Abstract

We prove a theorem for scalar-valued functions of tensors and further generalize it to relative scalar-valued functions of relative tensors of any weight and tensor objects of multiple index classes. In the context of classical field theories in dynamic space-times, the relevant Lagrangians constitute scalar densities, i.e. scalars of weight $w = 1$ formed by tensors. For these scalar densities, the theorem provides us with an important identity that establishes the correlations of the pertaining metric and canonical energy-momentum tensors. It also serves to set up a simple form of a generalized Einstein-type field equation that applies for any gravity Lagrangian, independent of the formulation (first or second order), with torsion and non-metricity not excluded.

I. INTRODUCTION

The theorem for scalar-valued functions of tensors constitutes the tensor analogue of Euler’s theorem on homogeneous functions of calculus. We first prove the theorem for absolute scalars constituted by contractions of $(n, n)$-tensors, which on its part may be tensor products of lower rank tensors. On this basis, the theorem is generalized for tensor of multiple index classes, such as tetrads and spinor-tensors (e.g. Dirac matrices), and relative tensors that contract to a relative scalar of weight $w$. In particular, the Lagrangians of classical field theories that describe the dynamics of classical scalar, vector, and spinor fields in a dynamic space-time represent relative scalars of weight $w = 1$, which are commonly referred to as scalar densities. The identity is then applied to derive the correlation of the metric energy-momentum tensor to the corresponding canonical tensor. This shows on a general level how metric and canonical energy-momentum tensors are related for the Klein-Gordon, Maxwell/Proca, and Dirac systems. Moreover, the consistency equation emerging from the Hamiltonian formulation of the gauge theory of gravity [1] may be cast via the identity into a simpler form while retaining its scope for non-vanishing torsion of space-time and non-metricity. Similar considerations were made earlier by Rosenfeld [2] and by Belinfante [3], the latter in the context of symmetrizing non-symmetric canonical energy-momentum tensors in order to render it eligible to act as the source term in the classical

Einstein equation with its symmetric Einstein tensor.

II. THEOREM FOR SCALAR-VALED FUNCTIONS OF TENSORS

A. Absolute tensors

In the following, we prove a theorem for a scalar that is formed from contractions of an arbitrary \((n,n)\) tensor.

**Proposition 1** Let \(S = S(T) \in \mathbb{R}\) be a scalar-valued function constructed from a complete contraction of a \((n,n)\)-tensor \(T^{\xi_1...\xi_n}_{\eta_1...\eta_n}\), with the ordered index set \(\{\eta_k\}\) a bijective permutation \(\{\xi_{\pi(k)}\}\) of the ordered index set \(\{\xi_j\}\) such that \(\eta_k \equiv \xi_{\pi(k)} \equiv \xi_j\). Then the following identity holds:

\[
-\frac{\partial S}{\partial T^\nu_{\xi_2...\xi_n \eta_1...\eta_n}} T^\mu_{\xi_2...\xi_n \eta_1...\eta_n} - \ldots - \frac{\partial S}{\partial T_{\xi_1...\xi_{n-1} \nu \eta_1...\eta_n}} T^{\xi_1...\xi_{n-1} \mu}_{\eta_1...\eta_n} \nonumber \\
+ \frac{\partial S}{\partial T_{\xi_1...\xi_n \mu \eta_2...\eta_n}} T^{\xi_1...\xi_n \nu \eta_2...\eta_n} + \ldots + \frac{\partial S}{\partial T_{\xi_1...\xi_n \eta_1...\eta_{n-1} \mu}} T^{\xi_1...\xi_n \eta_1...\eta_{n-1} \nu} \nonumber \\
\equiv 0. \quad (1)
\]

Thus, in each term, exactly one previously contracted index \(\xi_j\) resp. \(\eta_j\) of \(S\) is replaced by the now open indices \(\nu\) and \(\mu\).

**Proof 1** The proof is based on the simple relation

\[
\frac{\partial S}{\partial T^\alpha_{\mu \nu}} T^\alpha_{\nu} = \frac{\partial T^\beta_{\mu \nu}}{\partial T^\alpha_{\mu}} T^\alpha_{\nu} = \delta^\beta_\alpha \delta^\mu_\nu T^\alpha_{\nu} = T^\mu_{\nu} = \delta^\beta_\nu \delta^\nu_\alpha T^\mu_{\alpha} = \frac{\partial T^\beta_{\nu \alpha}}{\partial T^\alpha_{\nu}} T^\mu_{\alpha} = \frac{\partial S}{\partial T^\nu_{\alpha}} T^\mu_{\alpha}
\]

It is straightforward to see that this relation applies for any pair of contracted indices. Then for any pair \(\xi_j\) and \(\eta_k\) of contracted indices \(\eta_k \equiv \xi_{\pi(k)} \equiv \xi_j\) of \(S = T^{\xi_1...\xi_n}_{\eta_1...\eta_n}\) we find for
their respective replacement by $\nu$ and $\mu$ according to Eq. (1):

\[
- \frac{\partial S}{\partial T^{\xi_1 \ldots \xi_{j-1} \nu \xi_{j+1} \ldots \xi_n}} T^{\xi_1 \ldots \xi_{j-1} \mu \xi_{j+1} \ldots \xi_n}_{\eta_1 \ldots \eta_{k-1} \eta_k \eta_{k+1} \ldots \eta_n} + \frac{\partial S}{\partial T^{\xi_1 \ldots \xi_{j-1} \xi_j \xi_{j+1} \ldots \xi_n}} T^{\xi_1 \ldots \xi_{j-1} \xi_j \xi_{j+1} \ldots \xi_n}_{\eta_1 \ldots \eta_{k-1} \nu \eta_{k+1} \ldots \eta_n}
\]

\[
= -\delta^\xi_\nu T^{\xi_1 \ldots \xi_{j-1} \mu \xi_{j+1} \ldots \xi_n}_{\eta_1 \ldots \eta_{k-1} \eta_k \eta_{k+1} \ldots \eta_n} + \delta^\xi_\eta T^{\xi_1 \ldots \xi_{j-1} \xi_j \xi_{j+1} \ldots \xi_n}_{\eta_1 \ldots \eta_{k-1} \nu \eta_{k+1} \ldots \eta_n}
\]

\[
= -T^{\xi_1 \ldots \xi_{j-1} \mu \xi_{j+1} \ldots \xi_n}_{\eta_1 \ldots \eta_{k-1} \nu \eta_{k+1} \ldots \eta_n} + T^{\xi_1 \ldots \xi_{j-1} \mu \xi_{j+1} \ldots \xi_n}_{\eta_1 \ldots \eta_{k-1} \mu \eta_{k+1} \ldots \eta_n}
\]

\[
\equiv 0,
\]

which proves the assertion. \hfill \Box

The $\langle n, n \rangle$-tensor $T^{\xi_1 \ldots \xi_n}_{\eta_1 \ldots \eta_n}$ may be in particular a tensor product of tensors of lower ranks. This is demonstrated in the following example:

**Example 1** Let $S$ be a scalar emerging from the contraction of an arbitrary tensor $A^{\alpha \beta}_{\xi}$ with $B^\xi_{\alpha \eta}$ and $C^\eta_{\beta \eta}$:

\[
S = A^{\alpha \beta}_{\xi} B^\xi_{\alpha \eta} C^\eta_{\beta \eta}.
\] (2)

Then

\[
- \frac{\partial S}{\partial A^{\alpha \beta}_{\xi}} A^{\alpha \beta}_{\xi} - \frac{\partial S}{\partial A^\alpha_{\alpha \nu}} A^\alpha_{\alpha \nu} + \frac{\partial S}{\partial A^\alpha_{\alpha \beta \mu}} A^\alpha_{\alpha \beta \mu} - \frac{\partial S}{\partial B^\mu_{\alpha \eta}} B^\mu_{\alpha \eta}
\]

\[
= - \frac{\partial S}{\partial B^\xi_{\alpha \eta}} B^\xi_{\alpha \eta} + \frac{\partial S}{\partial C^\alpha_{\mu \eta}} C^\alpha_{\mu \eta} + \frac{\partial S}{\partial C^\eta_{\beta \mu}} C^\eta_{\beta \mu} \equiv 0.
\] (3)

For the prove of the identity (3) the respective terms of the sum are worked out explicitly:
\[
\frac{\partial S}{\partial C_{\beta\mu}} = A^{\alpha\beta}_{\xi} B_{\alpha \xi}^{\xi\eta} \delta_{\eta}^{\mu} C_{\beta\nu} = A^{\alpha\beta}_{\xi} B_{\alpha \xi}^{\xi\eta} C_{\beta\nu},
\]
\[
\frac{\partial S}{\partial C_{\mu\eta}} = A^{\alpha\beta}_{\xi} B_{\alpha \xi}^{\xi\eta} \delta_{\beta}^{\mu} C_{\nu\eta} = A^{\alpha\beta}_{\xi} B_{\alpha \xi}^{\xi\eta} C_{\nu\eta}.
\]

The terms on the right-hand sides in each case occur twice with opposite signs—and thus sum up to zero.

Of course, this example can be generalized to the contraction of any number of tensors of any kind.

**B. Scalar functions involving the metric tensor**

With \( S = S(g, T) \in \mathbb{R} \) a scalar-valued function constructed from the metric tensor \( g_{\mu\nu} \) and an \((n,m)\)-tensor \( T^{\xi_1...\xi_n}_{\eta_1...\eta_m} \) of the physical fields, the following identity then holds for \((n - m)/2 \in \mathbb{Z}\):

\[
\frac{\partial S}{\partial g_{\mu\beta}} g_{\nu\beta} + \frac{\partial S}{\partial g_{\beta\mu}} g_{\beta\nu} - \frac{\partial S}{\partial T^{\xi_1...\xi_n}_{\eta_1...\eta_m}} T^{\mu}_{\xi_2...\xi_n}_{\eta_1...\eta_m} - \ldots - \frac{\partial S}{\partial T^{\xi_1...\xi_{n-1}\nu}_{\eta_1...\eta_m}} T^{\xi_1...\xi_{n-1}\mu}_{\eta_1...\eta_m}
\]
\[
+ \frac{\partial S}{\partial T^{\xi_1...\xi_n}_{\mu\nu\eta_2...\eta_m}} + \ldots + \frac{\partial S}{\partial T^{\xi_1...\xi_n}_{\eta_1...\eta_m\nu\mu}}
\]
\[= 0. \tag{4}\]

**Corollary 1** The trace of Eq. \((4)\) then yields the scalar identity:

\[
\frac{\partial S}{\partial g_{\alpha\beta}} g_{\alpha\beta} \equiv \frac{n - m}{2} \frac{\partial S}{\partial T^{\xi_1...\xi_n}_{\eta_1...\eta_m}} T^{\xi_1...\xi_n}_{\eta_1...\eta_m}. \tag{5}\]

**Proof 2** Contracting Eq. \((4)\) immediately gives Eq. \((5)\). \qed

**C. Scalar functions involving tensors with multiple index classes**

**Corollary 2** The theorem \((1)\) holds also for scalars \( S \) constructed from generalized tensor objects—such as spinor-tensors—which are made of multiple index classes. Examples of such objects are Dirac matrices \( \gamma^\mu \), which are \((1,1)\)-spinor-(1,0)-tensors, as well as tetrads (vierbeins) with one Lorentz and one space-time index, respectively. One then encounters a specific identity for each particular index class, provided that all other indices are fully contracted.
Proof 3 For each fully contracted index group, Eq. (1) trivially vanishes. For the not fully contracted indices, Eq. (1) applies.

D. Scalar densities built from relative tensors

Corollary 3 Let a relative scalar of weight $w$—denoted by $\tilde{S} = S(\sqrt{-g})^w \in \mathbb{R}$—be given as a function of the metric $g_{\mu\nu}$ and a tensor $T^{\xi_1...\xi_n}_{\eta_1...\eta_m}$ of rank $(n, m)$. Then the following identity holds for $(n - m)/2 \in \mathbb{Z}$:

$$
\begin{aligned}
&+ \frac{\partial \tilde{S}}{\partial g_{\mu\beta}} g_{\nu\beta} + \frac{\partial \tilde{S}}{\partial g_{\beta\mu}} g_{\beta\nu} \\
&- \frac{\partial \tilde{S}}{\partial T^{\xi_1...\xi_n}_{\eta_1...\eta_m}} T^{\mu}_{\xi_1...\xi_n} - \cdots - \frac{\partial \tilde{S}}{\partial T^{\xi_1...\xi_{n-1}\nu}_{\eta_1...\eta_{m-1}\eta_m}} T^{\xi_1...\xi_{n-1}\mu}_{\eta_1...\eta_{n-1}\eta_m} \\
&+ \frac{\partial \tilde{S}}{\partial T^{\xi_1...\xi_n}_{\mu\eta_2...\eta_m}} T^{\nu}_{\xi_1...\xi_n} + \cdots + \frac{\partial \tilde{S}}{\partial T^{\xi_1...\xi_n}_{\eta_1...\eta_{m-1}\mu}} T^{\xi_1...\xi_n}_{\eta_1...\eta_{n-1}\nu}
\end{aligned}
\equiv \delta^\mu_{\nu} w \tilde{S}. \quad (6)

Proof 4 Multiply Eq. (4) with $(\sqrt{-g})^w$, add $\delta^\mu_{\nu} w \tilde{S}$ on both sides of the identity, and combine the appropriate terms on the left-hand side. With the general rule for the derivative of the determinant of the metric,

$$
\frac{\partial \sqrt{-g}}{\partial g_{\mu\beta}} = \frac{1}{2} g^{\beta\mu} \sqrt{-g},
$$

one then gets:

$$
\left( \frac{\partial S}{\partial g_{\mu\beta}} g_{\nu\beta} + \frac{\partial \tilde{S}}{\partial g_{\beta\mu}} g_{\beta\nu} + \delta^\mu_{\nu} w S \right) (\sqrt{-g})^w = \frac{\partial \tilde{S}}{\partial g_{\mu\beta}} g_{\nu\beta} + \frac{\partial \tilde{S}}{\partial g_{\beta\mu}} g_{\beta\nu}.
$$

Equation (6) is obviously a representation of Euler’s theorem on homogeneous functions in the realm of tensor calculus. The relative scalar $\tilde{S} = S(\sqrt{-g})^w$ of weight $w$ may in particular be the tensor product of some relative tensors of lower ranks and weights. The weight $w$ of $\tilde{S}$ is then the sum of the weights of the relative tensors.

As a direct application, the above used relation for the derivative of the metric-determinant may also be derived using (6).

Example 2 The components of the covariant metric tensor $(g_{\mu\nu}(x))$ transform under the transition $x \mapsto X$ of the space-time location as:

$$
g_{\mu\nu}(X) = \frac{\partial x^\alpha}{\partial X^\mu} g_{\alpha\beta}(x) \frac{\partial x^\beta}{\partial X^\nu},
$$
and hence its determinant $g \equiv |g_{\alpha \beta}(x)|$:
\[
|g_{\mu \nu}(X)| = |g_{\alpha \beta}(x)| \left| \frac{\partial x}{\partial X} \right|^2.
\]

The determinant $g$ of the covariant metric tensor thus transforms as a relative scalar of weight $w = 2$. According to the general form of the identity for relative scalars of weight $w$ from Eq. (6), we get for the relative scalar $g$ due to the symmetry $g_{\beta \alpha} = g_{\alpha \beta}$:
\[
\frac{\partial g}{\partial g_{\beta \mu}} g_{\beta \nu} + \frac{\partial g}{\partial g_{\mu \beta}} g_{\nu \beta} = 2 \delta_{\nu}^\mu \ g \quad \Rightarrow \quad \frac{\partial g}{\partial g_{\beta \mu}} g_{\beta \alpha} = \delta_{\alpha}^\mu \ g. \quad (7)
\]

Contracting (7) with the inverse metric $g^{\alpha \nu}$ yields the derivative of the determinant $g$ of the covariant metric with respect to the component $g_{\nu \mu}$ of the metric:
\[
\frac{\partial g}{\partial g_{\nu \mu}} \equiv g^{\mu \nu} \ g,
\]
and thus for the negative square root of $g$
\[
\frac{\partial \sqrt{-g}}{\partial g_{\nu \mu}} \equiv \frac{1}{2} g^{\mu \nu} \sqrt{-g}, \quad \frac{\partial \sqrt{-g}}{\partial g^{\nu \mu}} \equiv -\frac{1}{2} g_{\nu \mu} \sqrt{-g}. \quad (8)
\]

III. PHYSICAL APPLICATIONS

A. Lagrangian and Hamiltonian densities

In the following applications various relativistic field theories are considered where the underlying space-time is not restricted to the Minkowski geometry but takes general curvilinear space-times into account. In that case the invariance of the action integral requires that the Lagrangian is a scalar density rather than a density. This is accomplished by multiplying it with $\sqrt{-g}$.

Corollary 4 For a scalar density Lagrangian $\tilde{L}$, i.e. for a relative scalar of weight $w = 1$, the identity (6) writes for $(n - m)/2 \in \mathbb{Z}$:
\[
\begin{align*}
&= -\frac{\partial \tilde{L}}{\partial g^{\nu \beta}} g^{\mu \beta} - \frac{\partial \tilde{L}}{\partial g_{\beta \mu}} g^{\beta \nu} \\
&\quad - \frac{\partial \tilde{L}}{\partial T^{\nu} \xi_2 \ldots \xi_n} T^{\mu} \xi_2 \ldots \xi_n_{\eta_1 \ldots \eta_m} - \ldots - \frac{\partial \tilde{L}}{\partial T^{\xi_{n-1} \ldots \xi_1}} T^{\xi_{n-1} \ldots \xi_1}_{\eta_1 \ldots \eta_m} \\
&\quad + \frac{\partial \tilde{L}}{\partial T^{\xi_1 \ldots \xi_n}} T^{\xi_1 \ldots \xi_n}_{\mu \eta_2 \ldots \eta_m} + \ldots + \frac{\partial \tilde{L}}{\partial T^{\xi_{n-1} \ldots \xi_1}} T^{\xi_{n-1} \ldots \xi_1}_{\eta_1 \ldots \eta_m} \\
&\equiv \delta_{\nu}^\mu \tilde{L}. \quad (9)
\end{align*}
\]
Corollary 5 For a scalar density Hamiltonian $\tilde{H}$, the momentum fields $\tilde{p}$ representing tensor densities must be expressed as absolute tensors $p = \tilde{p}/\sqrt{-g}$ prior to setting up the identity according to Eq. (9). An example is worked out in III C.

The identity in particular provides the correlation of the metric and the canonical energy-momentum tensors of a given system. If the scalar $S$ is specifically a Lagrangian $\mathcal{L}$ of field theories, representing a function of some physical fields and the metric tensor $g_{\mu\nu}$, then the derivative of $\mathcal{L}$ with respect to the metric $g_{\mu\nu}$ can always be replaced by the derivatives with respect to the field functions of $\mathcal{L}$ that are made into a scalar by means of the metric.

B. Klein-Gordon Lagrangian and Hamiltonian

The Klein-Gordon Lagrangian density $\tilde{\mathcal{L}}_{\text{KG}} = \mathcal{L}_{\text{KG}}\sqrt{-g}$ for a massive complex scalar field $\phi(x)$ is given by:

$$\tilde{\mathcal{L}}_{\text{KG}}(\phi, \bar{\phi}, \partial_{\mu}\phi, \partial_{\nu}\bar{\phi}, g^{\mu\nu}) = \left( \frac{\partial \bar{\phi}}{\partial x^\alpha} \frac{\partial \phi}{\partial x^\beta} g_{\alpha\beta} - m^2 \bar{\phi}\phi \right) \sqrt{-g}$$

$$= \left[\frac{1}{2} \left( \frac{\partial \bar{\phi}}{\partial x^\alpha} \frac{\partial \phi}{\partial x^\beta} + \frac{\partial \bar{\phi}}{\partial x^\beta} \frac{\partial \phi}{\partial x^\alpha} \right) g_{\alpha\beta} - m^2 \bar{\phi}\phi \right] \sqrt{-g}. \tag{10}$$

In order to set up the pertaining identity (8), we set the required derivatives of $\tilde{\mathcal{L}}_{\text{KG}}$. This yields with the derivative of the determinant $g$ of the covariant metric $g_{\mu\nu}$ with respect to the contravariant metric from Eq. (8):

$$2 \frac{\partial \tilde{\mathcal{L}}_{\text{KG}}}{\partial g^{\nu\beta}} g_{\mu\beta} = \left( \frac{\partial \bar{\phi}}{\partial x^\nu} \frac{\partial \phi}{\partial x^\beta} + \frac{\partial \bar{\phi}}{\partial x^\beta} \frac{\partial \phi}{\partial x^\nu} \right) g^{\mu\beta} \sqrt{-g} - \delta^\mu_\nu \tilde{\mathcal{L}}_{\text{KG}}$$

$$\frac{\partial \bar{\phi}}{\partial x^\nu} \frac{\partial \tilde{\mathcal{L}}_{\text{KG}}}{\partial \left( \frac{\partial \phi}{\partial x^\nu} \right)} = \frac{1}{2} \frac{\partial \bar{\phi}}{\partial x^\nu} \left( \frac{\partial \phi}{\partial x^\alpha} g_{\alpha\beta} + \frac{\partial \phi}{\partial x^\beta} g^{\alpha\mu} \right) \sqrt{-g} = \frac{\partial \bar{\phi}}{\partial x^\nu} \frac{\partial \phi}{\partial x^\nu} \sqrt{-g} = \frac{\partial \bar{\phi}}{\partial x^\nu} \frac{\partial \phi}{\partial x^\nu} \sqrt{-g}.$$
The equivalent covariant Klein-Gordon Hamiltonian density \( \tilde{H}_{KG}(\phi, \bar{\phi}, \bar{\pi}^\alpha, \bar{\bar{\pi}}^\nu, g_{\mu\nu}) \) for a system of complex fields in a dynamic space-time is given by:

\[
\tilde{H}_{KG} = \tilde{\bar{\pi}}^\alpha \frac{\partial \phi}{\partial x^\alpha} + \frac{\partial \bar{\phi}}{\partial x^\alpha} \bar{\pi}^\alpha - \tilde{\bar{\bar{\pi}}}, \quad \bar{\pi}^\alpha = \frac{\partial \tilde{L}_{KG}}{\partial (\partial \bar{\phi}/\partial x^\alpha)}, \quad \bar{\bar{\pi}}^\nu = \frac{\partial \tilde{L}_{KG}}{\partial (\partial \phi/\partial x^\nu)}
\]

\[
= \frac{1}{2} \left( \bar{\pi}^\alpha \bar{\pi}^\beta + \bar{\bar{\pi}}^\alpha \bar{\bar{\pi}}^\beta \right) g_{\alpha\beta} \frac{1}{\sqrt{-g}} + m^2 \tilde{\phi} \tilde{\phi} \sqrt{-g}.
\] (13)

Here, the scalar density \( \tilde{H}_{KG} \) is defined as a function of the tensor densities \( \bar{\pi}^\alpha \) and \( \bar{\bar{\pi}}^\nu \) rather than of absolute tensors. To set up the pertaining identity, \( \tilde{H}_{KG} \) can be rewritten as:

\[
\tilde{H}_{KG}' = \left[ \frac{1}{2} \left( \bar{\pi}^\alpha \bar{\pi}^\beta + \bar{\bar{\pi}}^\alpha \bar{\bar{\pi}}^\beta \right) g_{\alpha\beta} + m^2 \tilde{\phi} \tilde{\phi} \right] \sqrt{-g}.
\] (14)

As can be directly verified, the identity now takes on the form:

\[
2 \frac{\partial \tilde{H}_{KG}'}{\partial g_{\mu\beta}} g_{\nu\beta} - \bar{\pi}^\mu \frac{\partial \tilde{H}_{KG}'}{\partial \bar{\pi}^\nu} - \frac{\partial \tilde{H}_{KG}'}{\partial \bar{\pi}^\nu} \bar{\pi}^\nu \equiv \delta^\mu_\nu \tilde{H}_{KG}'.
\] (15)

The correlation of the derivatives with respect to the metric of \( \tilde{H}_{KG}' \) and \( \tilde{H}_{KG} \) follows as:

\[
2 \frac{\partial \tilde{H}_{KG}}{\partial g_{\mu\beta}} g_{\nu\beta} = 2 \frac{\partial \tilde{H}_{KG}}{\partial g_{\beta\mu}} g_{\beta\nu} + \delta^\mu_\nu \left( \tilde{H}_{KG}' + \tilde{\bar{\bar{\pi}}} \right) = 2 \frac{\partial \tilde{L}_{KG}}{\partial g_{\beta\nu}} g_{\beta\mu} + \delta^\mu_\nu \left( \tilde{H}_{KG}' + \tilde{\bar{\bar{\pi}}} \right)
\]

hence

\[
\frac{\partial \tilde{H}_{KG}}{\partial g_{\mu\beta}} g_{\nu\beta} = \frac{\partial \tilde{L}_{KG}}{\partial g_{\beta\nu}} g_{\beta\mu}.
\]

In terms of the proper Hamiltonian (13), the identity writes:

\[
2 \frac{\partial \tilde{H}_{KG}}{\partial g_{\mu\beta}} g_{\nu\beta} - \bar{\pi}^\mu \frac{\partial \tilde{H}_{KG}}{\partial \bar{\pi}^\nu} - \frac{\partial \tilde{H}_{KG}}{\partial \bar{\pi}^\nu} \bar{\pi}^\nu \equiv -\delta^\mu_\nu \tilde{\bar{\bar{\pi}}} \tilde{L}_{KG},
\] (16)

or, as the Hamiltonian representations of the equivalence of metric and canonical energy-momentum tensor of the Klein-Gordon system:

\[
T_{\nu}^\mu = 2 \frac{\partial \tilde{H}_{KG}}{\partial g_{\mu\beta}} g_{\nu\beta} \equiv \bar{\pi}^\mu \frac{\partial \tilde{H}_{KG}}{\partial \bar{\pi}^\nu} + \frac{\partial \tilde{H}_{KG}}{\partial \bar{\pi}^\nu} \bar{\pi}^\nu - \delta^\mu_\nu \tilde{L}_{KG} = \theta_{\nu}^\mu,
\] (17)

C. Proca Lagrangian and Hamiltonian

In a dynamic space-time, the Proca Lagrangian is defined by:

\[
\tilde{L}_{P} = \left( -\frac{1}{4} f_{\alpha\beta} f_{\xi\eta} g^{\alpha\xi} g^{\beta\eta} + \frac{1}{2} m^2 a_\alpha a_\beta g^{\alpha\beta} \right) \sqrt{-g}, \quad f_{\alpha\beta} = \frac{\partial a_\beta}{\partial x^\alpha} - \frac{\partial a_\alpha}{\partial x^\beta}.
\]
The identity (9) for the scalar density $\mathcal{L}_P$ is then:

\[
-2 \frac{\partial \mathcal{L}_P}{\partial g^{\beta \nu}} \beta^\mu + \frac{\partial \mathcal{L}_P}{\partial f_{\mu \beta}} f_{\nu \beta} + \frac{\partial \mathcal{L}_P}{\partial f_{\beta \mu}} f_{\beta \nu} + \frac{\partial \mathcal{L}_P}{\partial a_\nu} a_\nu \equiv \delta^\mu_\nu \mathcal{L}_P. \tag{18}
\]

Rewriting the identity (18) as a correlation of metric and canonical energy-momentum tensors, $T_{\nu}^\mu$ and $\theta_{\nu}^\mu$, we observe that these tensors do not coincide for the Proca system:

\[
T_{\nu}^\mu = \frac{2}{\sqrt{-g}} \frac{\partial \mathcal{L}_P}{\partial g^{\beta \nu}} g^{\beta \mu} = \frac{\partial \mathcal{L}_P}{\partial f_{\beta \mu}} f_{\beta \nu} - \delta^\nu_\nu \mathcal{L}_P + \frac{\partial \mathcal{L}_P}{\partial f_{\mu \beta}} f_{\beta \nu} + \frac{\partial \mathcal{L}_P}{\partial a_\mu} a_\nu
\equiv \delta^\nu_\nu + \frac{\partial \mathcal{L}_P}{\partial f_{\mu \beta}} f_{\beta \nu} + \frac{\partial \mathcal{L}_P}{\partial a_\mu} a_\nu. \tag{19}
\]

The equivalent covariant Proca Hamiltonian density $\tilde{\mathcal{H}}_P \left( \tilde{p}^{\nu \mu}, a_\nu, g_{\mu \nu} \right)$ is obtained by a complete Legendre transformation as:

\[
\tilde{\mathcal{H}}_P = \tilde{p}^{\alpha \beta} \frac{\partial a_\alpha}{\partial \tilde{f}^{\alpha \beta}} - \tilde{\mathcal{L}}_P, \quad \tilde{p}^{\alpha \beta} = \frac{\partial \tilde{\mathcal{L}}_P}{\partial \tilde{f}^{\alpha \beta}} = f^{\alpha \beta} \sqrt{-g} = -\frac{1}{2} p^{\alpha \beta} \tilde{\xi}^\eta g_{\alpha \xi} g_{\beta \eta} \frac{1}{\sqrt{-g}} - \frac{1}{2} m^2 a_\alpha a_\xi g^{\alpha \xi} \sqrt{-g}. \tag{20}
\]

In order to set up the related identity, the Hamiltonian $\mathcal{H}_P$ must first be expressed as the equivalent function of absolute tensors:

\[
\mathcal{H}'_P = -\frac{1}{2} p^{\alpha \beta} \tilde{\xi}^\eta g_{\alpha \xi} g_{\beta \eta} \sqrt{-g} - \frac{1}{2} m^2 a_\alpha a_\xi g^{\alpha \xi} \sqrt{-g}. \tag{21}
\]

The identity (9) then follows as

\[
2 \frac{\partial \mathcal{H}'_P}{\partial g_{\mu \beta}} g_{\beta \nu} - \frac{\partial \mathcal{H}'_P}{\partial p^{\gamma \beta}} p^{\mu \beta} - \frac{\partial \mathcal{H}'_P}{\partial p^{\beta \nu}} p^{\beta \mu} + \frac{\partial \mathcal{H}'_P}{\partial a_\mu} a_\nu \equiv \delta^\mu_\nu \mathcal{H}'_P, \tag{22}
\]

which is again verified by direct calculation:

\[
-\frac{\partial \mathcal{H}'_P}{\partial p^{\beta \gamma}} p^{\beta \nu} = \frac{1}{2} p^{\beta \mu} \tilde{\xi}^\eta g_{\alpha \xi} g_{\beta \eta} \sqrt{-g} = \frac{1}{2} p^{\beta \mu} p_{\nu \beta} \sqrt{-g}
\]

\[
-\frac{\partial \mathcal{H}'_P}{\partial p^{\mu \nu}} p^{\rho \mu} = \frac{1}{2} p^{\rho \mu} \tilde{\xi}^\eta g_{\alpha \xi} g_{\rho \eta} \sqrt{-g} = \frac{1}{2} p^{\rho \mu} p_{\rho \nu} \sqrt{-g}
\]

\[
\frac{\partial \mathcal{H}'_P}{\partial a_\mu} a_\nu = -m^2 a_\alpha a_\xi g^{\alpha \xi} \sqrt{-g} = -m^2 a^\mu \ a_\nu \sqrt{-g}
\]

\[
2 \frac{\partial \mathcal{H}'_P}{\partial g_{\mu \beta}} g_{\beta \nu} = \left( \frac{1}{2} p^{\beta \lambda} \tilde{p}^{\mu \gamma} g_{\beta \nu} g_{\lambda \eta} - \frac{1}{2} m^2 a_\alpha a_\xi g^{\alpha \beta} g^{\xi \eta} \right) \sqrt{-g} + g^{\mu \beta} g_{\beta \nu} \mathcal{H}'_P
\]

\[
= -\frac{1}{2} p_{\beta \nu} p^{\beta \mu} \sqrt{-g} - \frac{1}{2} m^2 a_\nu a^\mu \sqrt{-g} + \delta^\mu_\nu \mathcal{H}'_P.
\]
Summing up, all terms on the right-hand side cancel—except $\delta^\mu_\nu \tilde{H}'_P$, which thus gives Eq. (22).

For the proper Hamiltonian \(\tilde{H}'_P\), we have
\[
\frac{\partial \tilde{H}'_P}{\partial p^\mu} p^\mu = -\frac{1}{2} p^\mu p^\nu \sqrt{-g} = -\frac{1}{2} \tilde{p}^\mu \tilde{p}_\nu \frac{1}{\sqrt{-g}} = \frac{\partial \tilde{H}'_P}{\partial \tilde{p}^\mu} \tilde{p}^\mu
\]
\[
\frac{\partial \tilde{H}'_P}{\partial a_\mu} a_\nu = -m^2 a_\nu a^\mu \sqrt{-g} = \frac{\partial \tilde{H}'_P}{\partial a_\mu} a_\nu.
\]

Yet the derivatives with respect to the metric of $\tilde{H}'_P$ and $\tilde{H}_P$ are different:
\[
2 \frac{\partial \tilde{H}'_P}{\partial g^\beta_\mu} \tilde{g}^\beta_\mu = 2 \frac{\partial \tilde{H}_P}{\partial g^\beta_\mu} \tilde{g}^\beta_\mu + \frac{\partial H'_P}{\partial g^\beta_\mu} \tilde{g}^\beta_\mu
\]
hence
\[
\frac{\partial \tilde{H}_P}{\partial g^\beta_\mu} \tilde{g}^\beta_\mu = \frac{\partial \tilde{L}_P}{\partial \tilde{g}^\beta_\mu} \tilde{g}^\beta_\mu.
\]

The identity (22) can now be expressed in terms of the proper Proca Hamiltonian $\tilde{H}_P$ as:
\[
2 \frac{\partial \tilde{H}'_P}{\partial g^\beta_\mu} \tilde{g}^\beta_\mu - 2 \frac{\partial \tilde{H}_P}{\partial g^\beta_\mu} \tilde{g}^\beta_\mu + \frac{\partial H'_P}{\partial g^\beta_\mu} \tilde{g}^\beta_\mu + \frac{\partial H'_P}{\partial a_\mu} a_\nu \equiv -\delta^\mu_\nu \tilde{L}_P.
\]

With the canonical energy-momentum tensor density $\tilde{\theta}^\mu_\nu = \theta^\mu_\nu \sqrt{-g}$ of the Proca system,
\[
\tilde{\theta}^\mu_\nu = f^\beta_\nu \frac{\partial \tilde{L}_P}{\partial f^\beta_\mu} - \delta^\mu_\nu \tilde{L}_P = \frac{\partial \tilde{H}_P}{\partial \tilde{p}^\beta} \tilde{p}^\beta_\mu - \delta^\mu_\nu \tilde{L}_P,
\]
this yields the correlation of metric and canonical energy-momentum tensors in the Hamiltonian representation for the Proca system:
\[
\tilde{\theta}^\mu_\nu = T^\mu_\nu - \frac{\partial \tilde{H}_P}{\partial \tilde{p}^\beta} \tilde{p}^\beta_\mu + \frac{\partial \tilde{H}_P}{\partial a_\mu} a_\nu.
\]

D. Dirac Lagrangian

1. Identity for the metric indices

The regularized Dirac Lagrangian $L_D(\psi, \partial \psi, \bar{\psi}, \partial \bar{\psi}, \gamma^\mu)$, constructed upon the Dirac equation writes
\[
L_D = \frac{i}{2} \left( \bar{\psi} \gamma^\alpha \partial x^\alpha - \frac{\partial \bar{\psi}}{\partial x^\alpha} \gamma^\alpha \psi \right) - m \bar{\psi} \psi + \frac{i}{3M} \partial \bar{\psi} \partial x^\alpha \sigma^{\alpha\beta} \partial \psi \partial x^\beta. \tag{23}
\]
wherein the (1, 1)-spinor-(2, 0)-tensor field $\sigma^{\alpha\beta}$ is defined as the commutator of the matrix product $\gamma^\alpha\gamma^\nu$:

$$\sigma^{\alpha\nu} = \frac{i}{2} (\gamma^\alpha\gamma^\nu - \gamma^\nu\gamma^\alpha) \quad \Leftrightarrow \quad \sigma^a_{\alpha\nu} = \frac{i}{2} (\gamma^a_{\alpha\nu} \gamma^b_{\beta\gamma} - \gamma^a_{\nu\beta} \gamma^b_{\alpha\gamma}).$$

With an explicit notation of the spinor indices as lower case Latin letters, the Dirac Lagrangian takes on the form:

$$L_D = \frac{i}{2} \left( \bar{\psi}_a \gamma^\alpha c \frac{\partial \psi_c}{\partial x^\alpha} - \frac{\partial \bar{\psi}_a}{\partial x^\alpha} \gamma^\alpha c \psi^c \right) - m \bar{\psi}_a \psi^a + \frac{i}{3M} \frac{\partial \bar{\psi}_a}{\partial x^\alpha} \sigma^a_{\alpha\beta} \frac{\partial \psi^c}{\partial x^\beta}. \quad (25)$$

With the spinor indices fully contracted, the identity (21) with respect to the metric indices for the scalar quantity $L_D$ is then given by:

$$\frac{\partial L_D}{\partial (\frac{\partial \psi^c}{\partial x^\nu})} \frac{\partial \psi^c}{\partial x^\nu} + \frac{\partial \bar{\psi}_a}{\partial x^\nu} \frac{\partial L_D}{\partial \left( \frac{\partial \psi^c}{\partial x^\nu} \right)} - \frac{\partial L_D}{\partial \gamma^\alpha c} \gamma^\alpha c \equiv 0. \quad (26)$$

Equation (26) is verified by direct calculation:

$$\frac{\partial \bar{\psi}_a}{\partial x^\nu} \frac{\partial L_D}{\partial (\frac{\partial \psi^c}{\partial x^\nu})} = \frac{i}{2} \bar{\psi}_a \gamma^a c \mu \frac{\partial \psi^c}{\partial x^\nu} + \frac{i}{3M} \frac{\partial \bar{\psi}_a}{\partial x^\nu} \sigma^a c \alpha \mu \frac{\partial \psi^c}{\partial x^\nu}$$

$$\frac{\partial \gamma^\alpha c}{\partial x^\nu} \frac{\partial L_D}{\partial \gamma^\alpha c} = -\frac{i}{2} \bar{\psi}_a \gamma^a c \mu \psi^c + \frac{i}{3M} \frac{\partial \bar{\psi}_a}{\partial x^\nu} \sigma^a c \mu \frac{\partial \psi^c}{\partial x^\nu}$$

$$\frac{\partial \gamma^\alpha c}{\partial \gamma^\alpha c} \frac{\partial L_D}{\partial \gamma^\alpha c} = \frac{i}{3M} \left( \frac{\partial \bar{\psi}_a}{\partial x^\nu} \sigma^a c \mu \frac{\partial \psi^c}{\partial x^\nu} + \frac{\partial \psi^c}{\partial x^\nu} \sigma^a c \mu \frac{\partial \psi^c}{\partial x^\nu} \right),$$

which obviously sums up to zero. The identity (22) for the scalar density $\bar{L}_D$ is then

$$\frac{\partial \bar{L}_D}{\partial (\frac{\partial \psi^c}{\partial x^\nu})} \frac{\partial \psi^c}{\partial x^\nu} + \frac{\partial \bar{\psi}_a}{\partial x^\nu} \frac{\partial \bar{L}_D}{\partial \left( \frac{\partial \psi^c}{\partial x^\nu} \right)} - \frac{\partial \bar{L}_D}{\partial \gamma^\alpha c} \gamma^\alpha c \equiv \delta^\alpha c \bar{L}_D,$$

hence, rearranging the terms and skipping the spinor indices:

$$\bar{\theta}_\nu^\mu \equiv \frac{\partial \bar{L}_D}{\partial (\frac{\partial \psi^c}{\partial x^\nu})} \frac{\partial \psi^c}{\partial x^\nu} + \frac{\partial \bar{\psi}_a}{\partial x^\nu} \frac{\partial \bar{L}_D}{\partial \left( \frac{\partial \psi^c}{\partial x^\nu} \right)} - \delta^\alpha c \bar{L}_D \equiv \operatorname{Tr} \left\{ \frac{\partial \bar{L}_D}{\partial \gamma^\alpha c} \gamma^\alpha c \right\} \equiv \bar{T}_\nu^\mu. \quad (27)$$

Equation (27) states that the canonical energy-momentum tensor density $\bar{\theta}_\nu^\mu$ coincides for the Dirac Lagrangian with the metric energy-momentum tensor $\bar{T}_\nu^\mu$. The explicit covariant representation of these tensors is not symmetric and thus also provides a source for torsion of space-time in a generalized Einstein-type equation:

$$T_{\nu\mu} = \theta_{\nu\mu} = \frac{i}{2} \left( \bar{\psi}_a \gamma_\mu \frac{\partial \psi^c}{\partial x^\nu} - \frac{\partial \bar{\psi}_a}{\partial x^\nu} \gamma_\mu \psi^c \right) + \frac{i}{3M} g_{\mu\alpha} \left( \frac{\partial \bar{\psi}_a}{\partial x^\nu} \sigma^a b \frac{\partial \psi^c}{\partial x^\beta} + \frac{\partial \bar{\psi}_a}{\partial x^\nu} \sigma^b a \frac{\partial \psi^c}{\partial x^\beta} \right) - g_{\mu\nu} L_D. \quad (28)$$
2. Identity for the spinor indices

The corresponding identity (1) for the scalar \( L_D \) is obtained if we contract the space-time indices and leave open the spinor indices:

\[
\frac{\partial L_D}{\partial \psi^a} \frac{\partial \psi}{\partial x^\alpha} - \frac{\partial \bar{\psi}_b}{\partial x^\alpha} \frac{\partial L_D}{\partial \bar{\psi}^b} - \bar{\psi}_b \frac{\partial L_D}{\partial \psi^a} + \frac{\partial L_D}{\partial \gamma^a_{\alpha \beta}} \gamma^a_{\beta} - \gamma^a_{b \alpha} \frac{\partial L_D}{\partial \gamma^a_{\alpha \beta}} = 0. \tag{29}
\]

The identity (29) is also verified by direct calculation:

\[
\frac{\partial L_D}{\partial \psi^a} \frac{\partial \psi}{\partial x^\alpha}, \quad \frac{\partial \bar{\psi}_b}{\partial x^\alpha} \frac{\partial L_D}{\partial \bar{\psi}^b} = \frac{i}{2} \psi_b \gamma^a_{\beta} \frac{\partial \psi^a}{\partial x^\alpha} + \frac{i}{3M} \sigma^a \frac{\partial \psi^a}{\partial x^\alpha},
\]

\[
-\frac{\partial \bar{\psi}_b}{\partial x^\alpha} \frac{\partial L_D}{\partial \psi^a} = -\frac{i}{2} \bar{\psi}_b \gamma^a_{\beta} \frac{\partial \psi^a}{\partial x^\alpha} + m \bar{\psi}_b \psi^a,
\]

\[
\frac{\partial L_D}{\partial \gamma^a_{\alpha \beta}} \gamma^a_{\beta} = \frac{i}{2} \left( \bar{\psi}_b \gamma^a_{\beta} \frac{\partial \psi^a}{\partial x^\alpha} - \frac{\partial \bar{\psi}_b}{\partial x^\alpha} \gamma^a_{\beta} \psi^a \right) + \frac{i}{3M} \sigma^a \frac{\partial \psi^a}{\partial x^\alpha} - \frac{1}{6M} \bar{\psi}_b \left( \gamma^a_{\beta} \gamma^a_{\beta} - \gamma^a_{\beta} \gamma^a_{\beta} \right) \frac{\partial \psi^d}{\partial x^\beta},
\]

Again, all terms on the right-hand side sum up to zero.

E. Dirac Hamiltonian

The Dirac momentum density fields \( \tilde{\pi}^\mu \) and \( \tilde{\pi}^\mu \) represent the conjugates of the spinor fields \( \psi \) and \( \bar{\psi} \), respectively, and hence the duals of their partial derivatives, \( \partial \psi / \partial x^\mu \) and \( \partial \bar{\psi} / \partial x^\mu \). They are derived from the Lagrangian density \( \tilde{L}_D = L_D \sqrt{-g} \) via

\[
\tilde{\pi}^\mu = \frac{\partial \tilde{L}_D}{\partial \left( \frac{\partial \psi}{\partial x^\mu} \right)}, \quad \tilde{\pi}^\mu = \frac{\partial \tilde{L}_D}{\partial \left( \frac{\partial \bar{\psi}}{\partial x^\mu} \right)}. \tag{30}
\]

Due to the quadratic “velocity” dependence of \( L_D \), the corresponding covariant Hamiltonian \( \tilde{\mathcal{H}}_D \) is obtained via the Legendre transformation

\[
\tilde{\mathcal{H}}_D \left( \psi, \tilde{\pi}^\alpha, \bar{\psi}, \bar{\pi}^\alpha, \gamma^a \right) = \tilde{\pi}^\alpha \frac{\partial \psi}{\partial x^\alpha} + \frac{\partial \bar{\psi}}{\partial x^\alpha} \tilde{\pi}^\alpha - \tilde{L}_D \left( \psi, \partial_\alpha \psi, \bar{\psi}, \partial_\alpha \bar{\psi}, \gamma^a \right)
\]
as:
\[
\mathcal{H}_D = \frac{iM}{2} \left( \bar{\psi} \gamma_\alpha \pi^\alpha - \bar{\pi}^\alpha \frac{6 \tau_{\alpha\beta}}{\sqrt{-g}} \pi^\beta - \bar{\pi}^\alpha \gamma_\alpha \psi \right) + (m - M) \bar{\psi} \psi \sqrt{-g},
\]
with \( \tau_{\alpha\beta} \) the inverse of the matrix \( \sigma^{\beta\alpha} \), the latter defined in Eq. (24),
\[
\tau_{\alpha\beta} = \frac{i}{6} \left( \gamma_\alpha \gamma_\beta + 3 \gamma_\beta \gamma_\alpha \right), \quad \tau_{\nu\alpha} \sigma^{\alpha\mu} = \delta_{\nu}^{\mu} \mathbf{I}.
\]

The Hamiltonian representation of the identity (27) is then:
\[
\text{Tr} \left\{ \partial \mathcal{H}_D / \partial \gamma_\mu \right\} \equiv \partial \mathcal{H}_D / \partial \bar{\pi}^\mu + \bar{\pi}^\mu \partial \mathcal{H}_D / \partial \pi^\nu - \delta^\mu_\nu \tilde{\mathcal{L}}_D,
\]

which display the identity of metric and canonical energy-momentum tensor densities in the Hamiltonian representation. Note that these tensors are not symmetric in their covariant or contravariant representations.

## IV. THEORIES OF GRAVITY

### A. Scalars depending on the Riemann-Cartan tensor and the metric

#### 1. General gravity Lagrangian for metric compatibility

Any relative scalar Lagrangian \( \tilde{\mathcal{L}}_R(R, g) \) of weight \( w = 1 \) built from the Riemann-Cartan curvature tensor
\[
R^{\eta}_{\xi\beta\lambda} = \frac{\partial \gamma^{\eta}_{\xi\lambda}}{\partial x^{\beta}} - \frac{\partial \gamma^{\eta}_{\xi\beta}}{\partial x^{\lambda}} + \gamma^{\eta}_{\tau\beta} \gamma^{\tau}_{\xi\lambda} - \gamma^{\eta}_{\tau\lambda} \gamma^{\tau}_{\xi\beta}
\]
and the metric satisfies the identity (9), whose particular form for \( \tilde{\mathcal{L}}_R \) is given by:
\[
\frac{\partial \tilde{\mathcal{L}}_R}{\partial g^{\nu\beta}} g^{\mu\beta} + \frac{\partial \tilde{\mathcal{L}}_R}{\partial g^{\beta\nu}} g^{\beta\mu} \equiv - \frac{\partial \tilde{\mathcal{L}}_R}{\partial R^{\mu}_{\alpha\beta\lambda}} R^{\mu}_{\alpha\beta\lambda} - \frac{\partial \tilde{\mathcal{L}}_R}{\partial R^{\nu}_{\alpha\beta\lambda}} R^{\nu}_{\alpha\beta\lambda} - \delta^{\mu}_{\nu} \tilde{\mathcal{L}}_R.
\]

The left-hand side of the identity (33) can again be interpreted as the metric energy-momentum tensor \( \hat{T}^{\nu}_{\mu} \) of the Lagrangian system \( \tilde{\mathcal{L}}_R(R, g) \), hence
\[
T^{\nu}_{\mu} = \frac{1}{\sqrt{-g}} \left( \frac{\partial \tilde{\mathcal{L}}_R}{\partial g^{\nu\beta}} g^{\beta\mu} + \frac{\partial \tilde{\mathcal{L}}_R}{\partial g^{\nu\beta}} g^{\beta\mu} \right),
\]

whereas the corresponding canonical energy-momentum tensor \( \theta^{\nu}_{\mu} \) is derived for the corresponding absolute scalar \( \mathcal{L}_R = \tilde{\mathcal{L}}_R / \sqrt{-g} \) by means of Noether’s theorem (4) as:
\[
\theta^{\nu}_{\mu} = \frac{\partial \mathcal{L}_R}{\partial R^{\eta}_{\alpha\mu\lambda}} R^{\eta}_{\alpha\nu\lambda} + \frac{\partial \mathcal{L}_R}{\partial R^{\eta}_{\alpha\beta\mu}} R^{\eta}_{\alpha\beta\nu} - \delta^{\mu}_{\nu} \mathcal{L}_R.
\]
The correlation of both tensors is given by:

\[ T_{\nu}^{\mu} = \theta_{\nu}^{\mu} - \frac{\partial \mathcal{L}_R}{\partial R^\nu_{\alpha\beta\lambda}} R^\mu_{\alpha\beta\lambda} + \frac{\partial \mathcal{L}_R}{\partial R^\eta_{\mu\beta\lambda}} R^\eta_{\nu\beta\lambda}. \]

2. General gravity Lagrangian

For the case of a non-vanishing covariant derivative of the metric, hence for \( g^{\alpha\beta;\mu} \neq 0 \), the gravity Lagrangian also depends on the covariant derivative of the metric \( \tilde{\mathcal{L}}_R = \tilde{\mathcal{L}}_R(R, g, \nabla g) \).

The metric energy-momentum tensor is then generalized to:

\[ T_{\nu}^{\mu} = \frac{1}{\sqrt{-g}} \left( \frac{\partial \tilde{\mathcal{L}}_R}{\partial g^{\nu\beta}} g^{\mu\beta} + \frac{\partial \tilde{\mathcal{L}}_R}{\partial g^{\nu\beta;\alpha}} g^{\mu\beta;\alpha} + \frac{\partial \tilde{\mathcal{L}}_R}{\partial g^{\beta\nu;\alpha}} g^{\mu\beta;\alpha} \right), \]

whereas the canonical energy-momentum tensor takes on the generalized form (see Eq. (48) of Ref. [4]):

\[ \theta_{\nu}^{\mu} = \frac{\partial \mathcal{L}_R}{\partial g^{\alpha\beta;\mu}} g^{\alpha\beta;\mu} + \frac{\partial \tilde{\mathcal{L}}_R}{\partial g^{\beta\nu;\alpha}} g^{\mu\beta;\alpha} + \frac{\partial \tilde{\mathcal{L}}_R}{\partial g^{\beta\nu;\alpha}} g^{\mu\beta;\alpha} - \delta^{\mu}_{\nu} \mathcal{L}_R. \]

Due to the identity (9), the so-defined energy-momentum tensors are correlated by:

\[ T_{\nu}^{\mu} \equiv \theta_{\nu}^{\mu} - \frac{\partial \mathcal{L}_R}{\partial R^\nu_{\alpha\beta\lambda}} R^\mu_{\alpha\beta\lambda} + \frac{\partial \tilde{\mathcal{L}}_R}{\partial R^\eta_{\mu\beta\lambda}} R^\eta_{\nu\beta\lambda} - \delta^{\mu}_{\nu} \mathcal{L}_R. \]

3. Einstein-Cartan Lagrangian \( \tilde{\mathcal{L}}_E \)

The Einstein-Cartan Lagrangian \( \tilde{\mathcal{L}}_E \) is defined by the Ricci scalar density \( \tilde{R} = R \sqrt{-g} \).

The latter emerges from the definition of the Riemann-Cartan curvature tensor from Eq. (33) via its non-trivial contraction \( R^{\xi\lambda} = R^{\eta}_{\xi\eta\lambda} \), followed by a contraction with the metric according to:

\[ 16\pi G \tilde{\mathcal{L}}_E = R^{\eta}_{\xi\eta\lambda} g^{\xi\lambda} \sqrt{-g} = R_{\xi\lambda} g^{\xi\lambda} \sqrt{-g} = \tilde{R}. \]  

Note that the Ricci tensor \( R_{\xi\lambda} \) is not symmetric for non-symmetric connection coefficients \( \gamma^{\eta}_{\xi\lambda} \neq \gamma^{\eta}_{\lambda\xi} \). For the scalar density \( \tilde{\mathcal{L}}_E \), the left-hand side of the general equation (34), hence the derivatives of \( \tilde{R} \) with respect to the metric are:

\[ \frac{\partial \tilde{R}}{\partial g^{\nu\beta}} g^{\mu\beta} + \frac{\partial \tilde{R}}{\partial g^{\beta\nu}} g^{\mu\beta} = \tilde{R}^{\mu}_{\nu} + \tilde{R}^{\mu}_{\nu} - \delta^{\mu}_{\nu} \tilde{R}. \]

(37a)
The derivatives of \( \tilde{R} \) with respect to the Riemann tensor follow as:

\[
\frac{\partial \tilde{R}}{\partial R_{\xi \beta \lambda}} R^\mu_{\xi \beta \lambda} = \delta^\mu_\nu \delta^\lambda_\eta g^{\xi \lambda} \tilde{R}^\eta_{\nu \beta \lambda} = \tilde{R}^\mu_{\nu \beta \lambda} = \tilde{R}^\mu_{\nu}
\]  

(37b)

\[
\frac{\partial \tilde{R}}{\partial R^\eta_{\mu \beta \lambda}} R^\nu_{\eta \beta \lambda} = \delta^\mu_\xi \delta^\beta_\eta g^{\xi \lambda} \tilde{R}^\eta_{\nu \lambda} = \tilde{R}^\mu_{\nu \lambda} = \tilde{R}^\mu_{\nu}
\]  

(37c)

\[
\frac{\partial \tilde{R}}{\partial R^\eta_{\xi \mu \lambda}} R^\nu_{\xi \nu \lambda} = \delta^\mu_\eta \delta^\lambda_\nu g^{\xi \lambda} \tilde{R}^\eta_{\xi \nu \lambda} = \tilde{R}^\mu_{\nu \lambda} = \tilde{R}^\mu_{\nu}
\]  

(37d)

\[
\frac{\partial \tilde{R}}{\partial R^\eta_{\xi \beta \mu}} R^\nu_{\xi \beta \nu} = \delta^\mu_\xi \delta^\beta_\lambda g^{\xi \lambda} \tilde{R}^\eta_{\xi \beta \nu} = \tilde{R}^\mu_{\nu \nu} = \tilde{R}^\mu_{\nu}
\]  

(37e)

The identity (34) is obviously satisfied by Eqs. (37). The derivatives of the \( \tilde{L}_E \) with respect to the metric define the metric energy-momentum tensor,

\[
T^\mu_\nu = \frac{1}{\sqrt{-g}} \left( \frac{\partial \tilde{L}_E}{\partial g^{\nu \beta}} g^{\mu \beta} + \frac{\partial \tilde{L}_E}{\partial g^{\beta \nu}} g^{\beta \mu} \right) = \frac{1}{16\pi G} (R^\mu_\nu + R^\mu_\nu - \delta^\mu_\nu R).
\]  

(38)

By virtue of the identity (34), this tensor can be identically replaced by its derivatives with respect to the Riemann tensor. The corresponding canonical energy-momentum tensor \( \theta^\mu_\nu \) is defined by:

\[
\theta^\mu_\nu = \frac{\partial \tilde{L}_E}{\partial R^\eta_{\xi \lambda}} R^\nu_{\xi \nu \lambda} + \frac{\partial \tilde{L}_E}{\partial R^\eta_{\xi \beta \mu}} R^\nu_{\xi \beta \nu} - \delta^\mu_\nu \tilde{L}_E = \frac{1}{16\pi G} (2R^\mu_\nu - \delta^\mu_\nu R).
\]  

(39)

Both tensors are thus related as:

\[
T^\mu_\nu = \theta^\mu_\nu - \frac{\partial \tilde{L}_E}{\partial R^\nu_{\xi \lambda}} R^\mu_{\xi \lambda} + \frac{\partial \tilde{L}_E}{\partial R^\nu_{\xi \beta \lambda}} R^\mu_{\xi \beta \lambda} = \theta^\mu_\nu + \frac{1}{16\pi G} (R^\mu_\nu - R^\mu_\nu)
\]

and thus agree for a symmetric Ricci tensor \( R_{\mu \nu} \equiv R_{\nu \mu} \), which is induced by symmetric connections \( \gamma^\eta_{\xi \lambda} \equiv \gamma^\eta_{\lambda \xi} \) and hence a torsion-free space-time. With Eqs. (38) and (39), the covariant representations of the energy-momentum tensors are:

\[
T_{\nu \mu} = \frac{1}{8\pi G} \left( R_{\nu \mu} - \frac{1}{2} g_{\nu \mu} R \right) = \theta_{\nu \mu} \quad \text{(40)}
\]

\[
\theta_{\nu \mu} = - \frac{1}{8\pi G} \left( R_{\nu \mu} - \frac{1}{2} g_{\nu \mu} R \right), \quad \theta_{[\nu \mu]} = \frac{1}{8\pi G} R_{[\nu \mu]}.
\]

(41)

In the case of a non-vanishing torsion of space-time, the (non-symmetric) canonical energy-momentum tensor (41) is then the correct constituent of the Einstein-type equation and thus compatible with a non-symmetric energy-momentum tensor of the source system. In the case of a symmetric energy-momentum tensor of the source system the (symmetric) tensor (40) is the appropriate one. Note further that no assumption of any special formulation was made. Hence these derivations hold for both, metric and Palatini formalism.
4. Vierbein formulation of the Einstein-Cartan Lagrangian

The Lagrangian (36) may be expressed equivalently in terms of tetrads $e^k_\lambda$ as:

$$16\pi G \tilde{\mathcal{L}}_E = R^k_{i\xi}\epsilon^e_k e^\lambda_j \eta^{ij} \varepsilon = R \varepsilon = \tilde{R},$$

with $\eta^{ij}$ the Minkowski metric and $\varepsilon$ the determinant of the tetrad $e^i_\lambda$. The identity (34) then separates into the two index classes, namely the metric index class (holonomic indices)

$$- \frac{\partial \tilde{\mathcal{L}}_E}{\partial e^\nu_m} e^\mu_m + \frac{\partial \tilde{\mathcal{L}}_E}{\partial R^n_{m\mu\lambda}} R^n_{m\nu\lambda} + \frac{\partial \tilde{\mathcal{L}}_E}{\partial R^n_{m\beta\mu}} R^n_{m\beta\nu} \equiv \delta^\mu_\nu \tilde{\mathcal{L}}_E,$$

and the tetrad index class (nonholonomic indices):

$$- \frac{\partial \tilde{\mathcal{L}}_E}{\partial e^\beta_n} e^\mu_m + \frac{\partial \tilde{\mathcal{L}}_E}{\partial \eta^{mk}} \eta^{kn} + \frac{\partial \tilde{\mathcal{L}}_E}{\partial R^k_{n\beta\lambda}} R^k_{n\mu\lambda} - \frac{\partial \tilde{\mathcal{L}}_E}{\partial R^k_{n\mu\lambda}} R^k_{n\beta\lambda} \equiv \delta^m_n \tilde{\mathcal{L}}_E.$$  (44)

To confirm Eqs. (43) and (44), we use

$$\frac{\partial \varepsilon}{\partial e^\nu_i} = -e^i_\nu \varepsilon,$$

to find for the terms with open metric indices and contracted tetrad indices:

$$- \frac{\partial \tilde{R}}{\partial e^\nu_m} e^\mu_m = -R^k_{i\xi}\lambda (\delta^\nu_\xi \delta^m_k e^\lambda_j + e^\xi_k e^\lambda_j \delta^m_j - \delta^\xi_k e^\lambda_j e^m_j) e^\mu_m \eta^{ij} \varepsilon
= - (R^m_{i\mu\lambda} e^\lambda_j e^\mu_m + R^k_{i\xi\lambda} e^\xi_k e^\lambda_j - \delta^\mu_\nu R^k_{i\xi\lambda} e^\xi_k e^\lambda_j) \eta^{ij} \varepsilon
= (\delta^\mu_\nu R - 2R^\mu_\nu) \varepsilon
$$

$$\frac{\partial \tilde{R}}{\partial R^n_{m\mu\lambda}} R^n_{m\nu\lambda} = \delta^k_n \delta^m_k \delta^\mu_\xi \delta^\lambda_\xi e^\lambda_j R^n_{m\mu\lambda} \eta^{ij} \varepsilon = R^k_{j\mu\lambda} e^\lambda_j \delta^\mu_\nu = R^\mu_\nu \varepsilon
$$

$$\frac{\partial \tilde{R}}{\partial R^n_{m\beta\mu}} R^n_{m\beta\nu} = \delta^k_n \delta^m_k \delta^\beta_\xi \delta^\mu_\xi e^\lambda_j R^n_{m\beta\nu} \eta^{ij} \varepsilon = R^k_{j\beta\mu} e^\lambda_j \delta^\mu_\nu = R^\mu_\nu \varepsilon,$$

describing the sum up to yield the identity (43). With the canonical energy-momentum tensor corresponding to Eq. (35), which is obtained here from Eq. (43) as

$$\theta^\mu_\nu = \frac{\partial \tilde{\mathcal{L}}_E}{\partial R^n_{m\mu\lambda}} R^n_{m\nu\lambda} + \frac{\partial \tilde{\mathcal{L}}_E}{\partial R^n_{m\beta\mu}} R^n_{m\beta\nu} - \delta^\nu_\nu \tilde{\mathcal{L}}_E,$$

the “tetrad” energy-energy-momentum tensor $\tilde{T}^\mu_\nu$ is not symmetric and coincides with the canonical one:

$$\tilde{T}^\mu_\nu = \frac{1}{\varepsilon} \frac{\partial \tilde{\mathcal{L}}_E}{\partial e^\nu_m} e^\mu_m = \theta^\mu_\nu = \delta^\mu_\nu R - 2R^\mu_\nu.$$
In the same way, we set up the terms with contracted metric indices while leaving the tetrad indices open:

\[ -\frac{\partial R}{\partial \epsilon^\tau_n} \epsilon^\tau_m = -R^k_{i\xi\lambda} \left( \delta^\xi_{\tau} \delta^n_k \epsilon^\lambda_j + \epsilon^\xi_k \delta^\lambda_j \delta^n_{\tau} - \epsilon^\xi_k \epsilon^\lambda_j \delta^n_{\tau} \right) \epsilon^\tau_m \eta^{ij} \varepsilon \]

\[ = (\delta^m_n R - 2R^n_m) \varepsilon \]

\[ \frac{\partial \tilde{R}}{\partial \eta^{nk}} \eta^{mk} + \frac{\partial \tilde{R}}{\partial \eta^{kn}} \eta^{km} = (R^n_m + R^m_n) \varepsilon \]

\[ = (R^k_{i\xi\lambda} \delta_m^i \delta^n_{k} \epsilon^\xi_k \epsilon^\lambda_j R^n_{k\beta\lambda} \eta^{ij} \varepsilon) = R^n_m \varepsilon \]

\[ -\frac{\partial \tilde{R}}{\partial R^n_{m\beta\lambda}} R^k_{m\beta\lambda} = -\delta^n_k \delta_m^i \delta^n_{\beta} \epsilon^\xi_k \epsilon^\lambda_j R^n_{k\beta\lambda} \eta^{ij} \varepsilon = -R^n_m \varepsilon, \]

which sums up to \( \delta^n_m \tilde{R} \) and thus verifies the identity (44).

5. Ricci tensor squared

The scalar density made of the square of the (not necessarily symmetric) Ricci tensor \( R_{\eta\alpha} = R^\rho_{\eta\rho\alpha} \) is defined by the following contraction with the metric

\[ \tilde{L}_{\text{Ric}}^2 = \frac{1}{2} R^\rho_{\eta\rho\alpha} R^\sigma_{\xi\sigma\lambda} g^{\eta\xi} g^{\rho\alpha\lambda} \sqrt{-g}. \]  

With Eq. (45), the general Eq. (34) consists of the derivative terms with respect to the metric

\[ \frac{\partial \tilde{L}_{\text{Ric}}^2}{\partial g^{\mu\beta}} g^{\mu\beta} + \frac{\partial \tilde{L}_{\text{Ric}}^2}{\partial g^{\rho\sigma}} g^{\rho\sigma} = R^\rho_{\eta\rho\alpha} R^\sigma_{\xi\sigma\lambda} \left( \delta^\mu_{\nu} \delta^\xi_{\beta} g^{\alpha\lambda} + g^{\eta\xi} \delta^\alpha_{\mu} \delta^\lambda_{\beta} \right) g^{\beta\mu} \sqrt{-g} - \delta^\mu_{\nu} \tilde{L}_R \]

\[ = (R_{\nu\alpha} R^\lambda_{\beta\lambda} g^{\alpha\lambda} + g^{\eta\xi} R^\eta_{\eta\nu\alpha} R^\xi_{\beta\lambda}) g^{\beta\mu} \sqrt{-g} - \delta^\mu_{\nu} \tilde{L}_R \]

\[ = (R_{\nu\beta} R^{\mu\beta} + R^{\mu\beta} R_{\nu\beta}) \sqrt{-g} - \delta^\mu_{\nu} \tilde{L}_R, \]

and the derivative terms with respect to the Riemann tensor:

\[ -\frac{\partial \tilde{L}_{\text{Ric}}^2}{\partial R^\mu_{\alpha\beta\lambda}} R^\rho_{\alpha\beta\lambda} = -R^\beta_{\lambda\nu} R^\mu_{\beta\lambda\nu} \sqrt{-g} \]  

\[ \frac{\partial \tilde{L}_{\text{Ric}}^2}{\partial R^\eta_{\mu\beta\lambda}} R^\eta_{\nu\beta\lambda} = R_{\nu\beta} R^{\mu\beta} \sqrt{-g} \]  

\[ \frac{\partial \tilde{L}_{\text{Ric}}^2}{\partial R^\eta_{\alpha\mu\lambda}} R^\eta_{\alpha\nu\lambda} = R^\beta_{\lambda\nu} R^\mu_{\beta\lambda\nu} \sqrt{-g} \]  

\[ \frac{\partial \tilde{L}_{\text{Ric}}^2}{\partial R^\eta_{\alpha\beta\mu}} R^\eta_{\alpha\beta\nu} = R_{\beta\nu} R^{\beta\mu} \sqrt{-g}. \]
In the present case, Eqs. (46a) and (46c) cancel.

The metric energy-momentum tensor is thus:

\[ T_{\mu \nu} = \frac{2}{\sqrt{-g}} \frac{\partial \tilde{L}_{\text{Ric}^2}}{\partial g^{\nu\beta}} g^{\mu\beta} = R^{\mu\beta} R_{\nu\beta} + R^{\beta\mu} R_{\beta\nu} - \delta^{\mu}_{\nu} R_{\beta\alpha} R^{\beta\alpha}, \]

whereas the canonical energy-momentum tensor (35) here emerges as:

\[ \theta_{\mu \nu} = \frac{\partial \tilde{L}_{\text{Ric}^2}}{\partial R^{\eta}_{\alpha\mu\lambda}} R^{\eta}_{\alpha\beta\nu} - \delta^\eta_{\nu} L_{\text{Ric}^2} = R^{\beta\lambda} R_{\mu\beta\lambda\nu} + R_{\beta\nu} R^{\beta\nu} - \delta^\mu_{\nu} L_{\text{Ric}^2}. \]

Their correlation thus follows as:

\[ \theta_{\nu \mu} = T_{\nu \mu} + R^{\beta\lambda} R_{\mu\beta\lambda\nu} - R_{\nu\beta} R_{\mu \beta}, \]

which shows that the canonical energy-momentum tensor is not symmetric in the case and hence complements a non-symmetric energy-momentum tensor of a source field in an Einstein-type equation.

6. Riemann tensor squared

The gravity Lagrangian \( \mathcal{L}_{\text{Ric}^2} \) constructed form the complete contraction of two Riemann-Cartan tensors, also referred to as the Kretschmann scalar, was already proposed by Einstein in a private letter to H. Weyl [5]. It is defined by:

\[ \tilde{\mathcal{L}}_{\text{Ric}^2} = -\frac{1}{4} R^\xi_{\eta\rho\sigma} R^\eta_{\xi\sigma\lambda} g^{\rho\sigma} g^{\alpha\lambda} \sqrt{-g}. \]

It is again directly verified that the left-hand side of the identity (34) amounts to

\[ \frac{\partial \tilde{\mathcal{L}}_{\text{Ric}^2}}{\partial g^{\nu\beta}} g^{\mu\beta} + \frac{\partial \tilde{\mathcal{L}}_{\text{Ric}^2}}{\partial g^{\beta\nu}} g^{\beta\mu} = R^\mu_{\eta\rho\tau} R^{\eta\rho\tau\nu} \sqrt{-g} \]

and agrees with the sum of the right-hand side:

\[ -\frac{\partial \tilde{\mathcal{L}}_{\text{Ric}^2}}{\partial R^{\mu}_{\alpha\beta\lambda}} R^{\mu}_{\alpha\beta\lambda} = -\frac{1}{2} R^\mu_{\alpha\beta\lambda} R^{\alpha\beta\lambda} \sqrt{-g} \]

(47a)

\[ \frac{\partial \tilde{\mathcal{L}}_{\text{Ric}^2}}{\partial R^{\eta}_{\mu\beta\lambda}} R^{\eta}_{\nu\beta\lambda} = \frac{1}{2} R^\mu_{\alpha\beta\lambda} R^{\alpha\beta\lambda} \sqrt{-g} \]

(47b)

\[ \frac{\partial \tilde{\mathcal{L}}_{\text{Ric}^2}}{\partial R^{\eta}_{\alpha\mu\lambda}} R^{\eta}_{\alpha\beta\nu} = \frac{1}{2} R^\mu_{\alpha\beta\lambda} R^{\alpha\beta\lambda} \sqrt{-g} \]

(47c)

\[ \frac{\partial \tilde{\mathcal{L}}_{\text{Ric}^2}}{\partial R^{\eta}_{\alpha\beta\mu}} R^{\eta}_{\alpha\beta\nu} = \frac{1}{2} R^\mu_{\alpha\beta\lambda} R^{\alpha\beta\lambda} \sqrt{-g}. \]

(47d)
As here the terms (47a) and (47b) cancel, the remaining terms (47c) and (47d) form the canonical energy-momentum tensor, which thus agrees with the metric one:

\[ T_{\nu\mu} = \frac{2}{\sqrt{-g}} \frac{\partial \tilde{L}_{\text{Rie}}}{\partial g^{\nu\mu}} = R_{\eta\tau\mu}^\eta R_{\tau\nu}^\eta - g_{\nu\mu} L_{\text{Rie}}^2 \]

\[ \theta_{\nu\mu} = \frac{\partial \tilde{L}_{\text{Rie}}}{\partial R^\eta_{\alpha\mu\lambda}} R^\eta_{\alpha\nu\lambda} + \frac{\partial \tilde{L}_{\text{Rie}}}{\partial R^\eta_{\alpha\beta\mu}} R^\eta_{\alpha\beta\nu} - g_{\nu\mu} L_{\text{Rie}}^2 = T_{\nu\mu}. \]

B. Consistency equation of the gauge theory of gravity

From the Hamiltonian formulation of the gauge theory of gravity \[1\] one derives the second rank tensor “consistency equation”:

\[ -2 \frac{\partial \tilde{H}_R}{\partial g_{\alpha\mu}} g_{\alpha
u} + 2 \tilde{k}_{\alpha\mu\beta} \frac{\partial \tilde{H}_R}{\partial k_{\alpha\nu\beta}} - \tilde{q}_{\nu \eta \beta} \frac{\partial \tilde{H}_R}{\partial q_{\eta \alpha \beta}} + \tilde{q}_{\eta \mu \alpha} \frac{\partial \tilde{H}_R}{\partial q_{\eta \nu \alpha}} = \frac{\partial \tilde{H}_0}{\partial a_{\alpha \mu}} a_{\nu} - \tilde{p}_{\mu \beta} \frac{\partial \tilde{H}_0}{\partial \eta_{\nu \beta}} + 2 \frac{\partial \tilde{H}_0}{\partial g_{\alpha \mu}} g_{\alpha \nu}, \]

which has the equivalent Lagrangian representation:

\[ -2 \frac{\partial \tilde{L}_R}{\partial g_{\alpha\mu}} g_{\alpha
u} + 2 \frac{\partial \tilde{L}_R}{\partial g_{\alpha\mu;\beta}} g_{\alpha\nu;\beta} - \frac{\partial \tilde{L}_R}{\partial R^\eta_{\nu \alpha \beta}} R^\mu_{\alpha \beta} + \frac{\partial \tilde{L}_R}{\partial R^\eta_{\alpha \beta \mu}} R^\mu_{\alpha \beta \nu} = - \frac{\partial \tilde{L}_0}{\partial a_{\alpha \mu}} a_{\nu} - \frac{\partial \tilde{L}_0}{\partial a_{\nu;\beta}} a_{\nu;\beta} + 2 \frac{\partial \tilde{L}_0}{\partial g_{\alpha \mu}} g_{\alpha \nu}. \]

By virtue of the identities for scalar density valued functions of arbitrary tensors and the metric \[4\], given here by

\[ \delta_{\nu}^\mu \tilde{L}_0 \equiv \frac{\partial \tilde{L}_0}{\partial (\frac{\partial \phi}{\partial x})} \frac{\partial \phi}{\partial x^\nu} + \frac{\partial \tilde{L}_0}{\partial a_{\alpha \mu}} a_{\nu} + \frac{\partial \tilde{L}_0}{\partial a_{\nu;\beta}} a_{\nu;\beta} + \frac{\partial \tilde{L}_0}{\partial a_{\beta;\mu}} a_{\beta;\nu} - 2 \frac{\partial \tilde{L}_0}{\partial g_{\alpha \nu}} g_{\alpha \mu} \]

\[ \delta_{\nu}^\mu \tilde{L}_R \equiv -2 \frac{\partial \tilde{L}_R}{\partial g_{\alpha \mu}} g_{\alpha \nu} + 2 \frac{\partial \tilde{L}_R}{\partial g_{\alpha \mu;\beta}} g_{\alpha \nu;\beta} + \frac{\partial \tilde{L}_R}{\partial g_{\alpha \beta;\mu}} g_{\alpha \beta;\nu} - \frac{\partial \tilde{L}_R}{\partial R^\eta_{\nu \alpha \beta}} R^\mu_{\alpha \beta} + \frac{\partial \tilde{L}_R}{\partial R^\eta_{\alpha \beta \mu}} R^\mu_{\alpha \beta \nu}, \]

the consistency equation \[49\] has the equivalent representation:

\[ \frac{\partial \tilde{L}_R}{\partial g_{\alpha \beta;\mu}} g_{\alpha \beta;\nu} + 2 \frac{\partial \tilde{L}_R}{\partial R^\eta_{\alpha \beta \mu}} R^\eta_{\alpha \beta \nu} - \delta_{\nu}^\mu \tilde{L}_R = - \left( \frac{\partial \tilde{L}_0}{\partial (\frac{\partial \phi}{\partial x})} \frac{\partial \phi}{\partial x^\nu} + \frac{\partial \tilde{L}_0}{\partial a_{\beta;\mu}} a_{\beta;\nu} - \delta_{\nu}^\mu \tilde{L}_0 \right). \]
We note that the covariant derivatives in the vector field term causes the connection besides the metric to act as an additional coupling to the left-hand side of Eq. (50). The latter can be interpreted as the canonical energy-momentum tensor density associated with the “free” gravitational field Lagrangian $\tilde{\mathcal{L}}_R$. Hence, Eq. (50) is equivalently written as

$$\frac{\partial \mathcal{L}_R}{\partial g_{\alpha\beta};\mu} g_{\alpha\beta;\mu} + 2 \frac{\partial \mathcal{L}_R}{\partial R^n_{\alpha\beta};\nu} R^n_{\alpha\beta;\nu} - \delta^{\mu}_{\nu} \mathcal{L}_R = -\theta^{\mu}_{\nu}. \tag{51}$$

This is the general Einstein-type equation that applies for any postulated “free gravity” Lagrangian $\mathcal{L}_R$ describing the dynamics of the gravitational field in source-free regions of space-time including torsion and non-metricity. With Eq. (37c) it immediately yields the Einstein equation for zero torsion and metric compatibility ($g_{\alpha\beta;\mu} \equiv 0$) for the Hilbert Lagrangian $\mathcal{L}_{R,H} = R/16\pi G$, which constitutes a particular model Lagrangian to describe the dynamics of the free gravitational field:

$$R^\mu_{\nu} - \frac{1}{2} \delta^\mu_{\nu} R = -8\pi G \theta^\mu_{\nu}.$$ 

V. CONCLUSIONS

The theorem on relative scalar-valued functions of relative tensors of any weight reflects the linear structure of tensor spaces and thereby constitutes an analogue to the Euler theorem on homogeneous functions. Especially for the Lagrangian densities $\tilde{\mathcal{L}}$ of classical field theories in a dynamic space-time, the identity established by the theorem provides us with an easy way to relate the pertaining metric and canonical energy-momentum tensors. The Einstein-type equation emerging from the gauge theory of gravity relates the energy-momentum tensors of both, the gravity Lagrangian and the source field Lagrangian and thereby constitutes a proper field equation, hence no identity. In combination with the identities that hold separately for both tensors, the Einstein-type equation may be cast into a simple but nevertheless most general form that includes both torsion of space-time and a non-zero covariant derivative of the metric. The relations derived in this way are valid in both, first or second order formulations.
