Abstract

We study the entropic Gromov-Wasserstein and its unbalanced version between (unbalanced) Gaussian distributions with different dimensions. When the metric is the inner product, which we refer to as inner product Gromov-Wasserstein (IGW), we demonstrate that the optimal transportation plans of entropic IGW and its unbalanced variant are (unbalanced) Gaussian distributions. Via an application of von Neumann’s trace inequality, we obtain closed-form expressions for the entropic IGW between these Gaussian distributions. Finally, we consider an entropic inner product Gromov-Wasserstein barycenter of multiple Gaussian distributions. We prove that the barycenter is Gaussian distribution when the entropic regularization parameter is small. We further derive closed-form expressions for the covariance matrix of the barycenter.

1 Introduction

The recent advance in computation of optimal transport [9, 4, 18, 1, 12, 20, 11, 23] has led to a surge of interest in using optimal transport for applications in machine learning and statistics. These applications include generative modeling [3, 31, 27, 14, 21], unsupervised learning [17, 16], domain adaptation [8, 10, 19], mini-batch computation [13, 24], and other applications [30, 25]. However, optimal transport requires that the probability measures lie in the same spaces.

When probability measures lie in different spaces, Gromov-Wasserstein distance [22] has been widely used to comparing these distributions. To circumvent the issue of defining distance between two points in different spaces, the main idea of Gromov-Wasserstein distance is to consider the transportation of similarity matrices among points in same spaces. However, such formulation of Gromov-Wasserstein distance is computationally expensive as we need to solve a quadratic programming problem. To improve the computational complexity of Gromov-Wasserstein distance, Peyré et al. [26] propose to regularizing the objective function of Gromov-Wasserstein based on the entropy of the transportation plan, which we refer to as entropic Gromov-Wasserstein. The entropic regularization idea had also been used earlier in optimal transport and had been shown to improve greatly the computation of optimal transport [9, 1, 12, 20]. The improvement in approximation of Gromov-Wasserstein distance via the entropic regularization has lead to an increasing interest of using that divergence to several applications, including deep generative model [5], computer graphics [30, 32, 6], and natural language processing [2, 15]. When measures are not probability measures and unbalanced, i.e., they may have different total masses, unbalanced version of

⋆ Huy Nguyen, Khang Le, Dung Le contributed equally to this work.
Gromov-Wasserstein, named unbalanced Gromov-Wasserstein, via the idea of unbalanced optimal transport [7] had been introduced in the recent work of [29]. The entropic unbalanced Gromov-Wasserstein has been used in robust machine learning applications [29]. Despite their practicalities, theoretical understandings of entropic (unbalanced) Gromov-Wasserstein are still nascent. The recent work of [28] studied the closed-form expression of Gromov-Wasserstein between Gaussian distributions in different dimensions. However, to the best of our knowledge, the full theoretical analysis of entropic Gromov-Wasserstein and its unbalanced version between (unbalanced) Gaussian distributions in different dimensions has remained poorly understood.

Our contribution. In this paper, we present a comprehensive study of the entropic Gromov-Wasserstein and its unbalanced version between (unbalanced) Gaussian distributions when inner product is considered as a cost function, which we refer to as entropic (unbalanced) inner product Gromov-Wasserstein (IGW). We also study its corresponding barycenter problem among multiple Gaussian distributions. Our contribution is three-fold and can be summarized as follows:

1. Balanced Gaussian measures: We first provide a closed-form expression of the entropic inner product Gromov-Wasserstein between Gaussian probability measures with zero means. We demonstrate that the expression depends mainly on eigenvalues of the covariance matrices of the two measures. Furthermore, an associate optimal transportation plan is shown to be also a zero-mean Gaussian measure. Our analysis hinges upon an application of von Neuman’s trace inequality for singular values of matrices.

2. Unbalanced Gaussian measures: Second, by relaxing marginal constraints via KL divergence, we further study the entropic unbalanced IGW between two unbalanced Gaussian measures with zero means. The main challenge comes from the two KL terms that add another level of constraint in the objective function. To overcome that challenge, we show that the objective function can be broken down into several sub-problems that can be solved explicitly through some cubic and quadratic equations. That leads to an almost closed-form formulation of the optimal Gaussian transport plan of the unbalanced IGW between the unbalanced Gaussian measures.

3. Barycenter problem: Finally, we study (entropic) Gromov-Wasserstein barycenter problems with inner product cost, which we refer to as (entropic) IGW barycenter, among zero-mean balanced Gaussian measures. We prove that the barycenter of zero-mean Gaussian distributions is also a zero-mean Gaussian distribution with a diagonal covariance matrix. Reposing on that Gaussian barycenter, we can directly obtain a closed-form expression for the barycenter problem when the regularized parameter is sufficiently small, which is also the setting people widely use in practice.

Paper organization. The paper is organized as follows. In Section 2, we provide backgrounds on the (unbalanced) inner product Gromov-Wasserstein and its corresponding entropic version. We then establish a closed-form expression of the entropic IGW distance between two balanced Gaussian distributions in Section 3 while proving that the entropic unbalanced IGW between unbalanced Gaussian measures also has a closed-form formulation in Section 4. In Section 5, we present our study of the (entropic) IGW barycenter problem among multiple Gaussian distributions before concluding with a few discussions in Section 6. Additional proofs and auxiliary results are presented in the Appendices.
Notation. We use the following notations throughout the paper. For a non-negative definite matrix $A$, if we do not specify the spectral decomposition of $A$, then generally, $\lambda_{a,i}$ or $\lambda_i(A)$ denotes the $i$th largest eigenvalues of $A$. For random vectors $X = (X_1, \ldots, X_m)$ and $Y = (Y_1, \ldots, Y_n)$, let $K_{xy}$ be the covariance matrix of $X$ and $Y$, which means that $(K_{xy})_{i,j} = \text{Cov}(X_i, Y_j)$. For square matrices $A$ and $B$, we write $A \succeq B$ or $B \preceq A$ if $A - B$ is non-negative definite. For a positive integer $r$, we denote by $\text{Id}_r$ the identity matrix of size $r \times r$. For any real number $a$, $[a]^+$ denotes $\max\{a, 0\}$.

2 Problem Settings

In this section, we first provide background on the inner product Gromov-Wasserstein distance between two Gaussian measures, and then we elaborate our settings of mean vectors and covariance matrices of these two measures.

Let $X, X' \sim \mu$ be i.i.d random multivariate variables in $\mathbb{R}^m$ while $Y, Y' \sim \nu$ are i.i.d random multivariate in $\mathbb{R}^n$. Next, we assume that both $(X, Y)$ and $(X', Y')$ are jointly distributed as $\pi$ which belongs to the set of joint probability distributions in $\mathbb{R}^m \times \mathbb{R}^n$, denoted by $\Pi(\mu, \nu)$, such that their marginal distributions are $\mu$ and $\nu$. Then, the inner product Gromov-Wasserstein (IGW) problem is defined as

$$\text{IGW}(\mu, \nu) := \min_{\pi \in \Pi(\mu, \nu)} \mathbb{E}_\pi \left\{ \left[ \langle X, X' \rangle - \langle Y, Y' \rangle \right]^2 \right\}.$$  

By adding the relative entropy term in the above objective function, the entropic version of the inner product Gromov-Wasserstein distance, named entropic IGW, is given by

$$\text{IGW}_\varepsilon(\mu, \nu) := \min_{\pi \in \Pi(\mu, \nu)} \mathbb{E}_\pi \left\{ \left[ \langle X, X' \rangle - \langle Y, Y' \rangle \right]^2 \right\} + \varepsilon \text{KL}(\pi\|\mu \otimes \nu),$$  

(1)

where $\varepsilon > 0$ is a regularized parameter and $\text{KL}(\alpha\|\beta) := \int \log \left( \frac{d\alpha}{d\beta} \right) d\alpha + \int (d\beta - d\alpha)$ for any positive measures $\alpha$ and $\beta$.

Entropic unbalanced IGW problem: When $\mu$ and $\nu$ are unbalanced Gaussian measures which are not probability distributions, the entropic IGW formulation in equation (1) is no longer valid. One solution to deal with this issue is by regularizing the marginal constraints via KL divergence [7]. The entropic IGW problem between unbalanced measures, which we refer to as entropic unbalanced IGW, admits the following form

$$\text{UIGW}_{\varepsilon, \tau}(\mu, \nu) := \min_{\pi \in \mathcal{M}^+(\mathbb{R}^m \times \mathbb{R}^n)} \mathbb{E}_\pi \left\{ \left[ \langle X, X' \rangle - \langle Y, Y' \rangle \right]^2 \right\} +$$

$$\tau \text{KL}(\pi_x\|\mu) + \tau \text{KL}(\pi_y\|\nu) + \varepsilon \text{KL}(\pi\|\mu \otimes \nu),$$

where $\tau > 0$, $\pi_x$ and $\pi_y$ are the projections of $\pi$ on $\mathbb{R}^m$ and $\mathbb{R}^n$, respectively, and $\text{KL}(\alpha\|\beta) := \text{KL}(\alpha \otimes \alpha\|\beta \otimes \beta)$. Using the quadratic-KL divergence $\text{KL}^\otimes$ in place of the standard KL will result in UIGW being 2-homogeneous, i.e. if $\mu$ and $\nu$ are multiplied by $\theta \geq 0$, then the value of UIGW is multiplied by $\theta^2$.

3 Entropic Gromov-Wasserstein between Balanced Gaussians

We present in this section a closed-form expression of the entropic inner product Gromov-Wasserstein distance between two Gaussian measures and a formula of a corresponding optimal transportation plan in Theorem 1.
Let \( \mu = \mathcal{N}(\theta_\mu, \Sigma_\mu) \) and \( \nu = \mathcal{N}(\theta_\nu, \Sigma_\nu) \). Note that, we assume the two measures have mean zero, i.e., \( \theta_\mu = \theta_\nu = 0 \), so that it is reasonable to use the inner product as a cost function. Otherwise, two distributions could have the same covariances, it means that their structures are the same, but if they have different means, then their inner product (inner structure) viewed from their origins are different. That is not the purpose of the Gromov-Wasserstein distance which is invariant to translation and rotation. To ease the ensuing presentation, in the entropic IGW problem we denote that the joint distribution \( \pi \) between \( \mu \) and \( \nu \) has the covariance matrix
\[
\Sigma_\pi = \begin{pmatrix}
\Sigma_\mu & K_{\mu\nu} \\
K_{\mu\nu}^\top & \Sigma_\nu
\end{pmatrix}.
\] (2)

For \( X \sim \mathcal{N}(0, \Sigma_\mu) \) and \( Y \sim \mathcal{N}(0, \Sigma_\nu) \), we could choose a system of coordinate for \( X \) and \( Y \) such that their covariance matrices are all diagonal. Hence, throughout this work, we assume without loss of generality that \( \Sigma_\mu \) and \( \Sigma_\nu \) are diagonal matrices. In particular,
\[
\Sigma_\mu = \text{diag}(\lambda_{\mu,1}, \ldots, \lambda_{\mu,m}), \\
\Sigma_\nu = \text{diag}(\lambda_{\nu,1}, \ldots, \lambda_{\nu,n}).
\] (3)

The following result gives the closed-form expression for the entropic IGW between two balanced Gaussian distributions.

**Theorem 1 (Closed Form of IGW Distance).** Let \( \mu = \mathcal{N}(0, \Sigma_\mu) \) and \( \nu = \mathcal{N}(0, \Sigma_\nu) \) be two zero-mean Gaussian measures in \( \mathbb{R}^m \) and \( \mathbb{R}^n \), respectively, with \( m \geq n \) where \( \Sigma_\mu \) and \( \Sigma_\nu \) are diagonal matrices with positive diagonal entries given in equation (3). The entropic inner product Gromov-Wasserstein between \( \mu \) and \( \nu \) then equals to
\[
\text{IGW}_\varepsilon(\mu, \nu) = \text{tr}(\Sigma_\mu^2) + \text{tr}(\Sigma_\nu^2) - 2 \sum_{k=1}^n \left( \lambda_{\mu,k} \lambda_{\nu,k} - \frac{\varepsilon}{4} \right) + \frac{\varepsilon}{2} \sum_{k=1}^n \left[ \log(\lambda_{\mu,k} \lambda_{\nu,k}) - \log\left(\frac{\varepsilon}{4}\right) \right].
\] (4)

Furthermore, the optimal transportation plan of the entropic IGW is \( \pi^* = \mathcal{N}(0, \Sigma_{\pi^*}) \), where
\[
\Sigma_{\pi^*} = \begin{pmatrix}
\Sigma_\mu & K_{\mu\nu}^* \\
K_{\mu\nu}^{*\top} & \Sigma_\nu
\end{pmatrix}
\]
in which \( K_{\mu\nu}^* = \text{diag}\left(\left[\lambda_{\mu,k} \lambda_{\nu,k} \left[1 - \frac{\varepsilon}{4 \lambda_{\mu,k} \lambda_{\nu,k}}\right]\right]^{1/2}\right)_{k=1,\ldots,n} \).

**Proof of Theorem 1.** First, we prove the following equality
\[
\mathbb{E}_\pi\left\{\left[\langle X, X' \rangle - \langle Y, Y' \rangle \right]^2\right\} = \text{tr}(\Sigma_\mu^2) + \text{tr}(\Sigma_\nu^2) - 2 \text{tr}(K_{\mu\nu}^\top K_{\mu\nu}).
\] (4)

Indeed, we have
\[
\mathbb{E}_\pi\left\{\left[\langle X, X' \rangle - \langle Y, Y' \rangle \right]^2\right\} = \mathbb{E}_\pi\langle X, X' \rangle^2 + \mathbb{E}_\pi\langle Y, Y' \rangle^2 - 2 \mathbb{E}_\pi\langle X, X' \rangle \langle Y, Y' \rangle.
\]

Note that the independence between \( X \) and \( X' \) and \( Y \) and \( Y' \) leads to
\[
\mathbb{E}_\pi\langle X, X' \rangle^2 = \text{tr}(\Sigma_\mu^2) \quad \text{and} \quad \mathbb{E}_\pi\langle Y, Y' \rangle^2 = \text{tr}(\Sigma_\nu^2).
\]
Meanwhile,
\[
\mathbb{E}_\pi \langle X, X' \rangle \langle Y, Y' \rangle = \mathbb{E}_\pi \left\{ \sum_{i,i'=1}^{m} \sum_{j,j'=1}^{n} [X_i X_{i'} Y_j Y_{j'}] \right\} = \sum_{i=1}^{m} \sum_{j=1}^{n} \mathbb{E}_\pi \{X_i Y_j\} \mathbb{E}_\pi \{X_i Y_j\} = \text{tr} \left( K_{\mu\nu}^\top K_{\mu\nu} \right).
\]

Putting the above results together, we obtain the desired equality (4). It indicates that we can rewrite the formulation of IGW_{\varepsilon}(\mu, \nu) as follows:

\[\text{IGW}_{\varepsilon}(\mu, \nu) = \min_{\pi} \left\{ \varepsilon \text{KL}(\pi \| \mu \otimes \nu) + \text{tr}(\Sigma^2_{\mu}) + \text{tr}(\Sigma^2_{\nu}) - 2 \text{tr} \left( K_{\mu\nu}^\top K_{\mu\nu} \right) \right\} \]

By Lemma 13, the optimal transportation plan \( \pi^* \) is a Gaussian distribution with zero mean, namely, \( \pi^* = N(0, \Sigma_{\pi^*}) \). Thus, according to Lemma 11, the entropic term in the objective function reads

\[
\varepsilon \text{KL}(\pi^* \| \mu \otimes \nu) = \frac{\varepsilon}{2} \left\{ \text{tr} \left( \Sigma_{\pi^*}^{-1} \Sigma_{\mu\otimes\nu} - (m + n) \right) + \log \left( \frac{\det(\Sigma_{\mu\otimes\nu})}{\det(\Sigma_{\pi^*})} \right) \right\} = -\frac{\varepsilon}{2} \sum_{i=1}^{n} \log(1 - \kappa_{\mu\nu,i}^*),
\]

where \( \kappa_{\mu\nu,1}, \ldots, \kappa_{\mu\nu,n} \) are singular values of matrix \( K_{\mu\nu}^* \). Therefore, we find that

\[\text{IGW}_{\varepsilon}(\mu, \nu) = \text{tr}(\Sigma^2_{\mu}) + \text{tr}(\Sigma^2_{\nu}) - 2 \sum_{k=1}^{n} \lambda_{\mu,k} \lambda_{\nu,k} \kappa_{\mu\nu,k}^* - \frac{\varepsilon}{2} \sum_{i=1}^{n} \log(1 - \kappa_{\mu\nu,i}^*). \]

(5)

By applying part (c) of Lemma 1 (cf. the end of this proof) to equation (5), we have

\[\text{IGW}_{\varepsilon}(\mu, \nu) = \min_{\substack{\kappa_{\mu\nu,k} \in (0,1) \\kappa_{\mu\nu,k} \in \{0,1\}}} \left\{ \text{tr}(\Sigma^2_{\mu}) + \text{tr}(\Sigma^2_{\nu}) - 2 \sum_{k=1}^{n} \lambda_{\mu,k} \lambda_{\nu,k} \kappa_{\mu\nu,k}^* - \frac{\varepsilon}{2} \sum_{k=1}^{n} \log(1 - \kappa_{\mu\nu,k}^*) \right\}.\]

The function \( f(x) = ax + \frac{\varepsilon}{4} \log(1 - x) \) for \( a > 0 \) determined in the interval \([0,1]\) attains its maximum at \( x \in \{0, 1 - \frac{\varepsilon}{4a} \} \). Thus,

\[\text{IGW}_{\varepsilon}(\mu, \nu) = \text{tr}(\Sigma^2_{\mu}) + \text{tr}(\Sigma^2_{\nu}) - 2 \sum_{k=1}^{n} \left( \lambda_{\mu,k} \lambda_{\nu,k} - \frac{\varepsilon}{4} \right)^+ + \frac{\varepsilon}{2} \sum_{k=1}^{n} \left[ \log(\lambda_{\mu,k} \lambda_{\nu,k}) - \log \left( \frac{\varepsilon}{4} \right) \right]^+.
\]

Part (c) of Lemma 1 points out that the equality happens when \( \kappa_{\mu\nu,k}^* = \left[ 1 - \frac{\varepsilon}{4 \lambda_{\mu,k} \lambda_{\nu,k}} \right]^+ \), which implies that

\[K_{\mu\nu}^* = \text{diag} \left\{ \left( \lambda_{\mu,k} \lambda_{\nu,k} \left[ 1 - \frac{\varepsilon}{4 \lambda_{\mu,k} \lambda_{\nu,k}} \right]^+ \right)^{1\over 2} \right\}_{k=1,\ldots,n}.
\]

As a consequence, the proof is completed. \( \square \)

To solve the above optimization problem, we need the following lemma:
Lemma 1 (Eigenvalues, determinant and trace). Let $U_{\mu\nu}\Lambda_{\mu\nu}^{\frac{1}{2}} V_{\mu\nu}^{\top}$ be the SVD of $\Sigma_{\mu\nu}^{\frac{1}{2}} K_{\mu\nu} \Sigma_{\mu\nu}^{-\frac{1}{2}}$, where $\Lambda_{\mu\nu}^{\frac{1}{2}} = \text{diag}(\kappa_{\mu\nu,k}^{\frac{1}{2}})$ and $\kappa_{\mu\nu,k}$ is the $k$th largest eigenvalue of $\Sigma_{\mu\nu}^{\frac{1}{2}} K_{\mu\nu} \Sigma_{\mu\nu}^{-\frac{1}{2}}$. Here $\Lambda_{\mu\nu}^{\frac{1}{2}}$ has size $m \times n$, with some of its singular values could be zero. $U_{\mu\nu}$ is a $m \times m$ matrix and $V_{\mu\nu}$ is a $n \times n$ matrix. Then, we find that

(a) All singular values $\kappa_{\mu\nu,k}$ lie between 0 and 1.

(b) The determinant of $\Sigma_{\pi}$ could be computed as follows

$$\det(\Sigma_{\pi}) = \det(\Sigma_{\mu}) \det(\Sigma_{\nu}) \prod_{j=1}^{n} (1 - \kappa_{\mu\nu,j}).$$

(c) We have

$$\text{tr} \left( K_{\mu\nu}^{\top} K_{\mu\nu} \right) \leq \sum_{j=1}^{n} \lambda_{\mu,j} \lambda_{\nu,j} \kappa_{\mu\nu,j}.$$  

The equality occurs when both $U_{\mu\nu}$ and $V_{\mu\nu}$ are diagonal matrices of entries 1.

Proof of Lemma 1. (a) We start with decomposing the matrix $K_{\mu\nu}$ as $K_{\mu\nu} = \Sigma_{\mu}^{\frac{1}{2}} U_{\mu\nu} \Lambda_{\mu\nu}^{\frac{1}{2}} V_{\mu\nu}^{\top} \Sigma_{\nu}^{\frac{1}{2}}$. It follows from the fact $\Sigma_{\pi}$ is non-negative definite that

$$\Sigma_{\nu} \succeq K_{\mu\nu}^{\top} \Sigma_{\mu}^{-1} K_{\mu\nu} \iff \Sigma_{\nu} \succeq \Sigma_{\nu}^{\frac{1}{2}} V_{\mu\nu} (\Lambda_{\mu\nu}^{\frac{1}{2}})^{\top} U_{\mu\nu}^{\top} U_{\mu\nu} \Lambda_{\mu\nu}^{\frac{1}{2}} V_{\mu\nu}^{\top} \Sigma_{\nu}^{\frac{1}{2}} \iff \Sigma_{\nu} \succeq \Sigma_{\nu}^{\frac{1}{2}} V_{\mu\nu} \Lambda_{\mu\nu} V_{\mu\nu}^{\top} \Sigma_{\nu}^{\frac{1}{2}} \iff \text{Id}_{n} \succeq V_{\mu\nu} \Lambda_{\mu\nu} V_{\mu\nu}^{\top},$$

where $\Lambda_{\mu\nu}$ is the diagonal matrix $\text{diag}(\kappa_{\mu\nu,k})$ for $k = 1, 2, \ldots, n$. Since $V_{\mu\nu}$ is an unitary matrix, all eigenvalues of matrix $\Lambda_{\mu\nu}$ belong to the interval $[0, 1]$.

(b) By the definition of matrix $\Sigma_{\pi}$, we have

$$\det(\Sigma_{\pi}) = \det(\Sigma_{\mu}) \det(\Sigma_{\nu} - K_{\mu\nu}^{\top} \Sigma_{\mu}^{-1} K_{\mu\nu}) = \det(\Sigma_{\mu}) \det(\Sigma_{\nu}) \det \left( \text{Id}_{n} - V_{\mu\nu} \Lambda_{\mu\nu} V_{\mu\nu}^{\top} \right) = \det(\Sigma_{\mu}) \det(\Sigma_{\nu}) \prod_{k=1}^{n} (1 - \kappa_{\mu\nu,k}).$$

The third equality results from the fact that all eigenvalues of matrix $\text{Id}_{n} - V_{\mu\nu} \Lambda_{\mu\nu} V_{\mu\nu}^{\top}$ are $1 - \kappa_{\mu\nu,k}$ for $k = 1, \ldots, n$.

(c) Using the decomposition of matrix $K_{\mu\nu}$ in part (a), we have

$$\text{tr} \left( K_{\mu\nu}^{\top} K_{\mu\nu} \right) = \text{tr} \left( \Sigma_{\mu}^{\frac{1}{2}} U_{\mu\nu} \Lambda_{\mu\nu}^{\frac{1}{2}} V_{\mu\nu}^{\top} \Sigma_{\mu} V_{\mu\nu}^{\top} \Lambda_{\mu\nu} V_{\mu\nu}^{\top} \Sigma_{\nu} \Sigma_{\nu}^{\frac{1}{2}} \right) = \text{tr} \left( [U_{\mu\nu} \Lambda_{\mu\nu}^{\frac{1}{2}}] [V_{\mu\nu}^{\top} \Sigma_{\mu}] [V_{\mu\nu} \Lambda_{\mu\nu}^{\frac{1}{2}}] [U_{\mu\nu}^{\top} \Sigma_{\nu}] \right).$$

Applying the generalization of the von Neumann’s inequality for singular value with a note that the equality happens when $U_{\mu\nu}$ and $V_{\mu\nu}^{\top}$ are diagonal matrix of 1, we obtain

$$\text{tr} \left( K_{\mu\nu}^{\top} K_{\mu\nu} \right) \leq \sum_{i=1}^{n} \lambda_{\mu,i} \lambda_{\nu,i} \kappa_{\mu\nu,i}.$$  

As a consequence, we obtain the conclusion of the lemma. \qed
4 Entropic Unbalanced Gromov-Wasserstein between Unbalanced Gaussians

In this section, we consider a more general setting when the two distributions \( \mu \) and \( \nu \) are unbalanced Gaussian measures given by:

\[
\mu = m_\mu \mathcal{N}_m(0, \Sigma_\mu), \\
\nu = m_\nu \mathcal{N}_n(0, \Sigma_\nu),
\]

where \( m \geq n \) and \( \Sigma_\mu, \Sigma_\nu \) are given in equation (3). Here, \( \mu \) and \( \nu \) do not necessarily have the same mass, i.e., \( m_\mu \) could be different from \( m_\nu \). For any positive measure \( \alpha \), we denote by \( \overline{\alpha} \) the normalized measure of \( \alpha \). Thus, \( \overline{\mu} = \mathcal{N}_m(0, \Sigma_\mu) \) and \( \overline{\nu} = \mathcal{N}_n(0, \Sigma_\nu) \).

Under the setting of entropic unbalanced IGW, we denote the covariance matrix of transportation plan \( \pi \) by

\[
\Sigma_\pi = \begin{pmatrix} \Sigma_x & K_{xy} \\ K_{xy}^\top & \Sigma_y \end{pmatrix},
\]

(7)

where \( \Sigma_x \) and \( \Sigma_y \) are covariance matrices of distributions \( \pi_x \) and \( \pi_y \), respectively.

**Lemma 2** (KL divergence between positive measures). Let \( \alpha = m_\alpha \mathcal{N}_k(0, \Sigma_\alpha) \) and \( \beta = m_\beta \mathcal{N}_k(0, \Sigma_\beta) \) be scaled Gaussian measures, then the generalized KL divergence between \( \alpha \) and \( \beta \) is

\[
\text{KL}(\alpha \| \beta) = m_\alpha \text{KL}(\overline{\alpha} \| \overline{\beta}) + \text{KL}(m_\alpha \| m_\beta),
\]

where the KL divergence between \( \overline{\alpha} \) and \( \overline{\beta} \) is

\[
\frac{1}{2} \left\{ \text{tr} \left( \Sigma_\alpha \Sigma_\beta^{-1} \right) - k + \log \left( \frac{\det(\Sigma_\beta)}{\det(\Sigma_\alpha)} \right) \right\}.
\]

**Proof of Lemma 2.** Let \( f(x, \Sigma_\alpha) \) and \( f(x, \Sigma_\beta) \) be the distribution functions of \( \mathcal{N}(0, \Sigma_\alpha) \) and \( \mathcal{N}(0, \Sigma_\beta) \), respectively.

\[
\text{KL}(\alpha \| \beta) = \int_{\mathbb{R}^k} \log \left( \frac{m_\alpha f(x, \Sigma_\alpha)}{m_\beta f(x, \Sigma_\beta)} \right) d\alpha(x) - m_\alpha + m_\beta
\]

\[
= \int_{\mathbb{R}^k} \log \left( \frac{f(x, \Sigma_\alpha)}{f(x, \Sigma_\beta)} \right) m_\alpha d\overline{\alpha}(x) + \log \left( \frac{m_\alpha}{m_\beta} \right) m_\alpha - m_\alpha + m_\beta
\]

\[
= m_\alpha \text{KL}(\overline{\alpha} \| \overline{\beta}) + \text{KL}(m_\alpha \| m_\beta).
\]

Next, we will compute \( \text{KL}(\overline{\alpha} \| \overline{\beta}) \). By the formula for KL divergence, one has

\[
\text{KL}(\overline{\alpha} \| \overline{\beta}) = \int_{\mathbb{R}^k} \log \left( \frac{d\overline{\alpha}(x)}{d\overline{\beta}(x)} \right) d\overline{\alpha}(x).
\]

Since \( \overline{\alpha} = \mathcal{N}(0, \Sigma_\alpha) \) and \( \overline{\beta} = \mathcal{N}(0, \Sigma_\beta) \), we get

\[
\log(d\overline{\alpha}(x)) = \left[ \frac{1}{2} k \log(2\pi) + \log(\det(\Sigma_\alpha)) + x^\top \Sigma_\alpha^{-1} x \right],
\]

\[
\log(d\overline{\beta}(x)) = \left[ \frac{1}{2} k \log(2\pi) + \log(\det(\Sigma_\beta)) + x^\top \Sigma_\beta^{-1} x \right],
\]

7
with a note that \( \pi \) denotes a constant number \( \pi \) only in this lemma. Then,

\[
\text{KL}(\alpha \| \beta) = \frac{1}{2} \left\{ \int_{\mathbb{R}^k} x^\top (\Sigma_\beta^{-1} - \Sigma_\alpha^{-1}) x d\alpha(x) + \log \left( \frac{\det(\Sigma_\beta)}{\det(\Sigma_\alpha)} \right) \right\}.
\]  

(8)

Notice that

\[
\int_{\mathbb{R}^k} x^\top (\Sigma_\beta^{-1} - \Sigma_\alpha^{-1}) x d\alpha(x) = \int_{\mathbb{R}^k} \text{tr}(x x^\top (\Sigma_\beta^{-1} - \Sigma_\alpha^{-1})) d\alpha(x)
\]

\[
= \text{tr} \left( \int_{\mathbb{R}^k} x x^\top (\Sigma_\beta^{-1} - \Sigma_\alpha^{-1}) d\alpha(x) \right)
\]

\[
= \text{tr} \left( \mathbb{E}_{X \sim \pi} [XX^\top] (\Sigma_\beta^{-1} - \Sigma_\alpha^{-1}) \right)
\]

\[
= \text{tr}(\Sigma_\alpha (\Sigma_\beta^{-1} - \Sigma_\alpha^{-1}))
\]

\[
= \text{tr}(\Sigma_\alpha \Sigma_\beta^{-1}) - k.
\]

By plugging this result in equation (8), we obtain the conclusion of Lemma 2. \( \Box \)

**Lemma 3** (Lower bound for the KL divergence). Let \( \pi \) be given in equation (7), \( \lambda_x = (\lambda_{x,i})_{i=1}^m \) be the eigenvalues of \( K_x \), \( \lambda_y = (\lambda_{y,j})_{j=1}^n \) be the eigenvalues of \( K_y \). Similarly, we define \( \lambda_\mu \) for \( \Sigma_\mu \) and \( \lambda_\nu \) for \( \Sigma_\nu \). Then,

1. \( \text{KL}(\pi_x \| \mu) \geq \frac{1}{2} \sum_{i=1}^m \Psi(\lambda_{x,i} \lambda_{\mu,i}^{-1}) \)

2. \( \text{KL}(\pi_y \| \nu) \geq \frac{1}{2} \sum_{j=1}^n \Psi(\lambda_{y,j} \lambda_{\nu,j}^{-1}) \)

3. \( \text{KL}(\pi \| \mu \otimes \nu) = \text{KL}(\pi_x \| \mu) + \text{KL}(\pi_y \| \nu) - \frac{1}{2} \sum_{k=1}^n \log(1 - \kappa_{xy,k}) \)

where \( \Psi(x) = x - \log(x) - 1 \), and \( (\kappa_{xy,k})_{k=1}^n \) are singular values of \( \Sigma_x^{-\frac{1}{2}} K_{xy} \Sigma_y^{-\frac{1}{2}} \).

**Proof of Lemma 3.** By the formula for KL divergence between Gaussians and applying the von Neumann’s inequality, we have

\[
\text{KL}(\pi_x \| \mu) = \frac{1}{2} \left\{ \text{tr}(\Sigma_x \Sigma_\mu^{-1}) - m + \log \left( \frac{\det(\Sigma_\mu)}{\det(\Sigma_x)} \right) \right\}
\]

\[
\geq \frac{1}{2} \sum_{i=1}^m \left\{ \frac{\lambda_{x,i}}{\lambda_{\mu,i}} - \log \left( \frac{\lambda_{x,i}}{\lambda_{\mu,i}} \right) - 1 \right\}.
\]

Similarly, we find that

\[
\text{KL}(\pi_y \| \nu) \geq \frac{1}{2} \sum_{j=1}^n \left\{ \frac{\lambda_{y,j}}{\lambda_{\nu,j}} - \log \left( \frac{\lambda_{y,j}}{\lambda_{\nu,j}} \right) - 1 \right\}.
\]
For the last equality,

\[ \text{KL}(\pi\|\mu \otimes \nu) = \frac{1}{2} \left\{ \text{tr} \left( \Sigma_x \Sigma^{-1}_\mu \right) + \text{tr} \left( \Sigma_y \Sigma^{-1}_\nu \right) - (m + n) - \log \left( \frac{\det(\Sigma_x) \det(\Sigma_y)}{\det(\Sigma_{\mu \otimes \nu})} \right) \right\} \]

\[ = \frac{1}{2} \left\{ \text{tr} \left( \Sigma_x \Sigma^{-1}_\mu \right) + \text{tr} \left( \Sigma_y \Sigma^{-1}_\nu \right) - (m + n) - \log \left( \frac{\det(\Sigma_x) \det(\Sigma_y) \sum_{k=1}^{n} \log(1 - \kappa_{xy,k})}{\det(\Sigma_{\mu \otimes \nu})} \right) \right\} \]

\[ = \text{KL}(\pi_x\|\mu) + \text{KL}(\pi_y\|\nu) - \frac{1}{2} \sum_{k=1}^{n} \log(1 - \kappa_{xy,k}). \]

We have thus proved our claims.

**Lemma 4** (Double integrals). For the sake of simple computation, we derive some relations between the quadratic-KL and the standard KL as follows:

\[ \text{KL}^\otimes(\alpha\|\beta) = 2m_\alpha \text{KL}(\alpha\|\beta) + (m_\alpha - m_\beta)^2, \]

\[ \text{KL}^\otimes(t\alpha\|r\beta) = t^2 \text{KL}^\otimes(\alpha\|\beta) + t^2 \log \left( \frac{t^2}{r^2} \right) m_\alpha^2 + (r^2 - t^2)m_\beta^2. \]

**Proof of Lemma 4.** We only provide the proof for double KL divergence. Indeed, we have

\[ \text{KL}^\otimes(t\alpha\|r\beta) = \int \int \log \left( \frac{t^2 p_\alpha(x)p_\alpha(x')}{r^2 p_\beta(x)p_\beta(x')} \right) t^2 p_\alpha(x)p_\alpha(x')dx\,dx' + r^2 m_\beta^2 - t^2 m_\alpha^2 \]

\[ = t^2 \left[ \int \int \log \left( \frac{p_\alpha(x)p_\alpha(x')}{p_\beta(x)p_\beta(x')} \right) p_\alpha(x)p_\alpha(x')dx\,dx' + \log \left( \frac{t^2}{r^2} \right) m_\alpha^2 + r^2 m_\beta^2 - t^2 m_\alpha^2 \right] \]

\[ = t^2 \left[ \int \int \log \left( \frac{p_\alpha(x)p_\alpha(x')}{p_\beta(x)p_\beta(x')} \right) p_\alpha(x)p_\alpha(x')dx\,dx' + m_\beta^2 - m_\alpha^2 \right] \]

\[ + t^2 \log \left( \frac{t^2}{r^2} \right) m_\alpha^2 + (r^2 - t^2)m_\beta^2 \]

\[ = t^2 \text{KL}^\otimes(\alpha\|\beta) + t^2 \log \left( \frac{t^2}{r^2} \right) m_\alpha^2 + (r^2 - t^2)m_\beta^2. \]

As a consequence, we obtain the conclusion of the lemma.

Based on these lemmas, we are now ready to state our main result regarding the entropic unbalanced IGW between two unbalanced Gaussian distributions.

**Theorem 2** (Entropic unbalanced IGW). Let \( \mu \) and \( \nu \) be two unbalanced Gaussian distributions given in (6). Then, the entropic unbalanced IGW between \( \mu \) and \( \nu \) can be computed as follows:

\[ \text{UIGW}_{\varepsilon,\tau}(\mu, \nu) = m_{\pi^*}^2 \cdot Y^* + \tau \left\{ \text{KL}(m_{\pi^*}^2\|m_\mu^2) + \text{KL}(m_{\pi^*}^2\|m_\nu^2) \right\} + \varepsilon \text{KL}(m_{\pi^*}^2\|m_\mu^2m_\nu^2), \]

where

\[ m_{\pi^*}^2 := \frac{2^2}{2^2 + \tau} m_\mu^{2^2} m_\nu^{2^2} (m_\mu m_\nu)^{2^2 + \tau} \exp \left\{ - \frac{Y^*}{2^2 + \varepsilon} \right\}, \]

\[ Y^* := \sum_{k=1}^{n} g_{\varepsilon,\tau,\alpha}(\varphi_k, \phi_k; \lambda_{\mu,k}, \lambda_{\nu,k}) + \sum_{k=n+1}^{m} h_{\varepsilon,\tau}(\varphi_k; \lambda_{\mu,k}), \]
in which
\[
g_{\epsilon,\tau,+}(x, y; a, b) := x^2 + y^2 + (\tau + \epsilon) \left\{ \frac{x}{a} + \frac{y}{b} - \log(\frac{xy}{ab}) - 2 \right\} - 2[xy - \frac{\epsilon}{2}]^+ + \epsilon \left[ \log(xy) - \log\frac{\epsilon}{2} \right]^+,
\]
\[
h_{\epsilon,\tau}(x; a) := x^2 + (\tau + \epsilon) \left\{ \frac{x}{a} - \log(\frac{x}{a}) - 1 \right\},
\]
\[
(\varphi_k, \phi_k) := \arg \min_{x,y>0} g_{\epsilon,\tau,+}(x, y; \lambda_{\mu,k} \lambda_{\nu,k}); \quad k = 1, 2, \ldots, n,
\]
\[
\varphi_k := \arg \min_{x,y>0} h_{\epsilon,\tau}(x, \lambda_{\mu,k}); \quad k = n + 1, \ldots, m.
\]
Furthermore, the optimal transportation plan is \( \pi^* = m_{\pi^*} \mathcal{N}(0, \Sigma_{\pi^*}) \), where
\[
\Sigma_{\pi^*} = \begin{pmatrix} \Sigma^*_x & K^*_{xy} \\ (K^*_{xy})^\top & \Sigma^*_y \end{pmatrix}
\]
with \( \Sigma^*_x = \text{diag}(\varphi_k)_{k=1}^m \); \( \Sigma^*_y = \text{diag}(\phi_k)_{k=1}^n \); \( K^*_{xy} = \text{diag}(\psi^*_k)_{k=1}^n \) and \( \psi_k^* = \left\{ 1 - \frac{\epsilon}{2\varphi_k \phi_k} \right\}^+ \varphi_k \phi_k \)^{1/2}.

**Remark 1.** A detailed calculation of \( \Upsilon^* \) can be found in Appendix A.

**Proof of Theorem 2.** By Lemma 4, we have
\[
\begin{align*}
\text{UIGW}_{\epsilon,\tau}(\pi; \mu, \nu) &= m_{\pi^*} \left\{ \text{tr}(\Sigma^2_x) + \text{tr}(\Sigma^2_y) - 2 \text{tr}(K_{xy}^\top K_{xy}) \right\} + \mathbb{E} \left\{ 2m_{\pi^*} \text{KL}(\bar{\pi}_x || \bar{\mu}) + \text{KL}(m_{\pi^*}^2 || m_{\mu}^2) \right\} \\
&\quad + \tau \left\{ 2m_{\pi^*} \text{KL}(\bar{\pi}_x || \bar{\mu}) + \text{KL}(m_{\pi^*}^2 || m_{\mu}^2) + 2m_{\pi^*} \text{KL}(\bar{\pi}_y || \bar{\nu}) + \text{KL}(m_{\pi^*}^2 || m_{\nu}^2) \right\} \\
&= m_{\pi^*} \Upsilon + \tau \left\{ \text{KL}(m_{\pi^*}^2 || m_{\mu}^2) + \text{KL}(m_{\pi^*}^2 || m_{\nu}^2) \right\} + \mathbb{E} \text{KL}(m_{\pi^*}^2 || m_{\mu}^2 m_{\nu}^2),
\end{align*}
\]
in which \( \Upsilon \) is defined as
\[
\Upsilon := \text{tr}(\Sigma^2_x) + \text{tr}(\Sigma^2_y) - 2 \text{tr}(K_{xy}^\top K_{xy}) + 2(\epsilon + \tau) \left\{ \text{KL}(\bar{\pi}_x || \bar{\mu}) + \text{KL}(\bar{\pi}_y || \bar{\nu}) \right\} - \epsilon \sum_{k=1}^n \log(1 - \kappa_{xy,k}).
\]
The second equality results from part (c) of Lemma 3. By Theorem 1, the minimum value of
\[
\mathbb{E}_{\pi} \left\{ \left( \langle X, X' \rangle - \langle Y, Y' \rangle \right)^2 \right\} = \| \lambda_x \|^2 + \| \lambda_y \|^2 - 2 \text{tr}(K_{xy}^\top K_{xy}) - \epsilon \sum_{k=1}^n \log(1 - \kappa_{xy,k})
\]
is equal to
\[
\| \lambda_x \|^2 + \| \lambda_y \|^2 - 2 \sum_{k=1}^n \left( \lambda_{x,k} \lambda_{y,k} - \frac{\epsilon}{2} \right)^+ + \frac{\epsilon}{2} \sum_{k=1}^n \left[ \log(\lambda_{x,k} \lambda_{y,k}) - \log \frac{\epsilon}{2} \right]^+.
\]
According to Lemma 1, minimizing $\Upsilon$ is equivalent to minimizing
\[
\sum_{k=1}^{n} g_{\varepsilon, \tau, +}(\lambda_{x,k}, \lambda_{y,k}; \lambda_{\mu,k}, \lambda_{\nu,k}) + \sum_{k=n+1}^{m} h_{\varepsilon, \tau}(\lambda_{x,k}; \lambda_{\mu,k}),
\]
where (with note that $(\lambda_{x,k})$ and $(\lambda_{y,k})$ are decreasing sequences)
\[
g_{\varepsilon, \tau, +}(x, y; a, b) := x^2 + y^2 + (\tau + \varepsilon)\left\{ \frac{x}{a} + \frac{y}{b} - \log \frac{xy}{ab} - 2 \right\} - 2[xy - \frac{\varepsilon}{2}]^+ + \varepsilon \left[ \log(xy) - \log \frac{\varepsilon}{2} \right]^+ \\
h_{\varepsilon, \tau}(x; a) := x^2 + (\tau + \varepsilon)\left\{ \frac{x}{a} - \log \left( \frac{x}{a} \right) - 1 \right\}.
\]

By Lemma 5, we obtain
\[
\min_{\lambda_{x,i}, \lambda_{y,j} > 0} D(\{\lambda_{x,i}\}, \{\lambda_{\mu,i}\}, \{\lambda_{\nu,j}\}) = \sum_{k=1}^{n} \min_{\lambda_{x,k}, \lambda_{y,k} > 0} g_{\varepsilon, \tau, +}(\lambda_{x,k}, \lambda_{y,k}; \lambda_{\mu,i}, \lambda_{\nu,j}) + \\
\sum_{k=n+1}^{m} \min_{\lambda_{x,k} > 0} h_{\varepsilon, \tau}(\lambda_{x,k}, \lambda_{\mu,k}).
\]

Applying Lemma 6, we obtain the stated results. $\square$

**Lemma 5 (Order solutions).** Let $\{a_i\}_{i=1}^{m}$ and $\{b_j\}_{j=1}^{n}$ be positive decreasing sequences. Let $\{\tilde{x}_i\}_{i=1}^{m}$ and $\{\tilde{y}_j\}_{j=1}^{n}$ be the minimizer of
\[
\min_{x_i > 0, y_j > 0} D(\{x_i\}, \{y_j\}; \{a_i\}, \{b_j\}) := \sum_{i=1}^{m} x_i^2 + \sum_{j=1}^{n} y_j^2 + (\tau + \varepsilon)\left\{ \sum_{i=1}^{m} \left[ \frac{x_i}{a_i} - \log(x_i) \right] + \sum_{j=1}^{n} \left[ \frac{y_j}{b_j} - \log(y_j) \right] \right\} \\
- 2\sum_{k=1}^{n} [x_ky_k - \frac{\varepsilon}{2}]^+ + \varepsilon \left[ \log(x_ky_k) - \log \frac{\varepsilon}{2} \right]^+.
\]

Then $\{\tilde{x}_i\}$ and $\{\tilde{y}_j\}$ are also decreasing sequences.

**Proof of Lemma 5.** Let’s consider any permutation $\{\tilde{x}_i\}$ and $\{\tilde{y}_j\}$ of $\{\tilde{x}_i\}$ and $\{\tilde{y}_j\}$, respectively. The difference between $D(\{\tilde{x}_i\}, \{\tilde{y}_j\}; \{a_i\}, \{b_j\})$ and $D(\{\tilde{x}_i\}, \{\tilde{y}_j\}; \{a_i\}, \{b_j\})$ lies in the part
\[
-2 \sum_{k=1}^{n} [x_ky_k - \frac{\varepsilon}{2}]^+ + \varepsilon \left[ \log(x_ky_k) - \log \frac{\varepsilon}{2} \right]^+,
\]
which is actually the minimum value of
\[
-2 \text{tr} \left( K_{xy}^T K_{xy} \right) + 2\varepsilon \text{KL}(\pi \| \hat{\pi} \otimes \hat{\pi}),
\]
where its solution has to match order by magnitude $\{\tilde{x}_i\}$ to $\{\hat{x}_i\}$ and $\{\tilde{y}_j\}$ to $\{\hat{y}_j\}$ of the largest eigenvalues. The part $\sum_{i=1}^{m} \frac{\tilde{x}_i}{a_i} + \sum_{j=1}^{n} \frac{\tilde{y}_j}{b_j}$ is minimized by the rearrangement inequality. Therefore, we obtain the conclusion of the lemma. $\square$

**Lemma 6.** Given $a, b, c > 0$ and given $\Upsilon > 0$, the function
\[
f(x) = \Upsilon x + \tau \text{KL}(x\|a) + \tau \text{KL}(x\|b) + \varepsilon \text{KL}(x\|c)
\]
attains its minimum at
\[
x = a^\frac{\Upsilon}{2\tau + \varepsilon} b^\frac{\Upsilon}{2\tau + \varepsilon} c^\frac{\Upsilon}{2\tau + \varepsilon} \exp \left\{ - \frac{\Upsilon}{2\tau + \varepsilon} \right\}.
\]
Proof of Lemma 6. Taking derivative of $f(x)$

$$f'(x) = Y + \tau \left\{ 2 \log(x) - \log(ab) \right\} + \varepsilon \left\{ \log(x) - \log(c) \right\}$$

Solve the equation $f'(x) = 0$, we obtain

$$x = \exp \left\{ \frac{\tau \log(a) + \tau \log(b) + \varepsilon \log(c) - S}{2\tau + \varepsilon} \right\} = a^{\frac{\tau}{2\tau + \varepsilon}} b^{\frac{\tau}{2\tau + \varepsilon}} e^{\frac{\tau}{2\tau + \varepsilon}} \exp \left\{ - \frac{Y}{2\tau + \varepsilon} \right\}.$$

As a consequence, we reach the conclusion of the lemma. \hfill \Box

5 \hspace{1cm} (Entropic) Gromov-Wasserstein Barycenter of Gaussian distributions

In this section, we consider the problem of computing the (entropic) Gromov-Wasserstein barycenter of $n$ Gaussian measures $\mu_1, \ldots, \mu_n$ defined in spaces of various dimensions. To tackle this problem, we need to fix the desired dimension of a barycenter, e.g., $d$, and choose beforehand the positive weighting coefficients $\alpha_1, \ldots, \alpha_n$ ($\sum_{\ell=1}^n \alpha_\ell = 1$) associated with the measures $\mu_1, \ldots, \mu_n$. We introduce the following definition of a barycenter of positive measures under the inner-product GW distance.

**Definition 1** (Inner product Gromov-Wasserstein barycenter). Let $\mu_\ell$ be a positive measure for $\ell = 1, 2, \ldots, n$ in $\mathbb{R}^{m_\ell}$. Let $\alpha_\ell$ be positive constants such that $\sum_{\ell=1}^n \alpha_\ell = 1$. The inner product Gromov-Wasserstein (IGW) barycenter of $\{\mu_\ell, \alpha_\ell\}_{\ell=1}^n$ is defined as the probability distribution of the random multivariate $Y$ in $\mathbb{R}^d$ which is the solution of the following problem

$$\arg \min_{X_\ell \sim \mu_\ell; \dim(Y) = d; (X_\ell, Y) \sim \pi_{\ell/y}; (X'_\ell, Y) \sim \pi_{\ell/y}} \sum_{\ell=1}^n \alpha_\ell \mathbb{E}_{\pi_{\ell/y}} \left\{ \| (X_\ell, X'_\ell) - (Y, Y') \|^2 \right\}, \quad (9)$$

where in the above minimum, $\{X'_\ell\}$ and $\{X_\ell\}$ are i.i.d. random vectors and $Y$ and $Y'$ are i.i.d. random vectors.

Based on this definition, the following theorem provides a closed-form expression for an IGW barycenter of $n$ Gaussian measures.

**Theorem 3** (Inner product Gromov-Wasserstein barycenter). Let $\mu_\ell = \mathcal{N}(\mathbf{0}, \Sigma)$ be Gaussian distribution for $\ell = 1, 2, \ldots, n$, where $\Sigma$ is an $m_\ell \times m_\ell$ positive definite matrix, which has the form $\operatorname{diag}(\lambda_{\ell,i}) : i = 1, \ldots, m_\ell$. Let $d$ be a positive integer and assume that $d \leq \max_{\ell=1}^n m_\ell$, the IGW barycenter of the formulation (9) has the form: $\mu^* = \mathcal{N}(\mathbf{0}, \Sigma_{\mu^*})$, where

$$\Sigma_{\mu^*} = \operatorname{diag}(\lambda_{\mu^*, j}); \quad j = 1, \ldots, d,$$

in which $\lambda_{\mu^*, j} = \sum_{\ell=1}^n \alpha_\ell \lambda_{\ell,j} 1_{j \leq m_\ell}$.

**Proof of Theorem 3.** Let $K_{\ell\mu}$ be the covariance matrix between $X_\ell$ and $Y$ and $\Sigma_y$ be covariance matrix of $Y$. Let $\lambda_{\ell,i}$ be the $i$th eigenvalue of $\Sigma_\ell$. Let $\lambda_{y,i}$ be the $i$th eigenvalue of $\Sigma_y$. Then the objective function is equal to

$$\sum_{\ell=1}^n \alpha_\ell \left\{ \sum_{i=1}^d \lambda_{y,i}^2 - 2 \operatorname{tr} \left( K_{\ell y} K_{\ell y}^T \right) + \sum_{j=1}^{m_\ell} \lambda_{\ell,j}^2 \right\}. \quad (9)$$
By Lemma 1 part (c), we have
\[ \text{tr}(K_{\ell y}^T K_{\ell y}) \leq \sum_{j=1}^{\min\{d,m\}} \lambda_{y,j} \lambda_{\ell,j}, \]
where the equality happens when \((X_\ell)_j = \sqrt{\lambda_{\ell,j}} Z_j\) and \(Y_j = \sqrt{\lambda_{y,j}} Z_j\) with the \(Z_j\) are i.i.d. standard normal random variables.

Thus the problem now is reduced to minimize
\[ \sum_{\ell=1}^{n} \alpha_{\ell} \left\{ \sum_{j=1}^{d} \lambda_{y,j}^2 - 2 \sum_{j=1}^{\min\{d,m\}} \lambda_{y,j} \lambda_{\ell,j} \right\} = \sum_{j=1}^{d} \left\{ \lambda_{y,j}^2 - 2 \lambda_{y,j} \sum_{\ell=1}^{n} \alpha_{\ell} \lambda_{\ell,j} 1_{j \leq m} \right\}. \]

It has a quadratic form, so the quantity attains its minimum at
\[ \lambda_{y,j} = \sum_{\ell=1}^{n} \alpha_{\ell} \lambda_{\ell,j} 1_{j \leq m}; \quad j = 1, 2, \ldots, d. \]

As a consequence, we obtain the conclusion of the theorem. \(\square\)

Subsequently, we define the formulation of a barycenter of positive measures using the entropic IGW distance.

**Definition 2** (Entropic inner product Gromov-Wasserstein barycenter). Let \(\mu_\ell\) be a positive measure for \(\ell = 1, 2, \ldots, n\) in \(\mathbb{R}^{m_\ell}\). Let \(\alpha_{\ell}\) be positive constants such that \(\sum_{\ell=1}^{n} \alpha_{\ell} = 1\). The entropic regularized Gromov-Wasserstein barycenter is defined as the probability distribution of the random multivariate \(Y\) in \(\mathbb{R}^d\) which is the solution of the following problem

\[ \arg \min_{X_\ell \sim \mu_\ell; \dim(Y)=d; \ Y \sim \mu; \ (X_\ell,Y) \sim \pi_{\ell,Y}; \ (X_{\ell}',Y) \sim \pi_{\ell,Y}} \sum_{\ell=1}^{k} \alpha_{\ell} \mathbb{E}_{\pi_{\ell,Y}} \left\{ \left[ \langle X_\ell, X_{\ell}' \rangle - \langle Y, Y' \rangle \right]^2 + \varepsilon \text{KL} (\pi_{\ell,Y} \| \mu_\ell \otimes \mu) \right\}, \quad (10) \]

where in the above minimum, \(\{X_\ell\}\) and \(\{X_\ell\}\) are i.i.d. random vectors and \(Y\) and \(Y'\) are i.i.d. random vectors.

From that definition, we have the following result for the entropic IGW barycenter of \(n\) Gaussian distributions.

**Theorem 4** (Entropic regularized Gromov-Wasserstein barycenter). Let \(\mu_\ell = \mathcal{N}(0, \Sigma_\ell)\) be Gaussian distribution for \(\ell = 1, 2, \ldots, n\), where \(\Sigma_\ell\) is an \(m_\ell \times m_\ell\) positive definite matrix, which has the form \(\text{diag}(\lambda_{\ell,i}) : i = 1, \ldots, m_\ell\). Let \(d\) be a positive integer such that \(d \leq \max_{\ell \in [n]} m_\ell\). Define \(d_\ell = \min\{d,m_\ell\}\). Let \(\varepsilon\) be a positive constant satisfying the following conditions:

\[ \varepsilon \leq 2 \lambda_{\ell,j} \left\{ A_j + (A_j^2 - \varepsilon B_j)^{\frac{1}{2}} \right\}; \quad \ell = 1, 2, \ldots, n; \quad j = 1, 2, \ldots, d; \quad (11) \]

and \(A_j^2 \geq \varepsilon B_j\), where \(A_j = \sum_{\ell=1}^{n} \alpha_{\ell} \lambda_{\ell,j} 1_{j \leq d_\ell}\) and \(B_j = \sum_{\ell=1}^{n} \alpha_{\ell} 1_{j \leq d_\ell}\). Then, a barycenter of the formulation (10) has the form: \(\mu^* = \mathcal{N}(0, \Sigma_{\mu^*})\), with \(\Sigma_{\mu^*}\) is a diagonal matrix, in which its \(j\)th diagonal element has the form

\[ \lambda_{\mu^*,j} = \sum_{\ell=1}^{n} \alpha_{\ell} \lambda_{\ell,j} 1_{j \leq d_\ell} \left\{ 1 - \frac{\varepsilon}{\lambda_{\ell,j} \left[ A_j + (A_j^2 - \varepsilon B_j)^{\frac{1}{2}} \right]} \right\}. \]
Remark 2. In the above theorem, we need a set of conditions for \( \varepsilon \), they could be satisfied when \( \varepsilon \) is small, which is often chosen in practice. When \( \varepsilon \) is not small, then the reader could follow the guideline in Lemma 7 to find the covariance matrix \( \Sigma_{\mu^*} \).

Proof of Theorem 4. Let \( \Sigma_{\ell,y} \) be the covariance matrix of \( \pi_{\ell,y} \) and \( \Sigma_{\ell \otimes y} \) be the covariance matrix of \( \mu_{\ell} \otimes \mu \) where the entropic term is equal to

\[
\frac{\varepsilon}{2} \left\{ \text{tr}(\Sigma_{\ell,y} \Sigma_{\ell \otimes y}^{-1}) + \log \left( \frac{\det(\Sigma_{\ell \otimes y})}{\det(\Sigma_{\ell,y})} \right) - d \right\} = \frac{\varepsilon}{2} \log \left( \frac{\det(\Sigma_{\ell \otimes y})}{\det(\Sigma_{\ell,y})} \right).
\]

The problem is reduced to minimize

\[
\sum_{j=1}^{d} \lambda_{y,j}^2 - 2 \sum_{\ell=1}^{n} \alpha_{\ell} \text{tr} \left( K_{\ell}^T K_{\ell} \right) + 2 \sum_{\ell=1}^{n} \alpha_{\ell} \varepsilon \log \left( \frac{\det(\Sigma_{\ell \otimes y})}{\det(\Sigma_{\ell,y})} \right).
\]

Note that \( \Sigma_{\ell} \) and \( \Sigma_{y} \) are diagonal matrices. Use the same approach of Lemma 1, we decompose \( K_{\ell y} \) as

\[
K_{\ell y} = \Sigma_{\ell y}^{\frac{1}{2}} U_{\ell y} \Lambda_{\ell y} \Sigma_{\ell y}^{\frac{1}{2}}
\]

with the \( j \)th singular values of \( \Lambda_{\ell y} \) denoted by \( \kappa_{\ell y,j} \). Then, we find that

\[
\log \left( \frac{\det(\Sigma_{\ell \otimes y})}{\det(\Sigma_{\ell,y})} \right) = - \sum_{j=1}^{d_{\ell}} \log(1 - \kappa_{\ell y,j}).
\]

Similarly as in Lemma 1, we have

\[
\text{tr}(K_{\ell y}^T K_{\ell y}) = \text{tr} \left( \Sigma_{\ell y}^{\frac{1}{2}} U_{\ell y} \Lambda_{\ell y} \Sigma_{\ell y}^{\frac{1}{2}} \Sigma_{\ell \otimes y} \Lambda_{\ell y} \Sigma_{\ell y}^{\frac{1}{2}} \right)
\]

\[
= \text{tr} \left( \left[ V_{\ell y} \Lambda_{\ell y} \right] \times \left[ U_{\ell y} \Sigma_{\ell} \right] \times \left[ U_{\ell} \Lambda_{\ell} \right] \times \left[ V_{\ell y} \Sigma_{\ell y} \right] \right)
\]

\[
\leq \sum_{j=1}^{d_{\ell}} \lambda_{\ell,j} \lambda_{y,j} \kappa_{\ell y,j}
\]

by the von Neumann’s inequality with a note that all \( \Lambda_{\ell y}, \Sigma_{y} \) and \( \Sigma_{\ell} \) are diagonal matrices. The inequality become equality when \( V_{\ell y} \) and \( U_{\ell y} \) are diagonal matrices of one.

Put the above results together, the objective function of entropic IGW is reduced to

\[
\sum_{j=1}^{d} \lambda_{y,j}^2 - \sum_{\ell=1}^{n} 2\alpha_{\ell} \sum_{t=1}^{\ell} \lambda_{\ell,t} \kappa_{\ell y,t} \lambda_{y,t} - \frac{\varepsilon}{2} \sum_{\ell=1}^{n} \alpha_{\ell} \sum_{t=1}^{\ell} \log(1 - \kappa_{\ell y,t})
\]

\[
= \sum_{j=1}^{n} \left\{ \lambda_{y,j}^2 - 2\lambda_{y,j} \sum_{\ell=1}^{n} \alpha_{\ell} \lambda_{\ell,j} \kappa_{\ell y,j} 1_{j \leq d_{\ell}} \right\} - \frac{\varepsilon}{2} \sum_{\ell=1}^{n} \alpha_{\ell} \sum_{t=1}^{\ell} \log(1 - \kappa_{\ell y,t}).
\]

This quantity attains its minimum at

\[
\lambda_{y,j} = \sum_{\ell=1}^{n} \alpha_{\ell} \lambda_{\ell,j} \kappa_{\ell y,j} 1_{j \leq d_{\ell}}.
\]
Therefore, the problem of entropic IGW is equivalent to find the maximum of

\[
\sum_{j=1}^{d} \left[ \sum_{\ell=1}^{n} \alpha_{\ell} \kappa_{\ell,j} \mathbf{1}_{j \leq d_{\ell}} \right]^2 + \frac{\varepsilon}{2} \sum_{\ell=1}^{n} \sum_{j=1}^{d_{\ell}} \alpha_{\ell} \log(1 - \kappa_{\ell,j}) \\
= \sum_{j=1}^{d} \left( \sum_{\ell=1}^{n} \alpha_{\ell} \kappa_{\ell,j} \mathbf{1}_{j \leq d_{\ell}} \right)^2 + \frac{\varepsilon}{2} \sum_{\ell=1}^{n} \alpha_{\ell} \log(1 - \kappa_{\ell,j}) \mathbf{1}_{j \leq d_{\ell}}
\]

where \( d_{\ell} = \min\{m_{\ell}, d\} \). We need to maximize each term, which is

\[
\left[ \sum_{\ell=1}^{n} \alpha_{\ell} \kappa_{\ell,j} \mathbf{1}_{j \leq d_{\ell}} \right]^2 + \frac{\varepsilon}{2} \sum_{\ell=1}^{n} \alpha_{\ell} \log(1 - \kappa_{\ell,j}) \mathbf{1}_{j \leq d_{\ell}}
\]

under the constraints that \( 0 \leq \kappa_{\ell,j} \leq 1 \). By Lemma 7, and when \( \varepsilon \) satisfying the condition (11) for \( j \leq \min\{d, m_{\ell}\} \), we have

\[
\kappa_{\ell,j} = 1 - \frac{\varepsilon}{2\lambda_{\ell,j} \left\{ A_j + \sqrt{A_j^2 - \varepsilon B_j} \right\}},
\]

where \( A_j = \sum_{\ell=1}^{n} \alpha_{\ell} \kappa_{\ell,j} \mathbf{1}_{j \leq d_{\ell}} \) and \( B_j = \sum_{\ell=1}^{n} \alpha_{\ell} \mathbf{1}_{j \leq d_{\ell}} \). As a consequence, we reach the conclusion of the theorem.

**Lemma 7.** Let \( \{a_s\}_1^s \) and \( \{b_i\}_1^s \) be positive sequences. The problem of finding the maximum value of

\[
\left\{ \sum_{i=1}^{s} a_i x_i \right\}^2 + \sum_{i=1}^{s} b_i \log(1 - x_i)
\]

where \( x_i \in [0, 1] \) is equivalent to find the set \( S \subset [s] \) in the below problem:

\[
\max_{S \subset [s]} \left\{ A_S - \frac{B_S}{2(A_S + (A_S^2 - B_S)^{\frac{1}{2}})} \right\}^2 + \sum_{i \in S} b_i \log(b_i) - B_S \log \left( A_S + (A_S^2 - B_S)^{\frac{1}{2}} \right),
\]

where \( A_S = \sum_{i \in S} a_i, B_S = \sum_{i \in S} b_i \) and \( A_S^2 \geq B_S \) and

\[
b_i \leq 2a_i \left\{ A_S + (A_S^2 - B_S)^{\frac{1}{2}} \right\}; \quad i \in S.
\]

**Proof of Lemma 7.** Note that the function \( f(x) = (ax + b)^2 + c \log(1 - x) \) in \([0, 1]\) has derivative

\[
f'(x) = 2a(ax + b) - \frac{c}{1 - x}.
\]

The equation \( f'(x) = 0 \) has either two solutions or no solution. It means that either \( f(x) \) is monotone or it has one minimum and one maximum. When \( x \to 1^- \), \( f(x) \) diverges to infinity. Thus, the \( x_{\max} \) where function \( f \) attains its maximum is closer to 1 than the \( x_{\min} \) where \( f \) attains its minimum. In the second case, \( f \) is monotone, then \( f \) is monotone decreasing, because \( f(0) = 0 \) and \( f(1^-) = -\infty \). Overall,

\[
x_{\max} = \begin{cases} 0 & \text{the larger solution of equation: } 2a(ax + b) = \frac{c}{1 - x}. \end{cases}
\]
Hence, if \( \{\tilde{x}_i\} \) is a maximiser of the objective function, then either \( \tilde{x}_i = 0 \) or \( \tilde{x}_i \) is the larger solution of the first derivative system of equations.

We consider the case of all \( \tilde{x}_i \) are not equal to zero. By taking the derivative with respect to \( x_i \), we obtain

\[
2a_i \left\{ \sum_{j=1}^{s} a_j \tilde{x}_j \right\} - \frac{b_i}{2} \frac{1}{1 - \tilde{x}_i} = 0,
\]

\[
4 \left\{ a_i - a_i \tilde{x}_i \right\} \times \left\{ \sum_{j=1}^{s} a_j \tilde{x}_j \right\} = b_i,
\]

\[
4 \left\{ \sum_{j=1}^{s} a_j - \sum_{j=1}^{s} a_j, \tilde{x}_j \right\} \times \left\{ \sum_{j=1}^{s} a_j \tilde{x}_j \right\} = \sum_{j=1}^{s} b_j.
\]

Denote \( A = \sum_{j=1}^{s} a_j \) and \( B = \sum_{j=1}^{s} b_j \), then solve the quadratic equation, we have

\[
\sum_{j=1}^{s} a_j \tilde{x}_j = \frac{1}{2} \left\{ A + \sqrt{A^2 - B} \right\}.
\]

Substituting it into the above equation, we obtain

\[
4 a_i (1 - \tilde{x}_i) = \frac{2b_i}{A + \sqrt{A^2 - B}},
\]

\[
\tilde{x}_i = 1 - \frac{b_i}{2a_i (A + \sqrt{A^2 - B})}.
\]

Then the minimum value of the objective function in this case equals

\[
\left\{ \sum_{i=1}^{s} a_i - \frac{1}{2(A + \sqrt{A^2 - B})} \sum_{i=1}^{s} b_i \right\}^2 + \sum_{i=1}^{s} b_i \log(b_i) - \log (A + \sqrt{A^2 - B}) \sum_{i=1}^{s} b_i.
\]

The problem is equivalent to finding a subset \( S \) such that the above quantity is maximized. \( \square \)

6 Conclusion

In this paper, we provide a comprehensive study of the entropic (unbalanced) inner product Gromov-Wasserstein (IGW) between (unbalanced) Gaussian distributions. We demonstrate that the optimal transportation plan is (unbalanced) Gaussian distribution. Based on that result and a novel application of von Neumann’s trace inequality, we derive the closed-form expression for the entropic (unbalanced) IGW between these distributions. Finally, we also consider the (entropic) Gromov-Wasserstein barycenter problem of multiple Gaussian measures. We prove that the barycenter is also a Gaussian distribution when the entropic regularization parameter is small and obtain the closed-form expression for the covariance matrix of the barycenter.

A Omitted Proofs

In this appendix, we discuss how to derive a closed-form formulation for \( \Upsilon^* \) in Theorem 2. It is equivalent to solving the minimizers of function \( g_{\varepsilon,\tau,+} \) in the following lemma.

Lemma 8 (Minimizer of \( g_{\varepsilon,\tau,+} \)). Let

\[
g_{\varepsilon,\tau,+}(x, y; a, b) := x^2 + y^2 + (\tau + \varepsilon)\left(\frac{x}{a} + \frac{y}{b} - \log\left(\frac{xy}{ab}\right) - 2\right) - 2\left(xy - \frac{\varepsilon}{2}\right) + \varepsilon\left[\log(xy) - \log\left(\frac{\varepsilon}{2}\right)\right].
\]

We define

\[
g_{\varepsilon,\tau,-1}(x, y; a, b) := x^2 + y^2 + (\tau + \varepsilon)\left[\frac{x}{a} + \frac{y}{b} - \log\left(\frac{xy}{ab}\right) - 2\right],
\]

\[
g_{\varepsilon,\tau,1}(x, y; a, b) := x^2 + y^2 + (\tau + \varepsilon)\left[\frac{x}{a} + \frac{y}{b} - \log\left(\frac{xy}{ab}\right) - 2\right] - 2(xy - \frac{\varepsilon}{2}) + \varepsilon\left[\log(xy) - \log\left(\frac{\varepsilon}{2}\right)\right],
\]

\[
(\hat{x}, \hat{y}) = \arg\min_{x,y>0} g_{\varepsilon,\tau,-1}(x, y; a, b),
\]

\[
(\hat{x}, \hat{y}) = \arg\min_{x,y>0} g_{\varepsilon,\tau,1}(x, y; a, b),
\]

\[
(x^*, y^*) = \arg\min_{x,y>0} g_{\varepsilon,\tau,+}(x, y; a, b).
\]

Then if \( x\hat{y} < \frac{\varepsilon}{2} \), then \((x^*, y^*) = (\hat{x}, \hat{y})\) where solutions are in Lemma 9, and if otherwise, then \((x^*, y^*) = (\hat{x}, \hat{y})\), where solutions are in Lemma 10.

Proof of Lemma 8. By definition of functions \( g_{\varepsilon,\tau,1} \), \( g_{\varepsilon,\tau,-1} \) and \( g_{\varepsilon,\tau,+} \), we have

\[
g_{\varepsilon,\tau,+}(x, y; a, b) = \frac{g_{\varepsilon,\tau,-1}(x, y; a, b)1_{\{xy < \frac{\varepsilon}{2}\}} + g_{\varepsilon,\tau,1}(x, y; a, b)1_{\{xy \geq \frac{\varepsilon}{2}\}}}{2}.
\]

We observe that both functions \( g_{\varepsilon,\tau,1} \) and \( g_{\varepsilon,\tau,-1} \) are convex functions. Moreover, we have

\[
g_{\varepsilon,\tau,-1}(x, y; a, b) - g_{\varepsilon,\tau,1}(x, y; a, b) = 2(xy - \frac{\varepsilon}{2}) - \varepsilon\left[\log(xy) - \log\left(\frac{\varepsilon}{2}\right)\right]
\]

\[
= \varepsilon\left(\frac{xy}{\varepsilon/2} - 1 - \log\left(\frac{xy}{\varepsilon/2}\right)\right) \geq 0.
\]

It means that \( g_{\varepsilon,\tau,-1}(x, y; a, b) \geq g_{\varepsilon,\tau,1}(x, y; a, b) \).

Next, we prove that \( \frac{\varepsilon}{2} \) cannot lie between \( \hat{x} \cdot \hat{y} \) and \( \bar{x} \cdot \bar{y} \). Assume the contradictory, then in the segment connecting \((\hat{x}, \hat{y})\) to \((\bar{x}, \bar{y})\) cuts the hyperpole \( xy = \frac{\varepsilon}{2} \) at a point with coordinates denoted by \((\bar{x}, \bar{y})\). Since \( g_{\varepsilon,\tau,1} \) is a convex function, we have

\[
\max\left\{g_{\varepsilon,\tau,1}(\bar{x}, \bar{y}; a, b), g_{\varepsilon,\tau,1}(\hat{x}, \hat{y}; a, b)\right\} > g_{\varepsilon,\tau,1}(\bar{x}, \bar{y}; a, b).
\]

Moreover, we find that

\[
g_{\varepsilon,\tau,1}(\bar{x}, \bar{y}; a, b) \geq g_{\varepsilon,\tau,1}(\hat{x}, \hat{y}; a, b)
\]

\[
g_{\varepsilon,\tau,1}(\bar{x}, \bar{y}; a, b) = g_{\varepsilon,\tau,-1}(\bar{x}, \bar{y}; a, b) \geq g_{\varepsilon,\tau,-1}(\hat{x}, \hat{y}; a, b) \geq g_{\varepsilon,\tau,1}(\bar{x}, \bar{y}; a, b).
\]

It contradicts inequality (12). Thus, both \( \hat{x} \hat{y} \) and \( \bar{x} \bar{y} \) have to be greater or smaller than \( \frac{\varepsilon}{2} \) at the same time. Given that, we have two separate cases:
Case 1: They are both greater than $\frac{\varepsilon}{2}$, then
\[
g_{\varepsilon, \tau, -1}(x, y; a, b) \geq g_{\varepsilon, \tau, -1}(\tilde{x}, \tilde{y}; a, b) \geq g_{\varepsilon, \tau, -1}(\tilde{x}, \tilde{y}; a, b) \geq g_{\varepsilon, \tau, -1}(x, y; a, b).
\]
It means that $\tilde{x} = x^*$ and $\tilde{y} = y^*$.

Case 2: Both of them are smaller than $\frac{\varepsilon}{2}$. For any $(x, y)$ such that $xy \geq \frac{\varepsilon}{2}$, there exists $(\overline{x}, \overline{y})$ lies in the segment connecting $(x, y)$ to $(\tilde{x}, \tilde{y})$ such that $\overline{x} \cdot \overline{y} = \frac{\varepsilon}{2}$. Since the function $g_{\varepsilon, \tau, 1}$ is convex, we find that
\[
t g_{\varepsilon, \tau, 1}(\tilde{x}, \tilde{y}; a, b) + (1 - t) g_{\varepsilon, \tau, 1}(x, y; a, b) \geq g_{\varepsilon, \tau, 1}(\overline{x}, \overline{y}; a, b),
\]
where $t = \frac{\| (\overline{x}, \overline{y}) - (\tilde{x}, \tilde{y}) \|^2}{\| (x, y) - (\tilde{x}, \tilde{y}) \|^2}$. However, $g_{\varepsilon, \tau, 1}(\tilde{x}, \tilde{y}; a, b) \leq g_{\varepsilon, \tau, 1}(x, y; a, b)$, it means that
\[
g_{\varepsilon, \tau, 1}(x, y; a, b) \geq g_{\varepsilon, \tau, 1}(\overline{x}, \overline{y}; a, b) = g_{\varepsilon, \tau, -1}(\overline{x}, \overline{y}; a, b) \geq g_{\varepsilon, \tau, -1}(\tilde{x}, \tilde{y}; a, b).
\]
It means that $\tilde{x} = x^*$ and $\tilde{y} = y^*$. As a consequence, we obtain the conclusion of the lemma.

\[
\text{Lemma 9 (Minimizer of function } g_{\varepsilon, \tau, -1}) \text{. With } a, b \geq 0, \text{ let}
\]
\[
g_{\varepsilon, \tau, -1}(x, y; a, b) = x^2 + y^2 + (\tau + \varepsilon) \left( \frac{x}{a} + \frac{y}{b} - \log(xy) - \log(ab) \right)
\]
subjected to $x, y > 0$. Let $(\tilde{x}, \tilde{y}) = \arg \min_{x, y} g_{\varepsilon, \tau, -1}$. Then,
\[
\tilde{x} = -\frac{\tau + \varepsilon}{4a} + \frac{1}{2} \sqrt{2(\tau + \varepsilon) + \frac{(\tau + \varepsilon)^2}{4a^2}}, \quad \tilde{y} = -\frac{\tau + \varepsilon}{4b} + \frac{1}{2} \sqrt{2(\tau + \varepsilon) + \frac{(\tau + \varepsilon)^2}{4b^2}}.
\]

\[
\text{Proof of Lemma 9. 1. Taking the derivative with respect to } x \text{ and } y \text{ of } g_{\varepsilon, \tau, -1},
\]
\[
\frac{\partial g_{\varepsilon, \tau, -1}}{\partial x} = 2x + \frac{\tau + \varepsilon}{a} - \frac{\tau + \varepsilon}{x}, \quad \frac{\partial g_{\varepsilon, \tau, -1}}{\partial y} = 2y + \frac{\tau + \varepsilon}{b} - \frac{\tau + \varepsilon}{y}.
\]

Thus, we have
\[
\frac{\partial^2 g_{\varepsilon, \tau, -1}}{\partial x^2} = 2 + \frac{\tau + \varepsilon}{x^2}, \quad \frac{\partial^2 g_{\varepsilon, \tau, -1}}{\partial x \partial y} = 0, \quad \frac{\partial^2 g_{\varepsilon, \tau, -1}}{\partial y^2} = 2 + \frac{\tau + \varepsilon}{y^2}.
\]
The Hessian matrix is positive definite, so this function is a convex function.

2. Solving the equations $\frac{\partial g_{\varepsilon, \tau, -1}}{\partial x} = 0, \frac{\partial g_{\varepsilon, \tau, -1}}{\partial y} = 0$, we have
\[
\tilde{x} = -\frac{\tau + \varepsilon}{4a} + \frac{1}{2} \sqrt{2(\tau + \varepsilon) + \frac{(\tau + \varepsilon)^2}{4a^2}}, \quad \tilde{y} = -\frac{\tau + \varepsilon}{4b} + \frac{1}{2} \sqrt{2(\tau + \varepsilon) + \frac{(\tau + \varepsilon)^2}{4b^2}}.
\]
Therefore, we reach the conclusion of the lemma.

\[
\text{Lemma 10 (Minimizer of function } g_{\varepsilon, \tau, 1}) \text{. Let}
\]
\[
g_{\varepsilon, \tau, 1}(x, y; a, b) = x^2 + y^2 + \varepsilon \left( \log(xy) - \log \left( \frac{x}{a} \right) - 2 \left( \frac{y}{b} - \log \left( \frac{y}{ab} \right) - 2 \right) \right),
\]
subjected to $a, b > 0$. Define $(\hat{x}, \hat{y}) = \text{arg min}_{x, y > 0} g_{\varepsilon, \tau, 1}$. Then the value of $(\hat{x}, \hat{y})$ are given in the following equations.

$$
\hat{x} = -\frac{\tau + \varepsilon}{4a} + \frac{1}{2} \sqrt{\left(\frac{\tau + \varepsilon}{4a^2}\right)^2 + 4\tau \left(\frac{1}{2} + \frac{1}{\hat{z}}\right)}; \quad \hat{y} = -\frac{\tau + \varepsilon}{4b} + \frac{1}{2} \sqrt{\left(\frac{\tau + \varepsilon}{4b^2}\right)^2 + 4\tau \left(\frac{1}{2} + \frac{1}{\hat{z}}\right)},
$$

where $\hat{z}$ is the unique positive root of the equation

$$
\tau z^3 + \left(8\tau - \frac{(\tau + \varepsilon)^2}{ab}\right)z^2 + \left(16\tau - 2(\tau + \varepsilon)^2 \left(\frac{1}{a} + \frac{1}{b}\right)^2\right)z - 4(\tau + \varepsilon)^2 \left(\frac{1}{a} + \frac{1}{b}\right)^2 = 0.
$$

Proof. Taking the first derivative with respect to $x$ and $y$ of $g_{\varepsilon, \tau, 1}$, we have

$$
\frac{\partial g_{\varepsilon, \tau, 1}}{\partial x} = 2x - 2y + \frac{\tau + \varepsilon}{a} - \frac{\tau}{x}, \quad \frac{\partial g_{\varepsilon, \tau, 1}}{\partial y} = 2y - 2x + \frac{\tau + \varepsilon}{b} - \frac{\tau}{y}.
$$

Thus, we have

$$
\frac{\partial^2 g_{\varepsilon, \tau, 1}}{\partial x^2} = 2 + \frac{\tau}{2x^2}, \quad \frac{\partial^2 g_{\varepsilon, \tau, 1}}{\partial x \partial y} = -2, \quad \frac{\partial^2 g_{\varepsilon, \tau, 1}}{\partial y^2} = 2 + \frac{\tau}{y^2}.
$$

Thus, the Hessian matrix of this function is positive definite, which implies that the function is convex.

The equations of the stationary point give us

$$
2\hat{x} - 2\hat{y} + \frac{\tau + \varepsilon}{a} - \frac{\tau}{x} = 0; \quad 2\hat{y} - 2\hat{x} + \frac{\tau + \varepsilon}{b} - \frac{\tau}{y} = 0.
$$

Taking the sum of both equations leads to

$$
\frac{\tau + \varepsilon}{a} + \frac{\tau + \varepsilon}{b} = \frac{\tau}{x} + \frac{\tau}{y} \iff \tau \left(\frac{1}{a} + \frac{1}{b} - \frac{1}{a} - \frac{1}{b}\right) = \frac{\varepsilon}{a} + \frac{\varepsilon}{b}.
$$

$$
\begin{aligned}
2(\hat{x} - \hat{y}) + \frac{\tau + \varepsilon}{a} &= \frac{\tau}{x} \\
2(\hat{y} - \hat{x}) + \frac{\tau + \varepsilon}{b} &= \frac{\tau}{y}.
\end{aligned}
$$

Taking the difference between two equations, we get

$$
(\hat{x} - \hat{y}) \left(4 + \frac{\tau}{x y}\right) = \frac{\tau + \varepsilon}{b} - \frac{\tau + \varepsilon}{a}.
$$

Let $z = \frac{\tau}{x y}$, we have $\hat{x} - \hat{y} = (\tau + \varepsilon) \frac{1/b - 1/a}{4 + z}$. Take the product of two equations, we have

$$
\left(2(\hat{x} - \hat{y}) + \frac{\tau + \varepsilon}{a}\right) \left(2(\hat{y} - \hat{x}) + \frac{\tau + \varepsilon}{b}\right) = \frac{\tau^2}{x y}
$$

Substitute $\hat{x} - \hat{y} = (\tau + \varepsilon) \frac{1/b - 1/a}{4 + z}$, we obtain

$$
(\tau + \varepsilon)^2 \left[2\left(\frac{1}{a} + \frac{1}{b}\right) + \frac{z}{a}\right] \left[2\left(\frac{1}{a} + \frac{1}{b}\right) + \frac{z}{b}\right] = \tau z(z + 4)^2,
$$

19
which is equal to a cubic equation

\[ t(z) := \tau z^3 + \left( 8\tau - \frac{(\tau + \varepsilon)^2}{ab} \right) z^2 + \left( 16\tau - 2(\tau + \varepsilon)\left(\frac{1}{a} + \frac{1}{b}\right)^2 \right) z - 4(\tau + \varepsilon)^2\left(\frac{1}{a} + \frac{1}{b}\right)^2 = 0. \]

It is cubic equation, then it has either three real roots or one real root. In the first case, we know that it has at least one positive root, since the highest coefficient of the equation is positive. Assume that it has another two positive root. By applying Viete’s theorem, we get

\[ 8\tau - \frac{(\tau + \varepsilon)^2}{ab} < 0; \quad 16\tau - 2(\tau + \varepsilon)^2\left(\frac{1}{a} + \frac{1}{b}\right)^2 > 0, \]

which implies that \( \left(\frac{1}{a} + \frac{1}{b}\right)^2 < \frac{2}{ab} \), it is contradiction by Cauchy-Schwarz’s inequality. Thus, \( z \) is the unique positive root of \( t(z) = 0 \), which we denote by \( \hat{z} \).

With \( \hat{z} = \frac{\tau}{\hat{x}\hat{y}} \), we have \( \hat{x}\hat{y} = \frac{\tau}{\hat{z}} \). Substituting it to the system of equation (13), we have

\[
\begin{align*}
\hat{x}^2 + \frac{\tau + \varepsilon}{2a} \hat{x} &= \frac{\tau}{\hat{z}} + \frac{\tau}{2}, \\
\hat{y}^2 + \frac{\tau + \varepsilon}{2b} \hat{y} &= \frac{\tau}{\hat{z}} + \frac{\tau}{2}.
\end{align*}
\]

This implies that

\[
\hat{x} = -\frac{\tau + \varepsilon}{4a} + \frac{1}{2} \sqrt{\frac{(\tau + \varepsilon)^2}{4a^2} + 4\tau \left(\frac{1}{2} + \frac{1}{\hat{z}}\right)}, \quad \hat{y} = -\frac{\tau + \varepsilon}{4b} + \frac{1}{2} \sqrt{\frac{(\tau + \varepsilon)^2}{4b^2} + 4\tau \left(\frac{1}{2} + \frac{1}{\hat{z}}\right)}.
\]

As a consequence, we obtain the conclusion of the lemma.

\[ \square \]

### B Auxiliary results

In this section, we provide additional lemmas that are used to derive the closed-form expressions of entropic (unbalanced) IGW between (unbalanced) Gaussian distributions.

**Lemma 11.** The Kullback-Leibler divergence between Gaussian measures on \( \mathbb{R}^n \) is

\[
\text{KL}(\mathcal{N}(\mu_\alpha, \Sigma_\alpha), \mathcal{N}(\mu_\beta, \Sigma_\beta)) = \frac{1}{2} \left( \text{trace}(\Sigma_\beta^{-1}\Sigma_\alpha) + (\mu_\beta - \mu_\alpha)^\top \Sigma_\alpha^{-1}(\mu_\beta - \mu_\alpha) - n + \log \left( \frac{\det(\Sigma_\beta)}{\det(\Sigma_\alpha)} \right) \right).
\]

As a result, when \( \Sigma_\beta, \Sigma_\alpha \) are fixed, \( \text{KL}(\mathcal{N}(\mu_\alpha, \Sigma_\alpha), \mathcal{N}(\mu_\beta, \Sigma_\beta)) \) achieves its minimum value when \( \mu_\alpha = \mu_\beta \).

**Lemma 12.** In the family of probability measures with a fixed covariance \( \Sigma \), the one that maximizes the differential entropy is a Gaussian measure, i.e.,

\[
\mathcal{N}(\cdot, \Sigma) = \arg\max_{\pi \in \Pi_\Sigma} H(\pi).
\]
Proof of Lemma 12. Let $\gamma$ be a probability measure with some mean $\mu_\gamma$ and known covariance $\Sigma$, and $\phi = \mathcal{N}(\mu_\gamma, \Sigma)$. Then

$$H(\phi) - H(\gamma) = - \int \phi(x) \log \phi(x) dx + \int \gamma(x) \log \gamma(x) dx$$

$$= - \int \gamma(x) \log \phi(x) dx + \int \gamma(x) \log \gamma(x) dx$$

$$= \int \gamma(x) \log \left( \frac{\gamma(x)}{\phi(x)} \right) dx$$

$$= \text{KL}(\gamma \| \phi)$$

$$\geq 0,$$

where the second equation comes from

$$\int \gamma(x) \log \phi(x) = \int \gamma(x) \left( -\frac{1}{2} \right) \left( \log [(2\pi)^n \det(\Sigma)] + (x - \mu_\gamma)\Sigma^{-1} (x - \mu_\gamma) \right) dx$$

$$= -\frac{1}{2} \log [(2\pi)^n \det(\Sigma)] - \frac{1}{2} \int \gamma(x) (x - \mu_\gamma)\Sigma^{-1} (x - \mu_\gamma) dx$$

$$= -\frac{1}{2} \log [(2\pi)^n \det(\Sigma)] - \frac{n}{2}$$

$$= -H(\phi)$$

$$= \int \phi(x) \log \phi(x) dx,$$

in which the third equality uses the fact that

$$\mathbb{E}_\gamma[(X - \mu_\gamma)\Sigma^{-1}(X - \mu_\gamma)] = \mathbb{E}_\gamma[\text{trace}((X - \mu_\gamma)(X - \mu_\gamma)\Sigma^{-1})]$$

$$= \text{trace}(\mathbb{E}_\gamma[(X - \mu_\gamma)(X - \mu_\gamma)\Sigma^{-1}])$$

$$= \text{trace}(\mathbb{E}_\gamma[(X - \mu_\gamma)(X - \mu_\gamma)])$$

$$= \text{trace}(\mathbb{E}_\gamma[(X - \mu_\gamma)(X - \mu_\gamma)]\Sigma^{-1})$$

$$= \text{trace}(\Sigma\Sigma^{-1})$$

$$= \text{trace}(I_n)$$

$$= n,$$

and the fourth equality comes from the form of the differential entropy of the Gaussian. \qed

Lemma 13. In the family of probability measures with a fixed mean $\mu$ and a fixed covariance $\Sigma$, the one that minimizes the Kullback-Leibler divergence to a Gaussian measure $\phi = \mathcal{N}(0_n, \Sigma_\phi)$ is another Gaussian measure, i.e.,

$$\mathcal{N}(\mu, \Sigma) = \arg\min_{\pi \in \Pi_{\mu, \Sigma}} \text{KL}(\pi \| \phi).$$
Proof. We have

\[
\text{KL}(\pi\|\phi) = \int p_\pi(x) \log \frac{p_\pi(x)}{p_\phi(x)} \, dx \\
= \int p_\pi(x) \log p_\pi(x) \, dx - \int p_\pi(x) \log p_\phi(x) \, dx \\
= -H(\pi) - \int p_\pi(x) \log \left( \frac{\exp \left( -\frac{1}{2} x^\top \Sigma_\phi^{-1} x \right)}{\sqrt{(2\pi)^n \det(\Sigma_\phi)}} \right) \, dx \\
= -H(\pi) - \int p_\pi(x) \log \left( -\frac{1}{2} x^\top \Sigma_\phi^{-1} x \right) \, dx - \log \left( \frac{1}{\sqrt{(2\pi)^n \det(\Sigma_\phi)}} \right) \\
= -H(\pi) - \frac{1}{2} \mathbb{E}_\pi \left[ x^\top \Sigma_\phi^{-1} x \right] + \log \left( \sqrt{(2\pi)^n \det(\Sigma_\phi)} \right) \\
= -H(\pi) + \frac{1}{2} \text{trace} \left( \mathbb{E}_\pi \left[ x x^\top \right] \Sigma_\phi^{-1} \right) + \log \left( \sqrt{(2\pi)^n \det(\Sigma_\phi)} \right) \\
= -H(\pi) + \frac{1}{2} \text{trace} \left( (\Sigma + \mu \mu^\top) \Sigma_\phi^{-1} \right) + \log \left( \sqrt{(2\pi)^n \det(\Sigma_\phi)} \right) \\
= -H(\pi) + \frac{1}{2} \mu^\top \Sigma_\phi^{-1} \mu + \frac{1}{2} \text{trace}(\Sigma \Sigma_\phi^{-1}) + \log \left( \sqrt{(2\pi)^n \det(\Sigma_\phi)} \right),
\]

where the third equality uses the formula of the differential entropy as well as the density Gaussian measure, and the seventh equality comes from the fact that \( \mathbb{E}[x^\top A x] = \text{trace}(\mathbb{E}[x x^\top] A) \) for any matrix \( A \). Regarding the final equality, the last three terms of are constants given \( \mu, \Sigma_\pi \) and \( \Sigma_\phi \), and the maximization of the entropy over a fixed-covariance family results in a Gaussian measure (see Lemma 12)

\[
\mathcal{N}(\cdot, \Sigma) = \arg \max_{\pi \in \Pi_\Sigma} H(\pi).
\]

Combining all the results, we have the claimed form of the optimizer, i.e., \( \mathcal{N}(\mu_\pi, \Sigma) \).
