Decoding Error Probability of the Random Matrix Ensemble over the Erasure Channel

Chin Hei Chan, Fang-Wei Fu and Maosheng Xiong

Abstract

Using tools developed in a recent work by Shen and the second author, in this paper we carry out an in-depth study on the average decoding error probability of the random matrix ensemble over the erasure channel under three decoding principles, namely unambiguous decoding, maximum likelihood decoding and list decoding. We obtain explicit formulas for the average decoding error probabilities of the random matrix ensemble under these three decoding principles and compute the error exponents. Moreover, for unambiguous decoding, we compute the variance of the decoding error probability of the random matrix ensemble and the error exponent of the variance, which imply a strong concentration result, that is, roughly speaking, the ratio of the decoding error probability of a random code in the ensemble and the average decoding error probability of the ensemble converges to 1 with high probability when the code length goes to infinity.

Index terms—Random matrix ensemble, parity-check codes, erasure channel, decoding error probability, error exponent, list decoding, maximum likelihood decoding, unambiguous decoding.

I. INTRODUCTION

A. Background

In digital communication, it is common that messages transmitted through a public channel may be distorted by the channel noise. The theory of error-correcting codes is the study of mechanisms to cope with this problem. This is an important research area with many applications in modern life. For example, error-correcting codes are widely employed in cell phones to correct errors arising from fading noise during high frequency radio transmission. One of the major challenges in coding theory remains to construct new error-correcting codes with good properties and to study their decoding and encoding algorithms.

In a binary erasure channel (BEC), a binary symbol is either received correctly or totally erased with probability $\varepsilon$. The concept of BEC was first introduced by Elias in 1955 \cite{2}. Together with the binary symmetric channel (BSC), they are frequently used in coding theory and information theory because they are among the simplest channel models, and many problems in communication theory can be reduced to problems in a BEC. Here we consider more generally a $q$-ary erasure channel in which a $q$-ary symbol is either received correctly, or totally erased with probability $\varepsilon$.

The problem of decoding linear codes over the erasure channel has received renewed attention in recent years due to their wide application in the internet and the distributed storage system in analyzing random packet losses \cite{1}, \cite{8}, \cite{9}. Three important decoding principles, namely unambiguous decoding, maximum likelihood decoding and list decoding, were studied in recent years for linear codes over the erasure channel, the corresponding decoding error probabilities under these principles were also investigated (see \cite{3}, \cite{6}, \cite{11}, \cite{13} and reference therein).

In particular in \cite{11}, upon improving previous results, the authors provided a detailed study on the decoding error probabilities of a general $q$-ary linear code over the erasure channel under the three decoding principles. Via the notion of $q^\ell$-incorrigible sets for linear codes, they showed that all these decoding error probabilities can be expressed explicitly by the $r$-th support weight distribution of the linear codes. As applications they obtained explicit formulas of the decoding error probabilities for some of the most interesting linear codes such as MDS codes, the binary Golay code, the simplex codes and the first-order Reed-Muller codes etc. where the $r$-support weight distributions were known. They also computed the average decoding error probabilities of a random $[n, k]_q$ code over the erasure channel and obtained the error exponent of a random $[n, nR]_q$ code ($0 < R < 1$) under one of the decoding principles.
B. Statement of the main results

In this paper we consider a new code ensemble, namely the random matrix ensemble $\mathcal{R}_{m,n}$, that is, the set of all $m \times n$ matrices over $\mathbb{F}_q$ endowed with uniform probability, each of which is associated with a parity-check code as follows: for each $H \in \mathcal{R}_{m,n}$, the corresponding parity-check code $C_H$ is given by

$$C_H = \{ x \in \mathbb{F}_q^n : Hx^t = 0 \}. \quad (1)$$

Here boldface letters such as $x$ denote row vectors.

As for previous results about the ensemble $\mathcal{R}_{m,n}$, the undetected error probability was studied in the binary symmetric channel by Wadayama [12] (i.e. $q = 2$), and some bounds on the error probability under the maximum likelihood decoding principle were obtained in the $q$-ary erasure channel [4], [7], but other than these results, not much is known. It is easy to see that $\mathcal{R}_{m,n}$ contains all linear codes in the random $[n, n-m]_q$ code ensemble considered in [11], but these two ensembles are quite different for two reasons: first, in the random $[n, k]_q$ code ensemble considered in [11], each $[n, k]_q$ code is counted exactly once, while in $\mathcal{R}_{m,n}$ each code is counted with some multiplicity as different choices for the matrix $H$ may give rise to the same code; second, some codes in $\mathcal{R}_{m,n}$ may have rates strictly larger than $1 - \frac{m}{n}$ as the rows of $H$ may not be linearly independent.

It is conceivable that most of the codes in $\mathcal{R}_{m,n}$ have rate $1 - \frac{m}{n}$, and the average behavior of codes in $\mathcal{R}_{m,n}$ should be similar to that of the random $[n, n-m]_q$ code ensemble considered in [11]. The advantage of studying the ensemble $\mathcal{R}_{m,n}$ is that it is much easier to deal with $\mathcal{R}_{m,n}$ in terms of mathematics than with the random $[n, n-m]_q$ ensemble – such an advantage has been exploited in [12] – hence we may be able to obtain much stronger results than what was obtained in [11]. We will show that this is indeed the case.

We first obtain explicit formulas for the average decoding error probability of the ensemble $\mathcal{R}_{m,n}$ over the erasure channel under the three different decoding principles. This is comparable to [11] Theorem 2] for the random $[n, k]_q$ code ensemble. Such formulas are useful as they allow explicit evaluations of the average decoding error probabilities for any given $m$ and $n$, hence giving us a meaningful guidance as to what to expect for a good $[n, n-m]_q$ code over the erasure channel.

**Theorem 1.** Let $\mathcal{R}_{m,n}$ be the random matrix ensemble described above. Denote by $[i]_q$ the Gaussian
q-binomial coefficient and denote

\[ \psi_m(i) := \prod_{k=0}^{i-1} (1 - q^{k-m}), \quad 1 \leq i \leq m. \]  

(2)

1) The average unsuccessful decoding probability of \( \mathcal{R}_{m,n} \) under list decoding with list size \( q^\ell \), where \( \ell \) is a non-negative integer, is given by

\[ P_{\text{ld}}(\mathcal{R}_{m,n}, \ell, \varepsilon) = \sum_{i=1}^{n} \sum_{j=\ell+1}^{\ell} q^{-mj} \psi_m(i - j) \left[ \frac{n}{i} \right] \left( \frac{q}{j} \right) \varepsilon^i (1 - \varepsilon)^{n-i}; \]  

(3)

2) The average unsuccessful decoding probability of \( \mathcal{R}_{m,n} \) under unambiguous decoding is given by

\[ P_{\text{ud}}(\mathcal{R}_{m,n}, \varepsilon) = \sum_{i=1}^{n} (1 - \psi_m(i)) \left( \frac{n}{i} \right) \varepsilon^i (1 - \varepsilon)^{n-i}; \]  

(4)

3) The average decoding error probability of \( \mathcal{R}_{m,n} \) under maximum likelihood decoding is given by

\[ P_{\text{mld}}(\mathcal{R}_{m,n}, \varepsilon) = \sum_{i=1}^{n} \sum_{\ell=1}^{\ell} q^{-m\ell} (1 - q^{-\ell}) \psi_m(i - \ell) \left[ \frac{i}{\ell} \right] \left( \frac{n}{i} \right) \varepsilon^i (1 - \varepsilon)^{n-i}. \]  

(5)

Next, letting \( m = (1 - R)n \) for \( 0 < R < 1 \), we compute the error exponents of the average decoding error probability of the ensemble series \( \{\mathcal{R}_{(1-R)n,n}\} \) as \( n \to \infty \) under these decoding principles.

**Theorem 2.** Let the rate \( 0 < R < 1 \) be fixed and \( n \to \infty \).

1) For any fixed integer \( \ell \geq 0 \), the error exponent \( T_{\text{ld}}(\ell, \varepsilon) \) for average unsuccessful decoding probability of \( \{\mathcal{R}_{(1-R)n,n}\} \) under list decoding with list size \( q^\ell \) is given by

\[ T_{\text{ld}}(\ell, \varepsilon) = \begin{cases} 0 & (1 - \varepsilon \leq R < 1) \\ (1 - R) \log_q \left( \frac{1-R}{\varepsilon} \right) + R \log_q \left( \frac{R}{1-\varepsilon} \right) & \left( \frac{1-\varepsilon}{1-\varepsilon+q^\ell+1} < R < 1 - \varepsilon \right) \\ (\ell + 1)(1 - R) - \log_q \left( 1 - \varepsilon + q^{\ell+1} \varepsilon \right) & \left( 0 < R \leq \frac{1-\varepsilon}{1-\varepsilon+q^\ell+1} \right). \end{cases} \]  

(6)

2) The error exponents for average unsuccessful decoding probability of \( \{\mathcal{R}_{(1-R)n,n}\} \) under unambiguous decoding and maximum likelihood decoding (respectively) are both given by

\[ T_{\text{ud}}(\varepsilon) = T_{\text{mld}}(\varepsilon) = \begin{cases} 0 & (1 - \varepsilon \leq R < 1) \\ (1 - R) \log_q \left( \frac{1-R}{\varepsilon} \right) + R \log_q \left( \frac{R}{1-\varepsilon} \right) & \left( \frac{1-\varepsilon}{1-\varepsilon+q \varepsilon} < R < 1 - \varepsilon \right) \\ 1 - R - \log_q \left( 1 - \varepsilon + q \varepsilon \right) & \left( 0 < R \leq \frac{1-\varepsilon}{1-\varepsilon+q \varepsilon} \right). \end{cases} \]  

(7)
A plot of the function $T_{ld}(\ell, \varepsilon)$ for $q = 2, \varepsilon = 0.25, \ell = 0, 1, 2$ in the range $0 < R < 1$ is given by Fig. 1.

It can be checked that the error exponent here under unambiguous decoding principle coincides with that for the random $[n, nR]_q$ code ensemble obtained in [11, Theorem 3].

Next, we establish a strong concentration result for the unsuccessful decoding probability of a random code in the ensemble $\mathcal{R}_{(1-R)n,n}$ towards the mean under unambiguous decoding.

**Theorem 3.** Let the rate $0 < R < 1$ be fixed and $n \to \infty$. Then as $H_n$ runs over the ensemble $\mathcal{R}_{(1-R)n,n}$, we have

$$
\frac{P_{ud}(H_n, \varepsilon)}{P_{ud}(\mathcal{R}_{(1-R)n,n}, \varepsilon)} \to 1 \quad \text{WHP,}
$$

under either of the following conditions:

1. if $\frac{1 - \varepsilon}{1 + (q-1)\varepsilon} \leq R < 1 - \varepsilon$ for any $q \geq 2$, or
2. if $\frac{1 - \varepsilon}{1 + (q-1)\varepsilon} \leq R < 1 - \varepsilon$ for $q = 2, 3, 4$.

Here the notion WHP in (8) refers to “with high probability”, that is, for any $\delta > 0$, there is $c > 0$ and $n_0 > 0$ such that

$$\Pr\left(\left| \frac{P_{ud}(H_n, \varepsilon)}{P_{ud}(\mathcal{R}_{(1-R)n,n}, \varepsilon)} - 1 \right| < \delta \right) > 1 - q^{-nc} \quad \forall n > n_0.$$

Noting that in the range $0 < R < 1 - \varepsilon$, it was known that $T_{ud}(\varepsilon) > 0$ (see Theorem 2), hence

$$P_{ud}(\mathcal{R}_{(1-R)n,n}, \varepsilon) = q^{-n(T_{ud}(\varepsilon) + o(1))} \to 0, \quad \text{as } n \to \infty,$$
so \(8\) shows that \(P_{ud}(H_n, \varepsilon)\) also tends to zero exponentially fast with high probability for the ensemble \(\mathcal{R}_{(1-R)n,n}\) under either Condition (1) or (2) of Theorem \([3]\).

Finally, we point out a weaker but more general concentration result:

**Theorem 4.** Let the rate \(0 < R < 1\) be fixed and \(n \to \infty\). Then as \(H_n\) runs over the ensemble \(\mathcal{R}_{(1-R)n,n}\), we have

\[
P_{ud}(H_n, \varepsilon) - P_{ud}(\mathcal{R}_{(1-R)n,n}) \to 0 \quad \text{WHP.} \tag{9}
\]

It is known that \(1 - \varepsilon\) is the capacity of the erasure channel, so if \(1 - \varepsilon < R < 1\), then by the converse to the coding theorem (see \([5\), Theorem 4.3.4]) or \([14\), Theorem 1.3.1]), there is a constant \(\delta := \delta(R) > 0\) such that \(P_{ud}(H_n, \varepsilon) > \delta\) and \(P_{ud}(\mathcal{R}_{(1-R)n,n}, \varepsilon) > \delta\); if \(0 < R < 1 - \varepsilon\), then \(T_{ud}(\varepsilon) > 0\) and

\[
P_{ud}(\mathcal{R}_{(1-R)n,n}, \varepsilon) = q^{-n(T_{ud}(\varepsilon) + o(1))} \to 0, \quad \text{as } n \to \infty,
\]

hence from \(9\) we also conclude that \(P_{ud}(H_n, \varepsilon) \to 0 \quad \text{WHP.}\)

**C. Discussion of Theorem 2**

It is interesting to make a comparison of Theorem 2 with what can be obtained by Gallager’s method for nonlinear code ensembles over the erasure channel (see \([5\), Exercise 5.20, page 538]): consider the ensemble of all block codes of length \(n\) and rate \(R\) \((0 < R < 1)\) over the erasure channel in which each letter of each codeword is selected independently as an element of \(\mathbb{F}_q\) with equal probability \(1/q\), then the average decoding error probability under list-decoding with list size \(L\) is upper bounded by

\[
\bar{P}_{L, \varepsilon} \leq q^{-n T_{ld}(L, \varepsilon)},
\]

where the function \(T_{ld}(L, \varepsilon)\) is given as

\[
T_{ld}(L, \varepsilon) = \begin{cases} 
0 & (1 - \varepsilon \leq R < 1) \\
(1 - R) \log_q \left( \frac{1-R}{\varepsilon} \right) + R \log_q \left( \frac{R}{1-\varepsilon} \right) & \left( \frac{1-\varepsilon}{1-\varepsilon+q^L \varepsilon} < R < 1 - \varepsilon \right) \\
L(1 - R) - \log_q \left( 1 - \varepsilon + q^L \varepsilon \right) & (0 < R \leq \frac{1-\varepsilon}{1-\varepsilon+q^L \varepsilon})
\end{cases} \tag{10}
\]

We compare the error exponent \(T_{ld}(L, \varepsilon)\) given in Theorem 2 corresponding to list decoding with list size \(q^L\) for the random matrix ensemble \(\mathcal{R}_{(1-R)n,n}\) with \(T_{ld}(L, \varepsilon)\) above where \(L = q^L\) which corresponds
to list decoding with list size $L$ for the random code ensemble of the same rate $0 < R < 1$ described by Gallager. We can observe that in the high rate region $\frac{1 - \varepsilon}{1 - \varepsilon + q^\ell + 1} \leq R < 1 - \varepsilon$, the two exponents $T_{\text{ld}}(\ell, \varepsilon)$ and $T_{\text{ld}}^{(\ast)}(L, \varepsilon)$ coincide with each other, but in the low rate region $0 < R < \frac{1 - \varepsilon}{1 - \varepsilon + q^\ell + 1}$, we have $T_{\text{ld}}^{(\ast)}(L, \varepsilon) > T_{\text{ld}}(\ell, \varepsilon) > 0$ whenever $q^\ell > 2$. As illustrations we plot the two exponents as functions of $R$ in Figs. 2 and 3 for $\varepsilon = 0.25$, $q = 2$, $L = q^\ell$ with $\ell = 2$ and 3. This shows that under the list decoding principle over the erasure channel, the performance of linear codes on average is as good as that of nonlinear codes in the high rate range, but is inferior in the low rate range if the list size $q^\ell$ is at least 3. It is well-known that they have the same performance when $\ell = 0$, that is, under the unambiguous decoding and the maximum likelihood decoding principles [5].

The paper is now organized as follows. In Section II we introduce the Gaussian $q$-binomial coefficient in more details. Then in Section III we provide three counting results regarding $m \times n$ matrices of certain rank over $\mathbb{F}_q$. Afterwards in Sections IV, V and VI we give the proofs of Theorems 1, 2 and 3-4 respectively. The proofs of Theorems 3 and 4 involves some technical calculus computations on the error exponent of the variance. In order to streamline their proofs, we put some of the arguments in Section VII Appendix. Finally we conclude this paper in Section VIII.
II. Preliminaries

For integers \( n \geq k \geq 0 \), the Gaussian binomial coefficients \( \left[ \begin{array}{c} n \\ k \end{array} \right]_q \) is defined as

\[
\left[ \begin{array}{c} n \\ k \end{array} \right]_q := \frac{(q)_n}{(q)_k(q)_{n-k}},
\]

where \((q)_n := \prod_{i=1}^{n} (1 - q^i)\). By convention \((q)_0 = 1\), \( \left[ \begin{array}{c} n \\ 0 \end{array} \right]_q = 1 \) for any \( n \geq 0 \) and \( \left[ \begin{array}{c} n \\ k \end{array} \right]_q = 0 \) if \( k < 0 \) or \( k > n \). The function \( \psi_m(i) \) defined in (2) can be written as

\[
\psi_m(i) = q^{-mi+i(i-1)/2}(q)_i\left[ \begin{array}{c} m \\ i \end{array} \right]_q.
\]

We may define \( \psi_m(0) = 1 \) for \( m \geq 0 \) and \( \psi_m(i) = 0 \) if \( i < 0 \) or \( i > m \). Next, recall the well-known combinatorial interpretation of \( \left[ \begin{array}{c} n \\ k \end{array} \right]_q \):

**Lemma 1 ([10]).** The number of \( k \)-dimensional subspaces of an \( n \)-dimensional vector space over \( \mathbb{F}_q \) is \( \left[ \begin{array}{c} n \\ k \end{array} \right]_q \).

The Gaussian binomial coefficient \( \left[ \begin{array}{c} n \\ k \end{array} \right]_q \) satisfies the property

\[
\left[ \begin{array}{c} n \\ k \end{array} \right]_q = \left[ \begin{array}{c} n \\ n-k \end{array} \right]_q, \quad \forall \ n \geq k \geq 0,
\]

and the identity

\[
\prod_{i=0}^{n-1} (1 + q^i x) = \sum_{i=0}^{n} \left[ \begin{array}{c} n \\ i \end{array} \right]_q q^{i(i-1)/2} x^i, \quad \forall \ n \geq 1.
\] (11)

III. Three counting results for the ensemble \( \mathcal{R}_{m,n} \)

In this section we provide three counting results about matrices of certain rank in the ensemble \( \mathcal{R}_{m,n} \). Such results may not be new, but since we cannot locate them in the literature, we prove them here. These results will be used repeatedly in the proofs later on.

For \( H \in \mathcal{R}_{m,n} \), denote by \( \text{rk}(H) \) the rank of the matrix \( H \) over \( \mathbb{F}_q \).

**Lemma 2.** Let \( H \) be a random matrix in the ensemble \( \mathcal{R}_{m,n} \). Then for any integer \( j \), we have

\[
\mathbb{P}(\text{rk}(H) = j) = q^{-m(n-j)}\psi_m(j)\left[ \begin{array}{c} n \\ j \end{array} \right]_q.
\] (12)

**Proof.** We may assume that \( j \) satisfies \( 0 \leq j \leq n \), because if \( j \) is not in the range, then both sides of Equation (12) are obviously zero.
Denote by $\text{Hom}(m, n)$ the set of $\mathbb{F}_q$-linear transformations from $\mathbb{F}_q^m$ to $\mathbb{F}_q^n$. Writing vectors in $\mathbb{F}_q^m$ and $\mathbb{F}_q^n$ as row vectors, we see that the random matrix ensemble $\mathcal{R}_{m,n}$ can be identified with the set $\text{Hom}(m, n)$ via the relation

$$H \leftrightarrow G : \mathbb{F}_q^m \rightarrow \mathbb{F}_q^n \quad \text{x} \mapsto xH .$$

(13)

Since $\text{rk}(H) = j$ if and only if $\dim(\text{Im} G) = j$, and $\# \mathcal{R}_{m,n} = q^{mn}$, we have

$$\mathbb{P}(\text{rk}(H) = j) = q^{-mn} \sum_{G \in \text{Hom}(m, n)} 1_{\dim(\text{Im} G) = j} = q^{-mn} \sum_{V \leq \mathbb{F}_q^n} \sum_{G \in \text{Hom}(m, n)} 1_{\dim V = j} .$$

The inner sum $\sum_{G \in \text{Hom}(m, n), \text{Im} G = V} 1$ counts the number of surjective linear transformations from $\mathbb{F}_q^m$ to $V$, a $j$-dimensional subspace of $\mathbb{F}_q^n$. Since $V \cong \mathbb{F}_q^j$, this is also the number of surjective linear transformations from $\mathbb{F}_q^m$ to $\mathbb{F}_q^j$, or, equivalently, the number of $m \times j$ matrices $K$ over $\mathbb{F}_q$ such that the columns of $K$ are linearly independent. The number of such matrices $K$ can be counted as follows: the first column of $K$ can be any nonzero vector over $\mathbb{F}_q$, there are $q^m - 1$ choices; given the first column, the second column can be any vector lying outside the space of scalar multiples of the first column, so there are $q^m - q$ choices; inductively, given the first $k$ columns, the $(k+1)$-th column lies outside a $k$-dimensional subspace, so the number of choices for the $(k+1)$-th column is $q^m - q^k$. Thus we have

$$\sum_{G \in \text{Hom}(m, n), \text{Im} G = V} 1 = \prod_{k=0}^{j-1} (q^m - q^k) = q^{mj} \psi_m(j), \quad \dim V = j .$$

(14)

Together with Lemma [1] we obtain

$$\mathbb{P}(\text{rk}(H) = j) = q^{-mn} q^{mj} \psi_m(j) \sum_{V \leq \mathbb{F}_q^n} 1_{\dim V = j} = q^{-m(n-j)} \psi_m(j) \binom{n}{j} ,$$

which is the desired result.

□

**Lemma 3.** Let $H$ be a random matrix in the ensemble $\mathcal{R}_{m,n}$. Let $A \subset [n] := \{1, 2, \cdots, n\}$ be a subset with cardinality $s$. Denote by $H_A$ the $m \times s$ submatrix formed by columns of $H$ indexed from $A$. Then
for any integers $j$ and $r$, we have

$$\mathbb{P}(\text{rk}(H) = j \cap \text{rk}(H_A) = r) = q^{-m(n-j)+r(n-j-s+r)}\psi_m(j)\begin{bmatrix} s \\ r \end{bmatrix} \begin{bmatrix} n-s \\ j-r \end{bmatrix}_q. \quad (15)$$

**Proof.** We may assume that $0 \leq j \leq n$ and $\max\{0, s - n + j\} \leq r \leq \min\{j, s\}$, because if $j$ or $r$ does not satisfy this condition, then both sides of Equation (15) are zero.

Using the relations (13) and (14), we can expand the term $\mathbb{P}(\text{rk}(H) = j \cap \text{rk}(H_A) = r)$ as

$$\mathbb{P}(\text{rk}(H) = j \cap \text{rk}(H_A) = r) = q^{-mn} \sum_{V \leq \mathbb{F}_q^n} \sum_{G \in \text{Hom}(m,n)} 1 \cdot q^{-m(n-j)}\psi_m(j) \sum_{V \leq \mathbb{F}_q^n} 1. \quad (16)$$

Here $V_A$ is the subspace of $\mathbb{F}_q^A$ formed by restricting $V$ to coordinates with indices from $A$. We may consider the projection given by

$$\pi_A : V \to V_A$$

$$(v_k)_{k=1}^n \mapsto (v_k)_{k \in A}.$$ 

The kernel of $\pi_A$ has dimension $j - r$ and is of the form $W \times \{(0)_A\}$ for some subspace $W \leq \mathbb{F}_q^{[n]-A}$. So we can further decompose the sum on the right hand side of (16) as

$$\sum_{V \leq \mathbb{F}_q^n} 1 = \sum_{W \leq \mathbb{F}_q^{[n]-A}} \sum_{V \leq \mathbb{F}_q^n} 1. \quad (17)$$

Now we compute the inner sum on the right hand side of (17). Suppose we are given an ordered basis of the $(j-r)$-dimensional subspace $W \times \{(0)_A\}$ of $\mathbb{F}_q^n$. We extend it to an ordered basis of some $j$-dimensional subspace $V$ as follows: first we need $r$ other basis vectors $v_1, v_2, \cdots, v_r$ to be linearly independent. At the same time, they have to be linearly independent with any nonzero vector in $\mathbb{F}_q^{[n]-A} \times \{(0)_A\}$ due to the kernel condition. This requires the set $\{\pi_A(v_1), \pi_A(v_2), \cdots, \pi_A(v_r)\}$ to be linearly independent in $\mathbb{F}_q^A$. On the other hand, if this condition is satisfied, then the $r$ vectors $v_1, v_2, \cdots, v_r$ are also linearly independent with one another as well as with any nonzero vector in $W \times \{(0)_A\}$. Therefore it reduces to counting the number of ordered linearly independent sets of $r$ vectors in $\mathbb{F}_q^A$. This number is clearly given by $\prod_{k=0}^{r-1}(q^s - q^k)$, so the total number of different ordered bases is given by $q^{r(n-s)} \prod_{k=0}^{r-1}(q^s - q^k)$.

On the other hand, given a fixed $j$-dimensional subspace $V$ with $\ker(\pi_A) = W \times \{(0)_A\}$, we count
the number of ordered bases of \( V \) of the form stated in previous paragraph as follows: we choose \( v_1 \) to be any vector in \( V \) but not in \( W \times \{(0)\}_A \), which gives \( q^j - q^{j-r} \) many choices for \( v_1 \); similarly \( v_2 \) is any vector in \( V \) but not in the span of \( W \times \{(0)\}_A \) and \( v_1 \), this gives us \( q^j - q^{j-r+1} \) many choices for \( v_2 \); using this argument, we see that the number of such ordered bases is given by \( \prod_{k=0}^{r-1}(q^j - q^{j-r+k}). \)

We conclude from the above arguments that

\[
\sum_{V \leq F_q^n \dim V = j \dim V_A = r \ker(\pi_A) = W \times \{(0)\}_A} 1 = q^{r(n-s)} \prod_{k=0}^{r-1}(q^s - q^k) \prod_{k=0}^{r-1}(q^j - q^{j-r+k})
= q^{r(n-j-s+r)} \left[ \begin{array}{c} s \\ r \end{array} \right]_q.
\]

Putting this into the right hand side of (17) and using Lemma 1 again, we get

\[
\sum_{V \leq F_q^n \dim V = j \dim W = j-r} 1 = \sum_{W \leq F_q^{n-A} \dim W = j-r} q^{r(n-j-s+r)} \left[ \begin{array}{c} s \\ r \end{array} \right]_q = q^{r(n-j-s+r)} \left[ \begin{array}{c} s \\ r \end{array} \right]_q \left[ \begin{array}{c} n - s \\ j - r \end{array} \right]_q.
\]

The desired result is obtained immediately by plugging this into the right hand side of (16). This completes the proof of Lemma 3.

**Lemma 4.** Let \( H \) be a random matrix in the ensemble \( \mathcal{R}_{m,n} \). Let \( E, E' \) be subsets of \( [n] \) such that

\[
i = \#E, \quad i' = \#E', \quad s = \#(E \cap E').
\]

Then

\[
\mathbb{P}(\text{rk}(H_E) = i \cap \text{rk}(H_{E'}) = i') = \frac{\psi_m(i)\psi_m(i')}{\psi_m(s)}.
\] (18)

**Proof.** It is clear that if a matrix \( H \) has full rank, then so is the submatrix \( H_A \) for any index subset \( A \). Hence we have

\[
\mathbb{P}(\text{rk}(H_E) = i \cap \text{rk}(H_{E'}) = i')
= \mathbb{P}(\text{rk}(H_E) = i \cap \text{rk}(H_{E'}) = i'|\text{rk}(H_{E \cap E'}) = s)\mathbb{P}(\text{rk}(H_{E \cap E'}) = s).
\]

It is easy to see that the two events \( \text{rk}(H_E) = i \) and \( \text{rk}(H_{E'}) = i' \) are conditionally independent given \( \text{rk}(H_{E \cap E'}) = s \), since columns of \( H_E \) and \( H_{E'} \) are independent as random vectors over \( \mathbb{F}_q \). Hence we
get
\[ P(\text{rk}(H_E) = i \cap \text{rk}(H_{E'}) = i') = P(\text{rk}(H_E) = i|\text{rk}(H_{E\cap E'}) = s)P(\text{rk}(H_E) = i'|\text{rk}(H_{E\cap E'}) = s)P(\text{rk}(H_{E\cap E'}) = s) = \frac{\psi_m(i)\psi_m(i')}{\psi_m(s)}. \]

Here we have applied Lemmas 2 and 3 in the last equality with \( j = i, j' = i' \) and \( r = s, H = H_E \) and \( A = E \cap E' \).

IV. PROOF OF THEOREM 1

The background of the three decoding principles unambiguous decoding, maximum likelihood decoding and list decoding of linear codes over the erasure channel, the computation of their decoding error probability functions \( P_{ld}(C, \ell, \varepsilon) \), \( P_{ml}(C, \varepsilon) \) and \( P_{ld}(C, \varepsilon) \), and their relation to the concept of \( q^\ell \)-incorrigible set of a linear code \( C \) were all laid out perfectly in [11, II. Preliminaries], so we do not repeat here. Interested readers may refer to that paper for more details. We focus on what are most relevant to the proof of Theorem 1 in this paper.

Let \( C \) be an \([n, k]_q\) linear code, that is, \( C \) is a \( k \)-dimensional subspace of \( \mathbb{F}_q^n \). Denote \([n] := \{1, 2, \cdots, n\}\). For any \( E \subset [n] \), define
\[ C(E) := \{ c = (c_1, \ldots, c_n) \in C : c_i = 0 \ \forall i \in [n] \setminus E \}. \]

Since \( C \) is a linear code, \( C(E) \) is also a vector space over \( \mathbb{F}_q \).

Denote by \( \{I_i^{(\ell)}(C)\}_{i=1}^n \) the \( q^\ell \)-incorrigible set distribution of \( C \), and \( \{I_i(C)\}_{i=1}^n \) the incorrigible set distribution of \( C \), which are defined respectively as follows:
\[
I_i^{(\ell)}(C) = \# \{ E \subset [n] : \#E = i, \dim C(E) > \ell \}, \\
I_i(C) = \# \{ E \subset [n] : \#E = i, C(E) \neq \{0\} \}. \tag{19}
\]

It is easy to see that \( \dim C(E) \leq \min\{k, \#E\} \), so if \( \ell \geq \min\{k, \#E\} \), then \( I_i^{(\ell)}(C) = \emptyset \). We also define
\[ \lambda_i^{(\ell)}(C) = \# \{ E \subset [n] : \#E = i, \dim C(E) = \ell \}. \]
It is easy to see that $I_i^{(0)}(C) = I_i(C)$, $\lambda_i^{(\ell)}(C) = 0$ if $\ell > \min\{i, k\}$ and
\[
\sum_{\ell=0}^{i} \lambda_i^{(\ell)} = \binom{n}{i}.
\] (20)

We also have the identity
\[
I_i^{(\ell)}(C) = \sum_{j=\ell+1}^{i} \lambda_i^{(j)}(C), \quad \forall i, \ell.
\] (21)

Recall from [11] that the values $P_{ud}(C, \varepsilon), P_{ld}(C, \varepsilon)$ and $P_{ml}(C, \ell, \varepsilon)$ can all be expressed in terms of $I_i^{(\ell)}(C), I_i(C)$ and $\lambda_i^{(\ell)}(C)$ as follows:
\[
P_{ud}(C, \varepsilon) = \sum_{i=1}^{n} I_i(C)\varepsilon^i(1 - \varepsilon)^{n-i},
\] (22)
\[
P_{ld}(C, \ell, \varepsilon) = \sum_{i=1}^{n} I_i^{(\ell)}(C)\varepsilon^i(1 - \varepsilon)^{n-i},
\] (23)
\[
P_{ml}(C, \varepsilon) = \sum_{i=1}^{n} \sum_{\ell=1}^{i} \lambda_i^{(\ell)}(C)(1 - q^{-\ell})\varepsilon^i(1 - \varepsilon)^{n-i}.
\] (24)

For $H \in R_{m,n}$, we write $P_{ld}(H, \ell, \varepsilon) := P_{ld}(C_H, \ell, \varepsilon)$ and $P_*(H, \varepsilon) := P_*(C_H, \varepsilon)$ for $* \in \{ud, mld\}$, where $C_H$ is the parity-check code defined by (1). The average decoding error probabilities over the matrix ensemble $R_{m,n}$ are given by
\[
P_{ld}(R_{m,n}, \ell, \varepsilon) := \mathbb{E}[P_{ld}(H, \ell, \varepsilon)],
\]
and
\[
P_*(R_{m,n}, \varepsilon) := \mathbb{E}[P_*(H, \varepsilon)], \quad * \in \{ud, mld\}.
\]

Here the expectation $\mathbb{E}$ is taken over the ensemble $R_{m,n}$.

Now we can start the proof of Theorem [1]. For $H \in R_{m,n}$, we denote
\[
I_i := I_i(C_H), I_i^{(\ell)} := I_i^{(\ell)}(C_H), \lambda_i^{(\ell)} := \lambda_i^{(\ell)}(C_H).
\]
Taking expectations on both sides of Equations (22)-(24), we obtain

\[ P_{ud}(R_{m,n}, \varepsilon) = \sum_{i=1}^{n} \mathbb{E}[I_i] \varepsilon^i (1 - \varepsilon)^{n-i}, \quad (25) \]

\[ P_{ld}(R_{m,n}, \ell, \varepsilon) = \sum_{i=1}^{n} \mathbb{E}[I_{i}(\ell)] \varepsilon^i (1 - \varepsilon)^{n-i}, \quad (26) \]

\[ P_{mld}(R_{m,n}, \varepsilon) = \sum_{i=1}^{n} \sum_{\ell=1}^{i} \mathbb{E}[\lambda_{i}(\ell)] (1 - q^{-\ell}) \varepsilon^i (1 - \varepsilon)^{n-i}. \quad (27) \]

We now compute \( \mathbb{E}[\lambda_{i}(\ell)] \). Noting that for \( H \in R_{m,n} \) and \( E \subset [n] \), we have \( \text{rk}(H_E) + \dim C_H(E) = \#E \), thus

\[ \mathbb{E}[\lambda_{i}(\ell)] = \frac{1}{\#R_{m,n}} \sum_{H \in R_{m,n}} \sum_{E \subset [n]} \mathbb{1}_{\dim C_H(E) = \ell} \]

\[ = \frac{1}{\#R_{m,n}} \sum_{E \subset [n]} \sum_{H \in R_{m,n} \atop \#E = i \atop \text{rk}(H_E) = i - \ell} 1. \]

By the symmetry of the ensemble \( R_{m,n} \), the inner sum on the right hand side depends only on the cardinality of \( E \), so we may assume \( E = [i] \) to obtain

\[ \mathbb{E}[\lambda_{i}(\ell)] = \frac{1}{\#R_{m,i}} \binom{n}{i} \sum_{H \in R_{m,i} \atop \text{rk}(H) = i - \ell} 1. \]

The right hand side is exactly \( \binom{n}{i} \mathbb{P}(\text{rk}(H) = i - \ell) \) where the probability is over the ensemble \( R_{m,i} \). So from Lemma 2 we have

\[ \mathbb{E}[\lambda_{i}(\ell)] = q^{-\ell} \psi_m(i - \ell) \binom{n}{i} \binom{i}{i - \ell} q^{\binom{n}{i}}. \quad (28) \]

Using this and (21), we also obtain

\[ \mathbb{E}[I_i(\ell)] = \sum_{j=\ell+1}^{i} \mathbb{E}[\lambda_{i}(j)] = \sum_{j=\ell+1}^{i} q^{-mj} \psi_m(i - j) \binom{i}{j} q^{\binom{n}{i}}. \]

Inserting the above values \( \mathbb{E}[I_i(\ell)] \) and \( \mathbb{E}[\lambda_{i}(\ell)] \) into (26) and (27) respectively, we obtain explicit expressions of \( P_{ld}(R_{m,n}, \ell, \varepsilon) \) and \( P_{mld}(R_{m,n}, \varepsilon) \), which agree with (3) and (5) of Theorem 1.

As for \( P_{ud}(R_{m,n}, \varepsilon) \), noting by (20) that \( \sum_{\ell=0}^{i} \mathbb{E}[\lambda_{i}(\ell)] = \binom{n}{i} \) and by (28) that \( \mathbb{E}[\lambda_{i}(0)] = \psi_m(i) \binom{n}{i} \),
therefore
\[ \mathbb{E}[I_i] = \sum_{j=1}^{i} \mathbb{E}[X_i^{(j)}] = \binom{n}{i} - \mathbb{E}[X_i^{(0)}] = (1 - \psi_m(i)) \binom{n}{i}. \] (29)

Inserting this value into (25), we also obtain the desired expression of \( P_{ud}(R_{m,n}, \varepsilon) \). This completes the proof of Theorem [1].

V. PROOF OF THEOREM [2]

In this section we provide a proof of Theorem [2].

First recall that the error exponents of the average decoding error probability of the ensemble \( \mathcal{R}_{(1-R)n,n} \) over the erasure channel under the three decoding principles are defined by

\[ T_{ld}(\ell, \varepsilon) := - \lim_{n \to \infty} \frac{1}{n} \log_q P_{ld}(\mathcal{R}_{(1-R)n,n}, \ell, \varepsilon), \] (30)

and

\[ T_*(\varepsilon) := - \lim_{n \to \infty} \frac{1}{n} \log_q P_*(\mathcal{R}_{(1-R)n,n}, \varepsilon), \quad * \in \{ \text{ud, mld} \}, \]

provided that the limit exists [5], [11], [14].

Unambiguous decoding corresponds to list decoding with \( \ell = 0 \), and it is also easy to see that

\[ \frac{1}{2} P_{ud}(C, \varepsilon) \leq P_{mld}(C, \varepsilon) \leq P_{ud}(C, \varepsilon), \]

hence we have

\[ T_{ud}(\varepsilon) = T_{mld}(\varepsilon) = T_{ld}(0, \varepsilon), \]

if the limit exists say in (30) for \( \ell = 0 \). So we only need to prove Part 1) of Theorem [2] for the case of list decoding.

Write \( m = (1-R)n \), and we define

\[ f_{i,j} := q^{-m_j} \psi_m(i-j) \binom{n}{j} \binom{n}{i} \varepsilon^i (1-\varepsilon)^{n-i}. \]

It is easy to see that \( f_{i,j} \geq 0 \) for all integers \( i, j \). In addition, \( f_{i,j} \neq 0 \) if and only if \( 1 \leq i \leq n, 1 \leq j \leq i \) and \( i - j \leq m \).
We can rewrite (3) as

\[ P_{ld}(R_{m,n}, \ell, \varepsilon) = \sum_{i,j} f_{i,j}, \]

where \( i, j \) are integers satisfying the conditions

\( \ell + 1 \leq i \leq n, \quad \max\{i-m, \ell+1\} \leq j \leq i. \) (31)

The number of such integer pairs \( (i, j) \) is at most \( mn \). Noting that \( \lim_{n \to \infty} \frac{\log_q (mn)}{n} = 0 \), we have

\[ \frac{1}{n} \log_q P_{ld}(R_{m,n}, \ell, \varepsilon) = o(1) + \frac{1}{n} \max_{i,j} \log_q f_{i,j}. \] (32)

Now we focus on the quantity \( f_{i,j} \). First, set \( T = q^{-1} \) so that \( 0 < T < 1 \). It is easy to verify that for \( 0 \leq j \leq i \),

\[ \left[ \frac{i}{j} \right]_q = q^{j(i-j)} \left[ \frac{i}{j} \right]_T, \quad \psi_m(i) = \frac{(T)_m}{(T)_{m-i}}. \] (33)

Hence we have

\[ f_{i,j} = q^{-j(m-i+j)} \frac{(T)_m}{(T)_{m-i+j}} \left[ \frac{i}{j} \right]_T \left( \frac{n}{i} \right)^{\psi_m(i)} (1 - \varepsilon)^{n-i}. \]

The infinite product \((T)_\infty := \prod_{r=1}^{\infty} (1 - T^r)\) converges absolutely to some positive real number \( M \) which only depends on \( q \), and \( M = (T)_\infty < (T)_m \leq 1 \) for any \( m \). This implies that

\[ M^2 \leq \frac{(T)_m}{(T)_{m-i+j}} \left[ \frac{i}{j} \right]_T \leq \frac{(T)_m (T)_i}{(T)_{m-i+j} (T)_{i-j}} \leq \frac{1}{M^3}, \]

and thus

\[ \frac{1}{n} \log_q \left( \frac{(T)_m}{(T)_{m-i+j}} \left[ \frac{i}{j} \right]_T \right) = o(1). \]

Therefore we have

\[ \frac{1}{n} \log_q f_{i,j} = -\frac{j(m-i+j)}{n} + \frac{1}{n} \log_q (\frac{n}{i}) + \frac{i}{n} \log_q \varepsilon + \frac{n-i}{n} \log_q (1 - \varepsilon) + o(1). \]

We want to maximize this quantity over \( i, j \) satisfying (31). Since the term \(-\frac{j(m-i+j)}{n}\) is always non-positive, it is easy to see that for any fixed \( i \), to maximize the term \( \frac{1}{n} \log_q f_{i,j} \), we shall take

\[ j = \begin{cases} \ell + 1 & : \text{if } \ell + 1 > i - m, \text{ or equivalently if } i < m + \ell + 1, \\ i - m & : \text{otherwise.} \end{cases} \]
So we can simplify (32) as

\[
\frac{1}{n} \log_q P_{ld}(\mathcal{R}_{m,n}, \ell, \varepsilon) = o(1) + \max_{\ell + 1 \leq i \leq n} \left[ \frac{(\ell + 1)(m - i + \ell + 1)}{n} + \frac{1}{n} \log_q \binom{n}{i} + \frac{i}{n} \log_q \varepsilon + \frac{n - i}{n} \log_q (1 - \varepsilon) \right],
\]

where \((x)_+ := \max\{0, x\}\).

Let \(i = tn\) with \(0 < t \leq 1\). Using the result (see [10] and [11, Lemma 3] for example)

\[
\frac{1}{n} \log_q \binom{n}{tn} = h(t) + o(1),
\]

where \(h(t) = -t \log_q t - (1 - t) \log_q (1 - t)\) is the binary entropy function (in \(q\)-its), and taking \(n \to \infty\), we obtain

\[
T_{ld}(\ell, \varepsilon) = - \sup_{0 < t \leq 1} f(t),
\]

where

\[
f(t) = -(\ell + 1)(1 - R - t)_+ + h(t) + t \log_q \varepsilon + (1 - t) \log_q (1 - \varepsilon).
\]

Note that \(f(t)\) is continuous on the interval \((0, 1)\).

Differentiating (35) with respect to \(t\), we get

\[
\frac{df}{dt} = \begin{cases} 
\ell + 1 + \log_q \left( \frac{\varepsilon}{t} \right) - \log_q \left( \frac{1 - \varepsilon}{1 - t} \right) & (0 < t < 1 - R) \\
\log_q \left( \frac{\varepsilon}{t} \right) - \log_q \left( \frac{1 - \varepsilon}{1 - t} \right) & (1 - R < t < 1)
\end{cases}
\]

It is easy to check from the right hand side that \(\frac{df}{dt} = 0\) at

\[
t_1 = \frac{q^{\ell+1} \varepsilon}{1 + (q^{\ell+1} - 1) \varepsilon}, \quad t_2 = \varepsilon,
\]

and at these points the function \(f(t)\) has a local maximum. There are three cases to consider:

**Case 1:** \(0 < R \leq \frac{1 - \varepsilon}{1 + (q^{\ell+1} - 1) \varepsilon}\)

In this case we have \(\varepsilon < t_1 \leq 1 - R\), then \(f(t)\) is maximized at \(t = t_1\), so

\[
T_{ld}(\ell, \varepsilon) = -f(t_1) = (\ell + 1)(1 - R) - \log_q [1 + (q^{\ell+1} - 1) \varepsilon].
\]

**Case 2:** \(\frac{1 - \varepsilon}{1 + (q^{\ell+1} - 1) \varepsilon} < R < 1 - \varepsilon\)
In this case we have \( \varepsilon < 1 - R < t_1 \), then \( f(t) \) is maximized at \( t = 1 - R \), so
\[
T_{ld}(\ell, \varepsilon) = -f(1 - R) = (1 - R) \log_q \left( \frac{1 - R}{\varepsilon} \right) + R \log_q \left( \frac{R}{1 - \varepsilon} \right).
\]

Case 3: \( 1 - \varepsilon \leq R < 1 \)

In this case we get \( 1 - R \leq \varepsilon < t_1 \), then \( f(t) \) is maximized at \( t = t_2 = \varepsilon \), so
\[
T_{ld}(\ell, \varepsilon) = -f(\varepsilon) = 0.
\]

Combining Cases 1-3 above gives Equation (6). This completes the proof of Theorem 2.

VI. PROOFS OF THEOREMS 3 AND 4

The proofs of Theorems 3 and 4 depend on the computation of the variance of the unsuccessful decoding probability under unambiguous decoding and its error exponent.

A. The variance of unsuccessful decoding probability and its error exponent

Note from (22) that the variance \( \sigma_{ud}^2(R_{m,n}, \varepsilon) \) of the unsuccessful decoding probability under unambiguous decoding can be expressed as
\[
\sigma_{ud}^2(R_{m,n}, \varepsilon) = \mathbb{E}[P_{ud}(H, \varepsilon)^2] - (\mathbb{E}[P_{ud}(H, \varepsilon)])^2
\]
\[
= \mathbb{E} \left[ \left( \sum_{i=1}^{n} I_i \varepsilon^i (1 - \varepsilon)^{n-i} \right)^2 \right] - \left( \sum_{i=1}^{n} \mathbb{E}[I_i] \varepsilon^i (1 - \varepsilon)^{n-i} \right)^2
\]
\[
= \sum_{i,i' = 1}^{n} \text{Cov}(I_i, I_{i'}) \varepsilon^{i+i'} (1 - \varepsilon)^{2n-i-i'},
\]
where the term \( \text{Cov}(I_i, I_{i'}) \) is given by
\[
\text{Cov}(I_i, I_{i'}) = \mathbb{E}[I_i I_{i'}] - \mathbb{E}[I_i] \mathbb{E}[I_{i'}].
\]

We first obtain:

Lemma 5. For \( 1 \leq i, i' \leq n \), we have
\[
\text{Cov}(I_i, I_{i'}) = \psi_m(i) \psi_m(i') \sum_{s=1}^{\min(i,i')} \left( \frac{1}{\psi_m(s)} - 1 \right) \left( s, i - s, i' - s, n - i - i' + s \right).
\]
Here the multinomial coefficient \( \binom{n}{a,b,c,d} \) for any non-negative integers \( a, b, c, d, n \) such that \( a + b + c + d = n \) is given by
\[
\binom{n}{a,b,c,d} := \frac{n!}{a!b!c!d!}.
\]

Proof of Lemma 5] Obviously if \( i \) or \( i' \) does not satisfy the relation \( 1 \leq i, i' \leq m \), then both sides of (36) are zero. So we may assume that \( 1 \leq i, i' \leq m \).

For any \( H \in \mathcal{R}_{m,n} \), from (19) we see that
\[
I_i(C_H) = \sum_{\substack{E \subset [n] \#E = i \\#E' = i'}} \left( 1 - \mathbb{1}_{\dim C_H(E) = 0} \right) = \sum_{\substack{E \subset [n] \#E = i \\#E' = i'}} \left( 1 - \mathbb{1}_{\rk(H_E) = i} \right).
\]
So we can expand the term \( \text{Cov}(I_i, I_{i'}) \) as
\[
\text{Cov}(I_i, I_{i'}) = \sum_{s} \sum_{\substack{E, E' \subset [n] \\#E = i \\#E' = i'}} \left( \psi_m(i) \psi_m(i') \frac{\psi_m(s)}{\psi_m(s)} - \psi_m(i) \psi_m(i') \right).
\]

Applying Lemmas 2 and 4 to the terms in the inner sums on the right hand side of (37), we have
\[
\text{Cov}(I_i, I_{i'}) = \sum_{s} \sum_{\substack{E, E' \subset [n] \\#E = i \\#E' = i'}} \left( \psi_m(i) \psi_m(i') \frac{\psi_m(s)}{\psi_m(s)} - \psi_m(i) \psi_m(i') \right).
\]
Together with the combinatorial identity
\[
\sum_{\substack{E, E' \subset [n] \\#E = i \\#E' = i'}} 1 = \binom{n}{i} \binom{n-i}{i'-s} = \binom{n}{s, i-s, i'-s, n-i-\i' + s},
\]
we obtain the desired result as described by Lemma 5.

From Lemma 5, the variance \( \sigma_{ud}^2(\mathcal{R}_{m,n}, \varepsilon) \) can be obtained easily, which we summarize below:
Theorem 5.

\[ \sigma_{ud}^2(\mathcal{R}_{m,n}, \varepsilon) = \sum_{i,i'=1}^{m} \sum_{s=1}^{\min(i,i')} \psi_m(i) \psi_m(i') \left( \frac{1}{\psi_m(s)} - 1 \right) \left( s, i - s, i' - s, n - i - i' + s \right) \varepsilon^{i+i'}(1 - \varepsilon)^{2n-i-i'}. \]

For \(0 < R < 1\), the error exponent of the variance \(\sigma_{ud}^2(\mathcal{R}_{(1-R)n,n}, \varepsilon)\) is defined by

\[ S_{ud}(\varepsilon) := -\lim_{n \to \infty} \frac{1}{n} \log q \sigma_{ud}^2(\mathcal{R}_{(1-R)n,n}, \varepsilon), \quad (40) \]

if the limit exists. We obtain:

Theorem 6.

\[ S_{ud}(\varepsilon) = \begin{cases} 1 - R - \log_q [1 + (q - 1)\varepsilon^2] & \left(0 < R \leq \frac{1-\varepsilon}{1+(q-1)\varepsilon^2}\right) \\ (1 - R) \log_q \left( \frac{\kappa_0}{\varepsilon^2} \right) + R \log_q \left( \frac{2R-1+\kappa_0}{1-\varepsilon} \right) & \left(\frac{1-\varepsilon}{1+(q-1)\varepsilon^2} < R < 1\right) \end{cases} \]

where \(\kappa_0 := \kappa_0(R)\) is given by

\[ \kappa_0(R) := 1 - R - \frac{\sqrt{4R(1-R)(q-1) + 1 - 1}}{2(q-1)}. \quad (41) \]

We remark that the proof of Theorem 6 follows a similar argument as that of Theorem 2, though here the computation of \(S_{ud}(\varepsilon)\) is much more complex as it involves a lot more technical manipulations. In order to streamline the idea of the proof in this section, we first assume Theorem 6 and leave its proof to Section VII Appendix. Then Theorems 3 and 4 can be proved easily by using the standard Chebyshev’s inequality.

B. Proof of Theorem 4

A plot of the function \(S_{ud}(\varepsilon)\) for \(q = 2, \varepsilon = 0.25\) in the range \(0 < R < 1\) is given by Fig. 4.

It will be clear from the proof of Theorem 6 that the function \(S_{ud}(\varepsilon)\) is continuous for \(R\) in the interval \((0, 1)\), that is, the two branches of \(S_{ud}(\varepsilon)\) agree at the point \(R = \frac{1-\varepsilon}{1+(q-1)\varepsilon^2}\), so the minimum of \(S_{ud}(\varepsilon)\) is attained for some \(R \in \left[\frac{1-\varepsilon}{1+(q-1)\varepsilon^2}, 1\right]\). It is also easy to verify that the constant \(\kappa_0\) always satisfies \((1 - R)^2 < \kappa_0 < 1 - R\). In addition, consider the function \(F(\varepsilon) := (1 - R) \log_q \varepsilon + R \log_q (1 - \varepsilon)\). By calculus it is easy to verify that \(F\) attains maximum at the point \(\varepsilon = 1 - R\). Therefore, we have, for any
Fig. 4. The error exponent $S_{ud}(\varepsilon)$ for $0 < R < 1$, where $q = 2, \varepsilon = 0.25$.

\[ S_{ud}(\varepsilon) \geq (1 - R) \log_q \left( \frac{k_0}{\varepsilon^2} \right) + R \log_q \left( \frac{2R - 1 + k_0}{(1 - \varepsilon)^2} \right) \]
\[ > (1 - R) \log_q \left( \frac{(1 - R)^2}{(1 - R)^2} \right) + R \log_q \left( \frac{2R - 1 + (1 - R)^2}{R^2} \right) = 0, \]
that is, $S_{ud}(\varepsilon) > 0$ for any $\varepsilon, R \in (0,1)$. Letting $H_n$ vary over the ensemble $\mathcal{R}_{(1-R)n,n}$, by Chebyshev’s inequality, we have, for any fixed $\varepsilon, R \in (0,1)$ and any fixed $\delta > 0$,

\[ \mathbb{P} \left[ |P_{ud}(H_n, \varepsilon) - P_{ud}(\mathcal{R}_{(1-R)n,n}, \varepsilon)| > \delta \right] \leq \delta^{-2} \sigma_{ud}^2(\mathcal{R}_{(1-R)n,n}, \varepsilon) \]
\[ = \delta^{-2} q^{-n(S_{ud}(\varepsilon) + o(1))}. \quad (42) \]

This completes the proof of Theorem 4.

C. Proof of Theorem 3

We have, by definition of error exponents,

\[ P_{ud}(\mathcal{R}_{(1-R)n,n}, \varepsilon) = q^{-n(T_{ud}(\varepsilon) + o(1))}, \]

and

\[ \sigma_{ud}^2(\mathcal{R}_{(1-R)n,n}, \varepsilon) = q^{-n(S_{ud}(\varepsilon) + o(1))}. \]

These imply

\[ \frac{\sigma_{ud}^2(\mathcal{R}_{(1-R)n,n}, \varepsilon)}{P_{ud}^2(\mathcal{R}_{(1-R)n,n}, \varepsilon)} = \frac{q^{-n(S_{ud}(\varepsilon) + o(1))}}{q^{-2n(T_{ud}(\varepsilon) + o(1))}} = q^{-n(S_{ud}(\varepsilon) - 2T_{ud}(\varepsilon) + o(1))}. \]
The right hand side of the above will tend to 0 as $n \to \infty$ if
\[ c(\varepsilon, R) := S_{ud}(\varepsilon) - 2T_{ud}(\varepsilon) > 0. \] (43)

Thus under (43), by Chebyshev’s inequality, we have, for any fixed $\delta > 0$,
\[ \mathbb{P}_{\mathcal{R}(1-R)n,n} \left[ \left| \frac{P_{ud}(H, \varepsilon)}{P_{ud}(\mathcal{R}(1-R)n,n, \varepsilon) - 1} \right| \geq \delta \right] \leq \frac{\sigma^2_{ud}(\mathcal{R}(1-R)n,n, \varepsilon)}{\delta^2 P^2_{ud}(\mathcal{R}(1-R)n,n, \varepsilon)} = q^{-n(c(\varepsilon,R)+o(1))}, \]
that is, $\frac{P_{ud}(H,\varepsilon)}{P_{ud}(\mathcal{R}(1-R)n,n,\varepsilon)} \to 1$ WHP as $n \to \infty$.

To prove Theorem 3, it remains to verify that (43) holds true under the assumptions of either (1) or (2) of Theorem 3.

Case 1. $\frac{1-\varepsilon}{1+(q - 1)\varepsilon^2} \leq R < 1 - \varepsilon$

Since $\frac{1-\varepsilon}{1+(q - 1)\varepsilon^2} < \frac{1-\varepsilon}{1+(q - 1)\varepsilon^2}$, by a simple calculation, we have
\[
c(\varepsilon, R) = (1 - R) \log_q \left( \frac{\kappa_0}{\varepsilon^2} \right) - R \log_q \left( \frac{2R - 1 + \kappa_0}{(1-\varepsilon)^2} \right) - 2 \left[ (1 - R) \log_q \left( \frac{1 - R}{\varepsilon} \right) + R \log_q \left( \frac{R}{1 - \varepsilon} \right) \right]
= (1 - R) \log_q \left( \frac{\kappa_0}{(1-R)^2} \right) + R \log_q \left( \frac{2R - 1 + \kappa_0}{R^2} \right)
> (1 - R) \log_q \left( \frac{(1-R)^2}{(1-R)^2} \right) + R \log_q \left( \frac{2R - 1 + (1-R)^2}{R^2} \right) = 0,
\]
so (43) always holds true in this case.

Case 2. $\frac{1-\varepsilon}{1+(q - 1)\varepsilon^2} \leq R < \frac{1-\varepsilon}{1+(q - 1)\varepsilon^2}$

We can actually obtain a slightly more general result than (2) of Theorem 3 as follows:

Lemma 6. If (43) holds for $R = R_0$ where $R_0$ satisfies $0 < R_0 \leq \frac{1-\varepsilon}{1+(q - 1)\varepsilon^2}$, then (43) also holds true for any $R \in \left[ R_0, \frac{1-\varepsilon}{1+(q - 1)\varepsilon^2} \right]$.

Proof of Lemma 6. First, from Case 1 and the continuity of $S_{ud}(\varepsilon)$ and $T_{ud}(\varepsilon)$, we know that (43) holds for $R = \frac{1-\varepsilon}{1+(q - 1)\varepsilon^2}$. Hence such $R_0$ always exists.

Now if $R \in \left[ \frac{1-\varepsilon}{1+(q - 1)\varepsilon^2}, \frac{1-\varepsilon}{1+(q - 1)\varepsilon^2} \right]$, then we have
\[
c(\varepsilon, R) = 1 - R - \log_q [1 + (q - 1)\varepsilon^2] - 2 \left[ (1 - R) \log_q \left( \frac{1 - R}{\varepsilon} \right) + R \log_q \left( \frac{R}{1 - \varepsilon} \right) \right].
\]
Differentiating $c(\varepsilon, R)$ twice with respect to $R$, we have
\[
\frac{\partial^2 c(\varepsilon, R)}{\partial R^2} = -\frac{2}{R(1-R) \ln q},
\]
which is negative for \( R \in \left[ \frac{1-\varepsilon}{1+(q-1)\varepsilon}, \frac{1-\varepsilon}{1+(q-1)\varepsilon^2} \right] \), and thus \( c(\varepsilon, R) \) is convex \( \cap \) for \( R \) within that interval.

Next, for \( 0 < R < \frac{1-\varepsilon}{1+(q-1)\varepsilon} \), we note that
\[
c(\varepsilon, R) = 1 - R - \log_q[1 + (q - 1)\varepsilon^2] - 2(1 - R - \log_q[1 + (q - 1)\varepsilon]) = R - 1 - \log_q[1 + (q - 1)\varepsilon^2] + 2 \log_q[1 + (q - 1)\varepsilon]
\]
is a linear function in \( R \) with positive slope. Hence the function \( c(\varepsilon, R) \) is convex \( \cap \) for \( R \) within the whole interval \( \left[ R_0, \frac{1-\varepsilon}{1+(q-1)\varepsilon^2} \right] \), and Lemma 6 follows. \( \square \)

Now we let \( q \in \{2, 3, 4\} \). Consider \( R = \frac{1-\varepsilon}{1+(q-1)\varepsilon} \). Under this special value,
\[
Q(\varepsilon) := c(\varepsilon, R) = -\frac{q\varepsilon}{1+(q-1)\varepsilon} - \log_q[1 + (q - 1)\varepsilon^2] + 2 \log_q[1 + (q - 1)\varepsilon].
\]

Differentiating \( Q(\varepsilon) \) with respect to \( \varepsilon \), we have
\[
Q'(\varepsilon) = \frac{q}{1+(q-1)\varepsilon^2} - \frac{2(q-1)}{1+(q-1)\varepsilon^2} \ln q + \frac{2(q-1)}{1+(q-1)\varepsilon} \ln q
\]
\[
= -\frac{(q-1)(q \ln q + 2q - 2)}{(1+(q-1)\varepsilon)(1+(q-1)\varepsilon^2) \ln q} \left( \varepsilon^2 - \frac{2(q-2)}{q \ln q + 2q - 2} \varepsilon - \frac{2 - \frac{q \ln q}{q-1}}{q \ln q + 2q - 2} \right).
\]

It is easy to check that when \( q \in \{2, 3, 4\} \), then we have
\[
0 \leq \frac{2(q-2)}{q \ln q + 2q - 2} < 1, \quad Q'(0) > 0, Q'(1) < 0.
\]

Therefore exactly one of the two roots for \( Q'(\varepsilon) \) lies in the desired range \( 0 < \varepsilon < 1 \), and \( Q(\varepsilon) \) attains local maximum at that point. Since \( Q(0) = Q(1) = 0 \), we conclude that \( Q(\varepsilon) \) is positive for \( 0 < \varepsilon < 1 \), and therefore (43) holds for \( R = \frac{1-\varepsilon}{1+(q-1)\varepsilon} \).

Now by Lemma 6, we see that Equation (43) holds for \( R \in \left[ \frac{1-\varepsilon}{1+(q-1)\varepsilon}, \frac{1-\varepsilon}{1+(q-1)\varepsilon^2} \right] \) when \( q = 2, 3, 4 \).

This completes the proof of Theorem 3.

VII. APPENDIX: PROOF OF THEOREM 6

To prove Theorem 6, we first obtain

**Lemma 7.**
\[
S_{ud}(\varepsilon) = -\sup_{t,t',\kappa} g(t, t', \kappa),
\]
where
\[ g(t, t', \kappa) = (\kappa - 1 + R) + h(\kappa, t - \kappa, t' - \kappa, 1 - t - t' + \kappa) + (t + t') \log q \varepsilon + (2 - t - t') \log q (1 - \varepsilon), \tag{44} \]

and the supremum is taken over positive real numbers \( t, t', \kappa \) satisfying
\[ t, t' \leq 1 - R, \quad t + t' - 1 \leq \kappa \leq \min \{ t, t' \}. \tag{45} \]

Here
\[ h(t_1, t_2, \cdots, t_r) = - \sum_{j=1}^r t_j \log_q t_j \left( t_j \geq 0, \sum_{j=1}^r t_j = 1 \right) \tag{46} \]
is the multi-entropy function (in \( q \)-its).

Proof of Lemma 7 Write \( m = (1 - R)n \). We define
\[ g_{i, i', s} := \psi_m(i) \psi_m(i') \left( \frac{1}{\psi_m(s)} - 1 \right) \left( s, i - s, i' - s, n - i - i' + s \right) \varepsilon^{i + i' - (1 - \varepsilon)^{2n - i - i'}. \]

We note that \( g_{i, i', s} \geq 0 \) for all integers \( i, i', s \), and is nonzero if and only if \( 1 \leq i, i' \leq m, 1 \leq s \leq \min \{ i, i' \} \) and \( i' - s \leq n - i \). Then we can rewrite the term \( \sigma_{ud}^2(\mathcal{R}_{m, n}, \varepsilon) \) (see Theorem 5) as
\[ \sigma_{ud}^2(\mathcal{R}_{m, n}, \varepsilon) = \sum_{i, i', s} g_{i, i', s}, \]

where summation is over all integers \( i, i', s \) satisfying the conditions
\[ 1 \leq i, i' \leq m, \quad \max \{ 1, i + i' - n \} \leq s \leq \min \{ i, i' \}. \tag{47} \]

There are at most \( m^3 \) such integer triples \( (i, i', s) \). Since \( \lim_{n \to \infty} \frac{\log_q m^3}{n} = 0 \), we have
\[ \frac{1}{n} \log_q \sigma_{ud}^2(\mathcal{R}_{m, n}, \varepsilon) = o(1) + \frac{1}{n} \max_{i, i', s} \log_q g_{i, i', s}. \tag{48} \]

Now we need a careful analysis of the quantity \( g_{i, i', s} \). First, using \( T := q^{-1} \) and \( M := (T)_\infty \in (0, 1) \), we observe that
\[ M^2 \leq \psi_m(i) \psi_m(i') = \frac{(T)^2_m}{(T)_{m-i}(T)_{m-i'}} \leq \frac{1}{M^2}, \quad \forall 1 \leq i, i' \leq m. \]

So
\[ \frac{1}{n} \log_q \left[ \psi_m(i) \psi_m(i') \right] = o(1). \]
Next, for $1 \leq s \leq m$, using (33), we have,
\[
\frac{1}{\psi_m(s)} - 1 = \frac{(T)_{m-s}}{(T)_m} - 1 = \frac{(T)_{m-s}}{(T)_m} \left( 1 - \prod_{j=m-s+1}^{m} (1 - T^j) \right).
\]

It is easy to see that
\[
1 - T^{m-s+1} \geq \prod_{j=m-s+1}^{m} (1 - T^j) > 1 - \sum_{j=m-s+1}^{\infty} T^j = 1 - \frac{q}{q-1} T^{m-s+1},
\]
so we have
\[
\frac{1}{n} \log_q \left( \frac{1}{\psi_m(s)} - 1 \right) = \frac{s - m - 1}{n} + o(1).
\]

Therefore we can simplify (48) as
\[
\frac{1}{n} \log_q \sigma_{ud}^2(R_{m,n}, \varepsilon) = o(1) + \max_{i,i',s} \left[ \frac{s - m - 1}{n} + \frac{1}{n} \log_q \left( \sum_{s,i-s,i'-s,n-i-i'+s}^{n} \frac{i + i'}{n} \log_q \varepsilon + \frac{2n - i - i'}{n} \log_q (1 - \varepsilon) \right) \right].
\]

Letting $i = tn, j = t'n$ and $s = \kappa n$, using the following generalization of (34) (which can be verified similarly)
\[
\frac{1}{n} \log_q \left( t^n_{1n,t_2n,\cdots,t_r n} \right) = h(t_1,t_2,\cdots,t_r) + o(1),
\]
where $h(t_1,t_2,\cdots,t_r) (\text{with } \sum_{j=1}^{r} t_j = 1)$ is defined as in (46), and then taking $n \to \infty$, we obtain
\[
S_{ud}(\varepsilon) = - \sup_{t,t',\kappa} g(t,t',\kappa),
\]
where $g(t,t',\kappa)$ is defined as in (44) and the supremum is taken over positive real numbers $t,t',\kappa$ satisfying (45). This completes the proof of Lemma 7.

Using Lemma 7, now we provide a detailed proof of Theorem 6.

We start from the function $g(t,t',\kappa)$ given in (44). It is best to first take the supremum over $t'$ while fixing $t$ and $\kappa$. Therefore we differentiate $g$ with respect to $t'$ while keeping $t$ and $\kappa$ fixed, where the range of $t'$ should be taken as $\kappa \leq t' \leq \min\{\kappa - t + 1, 1 - R\}$:
\[
\frac{\partial g}{\partial t'} = \log_q \left( \frac{(1 - t - t' + \kappa)\varepsilon}{(t' - \kappa)(1 - \varepsilon)} \right).
\]
Solving for $\frac{\partial g}{\partial t'} = 0$, we get $t' = \varepsilon(1 - t) + \kappa$, and we check that $g$ attains local maximum at that point.
This leads us to consider two cases:

**Case 1.** \( t \geq 1 - \frac{1 - R - \kappa}{\varepsilon} \)

In this case the critical point \( \varepsilon(1 - t) + \kappa \) lies within the required range of \( t' \). We see that the maximum of \( g \) is

\[
G_1(t, \kappa) := g(t, \varepsilon(1 - t) + \kappa, \kappa) = (\kappa - 1 + R) + h(\kappa, t - \kappa, \varepsilon(1 - t), (1 - \varepsilon)(1 - t)) + [(\varepsilon + \kappa) + (1 - \varepsilon)t] \log_q \varepsilon \\
+ [(2 - \varepsilon - \kappa) - (1 - \varepsilon)t] \log_q(1 - \varepsilon).
\]

Differentiating both sides with respect to \( t \) while keeping \( \kappa \) fixed, where the range of \( t \) is taken as \( \max\{\kappa, 1 - \frac{1 - R - \kappa}{\varepsilon}\} \leq t \leq 1 - R \), we have

\[
\frac{\partial G_1}{\partial t} = \log_q \left( \frac{\varepsilon(1 - t)}{t - \kappa} \right).
\]

Solving for \( \frac{\partial G_1}{\partial t} = 0 \), we get \( t = \frac{\varepsilon + \kappa}{1 + \varepsilon} \). We also see that \( G_1 \) attains local maximum at this point. We note that \( \kappa \leq \frac{\varepsilon + \kappa}{1 + \varepsilon} \) as \( \kappa < 1 \). In order for the range of \( t \) to be nonempty, we also need \( 1 - \frac{1 - R - \kappa}{\varepsilon} \leq 1 - R \), which is true if and only if \( 0 < \kappa \leq 1 - R - R\varepsilon \) (and this range is nonempty if and only if \( 0 < R < \frac{1}{1 + \varepsilon} \)).

We then obtain

\[
1 - \frac{1 - R - \kappa}{\varepsilon} \leq \frac{\varepsilon + \kappa}{1 + \varepsilon} \leq 1 - R,
\]

so the maximum of \( g \) is

\[
G_1(\kappa) := G_1\left(\frac{\varepsilon + \kappa}{1 + \varepsilon}, \kappa\right) = (\kappa - 1 + R) + h\left(\kappa, \frac{\varepsilon(1 - \kappa)}{1 + \varepsilon}, \frac{\varepsilon(1 - \kappa)}{1 + \varepsilon}, \frac{(1 - \varepsilon)(1 - \kappa)}{1 + \varepsilon}\right) + 2\left(\frac{\varepsilon + \kappa}{1 + \varepsilon}\right) \log_q \varepsilon + 2\left(\frac{1 - \kappa}{1 + \varepsilon}\right) \log_q(1 - \varepsilon).
\]

Differentiating both sides with respect to \( \kappa \) and checking for \( G_1'(\kappa) = 0 \), we have \( \kappa = \frac{q\varepsilon^2}{1 + (q - 1)\varepsilon^2} \). In addition, \( G_1 \) attains local maximum at this critical point.

Then we have the following two possible cases:

1) \( 0 < R \leq \frac{1 - \varepsilon}{1 + (q - 1)\varepsilon^2} \)

In this case \( \frac{q\varepsilon^2}{1 + (q - 1)\varepsilon^2} \leq 1 - R - R\varepsilon \), and so the maximum is

\[
G_1\left(\frac{q\varepsilon^2}{1 + (q - 1)\varepsilon^2}\right) = -1 + R + \log_q[1 + (q - 1)\varepsilon^2].
\]
2) \[ \frac{1 - \varepsilon}{1 + (q-1)\varepsilon^2} < R < \frac{1}{1 + \varepsilon} \]

In this case \( 0 < 1 - R - R\varepsilon < \frac{q \varepsilon^2}{1 + (q-1)\varepsilon^2} \), and so the maximum is

\[
G_1(1 - R - R\varepsilon) = -R\varepsilon - (1 - R - R\varepsilon) \log_q \left( \frac{1 - R - R\varepsilon}{\varepsilon^2} \right) - R(1 + \varepsilon) \log_q \left( \frac{R}{1 - \varepsilon} \right).
\]

**Case 2.** \( t < 1 - \frac{1 - R - \kappa}{\varepsilon} \)

In this case the critical point \( \varepsilon(1 - t) + \kappa \) is larger than the upper bound \( 1 - R \) of \( t' \). Hence maximum is

\[
G_2(t, \kappa) := g(t, 1 - R, \kappa) = (\kappa - 1 + R) + h(\kappa, t - \kappa, 1 - R - \kappa, R - t + \kappa) + (t + 1 - R) \log_q \varepsilon + (1 + R - t) \log_q (1 - \varepsilon).
\]

Differentiating both sides with respect to \( t \) while keeping \( \kappa \) fixed, where the range of \( t \) is taken as \( \kappa \leq t \leq \min\{1 - \frac{1 - R - \kappa}{\varepsilon}, 1 - R\} \), we get

\[
\frac{\partial G_2}{\partial t} = \log_q \left( \frac{\varepsilon(R + \kappa - t)}{(t - \kappa)(1 - \varepsilon)} \right).
\]

Solving for \( \frac{\partial G_2}{\partial t} = 0 \), we have \( t = R\varepsilon + \kappa \). We also see that \( G_2 \) attains local maximum at this point. We already see that \( \kappa \leq R\varepsilon + \kappa \). Hence we need to compare the critical point with \( \min\{1 - \frac{1 - R - \kappa}{\varepsilon}, 1 - R\} \).

First in order that the range of \( t \) is nonempty, we must have \( \kappa \leq \min\{1 - \frac{1 - R - \kappa}{\varepsilon}, 1 - R\} \), which is true if and only if \( 1 - \frac{R}{1 - \varepsilon} \leq \kappa \leq 1 - R \). We can further divide into two subcases:

**Case 2a.** \( 1 - \frac{R}{1 - \varepsilon} \leq \kappa \leq 1 - R - R\varepsilon \)

In this case we have \( 1 - \frac{1 - R - \kappa}{\varepsilon} \leq R\varepsilon + \kappa \leq 1 - R \). Hence the maximum occurs at \( t = 1 - \frac{1 - R - \kappa}{\varepsilon} \).

Note that this value of \( t \) is precisely the one in which \( t' = 1 - R = \varepsilon(1 - t) + \kappa \). Therefore it is covered in **Case 1** already, and the maximum so obtained cannot be larger than the value calculated in that case.

Note that this case can only happen when \( 0 < R < \frac{1}{1 + \varepsilon} \).

**Case 2b.** \( \max\{0, 1 - R - R\varepsilon\} < \kappa \leq 1 - R \)

In this case we have \( 1 - R < R\varepsilon + \kappa < 1 - \frac{1 - R - \kappa}{\varepsilon} \). Hence the maximum occurs at \( t = 1 - R \).

Then we get

\[
G_2(\kappa) := G_2(1 - R, \kappa) = (\kappa - 1 + R) + h(\kappa, 1 - R - \kappa, 1 - R - \kappa, 2R - 1 + \kappa) + 2(1 - R) \log_q \varepsilon + 2R \log_q (1 - \varepsilon).
\]
Differentiating both sides with respect to $\kappa$, we have

\[ G'_2(\kappa) = \log_q \left( \frac{q(1 - R - \kappa)^2}{\kappa(2R - 1 + \kappa)} \right). \tag{49} \]

Solving for $G'_2(\kappa) = 0$, we obtain two roots

\[ \kappa_{\pm} = 1 - R \pm \frac{1 \pm \sqrt{4R(1 - R)(q - 1) + 1}}{2(q - 1)}. \]

However under our assumption we require $\kappa \leq 1 - R$. It is easy to see that we should then take $\kappa_-$. This is precisely $\kappa_0$ given by (41).

Note that the number

\[ N(\kappa) = \frac{q(1 - R - \kappa)^2}{\kappa(2R - 1 + \kappa)} \]

inside the logarithm in right hand side of (49) is a strictly decreasing function within our range of $\kappa$. Hence it suffices to check the value of $N(\kappa)$ at the two bounds to see whether $\kappa_0$ is within our range (in particular $N(\kappa_0) = 1$). It is clear that

\[ N(1 - R) = 0, \quad N(1 - R - R\varepsilon) = \frac{qR\varepsilon^2}{(1 - \varepsilon)(1 - R - R\varepsilon)} \]

and

\[ \lim_{\kappa \to 0^+} N(\kappa) = +\infty. \]

Then we have two cases again:

1) $0 < R \leq \frac{1 - \varepsilon}{1 + (q - 1)\varepsilon}$

   In this case we have $N(1 - R - R\varepsilon) \leq 1$, and so $G'_2(\kappa) \leq 0$ within the range of $\kappa$. This shows that the maximum occurs at $\kappa = 1 - R - R\varepsilon$. Note that this also implies $t = 1 - R = 1 - \frac{1 - R - \kappa}{\varepsilon}$. Since this value is already covered in Case 2a, the maximum cannot be greater than in that case and thereby in Case 1 too.

2) $\frac{1 - \varepsilon}{1 + (q - 1)\varepsilon} < R < 1$

   In this case we have $N(1 - R - R\varepsilon) > 1$, so one of the critical points (in fact the smaller one) is within our range. That number is exactly $\kappa_0$ defined in (41). Since $G'_2(\kappa)$ is decreasing in our
range, this implies $G_2$ attains maximum at $\kappa_0$. The maximum will then be

$$G_2(\kappa_0) = (\kappa_0 - 1 + R) + h(\kappa_0, 1 - R - \kappa_0, 1 - R - \kappa_0, 2R - 1 + \kappa_0) + 2(1 - R) \log_q \varepsilon + 2R \log_q (1 - \varepsilon)$$

$$= -(1 - R) \log_q \left( \frac{\kappa_0}{\varepsilon^2} \right) - R \log_q \left( \frac{2R - 1 + \kappa_0}{(1 - \varepsilon)^2} \right)$$

after simplification and applying the relation $G'_2(\kappa_0) = 0$.

Note that in particular when $\frac{1 - \varepsilon}{1 + (q - 1)\varepsilon^2} < R < \frac{1}{1 + \varepsilon}$, this value is larger than $G_2(1 - R - R\varepsilon) = -R\varepsilon - (1 - R - R\varepsilon) \log_q \left( \frac{1 - R - R\varepsilon}{\varepsilon^2} \right) - R(1 + \varepsilon) \log_q \left( \frac{R}{1 - \varepsilon} \right) = G_1(1 - R - R\varepsilon)$.

Combining all above cases, we finally obtain

$$S_{ud}(\varepsilon) = -\sup_{t, t', \kappa} g(t, t', \kappa) = \begin{cases} 1 - R - \log_q [1 + (q - 1)\varepsilon^2] & \left( 0 < R \leq \frac{1 - \varepsilon}{1 + (q - 1)\varepsilon^2} \right) \\ (1 - R) \log_q \left( \frac{\kappa_0}{\varepsilon^2} \right) + R \log_q \left( \frac{2R - 1 + \kappa_0}{(1 - \varepsilon)^2} \right) & \left( \frac{1 - \varepsilon}{1 + (q - 1)\varepsilon^2} < R < 1 \right). \end{cases}$$

This completes the proof of Theorem 6.

VIII. Conclusion

In this paper we carried out an in-depth study on the average decoding error probabilities of the random matrix ensemble $R_{m,n}$ over the erasure channel under three decoding principles, namely unambiguous decoding, maximum likelihood decoding and list decoding.

(1). We obtained explicit formulas for the average decoding error probabilities of the ensemble under these three decoding principles and computed the error exponents.

(2). For unambiguous decoding, we computed the variance of the decoding error probability of the ensemble and the error exponent of the variance.

(3). For unambiguous decoding, we obtained a strong concentration result, that is, under general conditions, the ratio of the decoding error probability of a random code in the ensemble and the average decoding error probability of the ensemble converges to 1 with high probability when the code length goes to infinity.

It might be interesting to extend the results of (2) and (3) to general list decoding and maximum likelihood decoding for the ensemble $R_{m,n}$. As it turns out, the variance of decoding error probability in these two cases can still be computed, but the expressions are much more complicated and it is difficult to obtain explicit formulas for their error exponents, and hence a concentration result from them. We leave this as an open question for future research.
