\mathcal{T}, \mathcal{F})$-pair is an object $P \in \langle \mathcal{O}_Y[1], \text{Coh}_{\leq 1} \rangle$ such that

(i) $\text{rk}(P) = -1$,

(ii) $\text{Hom}(T, P) = 0$ for all $T \in \mathcal{T}$,

(iii) $\text{Hom}(P, F) = 0$ for all $F \in \mathcal{F}$.
The main body of this paper, i.e. Section 4, 5, deals with pairs in a different subcategory. As a rule of thumb, every Coh is replaced by $A$. In particular, we consider the extension closure

$$A = \left\langle \mathcal{O}_Y[1], \mathcal{A}_{\leq 1} \right\rangle_{\text{ex}},$$

and pairs $P \in A$, defined in the analogous way as above.

The categories $(\mathcal{T}, \mathcal{F})$ arise in two ways:

1. As torsion pairs associated to a stability function,
2. or in the passage of one torsion pair to another, i.e. when crossing a wall.

In the former case, the stability function is $\nu$ in Section 4 and $\zeta$ in Section 5. In the latter case, given two torsion pairs $(\mathcal{T}_\pm, \mathcal{F}_\pm)$ on different sides of a wall (and sufficiently close to the wall), we consider $(\mathcal{T}_+, \mathcal{F}_-)$. Joyce’s wall-crossing formula yields the comparison between pairs on either side of the wall via semi-stable objects on $W = \mathcal{T}_- \cap \mathcal{F}_+$.

The notion of $(\mathcal{T}, \mathcal{F})$-pairs with fixed numerical class $\alpha \in N(Y)$ defines a stack $\text{Pairs}(\mathcal{T}, \mathcal{F})_\alpha$ which is of finite type in all of our applications and defines an element in the Hall algebra. This follows from the theory developed with great care in [1, Section 4, Corollary 6.2, Lemma 6.5, Lemma 6.6, Theorem 6.8]. In particular, the argument in the proof of [1, Proposition 4.6] can be used to show that $\text{Pairs}(\mathcal{T}, \mathcal{F})_\alpha$ is open in $\mathcal{M}_\alpha$ (and in particular of finite type) as long as the torsion pair $(\mathcal{T}, \mathcal{F})$ is open. The openness of the torsion pairs that we’ll use can be proven as in [1] using Proposition 26.

1.4. Joyce’s wall-crossing formula. Let $(\mathcal{T}_\pm, \mathcal{F}_\pm)$ be two torsion pairs and $W = \mathcal{T}_- \cap \mathcal{F}_+$ be as above. When all the terms are defined, we have an identity in the Hall algebra

$$[W] * [\text{Pairs}(\mathcal{T}_-, \mathcal{F}_-)] = [\text{Pairs}(\mathcal{T}_+, \mathcal{F}_+)] * [W].$$

The “no-poles” theorem by Joyce [15, Theorem 8.7] and Behrend-Ronagh [2, Theorems 4, 5] tell us that in adequate conditions

$$(L - 1) \log(W) \in H^{gr,sc}(\mathcal{C})$$

and, therefore,

$$w = I((L - 1) \log(W)) \in \mathbb{Q}\{N(Y)\}$$

is well-defined. The conditions that guarantee this are the following:

1. $W_\alpha$ is an algebraic stack of finite-type,
(2) $W$ is closed under extensions and direct summands
(3) for every $\alpha \in N(Y)$ there are finitely many ways to decompose $\alpha = \alpha_1 + \ldots + \alpha_n$ such that $W_{\alpha_i} \neq \emptyset$.

When this is the case, we have Joyce’s wall-crossing formula which we’ll routinely use:
$$I\left( (\mathbb{L} - 1)\text{Pairs}(\mathcal{T}_+, \mathcal{F}_+) \right) = \exp \left( \{ w, - \} \right) \circ I\left( (\mathbb{L} - 1)\text{Pairs}(\mathcal{T}_-, \mathcal{F}_-) \right).$$

1.5. **Rational functions.** The wall-crossing formula in Section 4 involves generating series $p_{\mathcal{PT}_{\leq \gamma}}$ for fixed $\gamma \in N_1$, which is defined as a formal series in the Poisson algebra $\mathbb{Q}\{ N_{\text{eff}} \}_{\leq \gamma}$, a completion of $\mathbb{Q}[N_{\text{eff}}]_{\leq \gamma}$. It is the sum of all $p_{\mathcal{PT}_{\gamma'}} \in \mathbb{Q}\{ N_0 \}$ for $0 < \gamma' \leq \gamma$. Theorem 2 states that $p_{\mathcal{PT}_{\gamma}}$ is the expansion of a rational function $f_{\gamma} \in \mathbb{Q}(q, Q)$. The expansion is with respect to a linear function $L_\mu : N_0 \to \mathbb{R}$ with $\mu \gg 1$, which for $(jB, n) \in N_0$ is defined as
$$L_\mu(jB, n) = d(jB, n) + j \frac{j}{\mu(A \cdot C)}.$$

Here, $d(jB, n) = 2n + j$ is the degree as defined in Section 4.2. Theorem 3 states that $BS_{\beta}$ is the expansion of the same rational function $f_{(0, \beta)}$ but with respect to $L_\mu$ with $0 < \mu \ll 1$.

2. **Bryan–Steinberg type invariants**

In this section we introduce numerical invariants $BS_{n, \beta}$ that naturally realize the quotient
$$BS_{\beta}(q, Q) = \frac{\mathcal{PT}_{\beta}(q, Q)}{\mathcal{PT}_0(q, Q)}.$$

The equation will be a wall-crossing formula between BS and PT invariants. When $Y$ admits a contraction map $Y \to X$ as in Section 0.2 these invariants are precisely Bryan–Steinberg invariants \cite{7} of the crepant resolution. Roughly speaking they count a modification of pairs $\mathcal{O}_Y \to F$ where instead of requiring the cokernel to have dimension zero we allow it to have support in some of the fibers $B$.

We define BS-pairs using the torsion pair $\langle \mathcal{T}_\text{BS}, \mathcal{F}_\text{BS} \rangle = \text{Coh}_{\leq 1}(Y)$ defined below. Let $j : Y \setminus E \hookrightarrow Y$ be the complement of $i : E \hookrightarrow Y$; then we define
$$\mathcal{T}_\text{BS} = \{ \mathcal{T} \in \text{Coh}_{\leq 1}(Y) : j^*T \in \text{Coh}_0(Y \setminus E) \text{ and } R\pi_*i^*T \in \text{Coh}_0(Y) \}.$$
One easily checks that $\mathcal{T}_{BS}$ is closed under quotients and extensions (see [7, Lemma 13] for the case where a contraction exists), so

$$\mathcal{F}_{BS} = \{ F \in \text{Coh}_{\leq 1}(Y) : \text{Hom}(\mathcal{T}_{BS}, F) = 0 \}$$

defines the torsion free part of a torsion pair $\langle \mathcal{T}_{BS}, \mathcal{F}_{BS} \rangle = \text{Coh}_{\leq 1}(Y)$.

The numerical invariants are then defined via the integration map $I$. We denote by $\text{Pairs}^{BS}$ the stack of $\langle \mathcal{T}_{BS}, \mathcal{F}_{BS} \rangle$-pairs as defined in [1, Definition 3.9]. Then we define $BS_{n, \beta} \in \mathbb{Q}$ by the equation

$$I((L - 1) \text{Pairs}^{BS}) = \sum_{n, \beta} BS_{n, \beta} z^\beta q^n t^{-1}.$$

We also denote

$$BS_\beta(q, Q) = \sum_{n, j \in \mathbb{Z}} BS_{n, \beta + jB} (-q)^n Q^j \in \mathbb{Q}[\![q^{\pm 1}, Q^{\pm 1}]\!].$$

2.1. Wall-crossing between BS and PT. The wall-crossing between BS and PT invariants can be directly deduced from [1, Theorem 6.10]. Recall that the usual stable pairs are defined as stable pairs with respect to the torsion pair

$$\langle \mathcal{T}_{PT}, \mathcal{F}_{PT} \rangle = (\text{Coh}_0(Y), \text{Coh}_1(Y)).$$

This torsion pair satisfies the technical conditions discussed in section 1.4. It follows from [1, Lemma 6.6] that

$$\langle W, \text{Pairs}^{BS} \rangle = \langle \text{Pairs}^{PT}, W \rangle$$

where $W = \mathcal{T}_{BS} \cap F_{PT} = \mathcal{T}_{BS} \cap \text{Coh}_1(Y)$; and from [1, Theorem 6.10] we get the numerical wall-crossing formula: for every $\beta \in H_2(Y, \mathbb{Z})$,

$$PT_\beta(q, Q) = f(q, Q) BS_\beta(q, Q)$$

where $f(q, Q)$ is defined by

$$f(q, Q) = I((L - 1) \log(\text{Vol}(W))) \in \mathbb{Q}[\![q, Q]\!].$$

Note that $f \in \mathbb{Q}[\![q, Q]\!]$ because the support of sheaves in $W \subseteq \mathcal{T}_{BS}$ is a finite union of finitely many points and fibers $B$. Note also that $f$ doesn’t depend on $\beta$, so we get the relation

$$\frac{PT_\beta(q, Q)}{BS_\beta(q, Q)} = \frac{PT_0(q, Q)}{BS_0(q, Q)}.$$

Lemma 9. The only BS-pair with Chern class of the form $(-1, 0, jB, n)$ is the trivial pair $(\mathcal{O}_Y \to 0)$. In particular

$$BS_0(q, Q) = 1.$$
Proof. The hypothesis of [1, Lemma 3.11] applies to $\mathcal{T}_{BS}$, showing that BS-pairs have the form $(\mathcal{O}_Y \rightarrow G)$ where $G \in \mathcal{F}_{BS}$ and $\text{coker}(s) \in \mathcal{T}_{BS}$. Since $\text{Coh}_0(Y) \subseteq \mathcal{T}_{BS}$, $\mathcal{F}_{BS} \subseteq \text{Coh}_1(Y)$ so $G$ is a pure 1-dimensional sheaf. Since $\text{ch}_1(G) = jB$, the reduced support of $C$ is a finite union of fibers $B$.

Letting $D$ be the subscheme of $Y$ determined by $\ker(s) = I_D$, we get an inclusion $\mathcal{O}_D \hookrightarrow G$. The closed subspace underlying $D$ is a union of fibers $B$, so one easily sees that $\mathcal{O}_D \in \mathcal{T}_{BS}$. As $G \in \mathcal{F}_{BS}$ it follows that $G = 0$. \hfill \Box

As a consequence we get the key result of this section:

**Proposition 10.** We have

$$\text{BS}_\beta(q, Q) = \frac{\text{PT}_\beta(q, Q)}{\text{PT}_0(q, Q)}.$$ 

We recall that $\text{PT}_0(q, Q)$ can be computed (for example by localization on $K_E$, see appendix A) and is equal to

$$\text{PT}_0(q, Q) = \prod_{j \geq 1} (1 - q^jQ)^{-2j}.$$ 

3. **The anti-equivalence $\rho$**

3.1. **Spherical twist.** Consider a spherical object $G \in D^b(Y)$ and the associated spherical twist [13, Chapter 8], [28]:

$$\text{ST}_G \in \text{Aut } D^b(Y)$$

defined by the exact triangle

$$\bigoplus \text{Ext}^i(G, F) \otimes G[-i] \rightarrow F \rightarrow \text{ST}_G(F).$$

The spherical objects we use are pushforwards of line bundles on $E$. Let $C \subset E$ be the section of $E \to \mathbb{P}^1$ with $C^2 \leq 0$. For all $k \in \mathbb{Z}$ the sheaf $\mathcal{O}_E(-C + kB) \in D^b(Y)$ is spherical.

**Lemma 11.** For all $k \in \mathbb{Z}$

$$\text{ST}_{\mathcal{O}_E(-C + kB)}(\mathcal{O}_E(-C + kB + B)) = \mathcal{O}_E(-C + kB - B)[1].$$

**Proof.** We identify the action of the spherical twist with the pullback of the Euler sequence under $E \to \mathbb{P}^1$. Let $G = \mathcal{O}_E(-C + kB)$, then

$$\text{Ext}^*(G, \mathcal{O}_E(-C + kB + B)) \cong \text{Ext}^*(\mathcal{O}_E, \mathcal{O}_E(B)) \cong H^0(\mathcal{O}_{\mathbb{P}^1}(1)).$$
The spherical twist is defined by the exact triangle
\[
G \otimes H^0(\mathcal{O}_{\mathbb{P}^1}(1)) \to G \otimes \mathcal{O}_E(B) \to ST_G(\mathcal{O}_E(-C + kB + B))
\]
which is a shift of the pullback of the Euler sequence on $\mathbb{P}^1$ twisted by $G$.

**Lemma 12.** Let $k \in \mathbb{Z}$, then
\[
ST_{\mathcal{O}_E(-C+kB)} \circ ST_{\mathcal{O}_E(-C+kB+B)} \in \text{Aut}(D^b(Y))
\]
doesn’t depend on $k$.

**Proof.** We show that the auto-equivalence is the same for $k$ and for $k - 1$. By Lemma 11 we have
\[
ST_{\mathcal{O}_E(-C+kB)}(\mathcal{O}_E(-C + kB + B)) = \mathcal{O}_E(-C + kB - B)[1].
\]
Then it follows from the general identity [13, Lemma 8.21]
\[
\Psi \circ ST_F = ST_{\Psi(F)} \circ \Psi
\]
that
\[
ST_{\mathcal{O}_E(-C+kB)} \circ ST_{\mathcal{O}_E(-C+kB+B)} = ST_{\mathcal{O}_E(-C+kB-B)}[1] \circ ST_{\mathcal{O}_E(-C+kB)} = ST_{\mathcal{O}_E(-C+kB-B)} \circ ST_{\mathcal{O}_E(-C+kB)}.
\]

**Definition 13.** Let $\mathbb{D} = R\text{Hom}(-, \mathcal{O}_Y)[2]$ be the shifted derived dual. For any $k \in \mathbb{Z}$ define (independent of $k$ by the previous result)
\[
ST = ST_{\mathcal{O}_E(-C+kB)} \circ ST_{\mathcal{O}_E(-C+kB+B)}
\]
\[
\rho = ST \circ \mathbb{D}.
\]

**3.2. Properties of $\rho$.**

**Proposition 14.** The anti-equivalence $\rho$ defines an involution on $D^b(Y)$ and respects the structure sheaf, i.e.
\[
\rho \circ \rho = \text{id}, \quad \rho(\mathcal{O}_Y) = \mathcal{O}_Y[2].
\]

We show that $\rho \circ \rho$ is isomorphic to the identity by computing the images of skyscraper sheaves $k(x)$. Then, we use the general fact [13, 5.23] that any auto-equivalence $\Psi$ with $\Psi(k(x)) \cong k(f(x))$ is of the form
\[
\Psi = (M \otimes -) \circ f_*,
\]
where $f : Y \to Y$ is an isomorphism and $M$ is a line bundle.

**Lemma 15.** (i) Let $x \in Y \setminus E$, then $\rho(k(x)) \cong k(x)[-1]$. 

(ii) For a fiber $B$ of the projection $E \to \mathbb{P}^1$ we have
\[ \rho(\mathcal{O}_B(-1)) \cong \mathcal{O}_B(-1)[-1], \quad \rho(\mathcal{O}_B(-2)) \cong \mathcal{O}_B(-2)[1]. \]

(iii) Let $x \in E$ and $B$ the unique fiber of $E \to \mathbb{P}^1$ containing $x$. The image $\rho(k(x))$ sits in an exact triangle
\[ \mathcal{O}_B(-2) \to \rho(k(x)) \to \mathcal{O}_B(-1)[-1]. \]

(iv) For all points $x \in Y$ we have $(\rho \circ \rho)(k(x)) \cong k(x)$.

**Proof.** To prove the first claim (i) note that $\mathcal{D}(k(x)) = k(x)[-1]$. The spherical twists leave $k(x)$ invariant because all Ext-groups vanish, thus $\rho(k(x)) = k(x)[-1]$.

To prove the second claim (ii) we use $\mathcal{D}(\mathcal{O}_B(-1)) \cong \mathcal{O}_B(-1)$. The action of ST is computed successively, using the exact triangle
\[ \mathcal{O}_E(-C) \to \mathcal{O}_E(-C + B) \to \mathcal{O}_B(-1). \]
We apply $\text{ST}_{\mathcal{O}_E(-C)}$ followed by $\text{ST}_{\mathcal{O}_E(-C - B)}$ and use Lemmas 11 and 12 to obtain
\[ \mathcal{O}_E(-C - 2B)[-1] \to \mathcal{O}_E(-C - B)[-1] \to \text{ST}((\mathcal{O}_B(-1))). \]
from which we can deduce $\text{ST}((\mathcal{O}_B(-1)) \cong \mathcal{O}_B(-1)[-1]$.

For the second part we use that $\mathcal{D}(\mathcal{O}_B(-2)) \cong \mathcal{O}_B$ and for all $k \in \mathbb{Z}$
\[ \text{Ext}^*((\mathcal{O}_E(-C + kB), \mathcal{O}_B) \cong H^0(\mathcal{O}_B(1)). \]
Application of $\text{ST}_{\mathcal{O}_E(-C + B)}$ yields
\[ \mathcal{O}_E(-C + B) \otimes H^0(\mathcal{O}_B(1)) \to \mathcal{O}_B \to \text{ST}_{\mathcal{O}_E(-C + B)}. \]
Then, we apply $\text{ST}_{\mathcal{O}_E(-C)}$ and use Lemma 11 to obtain
\[ \mathcal{O}_B \downarrow \mathcal{O}_E(-C - B) \otimes H^0(\mathcal{O}_B(1))[1] \longrightarrow \text{ST}_{\mathcal{O}_E(-C)}(\mathcal{O}_B) \longrightarrow \text{ST}(\mathcal{O}_B) \downarrow \mathcal{O}_E(-C) \otimes H^0(\mathcal{O}_B(1))[1] \]
The cone of the dotted arrow is isomorphic to $\mathcal{O}_B(-1) \otimes H^0(\mathcal{O}_B(1))[1]$. We find an exact triangle (by octahedron axiom)
\[ \text{ST}(\mathcal{O}_B) \to \mathcal{O}_B(-1) \otimes H^0(\mathcal{O}_B(1))[1] \to \mathcal{O}_B[1], \]
which we identify with a shift of the Euler sequence on $B$.

Claim (iii) follows from the exact triangle
\[ \mathcal{O}_B(-1) \to k(x) \to \mathcal{O}_B(-2)[1], \]
by application of (ii). Claim (iv) is a consequence of (i)-(iii). □

Proof of Proposition 14. The spherical objects $O_E(-C+kB)$ are acyclic for all $k \in \mathbb{Z}$, thus

$$\text{Ext}^*(O_E(-C+kB), O_Y) \cong H^{3-*}(O_E(-C+kB)) \cong 0.$$ 

The associated spherical twists, therefore, act trivially on $O_Y$. The shift comes from the dual $D = \text{RHom}(-, O_Y)[2]$. 

To prove $\rho \circ \rho \cong \text{id}$ we use Lemmas 15 (iv). It follows that $\rho \circ \rho$ is isomorphic to the twist $M \otimes -$ by some line bundle, which has to be the trivial line bundle since $\rho(O_Y) \cong O_Y[2]$. □

3.3. Crepant case. We explain now our main motivation for the operator $\rho$ by considering the case of a type III contraction $Y \to X$, as described in Section 0.2.

In this setting, $X$ is the coarse moduli space of a Calabi–Yau orbifold $\mathcal{X}$ that has $B\mathbb{Z}_2$-singularities along a copy of $\mathbb{P}^1$. The derived categories of $Y$ and $\mathcal{X}$ are isomorphic via the derived McKay correspondence $[5]$

$$\Phi: D^b(Y) \xrightarrow{\sim} D^b(\mathcal{X}).$$

Under the McKay correspondence, the anti-equivalence $\rho$ coincides with the derived dual $D^X$ on the orbifold, i.e.

**Proposition 16.** In the setting above, we have

$$\rho = \Phi^{-1} \circ D^X \circ \Phi.$$ 

**Proof.** We let $\Psi = \Phi^{-1} \circ D^X \circ \Phi \circ \rho$. Since $\Phi$ is a derived equivalence, whereas $\rho$ and $D^X$ are derived anti-equivalences, the composition $\Psi$ is a derived equivalence. We prove that $\Psi$ is isomorphic to the identity by analysing $\Psi(k(x))$ and using again [13, 5.23].

If $x \in Y \setminus E$ then Lemma 15 shows that

$$\Psi(k(x)) = (\Phi^{-1} \circ D^X \circ \Phi)(k(x)[-1]) = (\Phi^{-1} \circ D^X)(k(\pi(x))[1]) = k(x).$$

For $x \in E$, one has the exact triangle of Lemma 15 and applying $\Phi^{-1} \circ D^X \circ \Phi$ to it produces the exact triangle

$$O_B(-1) \to \Psi(k(x)) \to O_B(-2)[1].$$

We used that $\Phi^{-1} \circ D^X \circ \Phi$ is an anti-equivalence and we determine the images of $O_B(-2), O_B(-1)[-1]$ using [6, 4.3], [1, Appendix A]

$$\Phi(O_B(-2)[1]) = O_p^+, \quad \Phi(O_B(-1)) = O_p^-,$$

$$D^X(O_p^+) = O_p^+,$$

$$D^X(O_p^-) = O_p^-.$$
Extensions determined by (4) are classified by

\[ \text{Hom}(O_B(-2), O_B(-1)) \cong \mathbb{C}^2 \]

and we get that \( \Psi(k(x)) \cong k(f(x)) \) for some \( f(x) \in B = \pi^{-1}(x) \).

By [13, 5.23] it follows that \( f: X \to X \) is an isomorphism and \( \Psi = (M \otimes -) \circ f_* \) for some line bundle \( M \). Since \( f|_{Y \setminus E} = \text{id}_{Y \setminus E} \), we conclude that \( f = \text{id} \). By Proposition 14 and the fact that \( \Phi \) preserves structure sheaves, one easily sees that \( \Psi(O_Y) = O_Y \) and thus \( M \) is the trivial line bundle, so \( \Psi \cong \text{id} \).

\[ \square \]

The previous proposition explains how \( \rho \) in our proof replaces \( D^X \) in the proof of the rationality and functional equation for the orbifold PT invariants [1].

3.4. Action on cohomology. To compute the action of \( \rho \) on cohomology we consider the triple \((\text{ch}_1, \text{ch}_2, \chi)\).

**Proposition 17.** The anti-equivalence \( \rho \) acts on \((\text{ch}_1, \text{ch}_2, \chi)\) as

\[
(lE, \beta, n) \mapsto (lE, \beta + (E \cdot \beta - 2l)B, -n).
\]

**Proof.** Recall that for a spherical object \( G \in D^b(Y) \) the action of \( \text{ST}_G \) on \( H^*(Y, \mathbb{Q}) \) is given by [13, Lemma 8.12]

\[
v \mapsto v - \langle v(G), v \rangle v(G),
\]

where \( v(-) = \text{ch}(-) \cup \sqrt{\text{td}}_Y \) is the Mukai vector and \( \langle , \rangle \) is the Mukai pairing. The pairing \( \langle , \rangle \) is related to the Euler pairing and the Hirzebruch–Riemann–Roch formula via

\[
\langle v(G), v(F) \rangle = \chi(G, F) = \sum (-1)^i \dim \text{Ext}^i(G, F)
\]

\[
= \int_Y \text{ch}(G^\vee) \cup \text{ch}(F) \cup \text{td}(Y)
\]

\[
= \int_Y v(G)^\vee \cup v(F).
\]

Here the dual Mukai vector is \((r, c, b, n)^\vee = (r, -c, b, -n)\) and

\[ v(D(F)) = v(F)^\vee. \]

The computation of \( \text{ch}(\rho(F)) \) and \( \chi(\rho(F)) \) is then straightforward. \[ \square \]
4. Perverse PT invariants

We have a modified dimension function on $\mathcal{A}$ given by

$$\dim(F) = \max\{\dim(\text{supp}(F_{|Y\setminus E})), \dim(p(\text{supp}(F_{|E})))\}.$$ 

We write $\mathcal{A}_{\leq k}$ for elements of $\mathcal{A}$ with modified dimension at most $k$ and $\mathcal{A}_k$ for elements with pure modified dimension $k$, i.e.

$$\text{Hom}(\mathcal{A}_{\leq k-1}, \mathcal{A}_k) = 0.$$ 

Analogously, $\mathcal{F}_k[1] = \mathcal{F}[1] \cap \mathcal{A}_k$, $\mathcal{T}_k = \mathcal{T} \cap \mathcal{A}_k$ etc.

**Definition 18.** A perverse stable pair of $Y$ is a $(\mathcal{A}_0, \mathcal{A}_1)$-pair in the sense of Section 1.3.

The action of the anti-equivalence $\rho$ on perverse sheaves should be thought of entirely analogous to the action of the derived dual $\mathbb{D}$ on coherent sheaves. In particular, it should preserve pure perverse sheaves.

**Proposition 19.**

$$\rho(\mathcal{A}_0) \subset \mathcal{A}_0[-1], \quad \rho(\mathcal{A}_1) \subset \mathcal{A}_1.$$ 

The proof is split into several parts. We will consider the full subcategory $\mathcal{D}_E(Y)$ of complexes whose cohomology sheaves are set-theoretically supported on $\iota: E \to Y$. This category was studied by Orlov in [26]. Complementary to that, we consider certain categories of sheaves on $Y$ relative to $E$. Let $\text{Coh}_0(Y/E)$ be the abelian category of zero-dimensional sheaves supported away from $E$ and let $\text{Coh}_{\leq 1}(Y/E)$ be the abelian category of sheaves $F$ on $Y$ supported in dimension $\leq 1$, such that the restriction $\iota^*(F)$ is zero-dimensional.

**Lemma 20.**

$$\mathcal{A}_0 = \langle \mathcal{A}_0 \cap \mathcal{D}_E(Y), \text{Coh}_0(Y/E) \rangle_{\text{ex}},$$

$$\mathcal{A}_{\leq 1} = \langle \mathcal{A}_{\leq 1} \cap \mathcal{D}_E(Y), \text{Coh}_{\leq 1}(Y/E) \rangle_{\text{ex}}.$$ 

**Proof.** The two claims follow from a few simple observations. Firstly, $\mathcal{T}_0$ contains $\text{Coh}_0(Y/E)$ and, therefore, is the extension closure

$$\mathcal{T}_0 = \langle \mathcal{T}_0 \cap \mathcal{D}_E(Y), \text{Coh}_0(Y/E) \rangle_{\text{ex}}.$$ 

Moreover $\mathcal{F}[1] \subset \mathcal{D}_E(Y)$, since $\mathcal{F}[1]$ is orthogonal to $\text{Coh}_0(Y/E)$ by definition. Together this implies the first claim. The second claim follows analogously with $\text{Coh}_0(Y/E)$ replaced by $\text{Coh}_{\leq 1}(Y/E)$. \qed
4.1. **Local Hirzebruch surface.** In the proof of Proposition 19 we use the decomposition in Lemma 20. The part coming from $D^b_E(Y)$ is analysed by reducing to the local case.

**Lemma 21.**

\[ \rho(\mathcal{A}_0 \cap D^b_E(Y)) \subset \mathcal{A}_0 \cap D^b_E(Y)[-1], \]
\[ \rho(\mathcal{F}_1 \cap D^b_E(Y)) \subset \mathcal{F}_1 \cap D^b_E(Y). \]

**Proof.** The two properties are analogous to the properties of the derived dual $D^X$ of an orbifold. We want to reduce to this situation using Proposition 16. The category $D^b_E(Y)$ depends only on the formal completion of $E \subset Y$ [26, Corollary 2.9] and the nefness assumption (ii) implies $D^b_E(Y) \cong D^b_E(K_E)$. Here, $K_E$ denotes the total space of the canonical bundle. It is the crepant resolution of the coarse moduli space of the orbifold $X = [\text{Tot}(\mathcal{O}_{\mathbb{P}^1}(-1 - r) \oplus \mathcal{O}_{\mathbb{P}^1}(-1 + r))/\mathbb{Z}_2]$, which has $B\mathbb{Z}_2$-singularities along the zero-section $C \subset X$. By a result of Calabrese [9, Theorem 1.4], the McKay correspondence induces an equivalence $\text{Coh}(X) \sim \text{Per}(K_E/X).$

As noted in Remark (6), the category $\text{Per}(K_E/X)$ coincides with the category of perverse sheaves $\mathcal{A}$. The dimension function on $\mathcal{A}$ resembles the notion of dimension on $\text{Coh}(X)$. Composed with the McKay correspondence we obtain an equivalence $\text{Coh}(X) \sim \mathcal{A} \cap D^b_E(Y),$ where the left hand side is the full abelian category of sheaves set-theoretically supported on $C \subset X$. We may apply Proposition 16 and deduce the two claims from the properties of the derived dual $D^X(\text{Coh}_0(X)) \subset \text{Coh}_0(X)[-1], \quad D^X(\text{Coh}_1(X)) \subset \text{Coh}_1(X).$

The derived dual $D^X$ preserves supports, thus both properties hold analogously for zero- resp. one-dimensional sheaves which are supported on $C$. \hfill \Box

**Proof of Proposition (19).** We use Lemma (20) to split the proof into several cases. Lemma (21) settles the claim for perverse sheaves supported on $E$. It is left to compute the action of $\rho$ on $\text{Coh}_0(Y/E)$ and $\mathcal{A}_1 \cap \text{Coh}_{\leq 1}(Y/E).$
The category \( \text{Coh}_0(Y/E) \) is the extension closure of points \( x \in Y \setminus E \) so it suffices to consider the sheaves \( k(x) \). By Lemma 15 (i), \( \rho(k(x)) = k(x)[-1] \).

For any \( F \in \mathcal{A}_1 \), purity of \( \rho(F) \) follows by the vanishing of \( \text{Ext}^{<0} \)-groups:

\[
\text{Hom}(\mathcal{A}_0, \rho(F)) = \text{Hom}(F, \mathcal{A}_0[-1]) = 0.
\]
We are left to prove that \( \rho(F) \in \mathcal{A}_{\leq 1} \).

Consider a sheaf \( F \in \mathcal{A}_1 \cap \text{Coh}_{\leq 1}(Y/E) \) such that the intersection \( \text{supp}(F) \cap E \) is a zero-dimensional scheme \( Z \). Then \( F \in \text{Coh}_1(Y) \) is pure since \( \text{Coh}_0(Y) \subset \mathcal{A}_0 \). Note also that \( \text{supp}(F) = \text{supp}(\mathcal{D}(F)) \).

Choosing a section \( \mathcal{O}_E(-B - C) \to \mathcal{O}_E(-C) \) which vanishes away from \( Z \) induces isomorphisms on Ext-groups

\[
\text{Ext}^i(\mathcal{O}_E(-C), \mathcal{D}(F)) \cong \text{Ext}^i(\mathcal{O}_E(-B - C), \mathcal{D}(F)).
\]
Since \( \text{supp}(F) \) is Cohen-Macaulay, only \( V = \text{Ext}^1(\mathcal{O}_E(-C), \mathcal{D}(F)) \) is non-vanishing. We obtain the following diagram in \( D^b(Y) \):

\[
\begin{array}{ccc}
\mathcal{D}^Y(F) & \to & \rho(F) \\
\downarrow & & \downarrow \\
V \otimes \mathcal{O}_E(-2B - C) & \overset{\text{ST}_{-B-C}(\mathcal{D}^Y(F))}{\longrightarrow} & V \otimes \mathcal{O}_E(-B - C)
\end{array}
\]

Let \( G \) be the cone of the dotted arrow. Since both \( \mathcal{O}_E(-2B - C) \) and \( \mathcal{O}_E(-B - C) \) are in \( \mathcal{T}_{\leq 1} \), which is closed under taking quotients, also \( G \in \mathcal{T}_{\leq 1} \). We obtain (octahedron axiom) an induced exact triangle

\[
\begin{array}{ccc}
\mathcal{D}^Y(F) & \longrightarrow & \rho(F) \longrightarrow G.
\end{array}
\]

Thus, \( \rho(F) \in \mathcal{A}_{\leq 1} \). \( \Box \)

4.2. **Slope stability.** This section makes essential use of Assumption (iii). The nef class \( A \) is used to define a notion of slope stability on \( \mathcal{A}_{\leq 1} \). In the crepant case, \( A \) can be taken as the pullback of an ample class from the coarse moduli space \( X \) and the stability matches the notion of Nironi’s slope stability \([23]\) on \( \text{Coh}_{\leq 1}(X) \).

Let \( F \in \mathcal{A}_{\leq 1} \) with

\[
(\text{ch}_1(F), \text{ch}_2(F), \chi(F)) = (lE, \beta, n).
\]
Define the slope \( \nu: \mathcal{A}_{\leq 1} \setminus \{0\} \to \mathbb{Q} \cup \{\infty\} \) as the quotient \( \nu(F) = \frac{d(F)}{\ell(F)} \) where

\[
\begin{align*}
d(F) &= l + 2n - \frac{1}{2} E \cdot \beta, \\
\ell(F) &= 2A \cdot \beta + l(A \cdot C).
\end{align*}
\]

Recall that Nironi’s slope stability is defined in the analogous way, using a self-dual generating bundle \( V \) and the modified Hilbert polynomial

\[
p_F(k) = \chi(V, F \otimes A^k) = \ell(F) k + d(F).
\]

Our definition resembles this notion replacing \( V \) by the \( \rho \)-invariant \( K \)-theory class of \( \mathcal{O}_Y \oplus \mathcal{O}_Y(E/2) \) and replacing the Euler pairing by the Mukai pairing.

**Example 22.** To illustrate \( \nu \) for zero-dimensional perverse sheaves, consider a skyscraper sheaf \( k(x) \) and the perverse sheaves \( \mathcal{O}_B(-2)[1] \) and \( \mathcal{O}_B(-1) \) associated to a fiber of \( E \to \mathbb{P}^1 \). These sheaves are analogous to a non-stacky point and the stacky points \( \mathcal{O}_p^+ \) and \( \mathcal{O}_p^- \) respectively. In all three cases \( \ell(-) = 0 \) and the computation for \( d(-) \) is

\[
\begin{align*}
d(k(x)) &= 0 + 2 - 0 = 2, \\
d(\mathcal{O}_B(-2)[1]) &= -d(\mathcal{O}_B(-2)) = -(0 - 2 + 1) = 1, \\
d((\mathcal{O}_B(-1))) &= 0 + 0 + 1 = 1.
\end{align*}
\]

**Lemma 23.** Let \( F \in \mathcal{A}_{\leq 1} \), then

1. \( \ell(F) \geq 0 \) with equality if and only if \( F \in \mathcal{A}_0 \),
2. if \( F \in \mathcal{A}_0 \) then \( d(F) \geq 0 \).

**Proof.** We use the decomposition of \( \mathcal{A}_{\leq 1} \), \( \mathcal{A}_0 \) proven in lemma 20. Firstly, it’s clear that for \( F \in \text{Coh}_{\leq 1}(Y/E) \) we have

\[
\ell(F) = \text{ch}_2(F) \cdot A \geq 0
\]

and for \( F \in \text{Coh}_0(Y/E) \)

\[
d(F) = 2\chi(F) \geq 0.
\]

So it’s enough to prove the result in the local case following the proof of Lemma 21; we use the notation there. Let \( \tilde{\ell}, \tilde{d} \) be defined by the composition of \( \ell, d \) with the McKay correspondence

\[
\tilde{\ell}, \tilde{d}: \text{Coh}_C(\mathcal{X}) \xrightarrow{\sim} \mathcal{A}_{\leq 1} \cap D^b_k(Y) \xrightarrow{\ell, d} \mathbb{Q} \cup \{\infty\}.
\]
We have
\[\tilde{\ell}(\mathcal{O}_C) = \ell(\mathcal{O}_E(-C - rB)) = A \cdot C\]
\[\tilde{\ell}(\mathcal{O}_C^+) = \ell(\mathcal{O}_E(-2C - rB)[1]) = A \cdot C\]
\[\tilde{d}(\mathcal{O}_p) = d(\mathcal{O}_p(-1)) = 1, \quad \tilde{d}(\mathcal{O}_p^+) = d(\mathcal{O}_p(-2)[1]) = 1\]

Letting \(\tilde{A}\) be the divisor on \(X\) such that \(\tilde{A} \cdot C = A \cdot C > 0\), we conclude that for \(F \in \text{Coh}_C(X)\)
\[\tilde{\ell}(F) = \text{ch}_2(\tau^*F) \cdot \tilde{A} \geq 0\]
where \(\tau : \mathcal{X} \to X\) is the map to the coarse moduli space. Similarly, for \(F \in \text{Coh}_{C,0}(X)\) (which is the image of \(\mathcal{A}_0 \cap \mathcal{D}_E^b(Y)\)) we have
\[\tilde{d}(F) = \chi(X, \tau^*F) \geq 0.\]

\[\square\]

**Proposition 24.** The slope \(\nu\) defines a stability condition on \(\mathcal{A}_{\leq 1}\).

**Proof.** The see-saw property is clear, so it’s enough to prove that \(\mathcal{A}_{\leq 1}\) is \(\nu\)-Artinian.

Suppose that \(E_1 \supseteq E_2 \supseteq \ldots \) in \(\mathcal{A}_{\leq 1}\). Then \(\ell(E_i)\) is a decreasing sequence bounded below by 0, so it must stabilize. Thus, for large enough \(i\) the cone \(C(E_{i+1} \to E_i) \in \mathcal{A}\) must be in \(\mathcal{A}_0\) so \(\nu(E_{i+1}) \leq \nu(E_i)\).

\[\square\]

**Proposition 25.** The slope \(\nu\) satisfies
\[\nu(\rho(F)) = -\nu(F), \quad \nu(F \otimes A) = \nu(F) + 1.\]

**Proof.** The equality \(\ell(\rho(F)) = \ell(F)\) is clear since \(A \cdot B = 0\). Using Proposition 17 we have
\[d(\rho(F)) = l - 2n - \frac{1}{2}E \cdot (\beta + (E \cdot \beta - 2l)B)\]
\[= -l - 2n + \frac{1}{2}E \cdot \beta = -d(F).\]

For the second equality, a computation using \(A^2 \cdot E = 0\) shows that
\[\ell(F \otimes \mathcal{O}_Y(A)) = \ell(F), \quad d(F \otimes \mathcal{O}_Y(A)) = d(F) + \ell(F).\]

\[\square\]

**4.3. Boundedness results.** We now prove a few boundedness and finiteness results that will be needed for the analysis of the wall-crossing formula and the proof of rationality. For \(I \subset \mathbb{R}\) denote by \(\mathcal{M}^\nu(I)\) the stack of all \(F \in \mathcal{A}_{\leq 1}\) such that all Harder–Narasimhan factors with respect to \(\nu\) have slope contained in \(I\). The substack \(\mathcal{M}^\nu_\gamma(I)\) parametrizes all such \(F\) with fixed \([F] = \gamma \in N_1\). The special case \(I =\)
$[\delta, \delta]$ parametrizes $\nu$-semistable $F$ of slope $\delta$ and is denoted $\mathcal{M}_{\gamma}^{\nu-ss}(\delta)$. The substack $\mathcal{M}_{(\gamma,c)}^{\nu-ss}(\delta) \subset \mathcal{M}_{\gamma}^{\nu-ss}(\delta)$ corresponds to a fixed class $(\gamma, c) \in N_{\leq 1}$.

**Proposition 26.** For any $\gamma \in N_{1}$ and $\delta, D \in \mathbb{R}$

1. The stack $\mathcal{M}_{\gamma}^{\nu-ss}(\delta) \subseteq \mathcal{A}_{\leq 1}$ is open of finite type.
2. The stacks
   $$\{ F \in \mathcal{M}_{\gamma}^{\nu}([\delta, +\infty)) : d(F) \leq D \}$$
   and
   $$\{ F \in \mathcal{M}_{\gamma}^{\nu}((-\infty, \delta]) : d(F) \geq D \}$$
   are open in $\mathcal{A}_{\leq 1}$ and of finite type.

In particular it follows as a corollary that for each $\gamma$ and fixed $D \in \mathbb{R}$ the set
$$\{ c \in N_{0} : \mathcal{M}_{(\gamma,c)}^{\nu-ss} \neq \emptyset \text{ and } d(c) = D \}$$
is finite.

We denote by $N_{1}^{\nu}$ the image of $\mathcal{A}_{\leq 1}$ in $N_{1}$.

**Lemma 27.** For any $L > 0$, the set
$$\{ \gamma \in N_{1}^{\nu} : \ell(\gamma) \leq L \}$$
is finite.

**Proof.** Using the decomposition in Lemma 20 we can write $\gamma = \gamma_{1} + \gamma_{2}$ where $\gamma_{i} = [F_{i}]$ and
$$F_{1} \in \mathcal{A}_{\leq 1} \cap D_{k}^{b}(Y), \quad F_{2} \in \text{Coh}_{\leq 1}(Y/E).$$
Then $0 \leq \ell(\gamma_{i}) \leq L$. The proof of Lemma 23 shows that there are only finitely many possibilities for $\gamma_{1}, \gamma_{2}$. \hfill $\square$

Let $A$ be the nef class of Assumption (iii). The intersection product $A \cdot E$ is a multiple of $B$, thus multiplication by $A$ defines a map
$$A \cdot (-) : N_{\leq 1} \to N_{0}.$$ 

**Lemma 28** ([1, Proposition 7.1.(3)]). For any $\gamma \in N_{1}$ the image of the set
$$\{ c \in N_{0} : \mathcal{M}_{(\gamma,c)}^{\nu-ss} \neq \emptyset \}$$
in the quotient
$$N_{0}/\mathbb{Z}(A \cdot \gamma) \cong \mathbb{Z}$$
is finite.
Proof. The proof is the same as in [1], using Proposition 26.

Lemma 29 ([1, Proposition 7.6.(1)]). For any $\delta \in \mathbb{R}$ and $\gamma \in N_1$ the set

$$\{ c \in N_0 : \text{Pairs}_{(\gamma,c)}^{\nu,\delta} \neq 0 \}$$

is finite.

Proof. Again the proof is an easy adaptation of the proof of [1, Proposition 7.6.(1)].

4.4. Rationality via $\nu$ wall-crossing. For $\delta \in \mathbb{R}$ we introduce the torsion pair $(T_{\nu,\delta}, F_{\nu,\delta})$ on $A_{\leq 1}$ by

$$T_{\nu,\delta} = \{ T \in A_{\leq 1} : T \rightarrow Q \neq 0 \Rightarrow \nu(Q) \geq \delta \}$$

$$F_{\nu,\delta} = \{ F \in A_{\leq 1} : 0 \neq S \hookrightarrow F \Rightarrow \nu(S) < \delta \}.$$  

We denote by Pairs$_{\nu,\delta}$ the category (or the stack, depending on the context) of $(T_{\nu,\delta}, F_{\nu,\delta})$-pairs. This stack admits a decomposition into connected components according to the class of its elements and we write Pairs$_{\nu,\delta}$ for the stack of pairs in class $(-1, \gamma, c)$. Applying the integration morphism in the Hall algebra produces numerical invariants $pDT_{(\gamma,c)}^{\nu,\delta} \in \mathbb{Q}$ defined by

$$I((L - 1)\text{Pairs}_{\nu,\delta}^{\nu,\delta}) = \sum_{(\gamma,j,n)} pDT_{(\gamma,j,n)}^{\nu,\delta} z^\gamma Q^j q^n t^{-[\mathcal{O}]}.$$

In the limit $\delta \rightarrow +\infty$ these invariants agree with the perverse PT invariants previously defined.

Lemma 30. Let $P \in A$ be an object of class $(-1, \gamma, c)$. For $\delta$ sufficiently big (depending on $\gamma, c$) we have

$$P \in \text{Pairs}_{\nu,\delta}^{\nu,\delta}$$

if and only if $P \in p\text{Pairs}$.

Proof. The proof is analogous to [1, Lemma 7.10].

For $\alpha \in N_{\leq 1}$ we define the invariants $J_{\alpha}^{\nu}$ by counting semi-stable perverse sheaves with respect to the slope $\nu$:

$$I((L - 1) \log (\mathcal{M}_{\nu\text{-ss}}(\delta))) = \sum_{\nu(\alpha) = \delta} J_{\alpha}^{\nu} z^\alpha.$$

The $J$-invariants are analogous to Toda’s $N$-invariants in the proof of the rationality of stable pairs generating functions.
The wall-crossing formula between $p_{PT}$ and $p_{DT}^{\nu, \delta_0}$ is

$$p_{PT} \leq L t^{-1} = \prod_{\delta \in W_L \cap [\delta_0, +\infty]} \exp \left\{ \{J_{\leq L}(\delta), -\} \right\} p_{DT}^{\nu, \delta_0} t^{-1}.$$  

Here the subscript $\leq L$ means we’re restricting the generating functions to the classes $\alpha \in N_{\leq 1}$ such that $\ell(\alpha) \leq L$. Moreover, 

$$W_L = \frac{1}{L!} \mathbb{Z}$$

is the set of possible walls since $\ell(\alpha) \leq L \Rightarrow \nu(\alpha) \in W_L$.

4.5. **Combinatorics of the wall-crossing formula.** Expanding the right-hand side of the wall-crossing formula (6) and extracting the coefficient of $z^{\gamma} t^{-1}$ we get the following expression for the perverse PT invariants in class $\gamma \in N_1$:

$$p_{PT, \gamma} = \sum_{j,n} p_{PT}(\gamma, j, n) Q^j q^n = \sum_{C} \cdots$$

The right-hand sum runs over a set of choices $C$ described by an integer $r \in \mathbb{Z}_{\geq 0}$ and classes $\alpha_1, \ldots, \alpha_r = (\gamma_i, c_i), \ldots, \alpha_r \in N_{\leq 1}$ and $\alpha' = (\gamma', c') \in N_{\leq 1}$, satisfying the following conditions:

1. $\gamma = \gamma' + \sum_{i=1}^r \gamma_i$;
2. $\delta_0 \leq \nu(\alpha_1) \leq \ldots \leq \nu(\alpha_r)$;
3. $J^\nu_{\alpha_i} \neq \emptyset$;
4. $p_{DT}^{\delta, \nu}_{\alpha_r} \neq \emptyset$.

We now use the boundedness results to analyse this sum. First, conditions (3) and (4) imply that $\gamma_i, \gamma' \in N_{\text{eff}}^1$. Together with condition (1) and Lemma 27 it follows that there is only a finite amount of possibilities for $\gamma_i, \gamma'$. Lemma 29 also tells us that there is only a finite number of possibilities for $\alpha'$. Finally, Lemma 28 says that, after we fix $\gamma_1, \ldots, \gamma_r$ there are finitely many possibilities for the classes $\kappa_i \equiv [c_i] \in N_0/\mathbb{Z}(A \cdot \gamma_i)$.

Since twisting by $O_Y(A)$ induces an isomorphism

$$\mathcal{M}^{\nu, \text{ss}}_{(\gamma_i, c_i)} \cong \mathcal{M}^{\nu, \text{ss}}_{(\gamma_i, c_i + A \cdot \gamma_i)}$$

it follows that $J^\nu_{(\gamma_i, c_i)}$ depends only on $\gamma_i$ and the class $\kappa_i = [c_i]$, so we write $J^\nu_{(\gamma_i, \kappa_i)} = J^\nu_{(\gamma_i, c_i)}$. 
Due to the combinatorical factor in (7) we also introduce the set \( \mathcal{J} \) tracking which of the inequalities in (2) are strict:

\[
\mathcal{J} = \{ i \in \{1, \ldots, r-1\} : \nu(\alpha_i) = \nu(\alpha_{i+1}) \}.
\]

We group the terms in the right hand side of (7) in finitely many groups according to the data \( \xi = (\{\gamma_i\}_i, \{\kappa_i\}_i, \gamma', c') \). Since \( \nu(\gamma_i, c_i + A \cdot \gamma_i) = \nu(\gamma_i, c_i) + 1 \), given a group \( \xi \) we can choose a minimal set of representatives \( c_0^i \in \kappa_i \) such that

\[
\delta_0 \leq \nu(\gamma_i, c_0^i) < \delta_0 + 1 \quad \text{and} \quad \nu(\gamma_i, c_0^i) \leq \nu(\gamma_{i+1}, c_0^{i+1}) < \nu(\gamma_i, c_0^i) + 1.
\]

Then we organize equation (7) as

\[
p_{\text{PT}} = \sum_{\xi} A(\xi) \sum_{(k_1, \ldots, k_r) \in S_{\mathcal{J}}} B_\xi(k_1, \ldots, k_r) z^{c' + \sum_{i=1}^r (c_0^i + k_i (A \cdot \gamma_i))}
\]

where the first sum runs over the finitely many possible groups and the second sum runs over the set

\[
S_{\mathcal{J}} = \{ (k_1 \leq \ldots \leq k_r) : k_i = k_{i+1} \Leftrightarrow i \in \mathcal{J} \}.
\]

Since \( B_\xi \) is a quasi-polynomial of period 2, the rationality of \( p_{\text{PT}} \) follows from [1, Lemma 2.21].

4.6. Functional equation.

**Lemma 31.** Let \( \delta \in \mathbb{R} \setminus \mathbb{Q} \). Then

\[
\rho(\text{Pairs}^\nu, \delta) = \text{Pairs}^\nu, -\delta.
\]

In particular,

\[
p_{\text{DT}}^\nu, \delta = p_{\text{DT}}^{\nu, -\delta}.
\]

**Proof.** The lemma is proven exactly as in [1, Lemma 7.4], replacing \( \text{Coh}(\mathcal{X}) \) by \( A \) and \( \mathbb{D}^X \) by \( \rho \). The properties of \( \rho \) needed for the proof are Propositions 19 and 25. \( \Box \)

**Lemma 32.** Let \( \gamma \in N_1 \). We have

\[
\lim_{\delta \to -\infty} \deg (p_{\text{PT}} - p_{\text{DT}}^\nu, \delta) = -\infty.
\]

**Proof.** We consider the wall-crossing equation (7), (8) with \( \delta = \delta_0 \). Note that the terms in (8) with \( r = 0 \) (that is, in groups \( \xi = (\emptyset, \emptyset, \gamma, c, \emptyset) \)) give precisely \( p_{\text{DT}}^\nu, \delta \), so we may express the difference \( p_{\text{PT}} - p_{\text{DT}}^\nu, \delta \) as the sum on the right-hand side of (8) restricted to \( r \geq 1 \). Thus we have

\[
\deg (p_{\text{PT}} - p_{\text{DT}}^\nu, \delta) \leq \max_{\xi} \left( d(c') + \sum_{i=1}^r d(c_0^i) \right)
\]
where the max is taken over the groups $\xi$ with $r > 0$. Summing $d(\gamma)$ to both sides
\[
\deg (p_{\text{PT}} - p_{\text{DT}}) + d(\gamma) \leq \max_{\xi} \left( d(\gamma', c') + \sum_{i=1}^{r} d(\gamma_i, c_i^0) \right).
\]
By the minimality of $c_i^0$ we know that $d(\gamma_i, c_i^0) < \delta_0 + i$, and therefore we get the bound
\[
\deg (p_{\text{PT}} - p_{\text{DT}}) + d(\gamma) \leq \max_{\xi} \left( d(\gamma', c') + r\delta_0 + \frac{r(r + 1)}{2} \right).
\]
Now taking $\delta \to -\infty$ gives the desired limit.

By Lemmas 30 and 31, for any $\alpha \in N_{\leq 1}$ and sufficiently small $\delta$ we have $p_{\text{DT}}^{\nu,\delta} = p_{\text{PT}}(\rho(\alpha))$. Thus, we have
\[
p_{\text{DT}}^{\nu,\infty} \equiv \lim_{\delta \to -\infty} p_{\text{DT}}^{\nu,\delta} = \lim_{\delta \to +\infty} p_{\text{DT}}^{\nu,\delta} = p_{\text{PT}}(\rho(\alpha)).
\]
Here $\rho(\alpha)$ denotes the action on cohomology induced by $\rho$ determined by Proposition 17. One can write this action as $\rho(\gamma, c) = (\gamma, \rho(\gamma)(c))$ where, for each $\gamma = (lE, \beta)$, $\rho_\gamma : N_0 \to N_0$ is an involution $\rho_\gamma(jB, n) = ((-j + E \cdot \beta - 2l)B, -n)$.

We write the previous relation between $p_{\text{DT}}^{\nu,\infty}$ and $p_{\text{PT}}$ as an equality of generating functions for $\gamma \in N_1$:
\[
p_{\text{DT}}^{\nu,\infty} = \sum_{c \in N_0} p_{\text{DT}}^{\nu,\infty}_{\gamma, c} z^c = \sum_{c \in N_0} p_{\text{PT}}(\gamma, \rho(\gamma)(c)) z^c = \rho_\gamma(p_{\text{PT}}).\]

It follows that $p_{\text{DT}}^{\nu,\infty}$ is the expansion of a rational function in $Q[q, Q]_{-\deg}$. On the other hand, by 30
\[
\lim_{\delta \to -\infty} \deg (p_{\text{DT}}^{\nu,\infty} - p_{\text{DT}}^{\nu,\delta}) = -\infty
\]
and, together with Lemma 32, we have an equality of rational functions
\[
p_{\text{PT}} = p_{\text{DT}}^{\nu,\infty} = \rho_\gamma(p_{\text{PT}}).\]
This finishes the proof of theorem 2.

5. Bryan–Steinberg vs. perverse PT invariants

In this section we will prove the wall-crossing between the Bryan-Steinberg invariants and perverse PT invariants. Together with the BS/PT wall-crossing of section 2, the output of this section is a proof of theorem 3.
We will use the stability condition $\zeta$ defined by
\[ \zeta(F) = \left( -\frac{l}{\ell(F)}, \nu(F) \right) \in (-\infty, +\infty)^2, \]
where as before $l$ denotes the integer for which $\text{ch}_1(F) = lE$. We give $(-\infty, +\infty)^2$ the lexicographic order. Note that the first component
\[ \zeta_1(F) = -\frac{l}{\ell(F)} \]
only depends on the class of $[F]$ in $N_1 = N_{\leq 1}/N_0$. For $\gamma \in N_1$ we will also write $\zeta_1(\gamma)$.

The wall-crossing is entirely analogous to [1, Section 8], where Bryan–Steinberg pairs are compared to orbifold PT pairs to prove the crepant resolution conjecture. For us, matters simplify and it is worth to point out how exactly.

The stability $\zeta$ leads to torsion pairs $(T_{\mu, \eta}, F_{\mu, \eta})$ on $A_{\leq 1}$ labelled by $(\mu, \eta) \in \mathbb{R}_{>0} \times \mathbb{R}$. The notion of $(\mu, \eta)$ stable pairs $\text{Pairs}(\mu, \eta)$ in
\[ A = \langle \mathcal{O}_Y[1], A_{\leq 1} \rangle_{\text{ex}} \]
is locally constant. More precisely, for fixed $\gamma \in N_1$ there is a finite set of possible walls $V_\gamma$ such that stability is constant on
\[ (\mathbb{R}_{>0} \setminus V_\gamma) \times \mathbb{R}. \]
The limit $0 < \mu \ll 1$ coincides with BS pairs, the limit $\mu \to \infty$ coincides with perverse stable pairs. Crossing a wall $\mu \in V_\gamma$ leads to a wall-crossing formula. This wall-crossing is controlled in a concrete way. There is precisely one effective class $0 < \gamma' \leq \gamma$ characterized by $L_\mu(A \cdot \gamma') = 0$, where as before
\[ L_\mu(jB, n) = 2n + j + \frac{j}{\mu(A \cdot C)}. \]
The asymmetry of $n$ and $j$ in this formula hints at how varying $\mu$ separates BS from perverse PT. Recall that $L_\mu$ is the same linear function introduced in Section 1 that controls the expansion of the rational function.

Then, to cross the $\mu$-wall, it is possible to enter the wall from either sides because for $0 < \epsilon \ll 1$ we have
\[ \text{Pairs}(\mu \pm \epsilon, \eta) = \text{Pairs}(\mu, \pm \infty). \]

The wall-crossing inside $\{\mu\} \times \mathbb{R}$ is similar to the $\nu$-wall-crossing in Section 4. The combinatorics is controlled in the same way.
5.1. Walls. Let $\gamma \in N_1$. Define the set of possible walls

$$V_\gamma = \{ \zeta_1(\gamma') : 0 < \gamma' \leq \gamma \} \cap \mathbb{R}_{>0}.$$

**Lemma 33.** Stability is constant on \((\mathbb{R}_{>0} \setminus V_\gamma) \times \mathbb{R}\).

In the following, when $\mu \in (\mathbb{R}_{>0} \setminus V_\gamma)$ we let $\eta \in \mathbb{R}$ arbitrary.

Crossing a wall $\mu \in V_\gamma$ is controlled by the linear function $L_\mu$. The basic reason is the following relation between $L_\mu$ and $\zeta_1$:

$$L_\mu(A \cdot \gamma) = d(A \cdot \gamma) \left(1 - \frac{\zeta_1(\gamma)}{\mu}\right).$$

**Lemma 34.** There is, up to scaling, a unique class $\gamma_\mu$ such that $0 < \gamma_\mu \leq \gamma$ and $L_\mu(A \cdot \gamma_\mu) = 0$. The class $A \cdot \gamma_\mu \in N_0$ is uniquely characterized by this property.

**Proof.** The proof is a simplified version of [1, Lemma 8.21].

**Example 35.** We illustrate the previous result for $E \cong \mathbb{P}^1 \times \mathbb{P}^1$ and the class $\gamma = C - B \in N_1$. It is an effective class:

$$\gamma = [O_E(-2C - B)[1]] + [O_E(-C - 2B)].$$

The two objects are contained in $F[1]$ and $T$ respectively and the sum gives rise to the effective decomposition

$$\gamma = (-E, C) + (E, -B).$$

Recall the line bundle $A$ and $\ell(l, \beta) = 2A \cdot \beta + l(A \cdot C)$. We have

$$\zeta_1(O_E(-2C - B)[1]) = \frac{-1}{2A \cdot C - A \cdot C} = \frac{1}{A \cdot C}$$

and there is only one wall

$$V_\gamma = \left\{ \frac{1}{A \cdot C} \right\}.$$

The unique class $\gamma_\mu$ is $[O_E(-2C - B)[1]] = (-E, C)$ and

$$A \cdot \gamma_\mu = (- (A \cdot C)B, (A \cdot C)) \in N_0.$$

The linear function $L_\mu$ uniquely specifies $A \cdot \gamma_\mu$ as

$$L_{\mu'}(A \cdot \gamma_\mu) \begin{cases} > 0, & \mu' > \frac{1}{A \cdot C}, \\ = 0, & \mu' = \frac{1}{A \cdot C}, \\ < 0, & \mu' < \frac{1}{A \cdot C}. \end{cases}$$

---

6In [1] the authors choose a very general ample class to define the stability $\zeta$ and function $L_\mu$. This choice is not necessary for our application because $\text{ch}_1(F)$ is proportional to $E$ for all $[F] \in N_{\leq 1}$ and $\text{ch}_2(F)$ is proportional to $B$ for all $[F] \in N_0$. 
Correspondingly, the class \( A \cdot \gamma = (A \cdot C)[O_B(-2)[1]] \in N_0 \) is considered effective in the expansion of the rational function with respect to \( L' \) for \( \mu' > \frac{1}{\alpha C} \) (pPT pairs), whereas it is non-effective for \( \mu' < \frac{1}{\alpha C} \) (BS pairs).

5.2. Limit stability I. We identify the limit of \((\mu, \eta)\)-stability for \( 0 < \mu \ll 1 \) with BS stability. First, we can give an explicit description of the limit of the torsion pair for \( 0 < \mu \ll 1 \).

**Definition 36.** We define the torsion pair \((T_{\zeta,0}, F_{\zeta,0})\) in \( A_{\leq 1} \) by

\[
T_{\zeta,0} = \{ A \in A_{\leq 1} : A \rightarrow Q \Rightarrow Q \in A_0 \text{ or } \text{ch}_1(Q) \in \mathbb{Z}_{\leq 0}E \}
\]

and the orthogonal complement \( F_{\zeta,0} = T_{\zeta,0}^\perp \).

**Lemma 37.** Let \( P \in A \) of class \((-1, \gamma, c)\) and \( 0 < \mu < \mu' \) for all \( \mu' \in V_\gamma \). Then, \( P \) is a \((T_{\zeta,0}, F_{\zeta,0})\) pair if and only if \( P \) is a \((T_{\mu,\eta}, F_{\mu,\eta})\) pair.

**Lemma 38.** We have

\[
T_{\zeta,0} = \langle F[1], T_0 \rangle \\
F_{\zeta,0} = T_1.
\]

**Proof.** We begin by proving that \( \langle F[1], T_0 \rangle \subseteq T_{\zeta,0} \).

We first note that we can write

\[
A_{\leq 1} = \langle F[1], T \rangle = \langle F[1], \langle T_0, T_1 \rangle \rangle = \langle \langle F[1], T_0 \rangle, T_1 \rangle,
\]

so \( \langle F[1], T_0 \rangle \) is closed under quotients. Hence it’s enough to show that if \( A \in F[1] \) or \( A \in T_0 \) then \( A \in A_0 \) or \( \text{ch}_1(A) \in \mathbb{Z}_{\leq 0}E \). For \( A \in T_0 \) this is clear. If \( A[1] \in F[1] \) then \( \text{ch}_1(A[1]) = lE \) with \( l \leq 0 \) and equality if and only if \( A \in \text{Coh}_{\leq 1}(Y) \). So it remains to show that if \( A \in F \) and \( \text{ch}_1(A) = 0 \) then \( A \in F_0 \), i.e. \( F \cap \text{Coh}_{\leq 1}(Y) = F_0 \).

We let \( F \in F \cap \text{Coh}_{\leq 1}(Y) \). Then \( \text{supp}(F) \subseteq E \) is (at most) 1-dimensional. If there is a fiber \( B = p^{-1}(c) \) such that \( \text{supp}(F) \cap B \) is 0-dimensional and non-empty then \( (R^0p_\ast F)_c \neq 0 \), which would contradict \( F \in F \). Thus \( \text{supp}(F) \) is a finite union of fibers \( B \), so \( F \in F_0 \) as we wanted and proving the first inclusion.

For the inclusion \( T_{\zeta,0} \subseteq \langle F[1], T_0 \rangle \), let \( A \in T_{\zeta,0} \) and consider the decomposition of \( A \) in the torsion pair \( A_{\leq 1} = \langle F[1], T \rangle \)

\[
0 \rightarrow F[1] \rightarrow A \rightarrow T \rightarrow 0.
\]

Since \( \text{ch}_1(T) = \mathbb{Z}_{\geq 0}E \), by the definition of \( T_{\zeta,0} \) we have \( T \in T \cap A_0 = T_0 \).
This finishes the proof of the first equality \( T_{\zeta,0} = \langle \mathcal{F}[1], \mathcal{T} \rangle \). The second equality follows from the first and
\[
\langle T_{\zeta,0}, F_{\zeta,0} \rangle = A_{\leq 1} = \langle \langle \mathcal{F}[1], \mathcal{T}_0 \rangle, \mathcal{T}_1 \rangle.
\]
\[\Box\]

Recall that \( \mathcal{T}_0 = \mathcal{T} \cap \mathcal{A}_0 = \mathcal{T}_{BS} \), so in particular \( \mathcal{T}_{BS} \subseteq T_{\zeta,0} \).

The key result of this section is

**Proposition 39.** Let \( P \in D^b(Y) \) be such that \( ch_1(P) = 0 \). Then \( P \) is a \((T_{\zeta,0}, F_{\zeta,0})\)-pair if and only if \( P \) is a \((T_{BS}, F_{BS})\)-pair.

**Proof.** We begin by the proof that if \( P \) is a \((T_{BS}, F_{BS})\)-pair then it’s a \((T_{\zeta,0}, F_{\zeta,0})\)-pair. If \( P \) is a \( BS \)-pair, by \([1, \text{Lemma 3.13}]\) we can write \( P = (\mathcal{O}_Y \to F) \) with \( F \in F_{BS} \) and \( Q = \text{coker}(\mathcal{O}_Y \to F) \in T_{BS} = \mathcal{T}_0 \subseteq A_{\leq 1} \).

We first prove that \( F \in A_{\leq 1} \), so \( P \in A \). If \( L \) is the scheme-theoretical support of \( F \) (which is a curve), we have the short exact sequence of sheaves
\[
0 \to \mathcal{O}_L \to F \to Q \to 0.
\]
Since \( \mathcal{O}_L, Q \in A_{\leq 1} \) and \( A_{\leq 1} \) is closed under extensions it follows that \( F \in A_{\leq 1} \). Moreover for \( T \in T_{\zeta,0} \)
\[
\text{Hom}(T, P) = \text{Hom}(T, F) = \text{Hom}(H^0(T), F) = 0
\]
The last vanishing holds because \( H^0(T) \in \mathcal{T}_0 = \mathcal{T}_{BS} \) by lemma 38 and \( F \in F_{BS} \). Similarly, for \( G \in F_{\zeta,0} \),
\[
\text{Hom}(P, G) = \text{Hom}(Q, G) = 0
\]
vansishes since \( Q \in \mathcal{T}_{BS} \subseteq T_{\zeta,0} \). So we conclude that \( P \) is a \((T_{\zeta,0}, F_{\zeta,0})\)-pair.

We now assume that \( P \) is a \((T_{\zeta,0}, F_{\zeta,0})\)-pair with \( ch_1(P) = 0 \). Since
\[
P \in A = \langle \mathcal{O}_Y[1], \mathcal{F}[1], \mathcal{T} \rangle_{ex}
\]
we can easily see that \( H^i(P) = 0 \) for \( i \neq -1, 0 \) and \( H^{-1}(P), H^0(P) \) have ranks 1 and 0, respectively. Moreover the torsion part \( T \hookrightarrow H^{-1}(P) \) is in \( \mathcal{F} \), so \( T[1] \in \mathcal{F}[1] \subseteq T_{\zeta,0} \). By definition of \((T_{\zeta,0}, F_{\zeta,0})\)-pair the composition
\[
T[1] \hookrightarrow H^{-1}(P)[1] \to P
\]
vanishes, forcing \( T \) to vanish. Thus \( H^{-1}(P) \) is torsion-free. By lemma 38 we have
\[
H^0(P) \in T_{\zeta,0} \cap \text{Coh}(Y) = \mathcal{T}_0 = \mathcal{T}_{BS}.
\]
In particular it follows that
\[ \text{ch}_1(H^{-1}(P)) = \text{ch}_1(H^0(P)) - \text{ch}_1(P) = 0. \]
Hence \( H^{-1}(P) \) is a torsion-free, rank 1 sheaf with trivial determinant, hence it’s an ideal sheaf \( H^{-1}(P) \cong I_C \). So \( P \) fits in an exact triangle
\[ I_C[1] \rightarrow P \rightarrow H^0(P). \]
Using the argument of \([30, \text{Lemma 3.11 (ii)}]\) with the fact that \( H^1(Y, H^0(P)) = 0 \) we get that \( P \) has the form \( P = (\mathcal{O}_Y \rightarrow F) \). We already know that \( H^0(P) \in \mathcal{T}_\text{BS} \) so it remains to show that \( F \in \mathcal{F}_\text{BS} \) (see \([1, \text{Remark 3.10}]\)). For \( T \in \mathcal{T}_\text{BS} \) we have
\[ \text{Hom}(T, F) = \text{Hom}(T, P) = 0 \]
since \( T \in \mathcal{T}_\text{BS} \subseteq T_{c,0} \), and we’re done.

5.3. Limit stability II. We identify the limit of \((\mu, \eta)\)-stability for \( \mu \to \infty \) with \( p\text{PT} \) stability.

**Lemma 40.** Let \( P \in \mathcal{A} \) of class \((-1, \gamma, c)\) and \( \mu > \mu' \) for all \( \mu' \in V_\gamma \). Then, \( P \) is a perverse stable pair if and only if \( P \) is a \((T_{\mu,\eta}, \mathcal{F}_{\mu,\eta})\) pair.

5.4. Crossing a wall. Let \( \mu \in V_\gamma \). First, we show that we can enter the wall \( \{\mu\} \times \mathbb{R} \) from either side in the following sense.

**Lemma 41.** Let \( \alpha \in N_{\leq 1} \) and \( 0 < \varepsilon \ll 1 \).

1. For sufficiently large \( \eta \gg 0 \)
\[ \text{Pairs}(\mu, \eta)_{\alpha} = \text{Pairs}(\mu + \varepsilon, \eta)_{\alpha}, \]
2. for sufficiently small \( \eta \ll 0 \)
\[ \text{Pairs}(\mu, \eta)_{\alpha} = \text{Pairs}(\mu - \varepsilon, \eta)_{\alpha}. \]

**Proof.** The proof is a simplified version of \([1, \text{Lemma 8.25}]\). \(\square\)

We explain now the wall-crossing inside \( \{\mu\} \times \mathbb{R} \). Let \( c_\mu \in N_0 \) be the unique class of \( \text{Lemma 34} \). For any \( c \in N_0 \) define
\[ p^{\text{DT}}_{(\mu, \eta)} = \sum_{k \in \mathbb{Z}} p^{\text{DT}}_{(\mu, \eta)} z^{c+kc_\mu}. \]
We have used the Novikov parameter \( z \) to track both \( q \) and \( Q \). By the previous lemma, the notion of \((\mu, \eta)\) pair is constant for \( \mu \gg 0 \) (respectively \( \mu \ll 0 \)) and fixed \( \alpha \in N_{\leq 1} \). Thus, we can define the limit for \( \eta \to \pm \infty \), which agrees with the generating series for \((\mu \pm \varepsilon, \eta)\):
\[ p^{\text{DT}}_{(\mu \pm \varepsilon, \eta)} = p^{\text{DT}}_{(\mu \pm \varepsilon, \eta)} z^{c+kc_\mu}. \]
Lemma 42. The two generating series \( p_{\gamma}^{\mathrm{DT}}(\mu, \pm \infty) \) are the expansion of the same rational function.

Proof. The combinatorics is the same as in 4.5, see also [1, Lemma 8.27].

The main result of this section is then a formal consequence.

Proposition 43. There exists a rational function \( f_\gamma(q, Q) \) such that for all \( \mu \in V_\gamma \) the series \( p_{\gamma}^{\mathrm{DT}}(\mu, \pm \varepsilon) \) are the expansion of \( f_\gamma \) with respect to \( L_{\mu \pm \varepsilon} \).

Proof. Let \( \mu = \max_{\mu \in V_\gamma} \mu' \) be the biggest wall and \( c_\mu \in \mathbb{N}_0 \) the class of Lemma 34. By Lemma 41 and Section 5.3 the series \( p_{\gamma}^{\mathrm{DT}}(\mu + \varepsilon, \eta) \) agrees with perverse stable pairs \( p_{\gamma}^{\mathrm{PT}} \) and it is the expansion of a rational function \( f_\mu ^\mu \) as proven in Section 4. Note that in the limit \( \mu' \to \infty \) the linear function
\[
L_{\mu'}(c) = \deg(c) + \frac{j}{\mu'(A \cdot C)}
\]
agrees with \( \deg \) in the sense that expansion of the rational function \( f_\mu ^\mu \) is the same for \( L_{\mu'} \) and \( \deg \).

The previous lemma says that the two series \( p_{\gamma}^{\mathrm{DT}}(\mu, \pm \infty) \) agree as rational function for each \( c \in \mathbb{N}_0 \). Their difference is a quasi-polynomial function in \( k \). Recall that, by definition of \( c_\mu \), we have
\[
L_{\mu + \varepsilon}(c_\mu) > 0, \quad L_{\mu - \varepsilon}(c_\mu) < 0.
\]
It is then a formal consequence [1, Lemma 2.22] that \( p_{\gamma}^{\mathrm{DT}}(\mu, -\varepsilon, \eta) \) is the expansion of the same rational function \( f_\mu ^\mu \), with respect to \( L_{\mu - \varepsilon} \).

Since stability is constant on \( (\mathbb{R}_{>0} \setminus V_\gamma) \times \mathbb{R} \) we can argue by induction on the finite set of walls \( \mu' \in V_\gamma \). In particular, we obtain the same rational function \( f_\gamma \) for each wall.

The limit of \( \zeta \)-stability for \( 0 < \mu \ll 1 \) was found to agree with BS stability in Section 5.2 which, together with Section 2, concludes the proof of Theorem 3.

6. Gromov–Witten theory

In this section we assume the GW/PT correspondence holds for \( Y \).
We denote
\[ R = \mathbb{C} \left[ Q, \left( \frac{1}{1 - Q^j} \right)_{j \geq 1} \right] [u^{-1}, u] \]
and
\[ R_a = \{ f \in R : f(Q, u) = Q^a f(Q^{-1}, -u) \}. \]
More explicitly, elements of \( R \) are written as
\[ f(u, Q) = \sum_{h \geq H} f_h(Q) u^h \]
where \( f_h(Q) \) are rational functions of the form
\[ f_h(Q) = \frac{p(Q)}{\prod_j (1 - Q^{a_j})} \]
with \( p(Q) \) a Laurent polynomial. Then \( f \in R_a \) if and only if
\[ Q^a f_h(Q^{-1}) = (-1)^h f_h(Q). \]

**Proposition 44.** Let \( \beta \in H_2(X, \mathbb{Z}) \). Then after the change of variables \( q = e^{iu} \) one has
\[ p^{PT}_\beta(e^{iu}, Q) \in R_{E, \beta}. \]

**Proof.** We prove first that \( p^{PT}_\beta \in R \). By Theorem 1 it holds that
\[ p^{PT}_\beta \in \mathbb{Q} \left[ Q^{\pm 1}, \left( \frac{1}{1 - Q^a Q^b} \right)_{a, b \geq 0} \right]. \]
Since clearly \( Q^{\pm 1}, Q^{\pm 1} \in R \) it suffices to show that \( \frac{1}{1 - q^a Q^b} \in R \), which follows from the following simple computation:
\[ \frac{1}{1 - e^{iau}Q^b} = \sum_{k \geq 0} e^{iku} Q^{kb} = \sum_{k, s \geq 0} u^s \frac{(ia)^s}{s!} k^s Q^{kb} = \sum_{s \geq 0} u^s \frac{(ia)^s}{s!} \text{Li}_{-s}(Q^b). \]
Since for \( s \geq 0 \) the polylogarithm \( \text{Li}_{-s}(Q) \) is a rational function with denominator \( (1 - Q)^{s+1} \) the claim follows.

The rest of the proposition follows from the functional equation part of Theorem 1. We have \( \rho_\beta(jB, n) = ((-j + E \cdot \beta)B, -n) \) by Proposition 17, so
\[ Q^{E \cdot \beta} (p^{PT}_\beta(q^{-1}, Q^{-1})) = p^{PT}_\beta(q, Q). \]
After the change of variables \( q = e^{iu} \) it follows that \( p^{PT}_\beta \in R_{E, \beta}. \) \( \Box \)
Conjecture 45. The proposition above still holds if we replace $R$ by the smaller ring

$$R = \mathbb{C} \left[ Q^{\pm 1}, \frac{1}{1-Q} \right][u^{-1}, u]$$

We now deal with the exceptional part. This requires that we exclude genus 0 and 1 terms. More precisely, define

$$\tilde{\text{PT}}_0(q, Q) = \text{PT}_0(q, Q) \cdot \exp \left( \frac{2}{u^2} \text{Li}_3(Q) + \frac{1}{6} \text{Li}_1(Q) \right).$$

Proposition 46. After the change of variables $q = e^{iu}$ one has

$$\tilde{\text{PT}}_0(e^{iu}, Q) \in R_0.$$

Proof. We have

$$\text{PT}_0(q, Q) = \exp \left( \sum_{k \geq 1} \frac{2(qQ)^k}{k(1-q^k)^2} \right).$$

Writing $c_h$ for the coefficients in the $u$-expansion of

$$\frac{2e^{iu}}{(1-e^{iu})^2} = \sum_{h \geq -2} c_h u^h$$

one has the formula

$$\text{PT}_0(q, Q) = \exp \left( \sum_{h \geq -2} c_h u^h \text{Li}_{1-h}(Q) \right).$$

As easy inspection shows that $c_{-2} = -2$, $c_{-1} = 0 = c_1$ and $c_0 = -1/6$. Thus, the definition of $\tilde{\text{PT}}_0$ removes the first terms in the previous formula and we find that

$$\tilde{\text{PT}}_0(q, Q) = \exp \left( \sum_{h \geq 2} c_h u^h \text{Li}_{1-h}(Q) \right).$$

This concludes the proof since, for $h \geq 2$, $\text{Li}_{1-h}(Q)$ is a rational function with denominator $(1-Q)^h$ and satisfies the symmetry property

$$\text{Li}_{1-h}(Q^{-1}) = (-1)^h \text{Li}_{1-h}(Q).$$

We provide now the proof to Corollary 4. We denote

$$\tilde{\text{PT}}_{\beta}(q, Q) = \text{PT}_{\beta}(q, Q) \cdot \exp \left( \frac{2}{u^2} \text{Li}_3(Q) + \frac{1}{6} \text{Li}_1(Q) \right).$$

By Theorem 3,

$$p^\beta \text{PT}_0(q, Q) \tilde{\text{PT}}_0(q, Q) = \tilde{\text{PT}}_{\beta}(q, Q)$$
so propositions 44 and 46 together imply that \( \tilde{PT}_\beta(q, Q) \in R_{E, \beta} \). Hence the generating function
\[
\sum_{\beta \in N_1} \tilde{PT}_\beta(q, Q) z^\beta
\]
belongs to the ring
\[
R = \left\{ \sum_{\beta \in N_1} f_\beta(q, Q) z^\beta : f_\beta \in R_{E, \beta} \right\}.
\]
Moreover, with the usual change of variable \( q = e^{iu} \), we have
\[
\exp \left( \sum_{(g, \beta) \neq (0,0),(1,0)} u^{2g-2} z^\beta \sum_{j \in \mathbb{Z}} GW_{g, \beta+jB} Q^j \right) = \sum_{\beta \in N_1} \tilde{PT}_\beta(q, Q) z^\beta \in R.
\]
Since \( R \) is a ring, taking the logarithm preserves \( R \), finishing the proof of Corollary 4.

**Appendix A. Local Hirzebruch Surface**

In this appendix we take a closer look at the case of local Hirzebruch surfaces \( K_E \) and we use the topological vertex to compute their enumerative invariants. In particular, we prove the following strengthening of Corollary 4 in the local case:

**Theorem 47.** Let \( Y = K_E \) be a local Hirzebruch surface. For all \( g \in \mathbb{Z}_{\geq 0} \) and \( \beta \in H_2(E) \) such that \((g, \beta) \neq (0, mB), (1, mB)\), the series
\[
\sum_{j \geq 0} GW_{g, \beta+jB} Q^j
\]
is the expansion of a rational function \( f_\beta(Q) \) of the form
\[
f_\beta(Q) = \frac{p_\beta(Q)}{(1 - Q)^{4(B \cdot \beta) + 2g - 2}}
\]
where \( p_\beta \) is a Laurent polynomial. Moreover \( f_\beta \) satisfies the functional equation
\[
f_\beta(Q^{-1}) = Q^{-K_E \cdot \beta} f_\beta(Q).
\]

In the theorem, the intersection products \( B \cdot \beta \) and \( K_E \cdot \beta \) are taken in \( H^* (E) \). The class \( K_E \in H^2(E) \) is
\[
K_E = -2C - (r + 2)B.
\]
Remark 48. The form of the rational function implies that if we fix $k, g, r$ then $\text{GW}_{g,mC+jB}^{K_F}$ is a polynomial in $j$ of degree $4m + 2g - 3$ for large enough $j$. In [16, Equation 5.2] the authors predict the asymptotic behavior for $g = 0$

$$\text{GW}_{g=0,mC+jB}^{K_F} \sim \gamma_m j^{4m-3}$$

for some constant $\gamma_m$ that doesn’t depend on $r$. The independence of $r$ is not difficult to see from our proof.

A.1. Combinatorics of the 2-leg topological vertex. The local Hirzebruch surface $K_E$ is a toric non-compact Calabi–Yau 3-fold, so its Pandharipande–Thomas invariants can be computed via the formalism of the topological vertex. The 2-leg case of the topological vertex admits simple combinatorial expressions, also known as Iqbal’s formula [14, 21, 36, 38]. We now describe such formula.

Given a partition $\mu$, we associate to it the Schur function $s_\mu(x_1, \ldots, x_n)$ (see for example [22, I.3]). An explicit way to define $s_\mu$ is the following:

$$s_\mu = \det (h_{\mu_i-i+j})_{1 \leq i,j \leq N}$$

where $N \geq \ell(\mu)$ and $h_k = h_k(x_1, \ldots, x_n)$ are the complete homogeneous polynomials. We’ll often consider the specialization of $s_\mu$ to the infinite set of variables $x = (1, q, q^2, \ldots)$; in this case the definition above is still valid with

$$h_k(1, q, q^2, \ldots) = \prod_{j=1}^{k} \frac{1}{1-q^j} \text{ for } k \geq 0$$

(if $k < 0$ then $h_k = 0$). An alternative way to write $s_\mu(1, q, Q^2, \ldots)$ is the hook-content product formula

$$s_\mu(1, q, Q^2, \ldots) = q^{n(\mu)} \prod_{\Box \in \mu} \frac{1}{1-q^{h(\Box)}}.$$ 

In the formula above $n(\mu)$ is $\sum_{i=1}^{\ell(\mu)} (i-1)\mu_i$, the product runs over boxes in the Young diagram of $\mu$ and $h(\Box)$ is the hook length of a square $\mu$.

Iqbal introduced $W$ functions for 1 and 2 partitions that play a role in the 1-leg and 2-leg vertex formulas, respectively. For one partition $\mu$, it’s defined as

$$W_\mu(q) = (-1)^{|\mu|} q^{k(\mu)/2+|\mu|^2/2} s_\mu(1, q, Q^2, \ldots).$$

Here

$$k(\mu) = \sum_{i=1}^{\ell(\mu)} \mu_i(\mu_i - 2i + 1) \in \mathbb{Z}.$$
For two partitions $\mu, \nu$ we define

$$W_{\mu\nu}(q) = q^{|\nu|/2} W_{\mu}(q) s_{|\nu|} (q^{\mu_1 - 1}, q^{\mu_2 - 2}, \ldots).$$

Although it’s not apparent from this definition, we have symmetry in the two partitions, i.e. $W_{\mu\nu} = W_{\nu\mu}$ [37, Theorem 5.1].

We can now formulate Iqbal’s formula for the Gromov-Witten invariants of local toric surfaces.

Let $E$ be a toric surface. Let $D_1, D_2, \ldots, D_N, D_{N+1} = D_1$ be the toric divisors in the order they appear in the moment polygon of $E$. Denote $s_j = D_j^2 \in \mathbb{Z}$ the self-intersection numbers.

**Theorem 49** (Theorem 1 in [36]). The partition function for the disconnected Gromov-Witten invariants of $K_E$ is

$$Z_{K_E} = \sum_{\mu_1, \ldots, \mu_N} \prod_{j=1}^N ((-1)^{s_j} |\mu_j| q^{k(\mu_j)} s_{|\mu_j|}/2) W_{\mu_j, \mu_{j+1}}(q) z^{\mu_j} D_j$$

after the change of variables $q = e^{iu}$.

Recall that under the change of variables $q = e^{iu}$ we have

$$Z_{K_E} = PT_{K_E}(q, z) = \sum_{n, \beta} P_{n, \beta}(-q)^n z^\beta.$$

A.2. **Iqbal’s formula for Hirzebruch surfaces.** We specialize theorem 49 to the case of the Hirzebruch surface $E = \mathbb{F}_r$. The homology $H_2(E, \mathbb{Z})$ is generated by two classes $B, C$ where $B$ is the fiber class and $C$ is the class of the section $\mathbb{P}^1 \hookrightarrow C$ with negative self-intersection $C^2 = -r$. The toric divisors of $E$ are

$$D_1 = B = D_3, \quad D_2 = C + rB, \quad D_4 = C.$$ 

We denote by $Q = z^B$ and $Q_C = z^C$ the Novikov variables relative to $B$ and $C$, respectively.

(9) $$Z_{K_E} = \sum_{\mu_1, \ldots, \mu_4} (q^{r(\mu_2 - k(\mu_4))} W_{\mu_1, \mu_2} W_{\mu_2, \mu_3} W_{\mu_3, \mu_4} W_{\mu_4, \mu_1}$$

$$\times ((-1)^r Q_C)^{|\mu_2| + |\mu_4|} Q^{\mu_1 + |\mu_3| + r|\mu_2|})$$

$$= \sum_{m=0}^{\infty} Q_C^m (-1)^{rm} \sum_{|\mu_2| + |\mu_4| = m} \left(q^{r(\mu_2 - k(\mu_4))} Q^{\mu_2}\right)$$

$$\times \left(\sum_{\lambda} W_{\mu_2, \lambda} W_{\mu_4, \lambda} Q^{\lambda}\right)^2.$$
The sum appearing in the last line
\[ S_{\mu\nu}(q, Q) = \sum_{\lambda} W_{\mu\lambda}(q)W_{\nu\lambda}(q)Q^{[\lambda]} \in \mathbb{Q}((q, Q)) \]
adopts a nice closed formula [10, Proposition 1]. We give a proof which is a bit more direct than the one found in [10]. Let
\[ p_{\mu}(q) = \sum_{i=1}^{\infty} q^{\ell_{\mu}(i)} = \frac{q^{-\ell_{\mu}(\lambda)}}{q - 1} + \sum_{i=1}^{\infty} q^{\ell_{\mu}(i)}. \]

**Lemma 50** (Proposition 1 in [10]). For any two partitions \( \mu, \nu \) we have the following identity in \( \mathbb{Q}((q, Q)) \):
\[ (10) \quad S_{\mu\nu} = W_{\mu}W_{\nu} \exp \left( \sum_{k=1}^{\infty} \frac{p_{\mu}(q^k)p_{\nu}(q^k)}{k} \right). \]

**Proof.** Let \( x_{i} = (qQ)^{1/2} q^{\mu_{i} - i}, y_{j} = (qQ)^{1/2} q^{\nu_{j} - j} \). Then
\[ p_{\mu}(q^k) = (qQ)^{-k/2} \sum_{i \geq 1} x_{i}^k = (qQ)^{-k/2} P_k(x), \]
where \( P_k(x) \) is the \( k \)-th power function. For a partition \( \lambda \) let
\[ P_\lambda(x) = \prod P_{\lambda_{i}}(x), \quad m_k = \# \{ i : \lambda_{i} = k \}, \quad z_\lambda = \prod k^{m_k} m_k!. \]
By expanding the exponential and cancelling \( W_{\mu}W_{\nu} \) on both sides, using
\[ W_{\mu\lambda} = q^{[\lambda]/2} W_{\nu}s_{\lambda}(q^{\mu_{1} - 1}, q^{\mu_{2} - 2}, \ldots), \]
we’re left to show
\[ \sum_{\lambda} (qQ)^{[\lambda]} s_{\lambda}(q^{\mu_{1} - 1}, q^{\mu_{2} - 2}, \ldots)s_{\lambda}(q^{\nu_{1} - 1}, q^{\nu_{2} - 2}, \ldots) \]
\[ = \sum_{\lambda} \prod_{k=1}^{\ell(\lambda)} m_k! \left( \frac{P_k(x)P_k(y)}{k} \right)^{m_k}. \]
By the Cauchy identity [22, Eq. 4.3] the LHS is
\[ \prod_{i,j \geq 1} \frac{1}{1 - x_{i}y_{j}}; \]
and the RHS is
\[ \sum_{\lambda} z_{\lambda}^{-1} P_\lambda(x)P_\lambda(y). \]
The two sides agree [22, Eq. 4.1, 4.3]. □
A.3. **Rationality of** $\text{PT}_\beta/\text{PT}_0$. We give now a quick proof of our main rationality statement 1 in the local case based on our computations. Equation (10) can also be written as an infinite product formula in the following way. If we write

$$p_\mu(q)p_\nu(q) = \sum_{i=-s}^s a_i q^i \frac{1}{(1-q)^2}$$

then

$$S_{\mu\nu} = W_\mu W_\nu \prod_{i=-s}^s \left( \prod_{j \geq 1} (1-q^{i+j}Q)^{-j} \right)^a_i.$$ 

Note in particular that taking the constant $Q_0^0$ coefficient in equation (9) we find

$$\text{PT}_0(q,Q) = \left[ Q_0^0 \right] Z_{KE} = S_{00}^2 = \prod_{j \geq 1} (1-q^jQ)^{-2j}.$$ 

Since $W_\mu, W_\nu \in \mathbb{Q}(q)$ and

$$\sum_{i=-s}^s a_i = 1 \text{ and } \sum_{i=-s}^s ia_i = 0$$

one can see that

$$\frac{S_{\mu\nu}}{S_{00}} \in \mathbb{Q}(q,Q).$$

Together with (9) it follows that

$$\frac{\text{PT}_{mC}(q,Q)}{\text{PT}_0(q,Q)} = \left[ Q_0^m \right] \frac{Z_{KE}}{S_{00}^2} \in \mathbb{Q}(q,Q).$$

A.4. **Proof of theorem 47.** We give the proof of theorem 47 based on the application of Iqbal’s formula (9). We first remark that it’s enough to prove the result when $\beta = jC$ for some $j \geq 0$. Indeed, if $\beta' = \beta + kB$ then the corresponding generating functions are related by multiplication by $Q^{-k}$ and

$$B \cdot \beta' = B \cdot \beta, \quad -K_E \cdot \beta' = -K_E \cdot \beta + 2k.$$ 

We define a refinement $R_{a,b} \subseteq R_a$ of the sets introduced in section 6. Elements of $R_{a,b}$ are Laurent series of the form

$$f(Q,u) = \sum_{h \geq H} f_h(Q) u^h$$

such that $f_h(Q)$ take the form

$$f_h(Q) = \frac{p(Q)}{(1-Q)^{b+h}}$$
and satisfy
\[ Q^a f_h(Q^{-1}) = (-1)^h f_h(Q). \]
For a Laurent series \( f(q, Q) \) in variables \( q, Q \) we say that \( f \in R_{a,b} \) if it’s in \( R_{a,b} \) after the change of variables \( q = e^{iu} \). We’re required to show that
\[ \tilde{PT}_{jC}(q, Q) \in R_{2j,(r+2)j} \]
(see section 6 for the definition of \( \tilde{PT} \)).

We consider the \( u \)-expansion of the series
\[ p_{\mu}(e^{iu})p_{\nu}(e^{iu})e^{iu} = \sum_{n=-2}^{\infty} c_{n}^{\mu\nu} u^n. \]
The first few terms of the expansion are easily computed:
\[ p_{\mu}(e^{iu})p_{\nu}(e^{iu})e^{iu} = -u^{-2} + \left( |\mu| + |\nu| - \frac{1}{12} \right) + \frac{iu}{2} (k(\mu) + k(\nu)) + O(u^2). \]
Plugging the expansion into equation (10) we get
\[ S_{\mu\nu} = \mathcal{W}_{\mu} \mathcal{W}_{\nu} \exp \left( \sum_{n=-2}^{\infty} c_{n}^{\mu\nu} u^n \text{Li}_{1-n}(Q) \right). \]
Defining now the modification
\[ \tilde{S}_{\mu\nu} = S_{\mu\nu} \exp \left( \frac{1}{u^2} \text{Li}_3(Q) + \frac{1}{12} \text{Li}_1(Q) \right) \]
we have the formula
\[ \tilde{S}_{\mu\nu} = (1 - Q)^{-2(|\mu| + |\nu|)} \tilde{\mathcal{W}}_{\mu} \tilde{\mathcal{W}}_{\nu} \exp \left( \frac{iu}{4} (k(\mu) + k(\nu))^2 \frac{1 + Q}{1 - Q} \right) \]
\[ \times \exp \left( \sum_{n=2}^{\infty} c_{n}^{\mu\nu} u^n \text{Li}_{1-n}(Q) \right). \]
where
\[ \tilde{\mathcal{W}}_{\mu}(q) = q^{-\frac{2|\mu|}{Q}} \mathcal{W}_{\mu}(q) = \exp \left( \frac{iu}{4} k(\mu) \right) \mathcal{W}_{\mu}(q). \]
We used the identities
\[ \text{Li}_1(Q) = - \log(1 - Q) \text{ and } \text{Li}_0(Q) = \frac{Q}{1 - Q}. \]
For \( n \geq 2 \), \( \text{Li}_{1-n}(Q) \) is a rational function with denominator \( (1 - Q)^n \) and satisfies the symmetry property
\[ \text{Li}_{1-n}(Q^{-1}) = (-1)^n \text{Li}_{1-n}(Q). \]
Moreover, \( \tilde{\mathcal{W}} \) satisfies \( \tilde{\mathcal{W}}(q) = \tilde{\mathcal{W}}(1/q) \) (see [37, Proposition 5.1]) so we have, for \( m = |\mu| + |\nu| \),
\[ \tilde{S}_{\mu\nu} \in R_{2m,2m}. \]
We can now easily finish the proof of Theorem 47. From (9) we have
\[
\tilde{PT}_m C(q, Q) = (-1)^{rm} \sum_{|\mu_2| + |\mu_4| = m} \left( q^{r(k(\mu_2) - k(\mu_4))} Q^{r|\mu_2|} \tilde{S}^{r|\mu_2\mu_4|} \right).
\]
We pair the \((\mu_2, \mu_4)\) and \((\mu_4, \mu_2)\) terms and note that
\[
q^{r(k(\mu_2) - k(\mu_4))} Q^{r|\mu_2|} + q^{r(k(\mu_4) - k(\mu_2))} Q^{r|\mu_4|} \in R_{0, rm}
\]
so
\[
PT_m C(q, Q) \in R_{2m, (r+2)m}.
\]
