On Azadkia–Chatterjee’s conditional dependence coefficient

Hongjian Shi∗, Mathias Drton† and Fang Han‡.

Abstract

In recent work, Azadkia and Chatterjee laid out an ingenious approach to defining consistent measures of conditional dependence. Their fully nonparametric approach forms statistics based on ranks and nearest neighbor graphs. The appealing nonparametric consistency of the resulting conditional dependence measure and the associated empirical conditional dependence coefficient has quickly prompted follow-up work that seeks to study its statistical efficiency. In this paper, we take up the framework of conditional randomization tests (CRT) for conditional independence and conduct a power analysis that considers two types of local alternatives, namely, parametric quadratic mean differentiable alternatives and nonparametric Hölder smooth alternatives. Our local power analysis shows that conditional independence tests using the Azadkia–Chatterjee coefficient remain inefficient even when aided with the CRT framework, and serves as motivation to develop variants of the approach; cf. Lin and Han (2021). As a byproduct, we resolve a conjecture of Azadkia and Chatterjee by proving central limit theorems for the considered conditional dependence coefficients, with explicit formulas for the asymptotic variances.

Keywords: conditional independence, graph-based test, rank-based test, nearest neighbor graphs, local power analysis.

1 Introduction

Conditional (in)dependence is a fundamental statistical concept that plays a central role in statistical inference and theory (Dawid, 1979, 1980). Testing conditional independence is nowadays a routine task in graphical modeling (Maathuis et al., 2019), causal discovery (Peters et al., 2017), feature selection (Koller and Sahami, 1996), and many other statistical applications. Formally, the problem of interest is to test for three random vectors \( X, Y, Z \) the hypothesis

\[
H_0: Y \text{ and } Z \text{ are conditionally independent given } X, \tag{1.1}
\]

based on a finite sample of size \( n \) from the joint distribution of \( (X, Y, Z) \). It is customary to denote the conditional independence by \( Y \perp \perp Z \mid X \).

In contrast to the discrete/categorical case or favorable parametric settings such as multivariate normality, the general problem of testing (1.1) when \( X \) is continuous is a remarkably challenging task (Bergsma, 2004; Shah and Peters, 2020; Neykov et al., 2021). A number of attempts have been

made to provide nonparametric solutions, and notable examples include Linton and Gozalo (1996) (on conditional cumulative distribution functions); Su and White (2007, 2008, 2014) (on conditional characteristic functions, conditional probability density functions, and smoothed empirical likelihood ratios, respectively); Huang (2010) (on maximal nonlinear conditional correlation); Fukumizu et al. (2008), Zhang et al. (2011), Doran et al. (2014), and Strobl et al. (2019) (on kernel-based conditional dependence); Póczos and Schneider (2012) and Runge (2018) (on conditional mutual information); Székely and Rizzo (2014) and Wang et al. (2015) (on conditional distance correlation); Song (2009) and Cai et al. (2021) (based on Rosenblatt transformation); Bergsma (2004, 2011) and Veraverbeke et al. (2011) (copula-based); Hoyer et al. (2009), Peters et al. (2011), Shah and Peters (2020), and Petersen and Hansen (2021) (regression-based); Canonne et al. (2018) and Neykov et al. (2021) (binning-based).

For the important special case where $Y$ is a random scalar (and hence denoted in regular font by $Y$), Azadkia and Chatterjee (2021) introduced a novel and rather different conditional dependence measure whose estimate ingeniously combines ideas from rank statistics, nearest neighbor graphs and associated minimum spanning trees for data sets. The dependence measure and estimate were shown to possess the following four appealing properties:

1. the conditional dependence measure takes values in $[0, 1]$, is 0 if and only if $Y \perp \perp Z \mid X$, and is 1 if and only if $Y$ is almost surely (a.s.) equal to a measurable function of $Z$ given $X$;
2. the estimate has a simple expression and can be computed in $O(n \log n)$ time;
3. the estimate is fully nonparametric and has no tuning parameter;
4. the estimate is consistent as long as $Y$ is not a.s. equal to a measurable function of $X$.

The new approach has quickly caught attention. First follow-up work studies extensions to topological spaces and multidimensional $Y$ and explores connections to general random graphs; see Deb et al. (2020) and Huang et al. (2020). Moreover, for the case of unconditional dependence, analyses were conducted to better understand the statistical power of the approach. These analyses treat the very closely related coefficient presented by Chatterjee (2021); see Cao and Bickel (2020), Shi et al. (2021b), and Auddy et al. (2021).

In this paper, we study the statistical efficiency of Azadkia–Chatterjee’s conditional dependence coefficient in testing the hypothesis of conditional independence from (1.1). Azadkia and Chatterjee (2021) themselves did not pursue using their coefficient for inferential problems such as testing. To implement a test, we employ the conditional randomization test (CRT) framework developed in Candès et al. (2018a); see Berrett et al. (2020) for a related proposal. The CRT framework, which was also adopted in Huang et al. (2020, Section 6.1.3), assumes that the conditional distribution of $Y$ given $X$ is known, and thus the null distribution of any conditional dependence coefficient can be approximated by simulation.

Local power analyses for tests rely on a choice of local alternatives. In the context of this paper, an important subtlety lies in the fact that in order to be relevant for a CRT-based Azadkia–Chatterjee-type test, the conditional distribution of $Y$ given $X$ should be identical between the null and local alternatives. Two such families of local alternatives are considered in this manuscript:

(a) the joint density of $(X, Y, Z)$ in the alternative is assumed to be “smoothly” changing to the null in the sense of quadratic mean differentiability (Lehmann and Romano, 2005, Definition 12.2.1). This is akin to parametric settings, and such families of local alternatives have
been explored in studies of rank- and graph-based tests in related statistical problems \cite{Bhattacharya2019, CaoBickel2020, Shi2020}. The critical detection boundary in such cases is known to be at root-$n$;

(b) the conditional distribution of $(Y, Z)$ given $X$ is assumed to be Hölder smoothly changing with regard to $X$. This is akin to nonparametric settings, and the case we will consider is an extension of the one that has been examined by Neykov et al. \cite{Neykov2021}. There, as $X, Y, Z$ are all random scalars, the critical detection boundary is $n^{-2s/(4s+3)}$, where $s$ denotes the Hölder smoothness exponent.

The local power analyses we report on in this manuscript provide, in both of the above scenarios, examples that show that the CRT-based Azadkia–Chatterjee-type test is unfortunately unable to achieve the critical detection boundary, i.e., the sum of type-I and type-II errors will not decrease to zero along the boundary. We emphasize here that the power of CRT-based Azadkia–Chatterjee-type test cannot simply be boosted to achieve the detection boundary by using the additional information coming from the CRT framework, in view of the Hájek representation theorem; compare Equation (S4) in Shi et al. \cite{Shi2021c}. Our theoretical analysis thus echoes the empirical observations made in Huang et al. \cite{Huang2020} and calls for developing new variants of the tests that use an increasing number of nearest neighbors when constructing the nearest neighbor graphs; see Bhattacharya \cite{Bhattacharya2019, Deb2020}, and in particular, a recent preprint by Lin and Han \cite{Lin2021} on boosting the power of Chatterjee’s original proposal which however cannot be directly applied to multidimensional cases. These conclusions are also connected to related claims made by Stone \cite{Stone1977, BiauDevroye2015}, and Berrett et al. \cite{Berrett2019, Theorems1and2} in other settings of nonparametric statistics.

Our local power analysis in Case (a) is built on the innovative new work of Deb et al. \cite{Deb2020}, who developed a general framework to study normalized graph-based dependence measures (combined with rank- and kernel-based ones) that invokes a Berry–Esseen theorem for dependency graphs \cite{ChenShao2004}. In order to complete our analysis of the local power, however, an additional ingredient is needed, namely, we have to prove the existence as well as calculate the asymptotic variance of the (unnormalized) Azadkia–Chatterjee conditional dependence coefficient. To obtain this crucial result we use asymptotic techniques devised for 1-nearest neighbor graphs in Henze \cite{Henze1987} and Devroye \cite{Devroye1988}. This part of our derivations shall occupy the main body of the proofs of our local power results. Our analysis covers as a special instance the case of full independence and, thus, resolves a conjecture of Azadkia and Chatterjee \cite{AzadkiaChatterjee2021} about a central limit theorem (CLT) for their statistic under full independence; see Section 3 ahead for details.

Our local power analysis in Case (b), on the other hand, is based on a brute-force calculation of the mean and variance of the Azadkia–Chatterjee conditional dependence coefficient along a special non-standard local alternative sequence that serves as the “worst case” in the minimax lower bound construction of Neykov et al. \cite{Neykov2021}. This involves handling permutation statistics for which permutation randomness is not (though close to) uniform over all possible rearrangements, a notoriously difficult task. Interestingly, in a very recent preprint, Auddy et al. \cite{Auddy2021} did related calculations in analyzing the local power of Chatterjee’s rank correlation coefficient \cite{Chatterjee2021} against a different family of non-standard local alternative sequences; see the proof of their Theorem 2.1. It appears, though, that the techniques used are substantially different from the ones present here, which of course also differs through the focus on conditional (in-)dependence.
The rest of the paper is organized as follows. Section 2 reviews the conditional dependence coefficient proposed by Azadkia and Chatterjee (2021), denoted $\xi_n$, as well as the conditional randomization test framework proposed by Candès et al. (2018a). Section 3 presents the asymptotic normality of $\xi_n$ under independence. Local power analyses of CRTs based on $\xi_n$, in the two cases of alternatives are presented in Section 4 and Section 5, respectively. A brief conclusion is provided in Section 6. The main proofs are given in Section 7, with auxiliary results and proofs of intermediate results deferred to the appendix.

Notation. For an integer $n \geq 1$, let $[n] := \{1, 2, \ldots, n\}$. A set consisting of distinct elements $x_1, \ldots, x_n$ is written as either $\{x_1, \ldots, x_n\}$ or $\{x_i\}_{i=1}^n$. The corresponding sequence is denoted $[x_1, \ldots, x_n]$ or $[x_i]_{i=1}^n$. For a sequence of vectors $v_1, \ldots, v_k$, we use $(v_1, \ldots, v_k)$ as a shorthand for $(v_1^\top, \ldots, v_k^\top)^\top$. For a vector $v \in \mathbb{R}^d$, $\|v\|$ stands for the Euclidean norm. The symbols $\lfloor \cdot \rfloor$ and $\lceil \cdot \rceil$ denote the floor and ceiling functions, respectively. The notation $1(\cdot)$ is used for the indicator function. For any real-valued random vectors $U$ and $V$, the (induced) probability measure, cumulative distribution function, and the probability density function of $U$ (if existing) are denoted as $P_U$, $F_U$, and $q_U$, respectively; the conditional probability density function of $U$ given $V$ (if existing) is written as $q_{U \mid V}$. In the following, the terms “absolutely continuous” and “almost everywhere” (shorthanded as “a.e.”) are with respect to the Lebesgue measure.

2 Conditional dependence measures and tests

In the sequel, let $Y \in \mathbb{R}$ be a random scalar, and let $X \in \mathbb{R}^p$ and $Z \in \mathbb{R}^q$ be two random vectors, all defined on the same probability space. The goal is to test (1.1) based on observations $(X_1, Y_1, Z_1), \ldots, (X_n, Y_n, Z_n)$ that consist of $n$ independent copies of the triple $(X, Y, Z)$. Note that the joint distribution of $(X, Y, Z)$ need not be continuous.

2.1 Conditional dependence measures and coefficients

Azadkia and Chatterjee (2021) proposed the following measure of conditional dependence between $Y$ and $Z$ given $X$:

$$
\xi = \xi(Y, Z \mid X) := \frac{\int \mathbb{E}[\text{Var}\{P(Y \geq y \mid X, Z) \mid X\}] \text{d}P_Y(y)}{\int \mathbb{E}[\text{Var}\{1(Y \geq y) \mid X\}] \text{d}P_Y(y)}.
$$

The following proposition describes the appealing properties we pointed out in the introduction.

Proposition 2.1. (Azadkia and Chatterjee, 2021, Theorem 2.1) Suppose that $Y$ is not a.s. equal to a measurable function of $X$. Then $\xi$ is well-defined and belongs to the interval $[0, 1]$. Moreover, $\xi$ is a consistent measure of conditional dependence with tailored extremal properties in the sense that $\xi = 0$ if and only if $Y$ and $Z$ are conditionally independent given $X$, and $\xi = 1$ if and only if $Y$ is a.s. equal to a measurable function of $Z$ given $X$.

The dependence measure $\xi$ clearly extends an earlier introduced measure of marginal dependence.
between \(Y\) and (a random scalar) \(Z\), namely,

\[
\xi_{\text{DSS}} = \xi_{\text{DSS}}(Y, Z) := \frac{\int \text{Var} \{ \mathbb{P}(Y \geq y \mid Z) \} \, d\mathbb{P}_Y(y)}{\int \text{Var} \{ \mathbb{1}(Y \geq y) \} \, d\mathbb{P}_Y(y)},
\]

which Dette et al. (2013) introduced for continuous distributions and Chatterjee (2021) considered in general. The quantities \(\xi\) and \(\xi_{\text{DSS}}\) share similar properties: (i) the consistency in measuring dependence is natural as the numerator (a nonnegative scalar) is zero if and only if either \(Y\) is independent of \(Z\) (for \(\xi_{\text{DSS}}\)), or \(Y\) is independent of \(Z\) given \(X\) (for \(\xi\)); (ii) the self-normalization structure yields tailored extremal properties as the numerator is always upper bounded by the denominator; (iii) both the numerator and the denominator involve the indicator \(\mathbb{1}(Y \geq y)\), which motivates estimation using the ranks of the \(Y_i\)'s and their regression on the \(Z_i\)'s or \((X_i, Z_i)\) to account for the conditioning in each term.

Both Chatterjee (2021) and Azadkia and Chatterjee (2021) advocate a 1-nearest neighbor (1-NN) approach to performing the aforementioned regression; note that in one dimension 1-NN is obviously corresponding to working with ranks. In detail, let

\[
R_i := \sum_{j=1}^n \mathbb{1}(Y_j \leq Y_i)
\]

be the rank of \(Y_i\) among \(Y_1, \ldots, Y_n\), and define

\[
N(i) := \{ j \neq i : X_j \text{ is the nearest neighbor of } X_i \},
\]

\[
M(i) := \{ j \neq i : (X_j, Z_j) \text{ is the nearest neighbor of } (X_i, Z_i) \},
\]

to be the indices of the nearest neighbors of \(X_i\) and \((X_i, Z_i)\), respectively. Here, nearest neighbors are determined by Euclidean distance and possible ties in distance are broken at random. Azadkia and Chatterjee’s conditional dependence coefficient is then defined as

\[
\xi_n = \xi_n\left( [(X_i, Y_i, Z_i)]_{i=1}^n \right) := \frac{\sum_{i=1}^n \min(R_i, R_{M(i)}) - \min(R_i, R_{N(i)})}{\sum_{i=1}^n \{R_i - \min(R_i, R_{N(i)})\}}.
\]

Although not at all immediate at first sight, Azadkia and Chatterjee (2021) showed that \(\xi_n\) is a strongly consistent estimator of \(\xi\) as long as the latter is well-defined. We summarize the fact in the following proposition.

**Proposition 2.2.** (Azadkia and Chatterjee, 2021, Theorem 2.2) As long as \(Y\) is not a.s. equal to a measurable function of \(X\), it holds that \(\xi_n\) converges to \(\xi\) a.s. as \(n \to \infty\).

**Remark 2.1.** The intuition behind the convergence is by no means transparent. We refer the readers of interest to Chatterjee (2021, Section 8) and the following heuristic arguments:

\[
R_1 - \min(R_1, R_{N(1)}) \approx F_Y(Y_1) - \min\{F_Y(Y_1), F_Y(Y_{N(1)})\}
\]

\[
= \int \left\{ \mathbb{1}(Y_1 \geq t) - \mathbb{1}(Y_1 \geq t) \mathbb{1}(Y_{N(1)} \geq t) \right\} \, d\mathbb{P}_Y(t)
\]

\[
\approx \frac{1}{2} \int \left\{ \mathbb{1}(Y_1 \geq t) - \mathbb{1}(Y_{N(1)} \geq t) \right\}^2 \, d\mathbb{P}_Y(t),
\]

with

\[
\mathbb{E}\{\mathbb{1}(Y_1 \geq t) - \mathbb{1}(Y_{N(1)} \geq t)^2 \approx 2\mathbb{E}[\text{Var}\{\mathbb{1}(Y_1 \geq t) \mid X_1]\}.
\]
Next we introduce the conditional randomization test (CRT) framework of Candès et al. (2018a). This framework is designed for settings where the conditional distribution of $Y$ given $X$ is known or can be accurately inferred from a large out-of-sample data set. See also Berrett et al. (2020, Section 2.2) for an illustration of application scenarios of this framework. In the sequel, we use $Q \equiv Q(\cdot|X)$ to denote the Markov kernel used in the algorithm implementing the test of conditional independence. Ideally, $Q$ is (very close to) the conditional distribution of $Y$ given $X = x$.

The CRT framework leverages that under $H_0$ the conditional distribution of $Y$ given $(X, Z)$ is the same as that of $Y$ given $X$. This yields the following observation: if $Q$ equals the conditional distribution of $Y$ given $X = x$ and $Y^{(1)}$ is drawn independently from $Q(\cdot|X)$, then the two triples $(X, Y, Z)$ and $(X, Y^{(1)}, Z)$ are equal in distribution under $H_0$. In contrast, any difference between the distributions of $(X, Y, Z)$ and $(X, Y^{(1)}, Z)$ will manifest itself as evidence against $H_0$.

To make the idea practical, consider a real-valued test statistic $\psi_n$ defined on the range of $[(X_i, Y_i, Z_i)]_{i=1}^n$. Let $B$ be a chosen number of Monte Carlo simulations. Then in each round $b \in [B]$, one independently draws a new copy $Y_i^{(b)}$ from $Q(\cdot|X_i)$ for $i \in [n]$, and calculates $\psi_n\left(\left[(X_i, Y_i^{(b)}, Z_i)\right]_{i=1}^n\right)$. The CRT then examines the difference between the distributions of $(X, Y, Z)$ and $(X, Y^{(1)}, Z)$ by comparing the observed test statistic $\psi_n\left(\left[(X_i, Y_i, Z_i)\right]_{i=1}^n\right)$ to the simulated values $\psi_n\left(\left[(X_i, Y_i^{(b)}, Z_i)\right]_{i=1}^n\right)$. The procedure is detailed in Algorithm 1.

### Algorithm 1: Conditional randomization test (CRT)

**Input:** Data $[(X_i, Y_i, Z_i)]_{i=1}^n$, the chosen conditional distribution $Q$, test statistic $\psi_n$, number of simulations $B$, and significance level $\alpha \in (0, 1)$.

**for** $b = 1, \ldots, B$ **do**

Draw a sample $[Y_i^{(b)}]_{i=1}^n$ from the product distribution $\bigotimes_{i=1}^n Q(\cdot|X_i)$, independent of the observed $[(Y_i, Z_i)]_{i=1}^n$ and conditionally on $[X_i]_{i=1}^n$.

**end**

**Output:** CRT $p$-value defined as

$$p_{CRT} = (1 + B)^{-1}\left[1 + \sum_{b=1}^B 1\{\psi_n\left(\left[(X_i, Y_i^{(b)}, Z_i)\right]_{i=1}^n\right) \geq \psi_n\left(\left[(X_i, Y_i, Z_i)\right]_{i=1}^n\right)\}\right].$$

The CRT is then

$$T_{\alpha}^{\psi_n}\left(\left[(X_i, Y_i, Z_i)\right]_{i=1}^n\right) = 1(p_{CRT} \leq \alpha).$$

Here the last step is intrinsically performed using a 1-NN regression.

### 2.2 Conditional randomization tests

Next we introduce the conditional randomization test (CRT) framework of Candès et al. (2018a). This framework is designed for settings where the conditional distribution of $Y$ given $X$ is known or can be accurately inferred from a large out-of-sample data set. See also Berrett et al. (2020, Section 2.2) for an illustration of application scenarios of this framework. In the sequel, we use $Q \equiv Q(\cdot|X)$ to denote the Markov kernel used in the algorithm implementing the test of conditional independence. Ideally, $Q$ is (very close to) the conditional distribution of $Y$ given $X = x$.

The CRT framework leverages that under $H_0$ the conditional distribution of $Y$ given $(X, Z)$ is the same as that of $Y$ given $X$. This yields the following observation: if $Q$ equals the conditional distribution of $Y$ given $X = x$ and $Y^{(1)}$ is drawn independently from $Q(\cdot|X)$, then the two triples $(X, Y, Z)$ and $(X, Y^{(1)}, Z)$ are equal in distribution under $H_0$. In contrast, any difference between the distributions of $(X, Y, Z)$ and $(X, Y^{(1)}, Z)$ will manifest itself as evidence against $H_0$.

To make the idea practical, consider a real-valued test statistic $\psi_n$ defined on the range of $[(X_i, Y_i, Z_i)]_{i=1}^n$. Let $B$ be a chosen number of Monte Carlo simulations. Then in each round $b \in [B]$, one independently draws a new copy $Y_i^{(b)}$ from $Q(\cdot|X_i)$ for $i \in [n]$, and calculates $\psi_n\left(\left[(X_i, Y_i^{(b)}, Z_i)\right]_{i=1}^n\right)$. The CRT then examines the difference between the distributions of $(X, Y, Z)$ and $(X, Y^{(1)}, Z)$ by comparing the observed test statistic $\psi_n\left(\left[(X_i, Y_i, Z_i)\right]_{i=1}^n\right)$ to the simulated values $\psi_n\left(\left[(X_i, Y_i^{(b)}, Z_i)\right]_{i=1}^n\right)$. The procedure is detailed in Algorithm 1.

### 2.3 CRT using the Azadkia–Chatterjee coefficient

We will be concerned with the CRT that is obtained by taking the test statistic $\psi_n$ in Algorithm 1 to be $\xi_n$, the Azadkia–Chatterjee conditional dependence coefficient. The resulting test for significance
level \( \alpha \) is denoted by \( T_\alpha^{Q,\xi_n} \); here \( Q \) is added to highlight the dependence of the implementation on the chosen conditional distribution \( Q \).

**Remark 2.2.** Berrett et al. (2020, Section 2.2) argue that in many cases the unlabeled data, i.e., data on \((X, Y)\) but without the \( Z \) component, are plentiful, but labeled data on \((X, Y, Z)\) jointly are scarce. In such cases, it is natural to assume that one not only knows (or may very accurately estimate) the needed conditional distribution but also the joint distribution of \((X, Y)\). When the distribution of \((X, Y)\) is known, the only term to be estimated from data is the numerator in (2.1); the denominator in (2.1) only depends on the distribution of \((X, Y)\).

However, we would like to emphasize that, in view of the Hájek representation theorem as given in Equation (S4) in Shi et al. (2021c), replacing each \( R_i \) by \( nF_Y(Y_i) \) in \( \xi_n \) will not result in an (asymptotic) improvement of \( \xi_n \). In detail, although it is tempting to define an “oracle version” of \( \xi_n \) that uses more information as

\[
\bar{\xi}_n = \xi_n \left( \left( \left[ X_i, Y_i, Z_i \right] \right)_{i=1}^n \right) := \frac{n^{-1} \sum_{i=1}^n \left[ \min\{F_Y(Y_i), F_Y(Y_M(i))\} - \min\{F_Y(Y_i), F_Y(Y_N(i))\} \right]}{\int E[\var{1(Y \geq y) | X}] dP_Y(y)},
\]

this change will not increase the CRT’s power (asymptotically), at least in all settings considered in this paper.

Later, in Sections 4–5, we shall study in detail the test based on \( \xi_n \). However, some preliminary results deserve to be documented first. In the following, let \( P_Q \) be the family of all joint distributions for \((X, Y, Z)\) such that \( Y \) is not a.s. equal to a measurable function of \( X \) and the conditional distribution of \( Y \) given \( X = x \) coincides with a given (non-trivial) Markov kernel \( Q \).

**Proposition 2.3 (Control of size and consistency).** Fix a Markov kernel \( Q \) for \( Y \) given \( X \).

(i) The test \( T_\alpha^{Q,\xi_n} \) is valid in the sense that for any \( P_{(X,Y,Z)} \in P_Q \) satisfying \( H_0 \), denoting \( P_{H_0} := P_{(X,Y,Z)}^{\otimes n} \) as the corresponding product measure, it holds for any \( n \geq 1 \) that

\[
P_{H_0}(T_\alpha^{Q,\xi_n} = 1) \leq \alpha;
\]

notice that no assumption concerning the number of simulations \( B \) is required at all.

(ii) In addition, \( T_\alpha^{Q,\xi_n} \) is consistent in the sense that for any \( P\) \((X, Y, Z) \in P_Q \) violating \( H_0 \), denoting \( P_{H_1} \) as the corresponding product measure, we have

\[
\lim_{n \to \infty} P_{H_1}(T_\alpha^{Q,\xi_n} = 1) = 1
\]

as long as the number of simulations \( B \) tends to infinity as \( n \to \infty \).

### 3 Asymptotic normality under independence

In this section we consider the asymptotic behavior of \( \xi_n \) under independence of \( Y \) and \((X, Z)\), which constitutes a special subfamily of the conditional independence hypothesis \( H_0 \) that our subsequent theoretic analysis shall be built on. In this (unconditional) independence scenario we then consider the coefficient \( \xi_n \) from Section 2 as well as a variant introduced in Azadkia and Chatterjee (2021).

In detail, Azadkia and Chatterjee (2021) also examined the case when \( p = 0 \), i.e., \( X \) has no component. In this case, the conditional dependence measure \( \xi \) from (2.1) reduces to the unconditional
dependence measure defined analogous to $\xi_{DSS}^{\text{DSS}}$ from (2.2); here the dimension of $Z$ is not necessarily one. They then introduced the following coefficient $\xi_n^\#$, which extends the original proposal of Chatterjee (2021, Eqn. (1)) to higher dimension $q \geq 1$:

$$\xi_n^\# := \frac{\sum_{i=1}^n \{n \min(R_i, R_{M(i)}) - L_i^2\}}{\sum_{i=1}^n L_i(n - L_i)},$$  \quad (3.1)$$

Here $R_i$ and $M(i)$ are defined in (2.3) and (2.4), respectively, with the understanding that $X$’s part in (2.4) is removed since it is of no component, and $L_i := \sum_{j=1}^n 1(Y_j \geq Y_i)$.

Azadkia and Chatterjee (2021) conjectured that under independence between $Y$ and $Z$, $\sqrt{n}\xi_n^\#$ obeys a CLT. Building on results of Deb et al. (2020), we are able to derive the following theorem that, in particular, gives an affirmative answer to this conjecture under (absolute) continuity.

**Theorem 3.1** (Asymptotic normality).

(i) Assume that $Y \in \mathbb{R}$ is continuous and independent of $(X, Z) \in \mathbb{R}^{p+q}$. In addition, assume $(X, Z)$ is absolutely continuous admitting a density continuous over its support. We then have as, $n \to \infty$,

$$\sqrt{n}\xi_n \xrightarrow{d} N\left(0, \frac{4}{5} + \frac{2}{5} q_{p+q} + q_p \right),$$

where for any integer $d \geq 1$, $q_d$ and $o_d$ are positive constants depending only on $d$. Their values are

$$q_d := \left\{2 - \frac{1}{3} \left(\frac{d + 1}{2}, \frac{1}{2}\right)^{-1}\right\}, \quad I_x(a, b) := \frac{x^a e^{-1}(1 - t)^{b-1}dt}{\int_0^1 t^{a-1}(1 - t)^{b-1}dt},$$

$$o_d := \int_{\Gamma_{d,2}} \exp \left[-\lambda \left\{ B(w_1, \|w_1\|) \cup B(w_2, \|w_2\|) \right\} \right] d(w_1, w_2),$$

$$\Gamma_{d,2} := \left\{ (w_1, w_2) \in (\mathbb{R}^d)^2 : \max(\|w_1\|, \|w_2\|) < \|w_1 - w_2\| \right\},$$

where $B(w_1, r)$ is the ball of radius $r$ centered at $w_1$, and $\lambda(\cdot)$ is the Lebesgue measure.

(ii) Assume $Y \in \mathbb{R}$ is continuous and independent of $Z \in \mathbb{R}^q$. In addition, assume $Z$ is absolutely continuous. We then have as, $n \to \infty$,

$$\sqrt{n}\xi_n^\# \xrightarrow{d} N\left(0, \frac{2}{5} + \frac{2}{5} q + \frac{4}{5} o_q \right).$$

**Remark 3.1.** The asymptotic variance of $\sqrt{n}\xi_n$ (or $\sqrt{n}\xi_n^\#$) under independence between $Y$ and $(X, Z)$ (or $Z$) is seen to be distribution-free, i.e., its value will not change with the particular distribution of $P_{(X,Y,Z)}$ as long as the (absolute) continuity conditions in Theorem 3.1 hold. This (asymptotic) distribution-freeness is in line with similar observations made earlier for related problems such as two-sample goodness-of-fit tests, where Friedman and Rafsky (1979) extended Wald and Wolfowitz (1940)’s rank-based run test to multivariate spaces via minimum spanning trees; see, also, Henze (1988), Liu and Singh (1993), Henze and Penrose (1999), and Bhattacharya (2019) for other notable results along that track.

**Remark 3.2.** It may be interesting to note that the asymptotic variance of $\sqrt{n}\xi_n^\#$ is strictly larger than $2/5$, the asymptotic variance of the rank correlation from Equation (1) in Chatterjee (2021). However, this observation should not be interpreted as an advantage of Chatterjee’s rank correlation
over $\sqrt{n}\xi_n^\#$ in terms of statistical efficiency. As a matter of fact, both are powerless when used for testing independence; cf. Shi et al. (2021b, Theorem 1) and Theorem 4.1 ahead.

**Remark 3.3.** In order to derive the above CLTs for $\xi_n$ and $\xi_n^\#$, we adopt techniques devised in Deb et al. (2020). We highlight here some of these technical ingredients of our proof. Deb et al. (2020) were focused on establishing general asymptotic results for graph-based statistics with an additional self-normalization step. In the present context of our Theorem 3.1, following Deb et al. (2020, Theorem 4.1), it is readily shown that

$$\sqrt{n}\xi_n / \left\{ \widehat{\text{Var}}(\xi_n) \right\}^{1/2} \xrightarrow{d} N(0, 1),$$

for some data-based normalization statistic $\widehat{\text{Var}}(\xi_n)$. Our main focus, accordingly, can be understood as proving the existence as well as deriving the value of the limit of $\widehat{\text{Var}}(\xi_n)$ as $n \to \infty$. This problem was not touched upon in Deb et al. (2020) for a good reason, but is crucial for our analysis of the power ahead. To fill the gap, our proof draws on the remarkable techniques developed in Henze (1987) and Devroye (1988), which will be detailed below.

The asymptotic variances of $\xi_n$ and $\xi_n^\#$ may look mysterious but they are in fact connected to the behavior of nearest neighbor graphs. We present here a series of results that illustrate this connection. The first is a well-known result by Bickel and Breiman (1983, Corollary S1) on maximum degrees in 1-NN graphs.

**Lemma 3.1** (Maximum degree in nearest neighbor graphs). Let $w_1, \ldots, w_n$ be any collection of $n$ distinct points in $\mathbb{R}^d$. Then there exists a constant $C_d$ depending only on the dimension $d$ such that $w_1$ is the nearest neighbor of at most $C_d$ points from $\{w_2, \ldots, w_n\}$.

The notation $C_d$, representing a constant upper bound of the maximum degree, will be used throughout the manuscript. For convenience, we take $C_d$ as the smallest constant for which the property in Lemma 3.1 holds.

In the following, consider a sample $[W_i]_{i=1}^n$ comprised of $n$ independent copies of a random vector $W \in \mathbb{R}^d$. Let $\mathcal{G}_n$ be the associated directed nearest neighbor graph (NNG), i.e., $\mathcal{G}_n$ has vertex set $[n]$ and contains a directed edge from $i$ to $j$ whenever $W_j$ is a nearest neighbor of $W_i$. We write $\mathcal{E}(\mathcal{G}_n)$ for the edge set of $\mathcal{G}_n$.

The parameter $q_d$ in Theorem 3.1 comes from the following crucial result of Devroye (1988, Theorem 2).

**Lemma 3.2** (Expected number of nearest-neighbor pairs). As long as $W$ is absolutely continuous, we have

$$\mathbb{E}\left( \frac{1}{n} \# \{(i, j) \text{ distinct: } i \to j, j \to i \in \mathcal{E}(\mathcal{G}_n)\} \right) \xrightarrow{\text{a.s.}} \frac{V_d}{U_d} = q_d,$$

where $V_d$ is the volume of the unit ball in $\mathbb{R}^d$, and $U_d$ is the volume of the union of two unit balls in $\mathbb{R}^d$ whose centers are a unit distance apart. The explicit value of $q_d$ shown in (3.2) is given by Li (2011, Equation (3)).

The parameter $q_d$ in Theorem 3.1, on the other hand, comes from the following new lemma, which is developed in this manuscript. The lemma builds on an earlier result of Henze (1987).
**Lemma 3.3.** As long as $W$ is absolutely continuous, we have

$$E\left(\frac{1}{n}\#\{(i,j,k) \text{ distinct} : i \to k, j \to k \in \mathcal{E}(G_n)\}\right) \to \sigma_d,$$

where $\sigma_d = \sigma_{d:2}$, a quantity defined in Lemma 3.4 below.

The next lemma is due to Henze (1987, Theorem 1.4, Corollaries 1.5 and 1.6).

**Lemma 3.4** (Expected number of vertices of specified degree). Let $d_j^-$ be the in-degree of vertex $W_j$ in $G_n$, i.e., $d_j^- := \#\{i : i \to j \in \mathcal{E}(G_n)\}$. If $W$ is absolutely continuous with a density continuous a.e., then for any integer $k \in [0, \mathcal{C}_d]$, we have

$$E\left(\frac{1}{n}\#\{j : d_j^- = k\}\right) \to p_{d,k} \quad \text{and} \quad \text{Var}(d_1^-) \to \sigma_{d:2},$$

where

$$p_{d,k} = \frac{1}{k!} \sum_{u=0}^k \frac{1}{u!} (-1)^u \sigma_{d,k+u}, \quad 0 \leq k \leq \mathcal{C}_d,$$

and

$$\sigma_{d:0} = \sigma_{d:1} = 1, \quad \sigma_{d:r} = \int_{\Gamma_{d,r}} \exp\left[-\lambda \left\{ \bigcup_{i=1}^r B(w_i, \|w_i\|) \right\} \right] d(w_1, \ldots, w_r),$$

$$\Gamma_{d,r} = \left\{ (w_1, \ldots, w_r) \in (\mathbb{R}^{d})^r : \|w_i\| < \min_{1 \leq j \leq r, j \neq i} \|w_i - w_j\|, 1 \leq i \leq r \right\}, \quad 2 \leq r \leq \mathcal{C}_d.$$

Notice that $p_{d,k} \in [0, 1]$ is a constant only depending on $d$ and $k$.

**Remark 3.4.** We note that in Theorem 3.1(i), a slightly stronger condition (continuity over its support) is required for the density function in order to establish CLTs. This additional requirement is made for handling the “cross terms” of 1-NN graphs built on $\{(X_i, Z_i)\}_{i=1}^n$ and $\{X_i\}_{i=1}^n$ separately (cf. Lemma 7.4 ahead as an analogue of Lemmas 3.2–3.4 for the cross terms). Such cross terms are not present in Devroye (1988) and Henze (1987). Roughly speaking, we will prove that the two 1-NN graphs built on $\{(X_i, Z_i)\}_{i=1}^n$ and $\{X_i\}_{i=1}^n$ are nearly independent from each other. The proof of Lemma 7.4 adopts Devroye’s and Henze’s idea but involves further analysis.

### 4 Power analysis: Parametric case

This section investigates the local power of the proposed tests for quadratic mean differentiable classes of alternatives (Lehmann and Romano, 2005, Definition 12.2.1), for which we show that the CRT based on Azadkia and Chatterjee $\xi_n$ possesses only trivial power in $n^{-1/2}$ neighborhoods.

We begin with a set of local alternatives

$$\left\{ q_\Delta(x, y, z) : |\Delta| < \Delta^* \right\}, \quad \Delta^* > 0,$$

where for each $|\Delta| < \Delta^*$, $q_\Delta(x, y, z)$ is a joint density with respect to the Lebesgue measure. We then make assumptions on the set in (4.1). In the following, $E_0(\cdot)$ is understood to be the expectation operator with regard to the density function $q_0(x, y, z)$ obtained for $\Delta = 0$.

**Assumption 4.1.** It is assumed that
(i) \( q_0(x, y, z) \) is such that \( Y \) and \( Z \) are conditionally independent given \( X \);
(ii) for all \( |\Delta| < \Delta^* \),
\[
\int q_{\Delta}(x, y, z)\,dz = q_{X,Y}(x, y),
\]
where \( q_{X,Y}(\cdot, \cdot, \cdot) \), the density of \( P_{X,Y} \), is fixed and equal to the product of densities of \( P_X \) and \( P_Y \), and invariant with regard to \( \Delta \);
(iii) the score function
\[
\ell_\Delta(x, y, z) := \frac{\partial}{\partial \Delta} \log q_{\Delta}(x, y, z)
\]
exists at \( \Delta = 0 \), and the family \( \{q_\Delta(x, y, z)\}_{|\Delta|<\Delta^*} \) is quadratic mean differentiable (QMD) at \( \Delta = 0 \) with score function \( \ell_0 \), that is,
\[
\int \left( \sqrt{q_\Delta(x, y, z)} - \sqrt{q_0(x, y, z)} - \frac{1}{2} \Delta \ell_0(x, y, z) \sqrt{q_0(x, y, z)} \right)^2 \,d(x, y, z) = o(\Delta^2)
\]
as \( \Delta \to 0 \);
(iv) \( \operatorname{E}_0\{\ell_0(X, Y, Z)^2\} > 0 \) (Assumption (iii) implies \( \operatorname{E}_0\{\ell_0(X, Y, Z)^2\} < \infty \) and \( \operatorname{E}_0\{\ell_0(X, Y, Z)\} = 0 \));
(v) \( \operatorname{E}_0\{\ell_0(X, Y, Z) \mid X, Z\} = 0 \) almost surely;
(vi) \( \operatorname{E}_0\{|\ell_0(X, Y, Z)|^{4+\epsilon}\} < \infty \) for some fixed constant \( \epsilon > 0 \);
(vii) \( \ell_0(x, y, z) \) cannot be written as \( h_1(y) + h_2(x, z) \).

**Example 4.1 (Rotation alternatives).** Suppose that \( X^* \in \mathbb{R}^p \), \( Y^* \in \mathbb{R} \), and \( Z^* \in \mathbb{R}^q \) are centered and jointly normally distributed random variables such that \( Y^* \) is independent of \((X^*, Z^*)\). Then Assumption 4.1 holds for rotation alternatives given as
\[
(X, Y, Z) = (X^*, Y^*, Z^* + \Delta(AX^* + BY^*)),
\]
where \( A \in \mathbb{R}^{q \times p}, B \in \mathbb{R}^{q \times 1} \) are deterministic matrices, and \( B \) is nonzero.

**Example 4.2 (Farlie alternatives).** Suppose that \( X^* \in \mathbb{R}^p \), \( Y^* \in \mathbb{R} \), and \( Z^* \in \mathbb{R}^q \) are absolutely continuous random variables such that \( Y^* \) is independent of \((X^*, Z^*)\). Then Assumption 4.1 holds for the (generalized) Farlie alternatives (see KöSSLER and RÖDEL (2007, Sec. 1.1.5) for the one-dimensional case) that are defined as
\[
q_\Delta(x, y, z) := q_{Y^*}(y)q_{(X^*, Z^*)}(x, z) \left[ 1 + \Delta \left\{ 1 - 2F_{Y^*}(y) \right\} \left\{ 1 - 2F_{(X^*, Z^*)}(x, z) \right\} \right].
\]

For a local power analysis for an alternative set under the listed assumptions, we examine the asymptotic power along a respective sequence of alternatives obtained as
\[
H_{1,n}(\Delta_0) : \Delta = \Delta_n, \text{ where } \Delta_n := n^{-1/2} \Delta_0
\]
with some constant \( \Delta_0 \neq 0 \). In this local model, testing the null hypothesis of independence reduces to testing
\[
H_0 : \Delta_0 = 0 \quad \text{versus} \quad H_1 : \Delta_0 \neq 0.
\]
We obtain the following theorem on the local power of the discussed tests. The result demonstrates the trivial power claimed for \( \xi_n \) in the beginning of this section.
Theorem 4.1 (Power analysis for $\xi_n$). Suppose that the considered set of local alternatives in (4.1) satisfies Assumption 4.1 and constitutes a subset of $P_1$. Then for any sequence of alternatives given in (4.2), for any fixed constant $\Delta_0 > 0$,

(i) assuming the number of simulations $B$ for the CRT tends to infinity as $n \to \infty$, it holds that
\[
\lim_{n \to \infty} P_{H_1,n}(\Delta_0) (T^Q_\alpha, \xi_n) = 1 \leq \alpha;
\]

(ii) in contrast, there exists a test $T^\text{opt}_\alpha$ such that for any $\alpha, \beta \in (0, 1)$, as long as $\Delta_0$ is sufficiently large, it holds that
\[
\lim_{n \to \infty} P_{H_0}(T^\text{opt}_\alpha) = 1 \leq \alpha \quad \text{and} \quad \lim_{n \to \infty} P_{H_1,n}(\Delta_0) (T^\text{opt}_\alpha) = 1 \geq 1 - \beta,
\]
while for small $\Delta_0$ the total variation distance vanishes as
\[
\lim_{\Delta_0 \to 0, n \to \infty} \lim TV(H_1,n(\Delta_0), H_0) = 0.
\]

Remark 4.1. We give a rigorous proof of Theorem 4.1(i) in Section 7.1.1. The main idea is to first derive the joint limiting null distribution of $\sqrt{n}\xi_n$ and the log likelihood ratio between two hypotheses, and then to use Le Cam’s third lemma. In addition to Theorem 3.1(i), combining results from Azadkia and Chatterjee (2021), we are able to prove joint asymptotic normality with deterministic variance of $\sqrt{n}\xi_n$ and the log likelihood ratio; in particular, zero asymptotic covariance between $\sqrt{n}\xi_n$ and the log likelihood ratio is the technical reason why the CRT-based Azadkia–Chatterjee-type test is inefficient in the quadratic mean differentiable class.

Remark 4.2. The phenomenon that a (1-NN) graph-based test has zero asymptotic efficiency has been encountered also in other situations. For example, the lack of power of the Wald–Wolowitz runs test is a classic result in the literature (Hájek et al., 1999, p. 102). A systematic analysis of this phenomenon in the two-sample test context was done recently in Bhattacharya (2019) and similar analyses for Chatterjee’s 1-NN tests of unconditional independence were performed in Cao and Bickel (2020), Shi et al. (2021b), and Auddy et al. (2021).

5 Power analysis: Nonparametric case

In this section, we conduct local power analyses of the proposed tests within the Hölder smooth class inspired by the work of Neykov et al. (2021). In this class, the conditional distribution of $(Y, Z)$ is allowed to change more dramatically (beyond the limit of QMD classes established in Section 4) as $X$ changes. In the sequel, following the settings treated in Neykov et al. (2021), we consider $X \in [0, 1]^p$, $Y \in [0, 1]$, and $Z \in [0, 1]$ to be continuous random vector/variables.

5.1 Rate of convergence

Let $\mathcal{E}_{[0, 1]^{p+2}}$ be the set of all absolutely continuous distributions $(X, Y, Z) \in [0, 1]^{p+2}$ such that the randomness of the triplet can be understood as first sampling $X$ from a density $q_X$ with support $[0, 1]^p$, and then sampling $Y$ and $Z$ from a conditional distribution $q_{(Y,Z)}|X$ of support $[0, 1] \times [0, 1]$ for (almost) all $X$. Let $P_0 \subseteq \mathcal{E}_{[0, 1]^{p+2}}$ be the subset for which $Y \perp \perp Z \mid X$, and let $P_1 = \mathcal{E}_{[0, 1]^{p+2}} \setminus P_0$. 

12
Next we separately define the two Hölder classes of density functions, belonging to \( \mathcal{P}_0 \) (the null class) and \( \mathcal{P}_1 \). Our main interest is on exponents \( s \) that are close to 0, representing those conditional distributions of \((Y, Z)\) that change possibly very roughly with the values of \( X \).

**Definition 5.1** (Null Hölder class). Let \( \mathcal{P}_0(L, s) \subseteq \mathcal{P}_0 \) with \( L > 1 \) and \( s \in (0, 1] \) be the collection of joint distributions of \((X, Y, Z)\) such that, for all \( x, x' \in [0, 1]^p \), \( y, y', z, z' \in [0, 1] \), we have

\[
q_{Y|X}(y|x) - q_{Y|X}(y|x') \leq L\|x - x'\|^s
\]

and

\[
q_{Z|X}(z|x) - q_{Z|X}(z|x') \leq L\|x - x'\|^s.
\]

**Definition 5.2** (Alternative Hölder class). Let \( \mathcal{P}_1(L, s) \subseteq \mathcal{P}_1 \) with \( L > 1 \) and \( s \in (0, 1] \) be the collection of joint distributions of \((X, Y, Z)\) such that, for all \( x, x' \in [0, 1]^p \), \( y, y', z, z' \in [0, 1] \), we have

\[
q_{Y,Z}(y,z|x) - q_{Y,Z}(y,z|x') \leq L\|x - x'\|^s,
\]

\[
q_{Y,Z}(y,z|x) - q_{Y,Z}(y,z'|x) \leq L\left(|y - y'|^s + |z - z'|^s\right),
\]

and

\[
L^{-1} \leq q_{Y,Z}(y,z|x) \leq L.
\]

To obtain the rate of convergence for \( \xi_n \) under \( \mathcal{P}_0(L, s) \) as well as \( \mathcal{P}_1(L, s) \), we establish the following two results. The first is a proposition that extends Theorem 4.1 in Azadkia and Chatterjee (2021), which focused on the Lipschitz class with \( s = 1 \). The second result is a lemma that shows that the distributions in \( \mathcal{P}_0(L, s) \) and \( \mathcal{P}_1(L, s) \) satisfy the conditions in the proposition.

**Proposition 5.1.** Restricted to this proposition, \( Z \in \mathbb{R}^q \) is allowed to be multidimensional. Suppose then that \( Y \) is not a.s. equal to a measurable function of \( X \) and that

(i) there are universal constants \( C_1 > 0 \) and \( s \in (0, 1] \) such that for any \( t \in \mathbb{R}, x, x' \in \mathbb{R}^p \), and \( z, z' \in \mathbb{R}^q \),

\[
\left| \mathbb{P}(Y \geq t \mid X = x, Z = z) - \mathbb{P}(Y \geq t \mid X = x', Z = z') \right| \leq C_1\left(\|x - x'\|^s + \|z - z'\|^s\right),
\]

and

\[
\left| \mathbb{P}(Y \geq t \mid X = x) - \mathbb{P}(Y \geq t \mid X = x') \right| \leq C_1\left(\|x - x'\|^s\right);
\]

(ii) there exists a universal constant \( C_2 > 0 \) such that \( \mathbb{P}(\|X\| \geq r) = 0 \) and \( \mathbb{P}(\|Z\| \geq r) = 0 \).

Then, as \( n \to \infty \),

\[
\xi_n - \xi = \mathcal{O}\left(\frac{(\log n)^p q}{n^{p+q+1}}\right).
\]

**Lemma 5.1.** (i) If \( P_{(X,Y,Z)} \in \mathcal{P}_0(L, s) \) for a fixed \( L > 1 \) and \( s \in (0, 1] \), then for all \( x, x' \in [0, 1]^p \), \( y, y', z, z' \in [0, 1] \), we have

\[
q_{Y|X}(y|x, z) - q_{Y|X}(y|x', z') \leq L\|x - x'\|^s.
\]

(ii) If \( P_{(X,Y,Z)} \in \mathcal{P}_1(L, s) \) for a fixed \( L > 1 \) and \( s \in (0, 1] \), then for all \( x, x' \in [0, 1]^p \), \( y, y', z, z' \in [0, 1] \), we have

\[
q_{Y|X}(y|x, z) - q_{Y|X}(y|x', z') \leq L'\left(\|x - x'\|^s + |z - z'|^s\right)
\]

for some \( L' \leq 2L^4 \).

13
Combining Lemma 5.1 with Proposition 5.1 gives the following corollary.

**Corollary 5.1.** Suppose \( P_{(X,Y,Z)} \in \mathcal{P}_0(L,s) \), or \( P_{(X,Y,Z)} \in \mathcal{P}_1(L,s) \) with \( Y \) not a.s. equal to a measurable function of \( X \). Then as \( n \to \infty \),
\[
\xi_n - \xi = O_P\left( \frac{(\log n)^{p+q+1}}{n^{s/(p+q)}} \right).
\]

5.2 Power analysis

Fix \( L > 1 \) and \( s \in (0,1] \). We consider now the problem of testing
\[
H_0 : P_{(X,Y,Z)} = P_0 \in \mathcal{P}_0(L,s)
\]
against a sequence of local alternatives,
\[
H_{1,n} : P_{(X,Y,Z)} = P_{1,n} \in \mathcal{P}_1(L,s).
\]

**Corollary 5.2.** Assume both \( P_0 \) and \( \{P_{1,n}, n = 1,2,\ldots\} \) belong to \( \mathcal{P}_Q \), and \( \xi(P_{1,n}) \), the conditional dependence measure \( \xi \) under the local alternative \( P_{1,n} \), satisfies that
\[
\xi(P_{1,n}) \gtrsim n^{-s/(p+1)+\delta}
\]
for some (arbitrarily small) constant \( \delta > 0 \). Further assume that the number of simulations \( B \) tends to infinity as \( n \to \infty \). Then
\[
\lim_{n \to \infty} P_{H_{1,n}}(T_Q^{\xi_n} = 1) = 1.
\]

We observe that unfortunately, even as the Hölder exponent \( s \) is small, the threshold \( n^{-s/(p+1)} \) is (from a worst case perspective) not the critical boundary in the studied nonparametric class. The following theorem shall confirm it rigorously. To this end, we consider a simplified setting when \( p = 1 \), so \( X,Y,Z \in \mathbb{R} \). Define the class
\[
\mathcal{P}_1(\epsilon;L,s) := \left\{ q \in \mathcal{P}_1(L,s) : \inf_{q^0 \in \mathcal{P}_0} \|q - q^0\|_1 \geq \epsilon \right\},
\]
where \( \|q - q^0\|_1 := \int |q(x,y,z) - q^0(x,y,z)|d(x,y,z) \). Consider testing
\[
H_0 : P_{(X,Y,Z)} = P_0 \in \mathcal{P}_0(L,s)
\]
against the following particular sequence of local alternatives:
\[
H_{1,n}(\Delta_0) : P_{(X,Y,Z)} = P_{1,n}(\Delta_0) \in \mathcal{P}_1(\Delta_0 n^{-2s/(4s+3)};L,s)\}
\]

**Theorem 5.1.** For any \( s \in (0,1] \), there exist
\[
P_0 \in \mathcal{P}_0(L,s) \quad \text{and} \quad P_{1,n}(\Delta_0) \in \mathcal{P}_1(\Delta_0 n^{-2s/(4s+3)};L,s)
\]
such that \( P_{(X,Y)} \in \mathcal{P}_Q \) does not vary under both the null and local alternatives, and

(i) assuming the number of simulations \( B \) tends to infinity as \( n \to \infty \), for any \( \Delta_0 > 0 \) and \( \alpha < 0.1 \), it holds that
\[
\limsup_{n \to \infty} P_{H_{1,n}(\Delta_0)}(T_Q^{\xi_n} = 1) \leq \beta_\alpha,
\]
where \( \beta_\alpha < 1 \) is a constant only depending on \( \alpha \);
(ii) if further $s \in [1/4, 1]$, then there exists a test $T_{\alpha}^{\bin}$ such that, for any $\alpha, \beta \in (0,1)$, as long as $\Delta_0$ is sufficiently large,

$$P_{H_0}(T_{\alpha}^{\bin} = 1) \leq \alpha \quad \text{and} \quad \lim_{n \to \infty} P_{H_1,n(\Delta_0)}(T_{\alpha}^{\bin} = 1) \geq 1 - \beta;$$

in contrast, as $\Delta_0$ becomes small,

$$\lim_{\Delta_0 \to 0} \lim_{n \to \infty} \text{TV}(H_{1,n}(\Delta_0), H_0) = 0.$$

**Remark 5.1.** Our proof of Theorem 5.1(i) is different from the approach we used to prove Theorem 4.1(i). It depends on the fact that $\sqrt{n} \xi_n$ has the same asymptotic mean and variance under a null hypothesis and a special non-standard local alternative sequence constructed in Neykov et al. (2021). We show this in a direct calculation.

## 6 Conclusion

In this manuscript, we explore the use of Azadkia–Chatterjee’s conditional dependence coefficient in inferential tasks. Specifically, we adopt the framework of conditional randomization tests in order to study the power of Azadkia–Chatterjee-type tests of conditional independence. Our analyses take up two types of local alternatives: First, a rather general quadratic mean differentiable class and second, a rougher Hölder class. In these settings, we prove that the CRT-based Azadkia–Chatterjee test is unfortunately statistically inefficient.

The current analyses are focused on the situation when $X$ and $Y$ are independent, which makes the required analysis of permutation statistics mathematically tractable. Indeed, while it would be natural and interesting to also study cases where $X$ and $Y$ are dependent, entirely new technical tools would need to be developed to attack this problem. This said, we conjecture that the inefficiency of Azadkia–Chatterjee-type test persists for more general local alternatives, with $X$ and $Y$ are dependent.

Finally, the inefficiency we demonstrate motivates further efforts to develop variants of the considered approach. One possible avenue would be to develop tests that use modified versions of Azadkia–Chatterjee’s conditional dependence coefficient, in which one uses $k$-nearest neighbor graph with $k$ allowed to tend to infinity as the sample size $n$ increases; cf. a recent progress made in Lin and Han (2021). Another interesting topic for future research would be a generalization of the coefficient to the setting where all of $X, Y, Z$ are multivariate.
7 Proofs

7.1 Proof of Theorem 4.1

7.1.1 Proof of Theorem 4.1(i)

Proof of Theorem 4.1(i). The proof is divided into three steps. The first step reviews Le Cam’s third lemma and introduces graph theoretic notions. The second step derives the distribution of \( \xi_n \) under the local alternative. The third step computes the local power.

Step I-1. To derive the local alternative distribution of \( \xi_n \), we will use Le Cam’s third lemma \( \text{(van der Vaart, 1998, Theorem 7.2 and Example 6.7)} \). The lemma states that if under the null hypothesis,

\[
\left( \sqrt{n} \xi_n, \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \ell_0(X_i, Y_i, Z_i) \right) \xrightarrow{d} N\left( \left( 0, \begin{pmatrix} \sigma^2 & \tau \\ \tau & I_0 \end{pmatrix} \right) \right) \quad (7.1)
\]

where \( \sigma^2, \tau \) are fixed constants and \( I_0 := E\{\ell_0(X, Y, Z)^2\} \) equals the Fisher information for \( \Delta \) at 0, then under the local alternative hypothesis, we have

\[
\sqrt{n} \xi_n \xrightarrow{d} N(\Delta_0 \tau, \sigma^2).
\]

In order to employ the Cramér–Wold device to prove \((7.1)\) for some \( \sigma^2 \) and \( \tau \), we need to show that under the null, for any real numbers \( a \) and \( b \),

\[
a \sqrt{n} \xi_n + bn^{-1/2} \sum_{i=1}^{n} \ell_0(X_i, Y_i, Z_i) \xrightarrow{d} N\left(0, a^2 \sigma^2 + 2ab \tau + b^2 I_0 \right). \quad (7.2)
\]

To this end, first notice that \( \text{Azadkia and Chatterjee (2021, Theorem 9.1)} \) show

\[
\frac{1}{n^2} \sum_{i=1}^{n} \{R_i - \min(R_i, R_{N(i)})\} \xrightarrow{a.s.} \int \text{E}[\text{Var}\{1(Y \geq t) \mid X\}]dP_Y(t).
\]

Therefore, by Slutsky’s theorem, it suffices to establish \((7.1)\) for \( \sqrt{n} \hat{\xi}_n \) instead of \( \sqrt{n} \xi_n \), where

\[
\hat{\xi}_n := \frac{n^{-2} \sum_{i=1}^{n} \{\min(R_i, R_{M(i)}) - \min(R_i, R_{N(i)})\}}{\int \text{E}[\text{Var}\{1(Y \geq t) \mid X\}]dP_Y(t)} \quad (7.3)
\]

Moreover, consider the “oracle” version of \( \hat{\xi}_n \) defined as

\[
\hat{\xi}_n := \frac{n^{-1} \sum_{i=1}^{n} \{\min(F_Y(Y_i), F_Y(Y_{M(i)}) - \min(F_Y(Y_i), F_Y(Y_{N(i)})\}}{\int \text{E}[\text{Var}\{1(Y \geq t) \mid X\}]dP_Y(t)} \quad (7.4)
\]

We have the following lemma for \( \hat{\xi}_n \) and \( \xi_n \). This result and lemmas given later in this section are derived in the appendix.

Lemma 7.1. Under the null hypothesis, \( \sqrt{n} \hat{\xi}_n - \sqrt{n} \xi_n = o_P(1) \).

Thus we only need to show

\[
a \sqrt{n} \hat{\xi}_n + bn^{-1/2} \sum_{i=1}^{n} \ell_0(X_i, Y_i, Z_i) \xrightarrow{d} N\left(0, a^2 \sigma^2 + 2ab \tau + b^2 I_0 \right). \quad (7.5)
\]
The idea of proving (7.5) is to first show a conditional central limit result,

\[ a\sqrt{n}\xi_n + bn^{-1/2} \sum_{i=1}^{n} \dot{\ell}_0(X_i, Y_i, Z_i) \bigg| F_n \xrightarrow{d} N\left(0, a^2\sigma^2 + 2ab\tau + b^2I_0\right) \]

for almost every sequence \([ (X_n, Z_n) ]_{n \geq 1} \), (7.6)

where \( F_n \) denotes the \( \sigma \)-field generated by \((X_1, Z_1), \ldots, (X_n, Z_n)\), and then deduce the desired unconditional central limit result (7.5), and thus (7.2).

**Step I-2.** To show (7.6), we introduce the language of graph theory. We write

\[ S_n = a\sqrt{n}\xi_n + bn^{-1/2} \sum_{i=1}^{n} \dot{\ell}_0(X_i, Y_i, Z_i) \]

\[ = a\gamma^{-1}n^{-1/2} \sum_{i=1}^{n} \min\{F_Y(Y_i), F_Y(Y_{M(i)})\} - a\gamma^{-1}n^{-1/2} \sum_{i=1}^{n} \min\{F_Y(Y_i), F_Y(Y_{N(i)})\} \]

\[ + bn^{-1/2} \sum_{i=1}^{n} \dot{\ell}_0(X_i, Y_i, Z_i) \]

\[ = a\gamma^{-1}n^{-1/2} \sum_{i=1}^{n} \sum_{j:i \rightarrow j \in E(G_n)} K_\Lambda(Y_i, Y_j) - a\gamma^{-1}n^{-1/2} \sum_{i=1}^{n} \sum_{k:i \rightarrow k \in E(G^X_n)} K_\Lambda(Y_i, Y_k) \]

\[ + bn^{-1/2} \sum_{i=1}^{n} \dot{\ell}_0(X_i, Y_i, Z_i), \]

where for all \( Y \) independent of \( X \),

\[ \gamma := \int \text{E}[\text{Var}\{1(Y \geq t) \mid X\}]dP_Y(t) = \int \text{E}[\text{Var}\{1(Y \geq t)\}]dP_Y(t) = \frac{1}{6}, \]

\( G_n \) is the directed nearest neighbor graph (NNG) of the vertices \([ (X_i, Z_i) ]_{i=1}^{n} \), \( G^X_n \) is the directed nearest neighbor graph (NNG) of the vertices \([ X_i ]_{i=1}^{n} \), and \( K_\Lambda(y_1, y_2) := \min\{F_Y(y_1), F_Y(y_2)\} \).

Next we define

\[ V_{i:1} := n^{-1/2}\left\{ 6a \sum_{j:i \rightarrow j \in E(G_n)} K_\Lambda(Y_i, Y_j) - 6a \sum_{k:i \rightarrow k \in E(G^X_n)} K_\Lambda(Y_i, Y_k) \right\}, \]

\[ V_{i:2} := n^{-1/2}b\dot{\ell}_0(X_i, Y_i, Z_i), \]

and \( V_i := V_{i:1} + V_{i:2}, \) (7.7)

such that \( S_n \) can be written as \( \sum_{i=1}^{n} V_i \). Observe that, since \([ Y_i ]_{i=1}^{n} \) is independent of \([ (X_i, Z_i) ]_{i=1}^{n} \) under the null,

\[ \text{E}(V_{i:1} \mid F_n) = n^{-1/2}\left\{ 6a\text{E}\left\{ K_\Lambda(Y_i, Y_{M(i)}) \mid F_n \right\} - 6a\text{E}\left\{ K_\Lambda(Y_i, Y_{N(i)}) \mid F_n \right\} \right\} \]

\[ = n^{-1/2}\left\{ 6a(1/3) - 6a(1/3) \right\} = 0, \]

\[ \text{E}(V_{i:2} \mid F_n) = \text{E}\left\{ \dot{\ell}_0(X_i, Y_i, Z_i) \mid F_n \right\} = 0, \] by Assumption 4.1(v),

and \( \text{E}(V_i \mid F_n) = a\text{E}(V_{i:1} \mid F_n) + b\text{E}(V_{i:2} \mid F_n) = 0. \)

To establish a conditional central limit theorem for \( S_n \), we make use of the following lemma.
Lemma 7.2. It holds that

\[ \sup_{z \in \mathbb{R}} \left| \mathbb{P} \left( \frac{S_n}{\sqrt{\text{Var}(S_n | F_n)}} \leq z \mid F_n \right) - \Phi(z) \right| \leq 75 C_{p+q}^5 (1+\epsilon) \frac{E(\sum_{i=1}^{n} |V_i|^{2+\epsilon} | F_n)}{\{\text{Var}(S_n | F_n)\}^{(2+\epsilon)/2}} a.s., \quad (7.8) \]

where \( C_{p+q} \) is a constant depending only on \( p + q \).

To control the right-hand side of (7.8), we get by the “\( c_r \)-inequality” that

\[ \mathbb{E} \left( \sum_{i=1}^{n} |V_i|^{2+\epsilon} \mid F_n \right) \leq 2^{1+\epsilon} \left\{ \mathbb{E} \left( \sum_{i=1}^{n} |V_i|^{2+\epsilon} \mid F_n \right) + \mathbb{E} \left( \sum_{i=1}^{n} |V_i|^{2+\epsilon} \mid F_n \right) \right\}. \]

Here

\[ n^{1/2} \mathbb{E} \left( \sum_{i=1}^{n} |V_i|^{2+\epsilon} \mid F_n \right) \leq |6a|^{2+\epsilon} \quad \text{and} \quad n^{1/2} \mathbb{E} \left( \sum_{i=1}^{n} |V_i|^{2+\epsilon} \mid F_n \right) \xrightarrow{a.s.} \mathbb{E} \left\{ |b\ell_0(X, Y, Z)|^{2+\epsilon} \right\}, \]

where the former follows from \(|V_i| \leq |6a|n^{-1/2}\) and the latter from the strong law of large numbers and Assumption 4.1(vi).

Step II. In order to show (7.6), in view of (7.8), it suffices to show

\[ \text{Var}(S_n \mid F_n) \xrightarrow{a.s.} a^2 \sigma^2 + 2ab\tau + b^2 I_0. \quad (7.9) \]

for some fixed \( \sigma^2 > 0 \) and \( \tau \), and recall \( I_0 := \mathbb{E} \{b\ell_0(X, Y, Z)^2\} \). We proceed in two sub-steps. We will first compute \( \text{Var}(S_n \mid F_n) \), then claim \( \text{Var}(S_n \mid F_n) - \text{Var}(S_n) \xrightarrow{a.s.} 0 \) and determine the limit value of \( \text{Var}(S_n) \) accordingly.

Step II-1. Set

\[ \gamma_{1;0} := \mathbb{E} \left\{ \left( 6aK(Y, Y') - 2a \right)^2 \right\}, \quad \gamma_{2;0} := \mathbb{E} \left\{ \left( 6aK(Y, Y'') - 2a \right)^2 \right\}, \]

\[ \gamma_{4;0;0}^{a,b}(x, z) := \mathbb{E} \left\{ \left( 6aK(Y, Y') - 2a \right)^2 \right\}, \quad \gamma_{4;0;0}^{a,b}(x, z) := \mathbb{E} \left\{ \left( 6aK(Y, Y'') - 2a \right)^2 \right\}, \]

\[ \gamma_{5;0;0}^{a,b}(x, z) := \mathbb{E} \left\{ \left( b\ell_0(x, Y, Z) \right)^2 \right\}, \quad \gamma_{5;0;0}^{a,b}(x, z) := \mathbb{E} \left\{ \left( b\ell_0(x, Z) \right)^2 \right\}, \quad (7.10) \]

where \( Y' \) and \( Y'' \) are independent copies of \( Y \). We obtain

\[ \text{Var}(S_n \mid F_n) = \mathbb{E}(S_n^2 \mid F_n) = \sum_{i=1}^{n} \mathbb{E}(V_i^2 \mid F_n) + \sum_{i \neq j} \mathbb{E}(V_i V_j \mid F_n), \]

where

\[ \sum_{i=1}^{n} \mathbb{E}(V_i^2 \mid F_n) = n^{-1} \sum_{i=1}^{n} \left\{ 2\gamma_{1;0} - 2 \sum_{j:i \rightarrow j \in \mathcal{E}(G_n) \cap \mathcal{E}(\bar{G}^X)} \gamma_{1;0} \right\} \]

\[ - 2 \sum_{(j,k):i \rightarrow j \in \mathcal{E}(G_n), i \rightarrow k \in \mathcal{E}(\bar{G}^X), j \neq k} \gamma_{2;0} + \gamma_{5;0,0}^{a,b}(X, Z), \quad (7.11) \]

and

\[ \sum_{i \neq j} \mathbb{E}(V_i V_j \mid F_n) \]
\[ n^{-1} \left\{ \sum_{(i,j) \text{ distinct}} \gamma_{1:a} + \sum_{(i,j,k) \text{ distinct}} \gamma_{2:a} \right. \]

\[ + 2 \sum_{(i,j) \text{ distinct}} \gamma_{1:a} - 2 \sum_{(i,j,k) \text{ distinct}} \gamma_{2:a} \]

\[-2 \sum_{(i,j) \text{ distinct}} \gamma_{1:a} + 2 \sum_{(i,j) \text{ distinct}} \gamma_{1:a} + \sum_{(i,j,k) \text{ distinct}} \gamma_{2:a} \]

\[ \sum_{i \to j, j \to i \in E(G_n)} \gamma_{4,a,b}(X_i, Z_i) + \sum_{j \to i \in E(G_n)} \gamma_{5,a,b}(X_i, Z_i) \right\}. \quad (7.12) \]

**Step II-2.** We employ the following result.

**Lemma 7.3.**

\[ \text{Var}(S_n | F_n) - \text{Var}(S_n) \xrightarrow{a.s.} 0. \quad (7.13) \]

Then it remains to prove

\[ \text{Var}(S_n) \to a^2 \sigma^2 + 2ab \tau + b^2 I_0 \quad (7.14) \]

for some fixed \( \sigma^2 > 0 \) and \( \tau \); notice (7.13) and (7.14) will imply (7.9). To this end, in addition to Lemmas 3.2 and 3.4, we also need the following lemma, which is a “covariance” version of Lemmas 3.2 and 3.4.

**Lemma 7.4.** Let \( [W_i]_{i=1}^n = [(X_i, Z_i)]_{i=1}^n \) be a sample comprised of \( n \) independent copies of \( W = (X, Z) \), with \( X \in \mathbb{R}^p \) and \( Z \in \mathbb{R}^q \). Let \( G_n \) be the directed nearest neighbor graph (NNG) of the vertices \( [W_i]_{i=1}^n \), and let \( G_n^X \) be the directed nearest neighbor graph (NNG) of the vertices \( [X_i]_{i=1}^n \).

If random vector \( W \) is absolutely continuous with a Lebesgue density \( f \) that is continuous, then

\[ \mathbb{E}\left( n^{-1} \sum_{(i,j) \text{ distinct}} 1 \right) \to 0, \quad (7.15) \]

\[ \mathbb{E}\left( n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 \right) \to 0, \quad (7.16) \]

\[ \mathbb{E}\left( n^{-1} \sum_{i \to j, j \to i \in E(G_n) \cap E(G_n^X)} 1 \right) \to 1. \quad (7.17) \]

Adding (7.11) and (7.12) together, we obtain

\[ \text{Var}(S_n) = \mathbb{E}\left( 2n^{-1} \sum_{i=1}^n \gamma_{1:a} \right) - \mathbb{E}\left( 2 \sum_{(i,j) \text{ distinct}} \gamma_{1:a} \right) \]

\[ - \mathbb{E}\left( 2n^{-1} \sum_{(i,j,k) \text{ distinct}} \gamma_{2:a} \right) + \mathbb{E}\left\{ n^{-1} \sum_{i=1}^n \gamma_{5,a,b}(X_i, Z_i) \right\} \]
\[ + E\left(n^{-1} \sum_{(i,j) \text{ distinct}} \gamma_{1:a} \right) + E\left(n^{-1} \sum_{(i,j,k) \text{ distinct}} \gamma_{2:a} \right) + E\left(n^{-1} \sum_{(i,j) \text{ distinct}} \gamma_{1:a} \right) + E\left(n^{-1} \sum_{(i,j,k) \text{ distinct}} \gamma_{2:a} \right) \\
- E\left(2n^{-1} \sum_{(i,j) \text{ distinct}} \gamma_{1:a} \right) - E\left(2n^{-1} \sum_{(i,j,k) \text{ distinct}} \gamma_{2:a} \right) + E\left\{2n^{-1} \sum_{(i,j) \text{ distinct}} \gamma_{4:a,b}(X_i, Z_i) \right\} - E\left\{2n^{-1} \sum_{(i,j) \text{ distinct}} \gamma^*_{4:a,b}(X_i, Z_i) \right\}. \]  

(7.18)

The first term is \(2\gamma_{1:a}\). The second term tends to 0 by Equation (7.15) in Lemma 7.4. For the third term, we have

\[ E\left(2n^{-1} \sum_{(i,j,k) \text{ distinct}} \gamma_{2:a} \right) = 2\gamma_{2:a} E\left(n^{-1} \sum_{(i,j) \text{ distinct}} 1 \right) \]

\[ = 2\gamma_{2:a} E\left(1 - n^{-1} \sum_{(i,j) \text{ distinct}} 1 \right) \]

\[ \to 2\gamma_{2:a}, \]

where the last step is by Equation (7.15). The fourth term is \(\gamma_{5:a}\). The fifth term tends to \(\gamma_{1:a}q_p + q\) by Lemma 3.2. The sixth term can be rewritten as

\[ \gamma_{2:a} E\left(n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 + n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 + n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 \right) \]

\[ = \gamma_{2:a} E\left(n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 + n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 + n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 \right) \]

\[ = \gamma_{2:a} E\left\{n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 + \left(1 - n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 \right) + \left(1 - n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 \right) \right\} \]

\[ \to \gamma_{2:a} \left(q_p + 2 - 2q_p\right), \]

where the last step is by Lemmas 3.3 and 3.2. Similarly, the seventh and eighth terms tend to \(\gamma_{1:a}q_p\) and \(\gamma_{2:a}(q_p + 2 - 2q_p)\), respectively. The ninth term tends to 0 by Equation (7.16) in Lemma 7.4. The tenth term is equal to

\[ 2\gamma_{2:a} E\left(n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 + n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 + n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 \right) \]

\[ \to 20 \]
\[= 2\gamma_{2,a} E \left( n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 + n^{-1} \sum_{i \rightarrow k \in E(\mathcal{G}_n), j \rightarrow k \in E(\mathcal{G}_n^X)} 1 + n^{-1} \sum_{i \neq j \in E(\mathcal{G}_n), j \rightarrow i \in E(\mathcal{G}_n^X)} 1 \right) \]

\[= 2\gamma_{2,a} E \left( n^{-1} \sum_{(i,j,k) \text{ distinct}} 1 \right) + \left( 1 - n^{-1} \sum_{i \rightarrow j \in E(\mathcal{G}_n), j \rightarrow i \in E(\mathcal{G}_n^X)} 1 \right) + \left( 1 - n^{-1} \sum_{i \neq j \in E(\mathcal{G}_n), j \rightarrow i \in E(\mathcal{G}_n^X)} 1 \right) \]

\[\rightarrow 2\gamma_{2,a} \{ 1 + (1 - 0) + (1 - 0) \} = 6\gamma_{2,a}, \]

where the second last step is by Lemma 7.4. For the last two terms, we obtain

\[E \left\{ n^{-1} \sum_{(i,j) \text{ distinct}} \gamma_{4,a,b}(X_i, Z_i) \right\} = E \left\{ n^{-1} \sum_{i=1}^{n} \gamma_{4,a,b}(X_{M(i)}, Z_{M(i)}) \right\} \]

\[= E \left\{ \gamma_{4,a,b}(X_{M(1)}, Z_{M(1)}) \right\} \rightarrow E \left\{ \gamma_{4,a,b}(X_1, Z_1) \right\} = \gamma_{4,a,b}, \]

where the second last step can be deduced in view of Lemmas 11.5 and 11.7 in Azadkia and Chatterjee (2021) and uniform integrability by way of Shorack (2017, Chap. 3, Exercise 5.4), and similarly

\[E \left\{ n^{-1} \sum_{(i,j) \text{ distinct}} \gamma_{4,a,b}(X_i, Z_i) \right\} \rightarrow \gamma_{4,a,b}. \]

Thus the last two terms are canceled out. Plugging all terms back into (7.18) yields

\[\text{Var}(S_n) \rightarrow \gamma_{1,a} \left\{ 2 + \left( q_{p+q} + q_p \right) \right\} + \gamma_{2,a} \left\{ -4 - 2 \left( q_{p+q} + q_p \right) + (o_{p+q} + o_p) \right\} + \gamma_{5,b}. \]

In addition,

\[\gamma_{1,a} = 2a^2, \quad \gamma_{2,a} = 4a^2 / 5, \quad \gamma_{5,b} = b^2 I_0. \]

Therefore,

\[\text{Var}(S_n) \rightarrow a^2 \left\{ \frac{4}{5} + \frac{2}{5} \left( q_{p+q} + q_p \right) + \frac{4}{5} \left( o_{p+q} + o_p \right) \right\} + b^2 I_0. \]

This completes the proof of (7.6) and thus (7.2) and (7.1) with

\[\sigma^2 := \frac{4}{5} + \frac{2}{5} \left( q_{p+q} + q_p \right) + \frac{4}{5} \left( o_{p+q} + o_p \right) \quad \text{and} \quad \tau := 0. \]

Finally, by Le Cam’s third lemma, under \( \{ P_{n,\Delta_n} \}_{n \geq 1} \),

\[\sqrt{n} \xi_n \left( \left( [X_i, Y_i, Z_i]_{i=1}^{n} \right) \right) \overset{d}{\rightarrow} N(0, \sigma^2). \]

Moreover, we also have

\[\sqrt{n} \xi_n \left( \left( [X_i, Y_i^{(b)}, Z_i]_{i=1}^{n} \right) \right) \overset{d}{\rightarrow} N(0, \sigma^2). \]

**Step III.** Since \( B \) tends to infinity as \( n \to \infty \), without loss of generality, we assume \( B > \alpha^{-1} - 1. \)
With the shorthand notation
\[ \xi_n^{(b)} \equiv \xi_n\left(\left(\{X_i, Y_i^{(b)}, Z_i\}\right)_{i=1}^n\right) \quad \text{and} \quad \xi_n^o \equiv \xi_n\left(\left(\{X_i, Y_i, Z_i\}\right)_{i=1}^n\right), \]
the test
\[ T_{\alpha}^{Q, \xi_n} := \mathbb{I}\left(\frac{1 + \sum_{b=1}^B \mathbb{1}(\xi_n^{(b)} \geq \xi_n^o)}{1 + B} \leq \alpha \right) \]
can be restated as
\[ T_{\alpha}^{Q, \xi_n} = \mathbb{I}\left(\sqrt{n}\xi_n^o > \sqrt{n}\xi_n^{[1+B-\lfloor\alpha(1+B)\rfloor]}\right), \quad (7.19) \]
where \( \xi_n^{[1]}, \xi_n^{[2]}, \ldots, \xi_n^{[B]} \) is a rearrangement of \( \xi_n^{(1)}, \xi_n^{(2)}, \ldots, \xi_n^{(B)} \) such that
\[ \xi_n^{[1]} \leq \xi_n^{[2]} \leq \cdots \leq \xi_n^{[B]} . \]
Write \( \Phi_\sigma(\cdot) \) and \( \Phi_\sigma^{-1}(\cdot) \) for the cumulative distribution function and quantile function of the normal distribution with mean zero and variance \( \sigma^2 \). We wish to prove
\[ \sqrt{n}\xi_n^{[1+B-\lfloor\alpha(1+B)\rfloor]} \overset{p}{\rightarrow} \Phi_\sigma^{-1}(1 - \alpha), \quad (7.20) \]
Using Theorem 3.1 in Hoeffding (1952), it suffices to prove
\[ B^{-1} \sum_{b=1}^B \mathbb{1}(\sqrt{n}\xi_n^{(b)} \leq y) \overset{p}{\rightarrow} \Phi_\sigma(y), \]
which is immediate from
\[ B^{-1} \sum_{b=1}^B \mathbb{1}(\sqrt{n}\xi_n^{(b)} \leq y) \bigg| \mathcal{F}_n \overset{p}{\rightarrow} \Phi_\sigma(y) \quad \text{for almost every sequence } \{(X_n, Z_n)\}_{n \geq 1}. \]
We obtain that
\[ \lim_{n \to \infty} \mathbb{P}_{H_{1,n}(\Delta_0), Q}\left(T_{\alpha}^{Q, \xi_n} = 1\right) = \lim_{n \to \infty} \mathbb{P}_{H_{1,n}(\Delta_0), Q}\left(\sqrt{n}\xi_n^o > \sqrt{n}\xi_n^{[1+B-\lfloor\alpha(1+B)\rfloor]}\right) \]
\[ = \lim_{n \to \infty} \mathbb{P}_{H_{1,n}(\Delta_0), Q}\left(\sqrt{n}\xi_n^o > \Phi_\sigma^{-1}(1 - \alpha)\right) = \alpha. \]
This completes the proof. \( \square \)

### 7.1.2 Proof of Theorem 4.1(ii)

**Proof of Theorem 4.1(ii).** Given that \( Y \) is independent of \( X \), the conditional independence between \( Y \) and \( Z \) given \( X \) is equivalent to the (unconditional) independence between \( Y \) and \( W = (X, Z) \).

To testing the independence between \( Y \in \mathbb{R}^1 \) and \( W \in \mathbb{R}^{p+q} \), we will adopt the test proposed in Shi et al. (2021a, Equation (13)); see Deb and Sen (2021) for a similar result. We will briefly illustrate the idea.

Let \( (Y_i, W_i) \), \( i = 1 \) to \( n \), be independent copies of \( (Y, W) \). Let \( F_{Y, \pm}^{(n)} \) and \( F_{W, \pm}^{(n)} \) be the empirical center-outward distribution functions as defined in Hallin et al. (2021, Definition 2.3) for \( \{Y_i\}_{i=1}^n \) and \( \{W_i\}_{i=1}^n \), respectively. We define the test statistic
\[ \widehat{M}_n := n \cdot \text{dCov}_n^2\left(\left[F_{X, \pm}^{(n)}(X_i)\right]_{i=1}^n, \left[F_{Y, \pm}^{(n)}(Y_i)\right]_{i=1}^n\right), \]
where the (sampled) distance covariance \( \text{dCov}_n^2(\cdot, \cdot) \) is given in Székely and Rizzo (2013, Defini-
tion 1), and then form the test
\[ T_{\alpha}^{\text{opt}} := 1\left(\hat{M}_n > q_{1-\alpha}\right), \quad q_{1-\alpha} := \inf\{x \in \mathbb{R} : P\left(\sum_{k=1}^{\infty} \lambda_k (\xi_k^2 - 1) \leq x\right) \geq 1 - \alpha\}. \]
Here, \( \lambda_k, k \in \mathbb{Z}_+ \), are the non-zero eigenvalues of the integral equation given by Shi et al. (2021a, Equation (12)) and depend only on \( p+q \), and \( [\xi_k]_{k=1}^{\infty} \) is a sequence of independent standard Gaussian random variables. Further details can be found in Shi et al. (2021a).

By Theorem 3.1 in Shi et al. (2021a),
\[ \lim_{n \to \infty} P_{H_0}(T_{\alpha}^{\text{opt}} = 1) \leq \alpha, \]
and by Theorem 5.3 in Shi et al. (2020), for sufficiently large \( \Delta_0 \),
\[ \lim_{n \to \infty} P_{H_{1,n}(\Delta_0)}(T_{\alpha}^{\text{opt}} = 1) \geq 1 - \beta. \]

Finally, we prove that
\[ \lim_{\Delta_0 \to 0} \lim_{n \to \infty} \text{TV}(H_0, H_{1,n}(\Delta_0)) = 0. \]
Equation (2.20) in Tsybakov (2009) states that total variation and Hellinger distances satisfy
\[ \text{TV}(H_{1,n}(\Delta_0), H_0) \leq \text{HL}(H_{1,n}(\Delta_0), H_0). \]
It is also known (Tsybakov, 2009, p. 83) that
\[ 1 - \frac{\text{HL}^2(H_{1,n}(\Delta_0), H_0)}{2} = \left(1 - \frac{\text{HL}^2(P_{1,n}(\Delta_0), P_0)}{2}\right)^n. \]
Lehmann and Romano (2005, Example 13.1.1) show that, under Assumption 4.1,
\[ n \times \text{HL}^2(P_{1,n}(\Delta_0), P_0)) \to \frac{\Delta_0^2 I_X(0)}{4}; \]
notice that here the definition of \( \text{HL}^2(Q,P) \) differs from that in Lehmann and Romano (2005, Definition 13.1.3) by a factor of 2. Therefore,
\[ \frac{\text{HL}^2(H_{1,n}(\Delta_0), H_0)}{2} \to 1 - \exp\left\{ - \frac{\Delta_0^2 I_X(0)}{8}\right\}. \]
where the right-hand side tends to 0 as \( \Delta_0 \to 0 \). This completes the proof.

### 7.2 Proof of Theorem 5.1

We revisit the example considered in the Proof of Theorem 4.2 in Neykov et al. (2021, Sec. B).

**Example 7.1.** Under the null hypothesis \( H_0 \) we specify the distribution \( P_0 \) with density
\[ q_{X,Y,Z}(x, y, z) = 1 \quad \text{(7.21)} \]
for all \((x, y, z) \in [0,1]^3\). Under the local alternative hypothesis \( H_{1,n} \) we specify the distribution \( P_{1,n} \) with density
\[ q_{X,Y,Z}(x, y, z) = 1 + \gamma_{\rho,m}(y, z)\eta_{\rho,m}(x), \quad \text{(7.22)} \]
where
\[ \eta_{\rho,m}(x) = \rho \sum_{k \in [m]} \nu_k h_{k,m}(x) \quad \text{and} \quad \gamma_{\rho,m}(y, z) = \rho^2 \sum_{i \in [m']} \sum_{j \in [m']} \delta_{ij} h_{i,m'}(y) h_{j,m'}(z). \]
In the definition of these functions $\rho > 0$ is a constant, $m$ and $m'$ are positive integers, $\nu_k, k \in [m]$ and $\delta_{ij}, i, j \in [m']$ are i.i.d. Rademacher random variables (taking values of 1 and $-1$ with probability $1/2$ each), and

$$h_{k,m}(x) = \sqrt{m} \times h(mx - k + 1) \quad \text{for } x \in [(k - 1)/m, k/m]$$

(and is zero elsewhere), where $h$ is an infinitely differentiable function supported on $[0, 1]$ such that

$$\int h(x)dx = 0 \quad \text{and} \quad \int h^2(x)dx = 1. \quad (7.23)$$

Let $c_1 = \int |h(x)|dx$ and $c_\infty = \max(\|h\|_\infty, \|h'\|_\infty)$. In addition, we assume that $h(x) = -h(1 - x)$ and $\int_0^1 \int_0^x h(u)du dx = 0. \quad (7.24)$

In order for the joint density $(7.22)$ to be bona fide, it suffices to have that $\rho^3 \sqrt{m} \sqrt{(m')^2} c_3^3 \leq 1$. Furthermore, we require that $\rho^3 \sqrt{m} \sqrt{(m')^2} c_3^3 \to 0$, as $n \to \infty. \quad (7.25)$

It is simple to check the following lemma for Example 7.1.

**Lemma 7.5.** The marginal of $(X, Y)$ is uniformly distributed on $[0, 1]^2$ for both $P_{X,Y,Z} = P_0$ and $P_{X,Y,Z} = P_{1,n}$.

Moreover, we are able to compute the population Chatterjee’s correlation for $P_{X,Y,Z} = P_{1,n}$.

**Lemma 7.6.** Under the local alternative, the population Azadkia–Chatterjee correlation is

$$\xi(P_{1,n}) = 6 \rho^6 m \int_0^1 \{H(u)\}^2 du, \quad (7.26)$$

where $H(x) := \int_0^x h(u)du$.

To prepare the proof of Claim (i), consider

$$\hat{\xi}_n := \frac{n^{-2} \sum_{i=1}^n \{\min(R_i, R_{M(i)}) - \min(R_i, R_{N(i)})\}}{\int E[\text{Var}\{1(Y \geq t) | X]\}dP_Y(t)}, \quad (7.27)$$

for which we have the following lemma.

**Lemma 7.7.** Let $\hat{\xi}_n(P_{1,n})$ and $\hat{\xi}_n(P_0)$ denote the estimates given by $(7.27)$ under the local alternative hypothesis and null hypothesis, respectively. Then

$$\left| \mathbb{E}\left\{\hat{\xi}_n(P_{1,n})\right\} - \mathbb{E}\left\{\hat{\xi}_n(P_0)\right\} \right| \lesssim \rho^6 m, \quad \text{and} \quad \left| \mathbb{E}\left[n\{\hat{\xi}_n(P_{1,n})\}^2\right] - \mathbb{E}\left[n\{\hat{\xi}_n(P_0)\}^2\right] \right| \lesssim n \rho^6 m. \quad (7.28)$$

We also have the following lemma for $\hat{\xi}_n$:

**Lemma 7.8.** Under the local alternative hypothesis, assuming $\rho^2 m \lesssim n^{-1}$, it holds that

$$\sqrt{n} \xi_n - \sqrt{n} \hat{\xi}_n = o_P(1). \quad (7.29)$$
In the sequel, we set
\[ m = m' = \lfloor K_1 n^{2/4s+3} \rfloor, \quad \rho^3 = K_2 n^{-2s/(4s+3)}, \]  
where \( K_1 \) and \( K_2 \) are positive absolute constants satisfying
\[ K_2 K_1^{3/2+s} = L/(8\sigma^3) \quad \text{and} \quad K_2 K_1^{3/2} = 12\Delta_0/\epsilon_1^3. \]  
(7.31)

We obtain the following result.

**Lemma 7.9.** Assumption (7.25) holds and \( P_0 \) is a probability measure on \( \mathcal{F}_n \), \( P_1, n \) is a probability measure on \( \mathcal{F}(\Delta_0 n^{-2s/(4s+3)}; L, s) \).

### 7.2.1 Proof of Theorem 5.1(i)

**Proof of Theorem 5.1(i).** In view of the proof of Theorem 4.2(i), we obtain from (7.28) that
\[ n\mathbb{E}[\{\xi_n(P_{1,n})\}^2] \rightarrow \frac{4}{5} + \frac{2}{5}\{q_2 + q_1\} + \frac{4}{5}\{q_2 + q_1\} =: \sigma^2. \]  
(7.32)

Using (7.19) and (7.20) once again, we obtain
\[ \limsup_{n \to \infty} P_{H_{1,n}, Q}(T_{\alpha}^{Q, \xi_n} = 1) = \limsup_{n \to \infty} P_{H_{1,n}, Q}\left(\sqrt{n}\xi_n(P_{1,n}) > \sqrt{n}\xi_n|1 + B - |\alpha(1 + B)|]\right) \]
\[ = \limsup_{n \to \infty} P_{H_{1,n}, Q}\left(\sqrt{n}\xi_n(P_{1,n}) > \Phi^{-1}_\sigma(1 - \alpha)\right). \]

Combining (7.29) and (7.32) yields
\[ \limsup_{n \to \infty} P_{H_{1,n}, Q}\left(\sqrt{n}\xi_n(P_{1,n}) > \Phi^{-1}_\sigma(1 - \alpha)\right) = \limsup_{n \to \infty} P_{H_{1,n}, Q}\left(\sqrt{n}\xi_n(P_{1,n}) > \Phi^{-1}_\sigma(1 - \alpha)\right) \]
\[ \leq \limsup_{n \to \infty} \frac{\mathbb{E}[n\{\xi_n(P_{1,n})\}^2]}{\{\Phi^{-1}_\sigma(1 - \alpha)\}^2} = \frac{1}{\{\Phi^{-1}(1 - \alpha)\}^2} =: \beta_\alpha. \]  
(7.33)

It is easy to check \( \beta_\alpha < 1 \) for any \( \alpha < 0.1 \). This completes the proof for \( \xi_n \). \( \square \)

### 7.2.2 Proof of Theorem 5.1(ii)

**Proof of Theorem 5.1(ii).** We first prove
\[ \lim_{\Delta_0 \to 0} \lim_{n \to \infty} \text{TV}(H_{1,n}(\Delta_0), H_0) = 0. \]

We use the relation (Tsybakov, 2009, Equation (2.27))
\[ \text{TV}\left(H_{1,n}(\Delta_0), H_0\right) \leq \left\{ \lambda^2\left(H_{1,n}(\Delta_0), H_0\right) \right\}^{1/2} \]
where the \( \lambda^2(Q, P) := \int (dQ/dP - 1)^2 dP \) denotes the chi-square distance between \( Q \) and \( P \). In view of the proof of Theorem 4.2 in Neykov et al. (2021, Appendix B), we have that
\[ \lambda^2\left(H_{1,n}(\Delta_0), H_0\right) \leq C_0 (np^6)^2 m(m')^2, \quad \text{for} \quad (np^6)^2 m(m')^2 \leq \frac{1}{2}, \]
where \( C_0 \) is some absolute constant. Using (7.30) and (7.31), we have
\[ (np^6)^2 m(m')^2 \to \frac{\{12\Delta_0/\epsilon_1^3\}^{1+3/s}}{(L/(8\sigma^3))^{3/s}}, \]
where the right-hand side tends to 0 as \( \Delta_0 \to 0 \). This concludes the proof.
Next, we prove the existence of $T^{\text{bin}}$. The testing strategy is exactly the same as described in Section 5.3 of Neykov et al. (2021) (see also Section 5.2). The only difference lies in the binning size. In detail, let
\[ d = \ell_1 = \ell_2 = \lceil n^{2/(4s+3)} \rceil. \]
We partition the support $[0, 1]$ into bins $\{C_j\}_{j=1}^d$, where $C_j := [(j-1)/d, j/d)$. Using a Poisson random variable $N$ with mean $n/2$, we will accept the null hypothesis if $N > n$, and if $N \leq n$ we draw without replacement a random sample $S$ of size $N$ from $[n]$. The set of discretized observations is defined as $\{(X_i, Y'_i, Z'_i)\}_{i \in S}$, where $Y'_i := j$ iff $Y_i \in C_j$ and $Z'_i := j$ iff $Z_i \in C_j$ for $j \in [d]$. Let $D_j := \{(Y'_i, Z'_i)\}_{i \in C_j, i \in S}$, and let $\sigma_j$ be the cardinality of $D_j$. For brevity, suppose that $D_j$ can be reindexed as $\{Y'_k, Z'_k\}_{k \in [\sigma_j]}$. For $\sigma_j \geq 4$, assume that $\sigma_j = 4 + 4t_j$ for some $t_j \in \mathbb{N}$. Define $t_{1,j} := \min(t_j, \ell_1)$ and $t_{2,j} := \min(t_j, \ell_2)$. Next we split $D_j$ into three datasets of sizes $t_{1,j}, t_{2,j},$ and $2t_j + 4$ as below: $D_j, y' = \{Y'_k\}_{k=1}^{t_{1,j}}, D_j, z' = \{Z'_k\}_{k=t_{1,j}+1}^{t_{1,j}+t_{2,j}},$ and $D_j, y', z' = \{(Y'_k, Z'_k)\}_{k=t_{2,j}+1}$, and we are able to compute $U_j := U_W(D_j)$ defined in Equation (5.5) of Neykov et al. (2021) for each $D_j$ with at least four observations. The statistic $U_j$ is a weighted U-statistic that has similarities with a Pearson $\chi^2$-statistic for testing independence of $Y'_j$ and $Z'_j$ based on $D_j$. We can now compute the test statistic defined in Equation (5.6) of Neykov et al. (2021):
\[ T = \sum_{j \in [d]} 1(\sigma_j \geq 4)\sigma_j \omega_j U_j, \]
where $\omega_j = \sqrt{\min(\sigma_j, \ell_1)} \min(\sigma_j, \ell_2)$. Finally, we define the test $T^{\text{bin}}$ as
\[ T^{\text{bin}} = 1(N \leq n)1(T \geq \zeta \sqrt{d}) \]
where $\zeta$ is a sufficiently large absolute constant.

The proof of our claim about $T^{\text{bin}}$ proceeds in parallel to the proof of Theorems 5.5 and 5.6 in Neykov et al. (2021). As we detail now, the following main differences arise. We start from the proof of their Theorem C.5 (which implies Theorem 5.5). Lemmas C.7–C.9 therein still hold. Suppose that
\[ q \in \mathcal{P}_1(L, s) \quad \text{and} \quad \inf_{q_0 \in \mathcal{P}_0} \|q - q_0\|_1 \geq \epsilon := \Delta_0 n^{-3s/(4s+3)}. \]
For the expression in (C.13) in Neykov et al. (2021), we have that
\[ \sum_{j \in [d]} \frac{\epsilon_j}{\sqrt{\ell_1 \ell_2}} |a_j| \geq \frac{n}{\sqrt{\ell_1 \ell_2}} \left( \epsilon - \frac{3L}{2d^s} \right) =: \frac{n}{\sqrt{\ell_1 \ell_2}} \eta. \]
We will assume that $\Delta_0 \geq 3L$ such that
\[ \epsilon \geq 3L/d^s \quad \text{and} \quad \eta \geq \epsilon/4. \]
It may be readily checked that the following conditions hold:
\[ \frac{n \eta^2}{\sqrt{\ell_1 \ell_2}} \geq C_1 \Delta_0^3 \sqrt{d}, \quad (7.34) \]
\[ \max \left( \frac{n^{3/2} \eta^2}{\ell_1 \sqrt{\ell_2} \sqrt{\kappa d}}, \frac{n^{3/2} \eta^2}{\ell_1 \sqrt{\ell_2} \sqrt{d}} \right) \geq C_2 \Delta_0^3 \sqrt{d}, \quad (7.35) \]
\[ \frac{n \eta^2}{36 \ell_1 \ell_2 d} \geq C_3 \Delta_0^3 \sqrt{d}, \quad (7.36) \]
and \[ \frac{n^4 \eta^4}{16 \ell_1 \ell_2 d^3} \geq C_4 \Delta_0^2 \sqrt{d}, \] (7.37)

where \(C_1, C_2, C_3, C_4\) are absolute constants.

Denote \(\sigma = \{\sigma_j\}_{j \in [d]}\) and \(R = \{\{D_{j,Y'}, D_{j,Z'}\}_{j \in [d]}\}.\) We have the following results.

**Lemma 7.10.** Suppose \(P_{X,Y,Z} \in \mathcal{P}_1(\epsilon; L, s)\), where \(\epsilon \geq 3L/d^5\) and Conditions (7.34)–(7.37) hold. Then with probability at least \(1 - \beta/2\) over \(\sigma, R\) we have for some absolute constants \(C_5, C_6\) depending on \(L, s\) that

\[ E[T|\sigma, R] \geq C_5 \Delta_0^2 \sqrt{d} \]

and

\[ \text{Var}[T|\sigma, R] \leq C_6 (d + (\sqrt{d} + 1)E[T|\sigma, R] + E[T|\sigma, R]^{3/2}). \]

**Lemma 7.11.** Suppose \(P_{X,Y,Z} \in \mathcal{P}_0(L, s)\), and

\[ \ell_1 \geq \ell_2 \quad \text{and} \quad d\ell_1 \lesssim n. \]

Then with probability at least \(1 - \alpha/2\) we have for some absolute constants \(C_7, C_8\) depending on \(L, s\) that

\[ E[T|\sigma, R] \leq \frac{C_7 n}{d^{2s} \sqrt{\ell_1 \ell_2}} \]

and

\[ \text{Var}[T|\sigma, R] \leq C_8 (d + (\sqrt{d} + 1)E[T|\sigma, R] + E[T|\sigma, R]^{3/2}). \]

The proofs of Lemmas 7.10 and 7.11 closely follow that of Lemmas C.10 and C.11 of Neykov et al. (2021). Using Lemmas 7.10 and 7.11 yields the following results, which are the revised version of Lemmas C.13 and C.12, respectively.

**Lemma 7.12.** Suppose \(P_{X,Y,Z} \in \mathcal{P}_1(\epsilon; L, s)\), where \(\epsilon \geq 3L/d^5\) and Conditions (7.34)–(7.37) hold. Then for a small enough absolute constant \(C_9\) depending on \(L, s, \beta\) we have that

\[ P(T \leq C_9 \Delta_0^2 \sqrt{d}) \leq \beta. \]

**Lemma 7.13.** If \(P_{X,Y,Z} \in \mathcal{P}_0(L, s)\) and

\[ \frac{n}{d^{2s} \sqrt{\ell_1 \ell_2}} \asymp \sqrt{d}, \]

then for a sufficiently large absolute constant \(C_{10}\) depending on \(L, s, \alpha\), we have

\[ P(T \geq \frac{C_{10} n}{d^{2s} \sqrt{\ell_1 \ell_2}}) \leq \alpha. \]

Finally, we choose \(\zeta = C_{10}\) such that

\[ C_9 \Delta_0^2 \sqrt{d} \geq \zeta \sqrt{d} \geq \frac{C_{10} n}{d^{2s} \sqrt{\ell_1 \ell_2}} \]

for all sufficiently large \(\Delta_0\). The rest of the proof is analogous to the steps in the proof of Theorems 5.6 and C.15 in Neykov et al. (2021), and hence omitted.
A Proof

Additional notation. For a function \( f : \mathcal{X} \to \mathbb{R} \), we define \( \|f\|_\infty := \max_{x \in \mathcal{X}} |f(x)| \). We use \( \xrightarrow{d} \), \( \xrightarrow{p} \), and \( \xrightarrow{a.s.} \) to denote convergence in distribution, convergence in probability, and almost sure convergence, respectively. For any two real sequences \([a_n], \ [b_n]\), we write \( a_n = O(b_n) \) if there exists \( C > 0 \) such that \( |a_n| \leq C|b_n| \) for all \( n \) large enough, and \( a_n = o(b_n) \) if for any \( c > 0 \), \( |a_n| \leq c|b_n| \) holds for all \( n \) large enough. For a sequence of random variables \([X_n]\) and a real sequence \([a_n]\), we write \( X_n = O_p(a_n) \) if for any \( \epsilon > 0 \) there exists \( C > 0 \) such that \( P(|X_n| \geq C|a_n|) < \epsilon \) for all \( n \) large enough, and \( X_n = o_p(a_n) \) if for any \( c > 0 \), \( \lim_{n \to \infty} P(|X_n| \geq c|a_n|) = 0 \).

A.1 Proofs for Section 2

A.1.1 Proof of Proposition 2.3

Proof of Proposition 2.3. We will use the shorthand notation

\[
\xi_n^{(b)} \equiv \xi_n \left( \left[ \left( X_i, Y^{(b)}_i, Z_i \right) \right]_{i=1}^n \right), \quad \xi_n^{(o)} \equiv \xi_n \left( \left[ \left( X_i, Y_i, Z_i \right) \right]_{i=1}^n \right), \quad \text{and} \quad \varepsilon_n^{(b)} := \mathbb{I} \left( \xi_n^{(b)} \geq \xi_n^{(o)} \right),
\]

and we have

\[
p_{\text{CRT}} = (1 + B)^{-1} + (1 + B)^{-1} \sum_{b=1}^B \varepsilon_n^{(b)}. \tag{A.1}
\]

Claim (i) is a corollary of Candès et al. (2018b, Lemma 2.1). Notice that

\[
p_{\text{CRT}} \geq (1 + B)^{-1} + (1 + B)^{-1} \sum_{b=1}^B \mathbb{I}^{\text{rtb}}(\xi_n^{(b)}, \xi_n^{(o)}; U_b) =: p_{\text{CRT}}^{\text{rtb}},
\]

where \( U_1, \ldots, U_B \) are independent Bernoulli random variables of equal probabilities to be 0 or 1, and

\[
\mathbb{I}^{\text{rtb}}(x, y; u) := \begin{cases} \mathbb{I}(x \geq y), & \text{if } x \neq y, \\ u, & \text{if } x = y. \end{cases}
\]

Under the null hypothesis and conditionally on \( \left[ \left( X_i, Z_i \right) \right]_{i=1}^n \), we have

\[
\xi_n^{(1)}, \ldots, \xi_n^{(B)}, \xi_n^{(o)}
\]

are independent and identically distributed, and accordingly \( p_{\text{CRT}}^{\text{rtb}} \) is discretely uniformly distributed over

\[
\left\{ \frac{1}{1+B}, \frac{2}{1+B}, \ldots, \frac{1+B}{1+B} \right\}.
\]

As a consequence,

\[
P_{H_0} \left( \mathbb{T}_a^{Q, \xi_n} = 1 \right) \left( \left[ \left( X_i, Z_i \right) \right]_{i=1}^n \right) = P_{H_0} \left( p_{\text{CRT}} \leq \alpha \right) \left( \left[ \left( X_i, Z_i \right) \right]_{i=1}^n \right) \leq P_{H_0} \left( p_{\text{CRT}}^{\text{rtb}} \leq \alpha \right) \left( \left[ \left( X_i, Z_i \right) \right]_{i=1}^n \right) = \frac{\alpha (1 + B)}{1 + B} \leq \alpha.
\]

Since this inequality holds conditionally, it also holds unconditionally.

It remains to prove Claim (ii), the consistency of \( \mathbb{T}_a^{Q, \xi_n} \). Since by Propositions 2.1 and 2.2, under
the fixed alternative $H_1$,

$$\xi_n^{(b)} \xrightarrow{a.s.} 0 \quad \text{and} \quad \xi_n^\circ \xrightarrow{a.s.} \xi_{H_1}$$

where $0 < \xi_{H_1} \leq 1$, we obtain

$$\Xi_n^{(b)} = \mathbb{1}\{\xi_n^{(b)} \geq \xi_n^\circ\} \xrightarrow{a.s.} 0.$$  \hfill (A.2)

Recall that $B = B_n$ tends to infinity as $n \to \infty$. Since random variables $\Xi_n^{(1)}, \Xi_n^{(2)}, \ldots, \Xi_n^{(B_n)}$ are exchangeable, applying Lemma 1.1 in Patterson and Taylor (1985) yields

$$B_n^{-1} \sum_{b=1}^{B_n} \Xi_n^{(b)} = E\left(\frac{\Xi_n^{(1)}}{B_n} \middle| \mathcal{G}_n\right) \quad \text{a.s.,}$$  \hfill (A.3)

where $\mathcal{G}_n$ is the $\sigma$-field generated as

$$\mathcal{G}_n := \sigma\left(\sum_{b=1}^{B_n} \Xi_n^{(b)}, \sum_{b=1}^{B_n+1} \Xi_n^{(b)}, \ldots\right).$$

Notice that (i) $[\mathcal{G}_n]_{n=1}^\infty$ is a decreasing sequence of $\sigma$-fields with $\mathcal{G}_n \to \mathcal{G}_\infty := \bigcap_{n=1}^\infty \mathcal{G}_n$, (ii) $0 \leq \Xi_n^{(1)} \leq 1$, and (iii) $\Xi_n^{(1)} \xrightarrow{a.s.} 0$. Using Lemma 2(c) in Isaac (1979), we obtain

$$E\left(\frac{\Xi_n^{(1)}}{B_n} \middle| \mathcal{G}_n\right) \xrightarrow{a.s.} E\left(0 \middle| \mathcal{G}_\infty\right) = 0.$$  \hfill (A.4)

Combining (A.3) and (A.4), we deduce

$$B_n^{-1} \sum_{b=1}^{B_n} \Xi_n^{(b)} \xrightarrow{a.s.} 0,$$

and moreover, in (A.1) that

$$p_{\text{CRT}} \xrightarrow{a.s.} 0,$$

Therefore,

$$\lim_{n \to \infty} P_{H_1, Q}(T_{\alpha}^{Q, \xi_n} = 1) = \lim_{n \to \infty} P_{H_1, Q}(p_{\text{CRT}} \leq \alpha) = 1,$$

and the proof is complete.

\section*{A.2 Proofs for Section 3}

\subsection*{A.2.1 Proof of Lemma 3.3}

\textit{Proof of Lemma 3.3.} Using Lemmas 3.1 and 3.4 yields

$$E\left(n^{-1} \sum_{(i,j,k) \text{ distinct}} 1\right) = E\left\{n^{-1} \sum_{k=1}^{n} d_{k}^- (d_{k}^- - 1)\right\} = E\{d_1^- (d_1^- - 1)\} = \text{Var}(d_1^-) \to \vartheta_{d,2},$$

where $d_{k}^- := \sum_{i \to k} \mathbb{1}(\mathcal{E}(\mathcal{G}_n))$ is the in-degree of vertex $(X_k, Z_k)$ in $\mathcal{G}_n$. \hfill $\square$

\subsection*{A.2.2 Proof of Theorem 3.1}

\textit{Proof of Theorem 3.1.} Claim (i) can be proved in view of the proof of Theorem 4.1(i).
We next give a proof of Claim (ii). When \( Y \) and \( Z \) are both absolutely continuous, we have
\[
\xi^\#_n = n \sum_{i=1}^n \min(R_i, R_{M(i)}) - \sum_{i=1}^n i^2 = \frac{n^{-2} \sum_{i=1}^n \min(R_i, R_{M(i)}) - (1 + n^{-1})(2 + n^{-1})/6}{(1 - n^{-2})/6}.
\]
Moreover, in view of Equation (A.8) in the Proof of Lemma 7.1, we have under the null,
\[
\sqrt{n} \xi^\#_n - \sqrt{n} \xi^1_n = o_P(1),
\]
where
\[
\xi^1_n := \frac{n^{-1} \sum_{i=1}^n \min\{F_Y(Y_i), F_Y(Y_{M(i)})\} - \sum_{i \neq j} \min\{F_Y(Y_i), F_Y(Y_j)\}}{1/6}.
\]
In view of the proof of Theorem 4.1(i), to establish the central limit theorem for \( \sqrt{n} \xi^\#_n \) and thus \( \sqrt{n} \xi^1_n \), it suffices to determine the limit of \( \text{Var}(\sqrt{n} \xi^1_n) \). Set \( K_{\lambda}(y_1, y_2) := \min\{F_Y(y_1), F_Y(y_2)\} \),
\[
\gamma_1 := E\left\{ 6K_{\lambda}(Y, Y') - 2 \right\}^2 = 2 \quad \text{and} \quad \gamma_2 := E\left\{ 6K_{\lambda}(Y, Y') - 2 \right\}\left\{ 6K_{\lambda}(Y, Y'') - 2 \right\} = 4/5,
\]
where \( Y' \) and \( Y'' \) are independent copies of \( Y \). Then
\[
\text{Var}(\sqrt{n} \xi^1_n) \to E\left( n^{-1} \sum_{i=1}^n \gamma_1 \right) + E\left( n^{-1} \sum_{i,j \in E(G_n)} \gamma_1 \right) + E\left( n^{-1} \sum_{i,j,k \in E(G_n)} \gamma_2 \right) - 4\gamma_2
\]
\[
\to \gamma_1 + \gamma_1 a_q + \gamma_2 \left( o_q + 2 - 2a_q \right) - 4\gamma_2 = \frac{2}{5} + \frac{2}{5} a_q + 4 \frac{4}{5} a_q.
\]
This completes the proof.

A.3 Proofs for Section 5
A.3.1 Proof of Lemma 5.1

Proof of Lemma 5.1. We first prove Claim (i). When \( Y \Perp Z \mid X \), we have \( q_{Y \mid X, Z}(y \mid x, z) = q_{Y \mid X}(y \mid x) \). The rest is obvious. Then we prove Claim (ii). Since
\[
|q_{Y \mid X, Z}(y, z \mid x) - q_{Y \mid X}(y', z' \mid x)| \leq L \left( |y - y'|^s + |z - z'|^s \right),
\]
it holds that
\[
|q_{Z \mid X}(z \mid x) - q_{Z \mid X}(z' \mid x)| = \left| \int_{[0,1]} q_{Y \mid X, Z}(y, z \mid x)dy - \int_{[0,1]} q_{Y \mid X, Z}(y, z' \mid x)dy \right|
\]
\[
\leq \int_{[0,1]} \left| q_{Y \mid X, Z}(y, z \mid x) - q_{Y \mid X, Z}(y, z' \mid x) \right|dy \leq L |z - z'|^s.
\]
Next, since
\[
|q_{Y \mid X, Z}(y, z \mid x) - q_{Y \mid X}(y, z \mid x')| \leq L \left\| x - x' \right\|^s,
\]
we have
\[
|q_{Z \mid X}(z \mid x) - q_{Z \mid X}(z' \mid x')| = \left| \int_{[0,1]} q_{Y \mid X, Z}(y, z \mid x)dy - \int_{[0,1]} q_{Y \mid X, Z}(y, z \mid x')dy \right|
\]
Also, \( L^{-1} \leq q_{Y,Z} \mid x = \mathbb{P} \) \( \leq \) \( L \) implies \( L^{-1} \leq q_{Z} \mid x = L \). Then for all \( x, x' \in [0,1]^p \) and \( y, z, z' \in [0,1] \), we have
\[
\frac{|q_{Y,Z} \mid x(y, z \mid x) - q_{Y,Z} \mid x(y, z' \mid x')|}{q_{Z} \mid x(z \mid x)} \leq L^{-1} \leq \frac{|q_{Y,Z} \mid x(y, z \mid x) - q_{Y,Z} \mid x(y, z' \mid x')|}{q_{Z} \mid x(z \mid x)}
\]

\[
\leq L^3 \left( |q_{Z} \mid x(z \mid x) - q_{Z} \mid x(z' \mid x')| + |q_{Y,Z} \mid x(y, z \mid x) - q_{Y,Z} \mid x(y, z' \mid x')| \right)
\]

\[
\leq L^3 \left( |q_{Z} \mid x(z \mid x) - q_{Z} \mid x(z' \mid x')| + |q_{Z} \mid x(z \mid x) - q_{Z} \mid x(z' \mid x')| + |q_{Y,Z} \mid x(y, z \mid x) - q_{Y,Z} \mid x(y, z \mid x')| + |q_{Y,Z} \mid x(y, z' \mid x) - q_{Y,Z} \mid x(y, z' \mid x')| \right)
\]

\[
\leq 2L^4(|z - z'|^s + \|x - x'|^s),
\]
which concludes the proof.

\[\square\]

\textbf{A.3.2 Proof of Proposition 5.1}

\textit{Proof of Proposition 5.1.} We first prove \( \xi_n - \xi = O_p\left((\log n)^{p+q+1} / n^{s/(p+q)}\right) \). Following the Proof of Theorem 4.1 in Azadkia and Chatterjee (2021, Sec. 14), we first generalize Lemma 14.1 in Azadkia and Chatterjee (2021, Sec. 14), i.e., show that there is some \( C_3 \) depending only on \( C_1, C_2, p \) and \( s \) such that

\[
E\{\min(\|X_1 - X_{N(1)}\|^s, 1)\} \leq \begin{cases} 
C_3n^{-1}(\log n)^2 & \text{if } p = 1 \text{ and } s = 1, \\
C_3n^{-s/p} \log n & \text{otherwise}.
\end{cases}
\]

In view of the Proof of Lemma 14.1 in Azadkia and Chatterjee (2021, Sec. 14), we get

\[
P(\|X_1 - X_{N(1)}\| \geq \epsilon) \leq (1 - \delta)^{n-1} + C_pC_2^p\epsilon^{-p}\delta
\]

and, by taking \( \delta = n^{-1} \log n \), find that

\[
P(\|X_1 - X_{N(1)}\| \geq \epsilon) \leq \frac{C_4 \log n}{ne^p}
\]

for some \( C_4 \) depending only on \( C_1, C_2 \) and \( p \). Thus,

\[
E\{\min(\|X_1 - X_{N(1)}\|^s, 1)\}
\]

\[
= \int_0^{n^{-s/p}} P(\|X_1 - X_{N(1)}\|^s \geq \epsilon) d\epsilon + \int_{n^{-s/p}}^{1} P(\|X_1 - X_{N(1)}\|^s \geq \epsilon) d\epsilon
\]

\[
\leq \int_0^{n^{-s/p}} 1d\epsilon + \frac{C_4 \log n}{ne^p} \int_{n^{-s/p}}^{1} \epsilon^{-p/s} d\epsilon = n^{-s/p} + \frac{C_4 \log n}{n} \int_{n^{-s/p}}^{1} \epsilon^{-p/s} d\epsilon.
\]

This completes the proof of (A.5). Next in view of the Proof of Lemma 14.2 and Theorem 4.1 in Azadkia and Chatterjee (2021, Sec. 14), the desired result follows. \[\square\]
A.3.3 Proof of Corollary 5.2

Proof of Corollary 5.2. We will use the shorthand notation
\[ \xi_n^{(b)} \equiv \xi_n\left(\left[(X_i, Y_i^{(b)}, Z_i)\right]_{i=1}^n\right), \quad \xi_n^\circ \equiv \xi_n\left(\left[(X_i, Y_i^j, Z_i)\right]_{i=1}^n\right), \quad \text{and} \quad \Xi_n^{(b)} : = \mathbb{1}\left(\xi_n^{(b)} \geq \xi_n^\circ\right). \]
We have
\[ p_{\text{CRT}} = (1 + B)^{-1} + (1 + B)^{-1} \sum_{b=1}^B \Xi_n^{(b)}. \quad (A.6) \]
Notice that \( P_{X_i, Y_i^{(b)}, Z_i} \in P_0(L, s) \) and \( P_{X_i, Y_i^j, Z_i} \in P_1(L, s) \) for \( i \in \llbracket n \rrbracket \). Moreover, Lemma 5.1 implies that all distributions in \( P_{[0,1]^p, \infty}(L, s) \) and \( Q_{[0,1]^p, \infty}(L, s) \) are such that the assumptions in Proposition 5.1 are satisfied. Since \( \xi(P_{1,n}) \gtrsim n^{-s/(p+1)+\delta} \), we have
\[ n^{s/(p+1)-\delta/2} \xi_n^{(b)} \overset{p}{\to} 0 \quad \text{and} \quad n^{s/(p+1)-\delta/2} \xi_n^\circ \overset{p}{\to} \infty. \]
Accordingly, we obtain
\[ \Xi_n^{(b)} = \mathbb{1}\left\{ n^{s/(p+1)-\delta/2} \xi_n^{(b)} \geq n^{s/(p+1)-\delta/2} \xi_n^\circ \right\} \overset{p}{\to} 0. \quad (A.7) \]
Recall that \( B = B_n \) tends to infinity as \( n \to \infty \). Since \( \Xi_n^{(1)} \overset{p}{\to} 0 \), using Theorem 5.7 in Shorack (2017, Chap. 3) yields that every subsequence \( \{n'\} \) contains a further subsequence \( \{n''\} \) for which \( \Xi_n^{(1)} \overset{a.s.}{\to} 0 \). In view of the Proof of Proposition 2.3, we obtain
\[ B_n^{-1} \sum_{b=1}^{B_n} \Xi_n^{(b)} \overset{a.s.}{\to} 0, \]
and then using Theorem 5.7 in Shorack (2017, Chap. 3) once again gives
\[ B_n^{-1} \sum_{b=1}^{B_n} \Xi_n^{(b)} \overset{p}{\to} 0. \]
Moreover, we deduce from (A.6) that
\[ p_{\text{CRT}} \overset{p}{\to} 0. \]
Therefore,
\[ \lim_{n \to \infty} P_{H_1,n}(T^{Q_{\alpha,\xi_n}} = 1) = \lim_{n \to \infty} P_{H_1,n}(p_{\text{CRT}} \leq \alpha) = 1, \]
and we have completed the proof. \( \square \)

A.4 Proofs for Section 7

A.4.1 Proof of Lemma 7.1

Proof of Lemma 7.1. Using a Hájek representation theorem (Deb et al., 2020, Lemma D.1), we have
\[ n^{-2} \sum_{i=1}^n \min(R_i, R_{M(i)}) - \{n^2(n-1)\}^{-1} \sum_{i \neq j} \min(R_i, R_j) \]
\[ = n^{-1} \sum_{i=1}^n \min\{F_Y(Y_i), F_Y(Y_{M(i)})\} - \{n(n-1)\}^{-1} \sum_{i \neq j} \min\{F_Y(Y_i), F_Y(Y_j)\} + o_P(1), \quad (A.8) \]
and, similarly,
\[ n^{-2} \sum_{i=1}^{n} \min(R_i, R_{N(i)}) - \{n^2(n-1)\}^{-1} \sum_{i \neq j} \min(R_i, R_j) \]
\[ = n^{-1} \sum_{i=1}^{n} \min\{F_Y(Y_i), F_Y(Y_{N(i)})\} - \{n(n-1)\}^{-1} \sum_{i \neq j} \min\{F_Y(Y_i), F_Y(Y_j)\} + o_P(1). \quad (A.9) \]
Combining (A.8) and (A.9) yields the desired result. \hfill \qed

### A.4.2 Proof of Lemma 7.2

**Proof of Lemma 7.2.** Let us construct an undirected graph \( G_n^{\text{Dep}} \) depending on \( G_n \) as follows: For any \( i \neq j \), we connect vertices \( i \) and \( j \) in \( G_n^{\text{Dep}} \) if and only if there is a path of length 1 or 2 joining \( (X_i, Z_i) \) and \( (X_j, Z_j) \) in \( G_n \) or in \( G_n^X \). As illustrated in the Proof of Theorem 4.1 in Deb et al. (2020, Appendix C.6), \( G_n^{\text{Dep}} \) is a dependency graph with maximum degree \( \lesssim (c_{p+q} + c_p)^2 \), where \( c_p \leq c_{p+q} \) by the definition of \( c_p \) as given in Lemma 3.1. Applying the Berry–Esseen theorem for dependency graphs (Chen and Shao, 2004, Theorem 2.7) to \( G_n^{\text{Dep}} \) yields the desired result (7.8). \hfill \qed

### A.4.3 Proof of Lemma 7.3

**Proof of Lemma 7.3.** We first prove
\[ \sum_{i=1}^{n} E(V_i^2 | F_n) \xrightarrow{a.s.} \sum_{i=1}^{n} E(V_i^2). \quad (A.10) \]
We only prove
\[ n^{-1} \sum_{(i,j) \text{ distinct}} 1 \xrightarrow{a.s.} E\left\{ n^{-1} \sum_{(i,j) \text{ distinct}} \right\}, \quad (A.11) \]
and the other summands in (7.11) can be handled similarly. Define
\[ U_n \equiv U_n\left( \left[ (X_i, Z_i) \right]_{i=1}^{n} \right) := n^{-1} \sum_{(i,j) \text{ distinct}} 1. \]
Let \( (\tilde{X}_1, \tilde{Z}_1), \ldots, (\tilde{X}_n, \tilde{Z}_n) \) be independent copies of \( (X_1, Z_1), \ldots, (X_n, Z_n) \). Set \( X_i^{(j)} := X_i \) if \( i \neq j \) and \( X_i^{(j)} := \tilde{X}_i \) if \( i = j \), \( Z_i^{(j)} := Z_i \) if \( i \neq j \) and \( Z_i^{(j)} := \tilde{Z}_i \) if \( i = j \), and
\[ U_n^{(j)} := U_n\left( \left[ (X_i^{(j)}, Z_i^{(j)}) \right]_{i=1}^{n} \right). \]
In view of Proof of Proposition 3.2(ii) in Deb et al. (2020, Appendix C.3), there exists a constant \( C_{p+q,p} \) depending only on \( c_{p+q} \) and \( c_p \) such that
\[ \left| U_n - U_n^{(j)} \right| \leq \frac{C_{p+q,p}}{n}. \]
Using a generalized Efron–Stein inequality (Boucheron et al., 2005, Theorem 2) with \( q = 4 \) and Jensen’s inequality, we have
\[
\sum_{n=1}^{\infty} \mathbb{E} \left[ \left| U_n - \mathbb{E}(U_n) \right|^4 \right] \leq \kappa_4^4 \sum_{n=1}^{\infty} \mathbb{E} \left[ \left| \sum_{j=1}^{n} \left( U_n - U_n^{(j)} \right)^2 \right| \mathcal{F}_n \right]^2 \]
\[
\leq \kappa_4^4 \sum_{n=1}^{\infty} \mathbb{E} \left[ \left| \sum_{j=1}^{n} \left( U_n - U_n^{(j)} \right)^2 \right| \right] \leq \kappa_4^4 \sum_{n=1}^{\infty} \frac{C_{p+q}^n}{n^2} < \infty.
\]
Combining Markov’s inequality and the Borel–Cantelli lemma yields (A.11).

Next we prove
\[
\sum_{i \neq j} \mathbb{E}(V_i V_j | \mathcal{F}_n) \xrightarrow{a.s.} \sum_{i \neq j} \mathbb{E}(V_i V_j), \quad (A.12)
\]
We only prove
\[
n^{-1} \sum_{\{i,j\} \text{ distinct } j \rightarrow i \in \mathcal{E}(G_n)} \max_{j \rightarrow i \in \mathcal{E}(G_n)} \gamma^*_{4,a,b}(X_i, Z_i) \xrightarrow{a.s.} \mathbb{E}\left\{ n^{-1} \sum_{\{i,j\} \text{ distinct } j \rightarrow i \in \mathcal{E}(G_n)} \gamma^*_{4,a,b}(X_i, Z_i) \right\}, \quad (A.13)
\]
and the other summands in (7.12) can be handled similarly. Define
\[
T_n \equiv T_n \left( \left[ (X_i, Z_i) \right]_{i=1}^{n} \right) := n^{-1} \sum_{\{i,j\} \text{ distinct } j \rightarrow i \in \mathcal{E}(G_n)} \gamma^*_{4,a,b}(X_i, Z_i).
\]
In view of Proof of Proposition 3.2(ii) in Deb et al. (2020, Appendix C.3), there exists a constant \( C_{p+q} \) depending only on \( C_{p+q} \) such that
\[
|T_n - T_n^{(j)}| \leq \frac{C_{p+q}}{2n} \left\{ \max_{1 \leq i \leq n} \gamma^*_{4,a,b}(X_i, Z_i) + \max_{1 \leq i \leq n} \gamma^*_{4,a,b}(X_i^{(j)}, Z_i^{(j)}) \right\}.
\]
Using a generalized Efron–Stein inequality (Boucheron et al., 2005, Theorem 2) with \( q = 4 \) and Jensen’s inequality, we have
\[
\sum_{n=1}^{\infty} \mathbb{E} \left[ \left| T_n - \mathbb{E}(T_n) \right|^4 \right] \leq \kappa_4^4 \sum_{n=1}^{\infty} \mathbb{E} \left[ \left| \sum_{j=1}^{n} \left( T_n - T_n^{(j)} \right)^2 \right|^2 \mathcal{F}_n \right] \leq \kappa_4^4 \sum_{n=1}^{\infty} \mathbb{E} \left[ \left| \sum_{j=1}^{n} \left( T_n - T_n^{(j)} \right)^2 \right|^2 \right]
\]
\[
\leq \kappa_4^4 \sum_{n=1}^{\infty} \frac{C_{p+q}^n}{n^2} \mathbb{E} \left\{ \max_{1 \leq i \leq n} \gamma^*_{4,a,b}(X_i, Z_i) \right\} < \infty,
\]
where the last step applies bounds on the expectation of the maximum of random variables (see Gilstein (1981) or Arnold (1985, Theorem 3)) to Assumption 4.1.(vi). Combining Markov’s inequality and the Borel–Cantelli lemma yields (A.13). Putting (A.10) and (A.12) together yields (7.13). \(\square\)

A.4.4 Proof of Lemma 7.4

Proof of Lemma 7.4. We will follow the ideas of Proof of Theorem 2 in Devroeye (1988) and that of Theorem 1.4 in Henze (1987).
**Claim (7.15).** It suffices to show that
\[
\lim_{n \to \infty} \mathbb{E} \left( n^{-1} \sum_{(i,j) \text{ distinct}} 1 \right) = 0.
\]
We have \(i \to j \in \mathcal{E}(G_n) \cap \mathcal{E}(G_n^X)\) if and only if the set \(S^*(W_i, W_j)\) contains no point in \([W_k]_{k=1}^n\) other than \(W_i, W_j\), where
\[
S^*(w_1, w_2) := \left\{ w : \| w - w_1 \| < \| w_2 - w_1 \| \right\} \cup \left\{ (x, z) : \| x - x_1 \| < \| x_2 - x_1 \| \right\},
\]
and \(x_i\) is the sub-vector consisting of the first \(p\) elements of \(w_i\), and \(z_i\) is the sub-vector consisting of the last \(q\) elements of \(w_i\).

For every \(\epsilon, \delta > 0\), we can partition \(\mathbb{R}^{p+q}\) into a set \(G_{\epsilon, \delta}\) and its complement \(H_{\epsilon, \delta}\), where \(G_{\epsilon, \delta}\) is the collection of all \(w_1\) for which \(\|w_1\| \leq 1/\delta\) and
\[
f(w_2) - f(w_1) \leq \epsilon f(w_1)
\]
for all \(\|w_2 - w_1\| \leq \delta\). By the continuity of density \(f\), it is possible to find \(\delta > 0\) depending upon \(\epsilon\), such that
\[
\mu(H_{\epsilon, \delta}) < \epsilon \quad \text{and} \quad G_{\epsilon, \delta} = \{ w_1 : \|w_1\| \leq 1/\delta \}.
\]
(A.14)
We pick \(\delta\) in this manner, and write \(G_{\epsilon}\) and \(H_{\epsilon}\) hereafter if no confusion arises.

The data points are partitioned into two sets, according to membership in \(G_{\epsilon}\), or its complement. The number of edges in \(\mathcal{E}(G_n) \cap \mathcal{E}(G_n^X)\) can be written as \(N_{G_{\epsilon}} + N_{H_{\epsilon}}\), where \(N_{G_{\epsilon}}\) refers to the edges in which both vertices are in \(G_{\epsilon}\), and \(N_{H_{\epsilon}}\) refers to the other edges. The expected number of \(N_{H_{\epsilon}}\) is bounded by \(2C_{p+q}\) times the expected number of vertices in \(H_{\epsilon}\) (because every vertex has degree no larger than \(2C_{p+q}\)). Then
\[
\mathbb{E}(n^{-1} N_{H_{\epsilon}}) \leq 2C_{p+q}\mu(H_{\epsilon}) < 2C_{p+q}\epsilon.
\]
Recall that \(B(w_1, r)\) denotes the ball of radius \(r\) centered at \(w_1\), and \(\lambda(\cdot)\) denotes the Lebesgue measure. We let \(\mu(\cdot)\) denote the probability measure of a set, i.e., the integral of \(f\) over the set, and \(V_d\) is the volume of the unit ball in \(\mathbb{R}^d\). Define
\[
S(w_1, w_2; \Theta) := \left\{ (x, z) : \|x - x_1\| < \|x_2 - x_1\|, \|z - z_1\| < \Theta \|w_2 - w_1\| \right\}
\]
for \(\Theta > 0\). It is clear that
\[
B(w_1, \|w_2 - w_1\|), S(w_1, w_2; \Theta) \subseteq S^*(w_1, w_2).
\]
For any fixed and arbitrarily small \(\epsilon > 0\), fix a \(\delta > 0\) such that (A.14) holds, and consider \(N_{G_{\epsilon}}\) (the edges in which both vertices are in \(G_{\epsilon}\)). In what follows, we write \(r_{12} := \|w_2 - w_1\|, r_{12}^p := \|x_2 - x_1\|, \) and \(r_{12}^z := \|z_2 - z_1\|\), where \(w_i = (x_i, z_i)\) for simplicity. We observe that
\[
\mathbb{E}(n^{-1} N_{G_{\epsilon}}) \leq (n - 1) \int_{w_1, w_2 \in G_{\epsilon}} \exp\left[-(n - 2)\mu(S^*(w_1, w_2))\right] f(w_1) f(w_2) dw_2 dw_1
\]
\[
\leq (n - 1) \int_{w_1, w_2 \in G_{\epsilon}} \exp\left[-(n - 2)\mu(S^*(w_1, w_2))\right] f(w_1) f(w_2) dw_2 dw_1
\]
\[
+ (n - 1) \int_{w_1, w_2 \in G_{\epsilon} : r_{12} \leq \delta_n} \exp\left[-(n - 2)\mu(S^*(w_1, w_2))\right] f(w_1) f(w_2) dw_2 dw_1
\]
\[
+ (n - 1) \int_{w_1, w_2 \in G_{\epsilon} : r_{12} > \delta_n} \exp\left[-(n - 2)\mu(S^*(w_1, w_2))\right] f(w_1) f(w_2) dw_2 dw_1
\]
\[
35
\[
\leq (n - 1) \int_{w_1, w_2 \in G, \|r\| \leq \delta_n,} \exp[-(n - 2)\mu\{S^*(w_1, w_2)\}] f(w_1)f(w_2)dw_2dw_1 \\
+ (n - 1) \int_{w_1, w_2 \in G, \|r\| \leq \delta_n,} \exp[-(n - 2)\mu\{S^*(w_1, w_2)\}] f(w_1)f(w_2)dw_2dw_1 \\
+ (n - 1) \int_{w_1, w_2 \in G, \|r\| > \delta_n} \exp[-(n - 2)\mu\{S^*(w_1, w_2)\}] f(w_1)f(w_2)dw_2dw_1 \\
=: I + II + III, \quad \text{say}, \quad (A.15)
\]

where \(\delta_n, \theta_n\) will be specified later.

As long as \((1 + \theta_n)\delta_n < \delta\),

\[
I \leq (n - 1) \int_{w_1, w_2 \in G, \|r\| \leq \delta_n,} \exp[-(n - 2)\mu\{B(w_1, r_{12})\}] f(w_1)f(w_2)dw_2dw_1 \\
\leq (n - 1) \int_{w_1, w_2 \in G, \|r\| \leq \delta_n,} \exp[-(n - 2)(1 - \epsilon)\mu\{B(w_1)V_{p+q\|r_{12}\|^q}\}] f(w_1)f(w_2)dw_2dw_1 \\
\leq \left[n - 1 \int_{w_1 \in G} \mu(\{w_2 = (x_2, z_2) : r_{12} \leq \delta_n, \ r_{12}^x \leq \theta_n\delta_n\}) f(w_1)dw_1 \right]^{1/2} \\
\leq \left[n - 1 \int_{w_1 \in G} \mu(\{w_2 = (x_2, z_2) : r_{12} \leq \delta_n, \ r_{12}^x \leq \theta_n\delta_n\}) f(w_1)dw_1 \right]^{1/2} \\
\leq \left[\theta_n \max_{w_1 \in G} f(w_1)V_{q}(\delta_n)^qV_{p}(\theta_n\delta_n)^p \right]^{1/2},
\]

where in the last step, the first term is covered by the Proof of Theorem 2 in Devroye (1988), and the latter term is handled by the fact \(r_{12} \leq r_{12}^x + r_{12}^x = (1 + \theta_n)\delta_n < \delta\).

For the second summand in (A.15), if \(0 < \Theta_n < \delta/\delta_n - 1\) and \(\theta_n^p\Theta_n^q = \Omega\) for some constant \(\Omega > 0\), then

\[
II \leq (n - 1) \int_{w_1, w_2 \in G, \|r\| \leq \delta_n,} \exp[-(n - 2)\mu\{S(w_1, w_2; \Theta_n)\}] f(w_1)f(w_2)dw_2dw_1 \\
\leq (n - 1) \int_{w_1, w_2 \in G, \|r\| \leq \delta_n,} \exp[-(n - 2)(1 - \epsilon)\mu\{B(w_1)\}] f(w_1)f(w_2)dw_2dw_1 \\
\leq \left[n - 1 \int_{w_1 \in G} \mu(\{w_2 = (x_2, z_2) : r_{12} \leq \delta_n, \ r_{12}^x \leq \theta_n\delta_n\}) f(w_1)dw_1 \right]^{1/2} \\
\leq \left[n - 1 \int_{w_1 \in G} \mu(\{w_2 = (x_2, z_2) : r_{12} \leq \delta_n, \ r_{12}^x \leq \theta_n\delta_n\}) f(w_1)dw_1 \right]^{1/2} \\
\leq \left[\theta_n \max_{w_1 \in G} f(w_1)V_{q}(\delta_n)^qV_{p}(\theta_n\delta_n)^p \right]^{1/2},
\]

36
\[ (n - 1) \int_{w_1, w_2 \in G : r_{12} \leq \delta_n} \exp\{- (n - 2) (1 - \epsilon) f(w_1) \Omega V_p V_q r_{12}^{p+q}\} f(w_1) f(w_2) \, dw_2 \, dw_1 \]

\[ \leq (n - 1) \int_{w_1, w_2 \in G : r_{12} \leq \delta_n} \exp\{- (n - 2) (1 - \epsilon) f(w_1) \Omega V_p V_q r_{12}^{p+q}\} f(w_1) f(w_2) \, dw_2 \, dw_1 \]

\[ \leq (n - 1) \int_{w_1, w_2 \in G : r_{12} \leq \delta_n} \exp\{- (n - 2) (1 - \epsilon) f(w_1) V_p+q (\delta_n)^{p+q}\} f(w_1) f(w_2) \, dw_2 \, dw_1 \]

\[ \leq o(1) + \frac{1 + \epsilon (n - 1)}{1 - \epsilon (n - 2)} \frac{V_p+q}{V_p V_q} \]

where the last step is by the Proof of Theorem 2 in Devroye (1988).

Lastly, if \( n(\delta_n)^{p+q} \geq an^b \) for some constants \( a, b > 0 \) and all sufficiently large \( n \), then for all \( n \) large enough,

\[ III \leq (n - 1) \int_{w_1, w_2 \in G : r_{12} > \delta_n} \exp\{- (n - 2) \mu \{ B(w_1, r_{12})\}\} f(w_1) f(w_2) \, dw_2 \, dw_1 \]

\[ \leq (n - 1) \int_{w_1, w_2 \in G : r_{12} > \delta_n} \exp\{- (n - 2) (1 - \epsilon) f(w_1) V_p+q (\delta_n)^{p+q}\} f(w_1) f(w_2) \, dw_2 \, dw_1 \]

\[ \leq (n - 1) \int_{w_1 \in G} \exp\{- (n - 2) (1 - \epsilon) f(w_1) V_p+q (\delta_n)^{p+q}\} f(w_1) \, dw_1 \]

\[ \leq o(1). \]

Here the proof of the last step is similar to that of Theorem 2 in Devroye (1988).

Taking \( \delta_n, \theta_n, \) and \( \Theta_n \) such that

\[ \delta_n^{p+q/2} = n^{-1}, \quad \theta_n = \epsilon^{-1} \delta_n, \quad \text{and} \quad \Theta_n = \delta / (2 \delta_n), \]

we deduce the result.

**Claim (7.16).** It suffices to show that

\[ \limsup_{n \to \infty} \mathbb{E}\left(n^{-1} \sum_{\{i, j\} \text{ distinct}} 1\right) = 0. \]

We have \( i \to j \in \mathcal{E}(G_n) \) and \( j \to i \in \mathcal{E}(G_n^X) \) if and only if the set \( S^* (W_i, W_j) \) contains no point in \( [W_k]_{k=1}^n \) other than \( W_i, W_j \), where

\[ S^* (w_1, w_2) := \left\{ w : \|w - w_1\| < \|w_2 - w_1\| \right\} \bigcup \left\{ (x, z) : \|x - x_2\| < \|x_2 - x_1\| \right\}, \]

and \( x_i \) is the sub-vector consisting of the first \( p \) elements of \( w_i \), and \( z_i \) is the sub-vector consisting of the last \( q \) elements of \( w_i \). The rest of the proof will be in analogy to that of Claim I.

**Claim (7.17).** We have

\[ \mathbb{E}\left(n^{-1} \sum_{\{i, j, k\} \text{ distinct}} 1\right) = \mathbb{E}\left(n^{-1} \sum_{\{i, j\} \text{ distinct}} 1\right) - \mathbb{E}\left(n^{-1} \sum_{\{i, j, k\} \text{ distinct}} 1\right) \]

37
where \( d_j^- := \sum_{i:j \to j \in E(G_n)} 1 \) is the in-degree of vertex \((X_j, Z_j)\) in \(G_n\), and \( d_j^{X^-} \) is the in-degree of vertex \(X_j\) in \(G_n\). It suffices to show that
\[
\lim_{n \to \infty} P(d_j^- = k, d_j^{X^-} = \ell) = p_{p+q,k} p_{p,\ell}
\]
for all fixed \( j \), where \( p_{d,k} \) is as defined in Lemma 3.4. For the sake of notational simplicity, let \( W_0 = (X_0, Z_0) \) be an additional random variable with density \( f \), independent of \( W_1, \ldots, W_n \). Let \( A_j \) denote the event that \( W_0 \) is the nearest neighbor of \( W_j \), and let \( B_j \) denote the event that \( X_0 \) the nearest neighbor of \( X_j, 1 \leq j \leq n \). Put
\[
d_0^- = \sum_{j=1}^n 1(A_j) \quad \text{and} \quad d_0^{X^-} = \sum_{j=1}^n 1(B_j).
\]
Jordan’s formula, generalized to two systems of events, yields that
\[
P(d_0^- = k, d_0^{X^-} = \ell) = \sum_{u=0}^k \sum_{v=0}^\ell (-1)^{u+v} \binom{u+k}{k} \binom{v+\ell}{\ell} \beta_{u+k,v+\ell},
\]
for \( 0 \leq k \leq \epsilon_{p+q} \), \( 0 \leq \ell \leq \epsilon_p \), where
\[
\beta_{0,0} = 1, \quad \beta_{r,0} = \sum_{1 \leq i_1 < \ldots < i_r \leq n} P\left(A_{i_1} \cap \cdots \cap A_{i_r}\right), \quad \beta_{0,s} = \sum_{1 \leq j_1 < \ldots < j_s \leq n} P\left(B_{j_1} \cap \cdots \cap B_{j_s}\right),
\]
\[
\beta_{r,s} = \sum_{1 \leq i_1 < \ldots < i_r \leq n} \sum_{1 \leq j_1 < \ldots < j_s \leq n} P\left(A_{i_1} \cap \cdots \cap A_{i_r} \cap B_{j_1} \cap \cdots \cap B_{j_s}\right),
\]
for \( r, s \geq 1 \). We have \( \beta_{r,0} \to \delta_{p+q,r}/r! \) and \( \beta_{0,s} \to \delta_{p,s}/s! \) by (3.1) in Henze (1987). Using symmetry gives
\[
\beta_{r,s} = \sum_{t=0}^{\min(r,s)} \binom{n}{t} \binom{n-t}{r-t} \binom{n-r}{s-t} P\left(A_1 \cap \cdots \cap A_r \cap B_1 \cap \cdots \cap B_t \cap B_{r+1} \cdots \cap B_{r+s-t}\right).
\]
It remains to prove
\[
n^{r+s} P\left(A_1 \cap \cdots \cap A_r \cap B_{r+1} \cdots \cap B_{r+s}\right) \to \delta_{p+q,r} \delta_{p,s}
\]
and
\[
n^{r+s-t} P\left(A_1 \cap \cdots \cap A_r \cap B_1 \cap \cdots \cap B_t \cap B_{r+1} \cdots \cap B_{r+s-t}\right) \to 0
\]
for all \( 1 \leq t \leq \min(r,s) \). Straightforward arguments paralleling those of (3.9) and (3.12) in Henze (1987) yield these desired results. Finally,
\[
E\left(n^{-1} \sum_{j=1}^n d_j^- d_j^{X^-}\right) = E[d_1^- d_1^{X^-}] + \sum_{k=0}^{\epsilon_p} \sum_{\ell=0}^{\epsilon_{p+q}} k\ell p_{p+q,k} p_{p,\ell} = \sum_{k=0}^{\epsilon_p} k p_{d,k} \sum_{\ell=0}^{\epsilon_{p+q}} \ell p_{p,\ell} = 1.
\]
Combining with Claim (7.15) concludes the proof.
A.4.5  Proof of Lemma 7.5

Proof of Lemma 7.5. It is clear the marginal of \((X, Y)\) is uniformly distributed on \([0, 1]^2\) for \(P_{X,Y,Z} = P_0\). When \(P_{X,Y,Z} = P_{1,n}\), we have for any fixed sequence \(\nu := [\nu_k]_{k \in [m]}\) and \(\delta = [\delta_{ij}]_{i,j \in [m']}, \) where \(\nu_k, \delta_{ij} \in \{-1, +1\},\)

\[
q_{X,Y}(x, y) = \int_0^1 q_{X,Y,Z}(x, y, z) dz = 1 + \eta_{x,m}(x) \int_0^1 \gamma_{x,m'}(y, z) dz
\]

\[
= 1 + \eta_{x,m}(x) \times \rho^2 \sum_{i \in [m']} \sum_{j \in [m']} \delta_{ij} h_{i,m'}(y) \left\{ \int_0^1 h_{j,m'}(z) dz \right\} = 1. \tag{A.16}
\]

Taking expectation over all Rademacher sequences \(\nu\) and \(\delta\) completes the proof. □

A.4.6  Proof of Lemma 7.6

Proof of Lemma 7.6. Recall that

\[
\xi = 1 - \frac{\int E[\text{Var}\{1(Y \geq y) | Z, X\}] dP_Y(y)}{\int E[\text{Var}\{1(Y \geq y) | X\}] dP_Y(y)} \tag{A.17}
\]

We first compute \(\xi\) for any fixed sequence \(\nu := [\nu_k]_{k \in [m]}\) and \(\delta = [\delta_{ij}]_{i,j \in [m']}, \) where \(\nu_k, \delta_{ij} \in \{-1, +1\}. \) Here, we have \(q_{Y|X}(y | x) = 1\) by (A.16). We also have \(q_{X,Z}(x, z) = 1\) similarly as for (A.16), and thus

\[
q_{Y|Z,X}(y | z, x) = 1 + \gamma_{x,m'}(y, z) \eta_{x,m}(x).
\]

Accordingly, we obtain

\[
\int E[\text{Var}\{1(Y \geq y) | X\}] dP_Y(y)
\]

\[
= \int E[\text{Var}\{1(Y \leq y) | X\}] dP_Y(y)
\]

\[
= \int E[P(Y \leq y | X) - \{P(Y \leq y | X)\}^2] dP_Y(y)
\]

\[
= \int_0^1 \int_0^1 \left[ \int_0^y q_{Y|X}(t | x) dt - \left\{ \int_0^y q_{Y|X}(t | x) dt \right\}^2 \right] dxdy
\]

\[
= \int_0^1 \int_0^1 (y - y^2) dxdy = \frac{1}{2} - \frac{1}{3} = \frac{1}{6}. \tag{A.18}
\]

We also obtain that

\[
\int E[\text{Var}\{1(Y \geq y) | Z, X\}] dP_Y(y)
\]

\[
= \int E[\text{Var}\{1(Y \leq y) | Z, X\}] dP_Y(y)
\]

\[
= \int E[P(Y \leq y | Z, X) - \{P(Y \leq y | Z, X)\}^2] dP_Y(y)
\]

\[
= \int_0^1 \int_0^1 \left[ \int_0^y q_{Y|(Z,X)}(t | z, x) dt - \left\{ \int_0^y q_{Y|(Z,X)}(t | z, x) dt \right\}^2 \right] dzdxdy,
\]

39
where
\[
\begin{align*}
\int_0^1 \int_0^1 \int_0^1 \left[ \int_0^y q_{Y|Z,X}(t \mid z, x) \mathrm{d}t \right] \mathrm{d}z \mathrm{d}x \\
= \int_0^1 \int_0^1 \int_0^1 \left[ y + \int_0^y \gamma_{ \rho, m'}(t, z) \eta_{\rho, m}(x) \mathrm{d}t \right] \mathrm{d}z \mathrm{d}x \\
= \int_0^1 \int_0^1 \int_0^1 y \mathrm{d}z \mathrm{d}x dy = \frac{1}{2},
\end{align*}
\]
and
\[
\begin{align*}
\int_0^1 \int_0^1 \int_0^1 \left[ \left\{ \int_0^y q_{Y|Z,X}(t \mid z, x) \mathrm{d}t \right\}^2 \right] \mathrm{d}z \mathrm{d}x \\
= \int_0^1 \int_0^1 \int_0^1 \left[ \left\{ y + \int_0^y \gamma_{ \rho, m'}(t, z) \eta_{\rho, m}(x) \mathrm{d}t \right\}^2 \right] \mathrm{d}z \mathrm{d}x \\
= \int_0^1 \int_0^1 \int_0^1 \left[ y^2 + 2y \left\{ \int_0^y \gamma_{ \rho, m'}(t, z) \eta_{\rho, m}(x) \mathrm{d}t \right\} + \left\{ \int_0^y \gamma_{ \rho, m'}(t, z) \eta_{\rho, m}(x) \mathrm{d}t \right\}^2 \right] \mathrm{d}z \mathrm{d}x \\
= \frac{1}{3} + \int_0^1 \int_0^1 \int_0^1 \left[ \left\{ \int_0^y \gamma_{ \rho, m'}(t, z) \eta_{\rho, m}(x) \mathrm{d}t \right\}^2 \right] \mathrm{d}z \mathrm{d}x dy.
\end{align*}
\]
Hence,
\[
\begin{align*}
\int \mathbb{E}[\text{Var}\{1(Y \geq y) \mid Z, X\}] \mathrm{d}P_Y(y) \\
= \frac{1}{6} - \int_0^1 \int_0^1 \int_0^1 \left[ \left\{ \int_0^y \gamma_{ \rho, m'}(t, z) \eta_{\rho, m}(x) \mathrm{d}t \right\}^2 \right] \mathrm{d}z \mathrm{d}x dy \\
= \frac{1}{6} - \int_0^1 \int_0^1 \int_0^1 \left[ \left\{ \eta_{\rho, m}(x) \int_0^y \gamma_{ \rho, m'}(t, z) \mathrm{d}t \right\}^2 \right] \mathrm{d}z \mathrm{d}x dy \\
= \frac{1}{6} - \int_0^1 \int_0^1 \int_0^1 \left[ \left\{ \eta_{\rho, m}(x) \times \rho^2 \sum_{i \in [m']} \sum_{j \in [m']} \delta_{ij} h_{i,m'}(t) h_{j,m'}(z) \mathrm{d}t \right\}^2 \right] \mathrm{d}z \mathrm{d}x dy \\
= \frac{1}{6} - \int_0^1 \int_0^1 \int_0^1 \left[ \rho \sum_{k \in [m]} v_k h_{k,m}(x) \times \rho^2 \sum_{i \in [m']} \sum_{j \in [m']} \delta_{ij} H_{i,m'}(y) h_{j,m'}(z) \right]^2 \mathrm{d}z \mathrm{d}x dy,
\end{align*}
\]
where
\[
H_{k,m}(x) := \int_0^x h_{k,m}(t) \mathrm{d}t \\
= \int_0^x \sqrt{m} \times h(mt - k + 1) \mathrm{d}t \\
= \int_0^m x \times \sqrt{m} \times h(u - k + 1) \mathrm{d}u \\
= \sqrt{m} \times \int_{-k + 1}^{m \times k + 1} h(u) \mathrm{d}u
\]
\[
\int E[\text{Var}\{1(Y \geq y) | Z, X\}]dP_Y(y) \\
= \left\{ \begin{array}{ll}
m^{-1/2} \int_0^{m-1} h(u)du & \text{if } x \in [(k-1)/m, k/m], \\
0 & \text{otherwise}
\end{array} \right.
\]

where

\[
H_{k,m}(x) = \left\{ \begin{array}{ll}
m^{-1/2}H(mx - k + 1) & \text{and } H(x) := \int_0^x h(u)du.
\end{array} \right.
\]

It is easy to verify that \( h_{k,m}(x)h_{k',m}(x) = 0 \) and \( H_{k,m}(x)H_{k',m}(x) = 0 \) for \( k \neq k' \). Thus we deduce

\[
\rho \sum_{k \in [m]} \nu_k h_{k,m}(x) \times \rho^2 \sum_{i \in [m']} \sum_{j \in [m']} \delta_{ij} H_{i,m'}(y) h_j(m'(z))^2
\]

and accordingly

\[
\int E[\text{Var}\{1(Y \geq y) | Z, X\}]dP_Y(y) \\
= \frac{1}{6} - \int_0^1 \int_0^1 \left[ \rho^6 \sum_{k \in [m]} \sum_{i \in [m']} \sum_{j \in [m']} \{h(k,m(x)) \times \rho^2 \sum_{i \in [m']} \sum_{j \in [m']} \delta_{ij} H_{i,m'}(y) h_j(m'(z))^2 \} \right] dz dx dy
\]

where

\[
\int_0^1 \{h_{k,m}(x)\}^2 dx = \int_0^1 m \times \{h(mx - k + 1)\}^2 dx = \int_0^m \{h(u - k + 1)\}^2 du
\]

\[
= \int_{-k+1}^{m-k+1} \{h(u)\}^2 du = \int_0^1 \{h(u)\}^2 du = 1.
\]

Similarly,

\[
\int_0^1 \{H_{k,m}(x)\}^2 dx = \int_0^1 m^{-1} \{H(mx - k + 1)\}^2 dx = \int_0^m m^{-2} \{H(u - k + 1)\}^2 du
\]

\[
= \int_{-k+1}^{m-k+1} m^{-2} \{H(u)\}^2 du = m^{-2} \int_0^1 \{H(u)\}^2 du.
\]

Therefore,

\[
\int E[\text{Var}\{1(Y \geq y) | Z, X\}]dP_Y(y) \\
= \frac{1}{6} - \rho^6 \sum_{k \in [m]} \sum_{i \in [m']} \sum_{j \in [m']} \left[ \int_0^1 \{h_{k,m}(x)\}^2 dx \right] \left[ \int_0^1 \{H_{i,m'}(y)\}^2 dy \right] \left[ \int_0^1 \{h_j(m'(z))\}^2 dz \right]
\]

\[
= \frac{1}{6} - \rho^6 mm'm'(m')^{-2} \int_0^1 \{H(u)\}^2 du
\]
In order to prove (\ref{eq:proof_of_lemma_7.7}) taking expectation over all Rademacher sequences \( \nu := [\nu_k]_{k \in [m]} \) and \( \delta = [\delta_{ij}]_{i,j \in [m']} \) completes the proof. \hfill \square

### A.4.7 Proof of Lemma 7.7

**Proof of Lemma 7.7.** Notice that

\[
\min(R_i, R_{M(i)}) = 1 + \sum_{k \neq i, M(i)} \mathbb{1}\{Y_k \leq \min(Y_i, Y_{M(i)})\}.
\]

We write

\[
\hat{\xi}_n = \frac{n^{-2} \sum_{i=1}^n \{\min(R_i, R_{M(i)}) - 1\} - n^{-2} \sum_{i=1}^n \{\min(R_i, R_{N(i)}) - 1\}}{1/6} =: \hat{\gamma}_n - \hat{\gamma}_n^X.
\]

Since the marginal of \((X, Y)\), is uniformly distributed on \([0, 1]^2\) under both null hypothesis \( P_0 \) and local alternative hypothesis \( P_{1,n} \), it holds that

\[
\mathbb{E}[\hat{\gamma}_n^X(P_{1,n})] = \mathbb{E}[\hat{\gamma}_n^X(P_0)] \quad \text{and} \quad \mathbb{E}[(\hat{\gamma}_n^X(P_{1,n}))^2] = \mathbb{E}[(\hat{\gamma}_n^X(P_0))^2].
\]

In order to prove (\ref{eq:bound_on_gammahat}), we aim to prove

\[
\left| \mathbb{E}[\hat{\gamma}_n(P_{1,n})] - \mathbb{E}[\hat{\gamma}_n(P_0)] \right| \lesssim \rho^6 m, \tag{A.20}
\]

and

\[
\left| \mathbb{E}[n\{\hat{\gamma}_n(P_{1,n})\}] - \mathbb{E}[n\{\hat{\gamma}_n(P_0)\}] \right| \lesssim n\rho^6 m. \tag{A.21}
\]

We start from computing \( \mathbb{E}[\hat{\gamma}_n(P_{1,n})] \) and \( \mathbb{E}[(\hat{\gamma}_n(P_{1,n}))^2] \). Recall our notation \( W = (X, Z), \ W_i = (X_i, Z_i), \ w = (x, z), \ w_i = (x_i, z_i), \ r_{ij} := \|w_j - w_i\|, \) and that \( B(w_1, r) \) denotes the ball of radius \( r \) centered at \( w_1 \), and \( \lambda(\cdot) \) denotes the Lebesgue measure. We obtain

\[
\mathbb{E}[\hat{\gamma}_n(P_{1,n})]
\]

\[
= n^{-2} \sum_{i=1}^n \mathbb{E}\left[ \sum_{k \neq i, M(i)} \mathbb{1}\{Y_k \leq \min(Y_i, Y_{M(i)})\} \right]
\]

\[
= n^{-1} \mathbb{E}\left[ \sum_{k \neq 1, M(1)} \mathbb{1}\{Y_k \leq \min(Y_1, Y_{M(1)})\} \right]
\]

\[
= n^{-1}(n - 1) \mathbb{E}\left[ \sum_{k \neq 1, 2} \mathbb{1}\{Y_k \leq \min(Y_1, Y_2)\} \mathbb{1}\{M(1) = 2\} \right]
\]

\[
= n^{-1}(n - 1)(n - 2) \mathbb{E}\left[ \mathbb{1}\{Y_3 \leq \min(Y_1, Y_2)\} \mathbb{1}\{M(1) = 2\} \right]
\]
\[= n^{-1}(n-1)(n-2)E \left( E \left[ \mathbb{1} \left\{ Y_3 \leq \min(Y_1, Y_2) \right\} \mathbb{1} \left( M(1) = 2 \right) \mid Y_1, W_1, Y_2, W_2, Y_3, W_3 \right] \right) \]
\[= n^{-1}(n-1)(n-2)E_{\nu, \delta} \left( \int \mathbb{1} \{ y_3 \leq \min(y_1, y_2) \} q_{Y,W}(y_1, w_1)q_{Y,W}(y_2, w_2)q_{Y,W}(y_3, w_3) \right. \]
\[\times \mathbb{1} (r_{13} < r_{12}) \times \left[ \lambda \{ 0, 1 \}^2 \setminus B(w_1, r_{12}) \right]^{n-3} dy_3 dw_3 dy_2 dw_2 dy_1 dw_1 \]
\[= n^{-1}(n-1)(n-2) \int \mathbb{1} \{ y_3 \leq \min(y_1, y_2) \} \mathbb{1} (r_{13} < r_{12}) \times \left[ \lambda \{ 0, 1 \}^2 \setminus B(w_1, r_{12}) \right]^{n-3} dy_3 dw_3 dy_2 dw_2 dy_1 dw_1, \quad (A.23) \]

where the expectation \( E_{\nu, \delta} \) is taken over all Rademacher sequences \( \nu := [\nu_k]_{k \in [m]} \) and \( \delta = [\delta_{ij}]_{i,j \in [m']} \).

Recall that
\[q_{X,Y,Z}(x, y, z) = 1 + \rho^3 \sum_{k \in [m]} \sum_{i \in [m']} \sum_{j \in [m']} \nu_k \delta_{ij} h_{k,m}(x) h_{i,m'}(y) h_{j,m'}(z),\]
and accordingly
\[E_{\nu, \delta} \left\{ q_{Y,W}(y_1, w_1)q_{Y,W}(y_2, w_2)q_{Y,W}(y_3, w_3) \right\} \]
\[= 1 + \rho^6 \sum_{k \in [m]} \sum_{i \in [m']} \sum_{j \in [m']} \{ h_{k,m}(x_1) h_{k,m}(x_2) \} \{ h_{i,m'}(y_1) h_{i,m'}(y_2) \} \{ h_{j,m'}(z_1) h_{j,m'}(z_2) \} \]
\[+ \rho^6 \sum_{k \in [m]} \sum_{i \in [m']} \sum_{j \in [m']} \{ h_{k,m}(x_1) h_{k,m}(x_3) \} \{ h_{i,m'}(y_1) h_{i,m'}(y_3) \} \{ h_{j,m'}(z_1) h_{j,m'}(z_3) \} \]
\[+ \rho^6 \sum_{k \in [m]} \sum_{i \in [m']} \sum_{j \in [m']} \{ h_{k,m}(x_2) h_{k,m}(x_3) \} \{ h_{i,m'}(y_2) h_{i,m'}(y_3) \} \{ h_{j,m'}(z_2) h_{j,m'}(z_3) \}. \]

Notice that
\[n^{-1}(n-1)(n-2) \int \mathbb{1} \{ y_3 \leq \min(y_1, y_2) \} \times \mathbb{1} (r_{13} < r_{12}) \]
\[\times \left[ \lambda \{ 0, 1 \}^2 \setminus B(w_1, r_{12}) \right]^{n-3} dy_3 dw_3 dy_2 dw_2 dy_1 dw_1 = E \{ \gamma_m(P_0) \} = \frac{n-2}{3n}, \]
\[(n-1) \int \mathbb{1} (r_{13} < r_{12}) \times \left[ \lambda \{ 0, 1 \}^2 \setminus B(w_1, r_{12}) \right]^{n-3} dw_3 dw_2 dw_1 = 1, \]
\[(n-2) \int \sum_{k \in [m]} \{ h_{k,m}(x_1) h_{k,m}(x_2) \} \sum_{j \in [m']} \{ h_{j,m'}(z_1) h_{j,m'}(z_2) \} \]
\[\times \mathbb{1} (r_{13} < r_{12}) \times \left[ \lambda \{ 0, 1 \}^2 \setminus B(w_1, r_{12}) \right]^{n-3} dw_3 dw_2 dw_1 \lesssim mm', \]
\[(n-2) \int \sum_{k \in [m]} \{ h_{k,m}(x_1) h_{k,m}(x_3) \} \sum_{j \in [m']} \{ h_{j,m'}(z_1) h_{j,m'}(z_3) \} \]
\[\times \mathbb{1} (r_{13} < r_{12}) \times \left[ \lambda \{ 0, 1 \}^2 \setminus B(w_1, r_{12}) \right]^{n-3} dw_3 dw_2 dw_1 \lesssim mm', \]
\[(n-2) \int \sum_{k \in [m]} \{ h_{k,m}(x_2) h_{k,m}(x_3) \} \sum_{j \in [m']} \{ h_{j,m'}(z_2) h_{j,m'}(z_3) \} \]
\[\times \mathbb{1} (r_{13} < r_{12}) \times \left[ \lambda \{ 0, 1 \}^2 \setminus B(w_1, r_{12}) \right]^{n-3} dw_3 dw_2 dw_1 \lesssim mm'. \quad (A.24)\]
In addition, by (7.24),
\[
\int \mathbb{1}\{y_3 \leq \min(y_1, y_2)\} \sum_{i \in [m']} h_{i, m'}(y_1)h_{i, m'}(y_2)dy_3dy_2dy_1 \lesssim \frac{1}{m'},
\]
\[
\int \mathbb{1}\{y_3 \leq \min(y_1, y_2)\} \sum_{i \in [m']} h_{i, m'}(y_1)h_{i, m'}(y_3)dy_3dy_2dy_1 \lesssim \frac{1}{m'},
\]
\[
\int \mathbb{1}\{y_3 \leq \min(y_1, y_2)\} \sum_{i \in [m']} h_{i, m'}(y_2)h_{i, m'}(y_3)dy_3dy_2dy_1 \lesssim \frac{1}{m'}. \tag{A.25}
\]

Putting these together yields the desired result (A.20).

Now we turn to \(E[n\{\gamma_n(P_{1, n})\}]^2\). We have
\[
E[n\{\gamma_n(P_{1, n})\}]^2
= n^{-2}E\left(\left[ \sum_{k \neq 1, M(1)} \mathbb{1}\{Y_k \leq \min(Y_1, Y_{M(1)})\} \right]^2\right) + n^{-2}(n - 1)
\times E\left(\left[ \sum_{k \neq 1, M(1)} \mathbb{1}\{Y_k \leq \min(Y_1, Y_{M(1)})\} \right] \times \left[ \sum_{\ell \neq 2, M(2)} \mathbb{1}\{Y_\ell \leq \min(Y_2, Y_{M(2)})\} \right]\right). \tag{A.26}
\]
The first term in (A.26) can be expanded as
\[
E\left(\left[ \sum_{k \neq 1, M(1)} \mathbb{1}\{Y_k \leq \min(Y_1, Y_{M(1)})\} \right]^2\right)
= (n - 1)E\left(\left[ \sum_{k \neq 1, 2} \mathbb{1}\{Y_k \leq \min(Y_1, Y_2)\} \right]^2 \mathbb{1}\{M(1) = 2\}\right)
= (n - 1)E\left(\left[ \sum_{k \neq 1, 2} \sum_{\ell \neq 1, 2} \mathbb{1}\{\max(Y_k, Y_\ell) \leq \min(Y_1, Y_2)\} \right] \mathbb{1}\{M(1) = 2\}\right)
= (n - 1)(n - 2)E\left[ \mathbb{1}\{Y_3 \leq \min(Y_1, Y_2)\} \mathbb{1}\{M(1) = 2\}\right]
+ (n - 1)(n - 2)(n - 3)E\left[ \mathbb{1}\{\max(Y_3, Y_4) \leq \min(Y_1, Y_2)\} \mathbb{1}\{M(1) = 2\}\right]
= (n - 1)(n - 2) \int \mathbb{1}\{y_3 \leq \min(y_1, y_2)\}E_{Y, \nu, \delta}\left\{q_{Y, W}(y_1, w_1)q_{Y, W}(y_2, w_2)q_{Y, W}(y_3, w_3)\right\}
\times \mathbb{1}\{r_{12} < r_{13}\} \times [\lambda[0, 1]^2\{B(w_1, r_{12})\}]^{n-3}dy_3dw_3dy_2dw_2dy_1dw_1
+ (n - 1)(n - 2)(n - 3) \int \mathbb{1}\{\max(y_3, y_4) \leq \min(y_1, y_2)\}E_{Y, \nu, \delta}\left\{\prod_{k=1}^{4} q_{W}(y_k, w_k)\right\}
\times \mathbb{1}\{r_{12} < \min(r_{13}, r_{14})\} \times [\lambda[0, 1]^2\{B(w_1, r_{12})\}]^{n-4}dy_4dw_4dy_3dw_3dy_2dw_2dy_1dw_1.
\]
The second term in (A.26) can be similarly expanded. Similar computations as for (A.24) and (A.25), but more involved, yield (A.21).

We can similarly prove (A.22) and thus skip the details for brevity. This completes the proof.  □
A.4.8 Proof of Lemma 7.8

Proof of Lemma 7.8. We have

\[
\sqrt{n}\xi_n - \sqrt{n}\hat{\xi}_n := \sqrt{n}\xi_n \left( \frac{\int \mathbb{E}[\text{Var}\{1(Y \geq t) \mid X\}] dP_Y(t)}{n^{-2} \sum_{i=1}^{n} \{R_i - \min(R_i, R_{N(i)})\}} - 1 \right).
\] (A.27)

For the first term in the right-hand side of (A.27), (7.32) yields \( \sqrt{n}\hat{\xi}_n = O_p(1) \). For the latter term, recall that Azadkia and Chatterjee (2021, Theorem 9.1) show

\[
\frac{1}{n^2} \sum_{i=1}^{n} \{R_i - \min(R_i, R_{N(i)})\} \xrightarrow{a.s.} \int \mathbb{E}[\text{Var}\{1(Y \geq t) \mid X\}] dP_Y(t) = \frac{1}{6}.
\]

Accordingly, the latter term in (A.27) is \( o_p(1) \). This concludes the proof of (7.29). \( \square \)

A.4.9 Proof of Lemma 7.9

Proof of Lemma 7.9. It is clear that (7.25) holds and \( P_0 \in \mathcal{P}_0(L, s) \). Next, we show that \( P_{1,n} \in \mathcal{P}_1(\Delta_0 n^{-2s/(4s+3)}; L, s) \). To show \( P_{1,n} \in \mathcal{P}_1(L, s) \), in view of the Proof of Theorem 4.2 in Neykov et al. (2021, Appendix B), it suffices to notice that

\[
\begin{align*}
|q_{Y,Z} \mid X(y, z \mid x) - q_{Y,Z} \mid X(y, z \mid x')| &\leq \left( \rho^3 \sqrt{m} m^2 c_2 \times 4m^3 \right) \left( |x - x'|^s \right), \\
|q_{Y,Z} \mid X(y, z \mid x) - q_{Y,Z} \mid X(y', z' \mid x)| &\leq \left( \rho^3 \sqrt{m} m^2 c_2 \times 4(m')^3 \right) \left( |y - y'|^s + |z - z'|^s \right),
\end{align*}
\]

and \( \rho^3 \sqrt{m} m^2 c_2 \rightarrow 0 \). To show \( \inf_{q \in \mathcal{P}_0} \left\| q_{1,n} - q^0 \right\|_1 \geq \Delta_0 n^{-2s/(4s+3)} \), where \( q_{1,n} \) denotes the corresponding density of \( P_{1,n} \), using Lemma B.4 in Neykov et al. (2021, Appendix B) yields

\[
\inf_{q \in \mathcal{P}_0} \left\| q_{1,n} - q^0 \right\|_1 \geq \frac{\left\| q_{1,n} - 1 \right\|_1}{6} = \frac{\rho^3 \sqrt{m} m^2 c_2^3}{6} \geq \Delta_0 n^{-2s/(4s+3)}.
\]

This completes the proof. \( \square \)
