POST-LIE MAGNUS EXPANSION AND BCH-RECURSION

MAHDI J. HASAN AL-KAABI, KURUSCH EBRAHIMI-FARD, AND DOMINIQUE MANCHON

Abstract. We identify the Baker–Campbell–Hausdorff recursion driven by a weight \( \lambda = 1 \) Rota–Baxter operator with the Magnus expansion relative to the post-Lie structure naturally associated to the corresponding Rota–Baxter algebra.

Keywords: Post-Lie algebra, pre-Lie algebra, Rota–Baxter algebra, Magnus expansion, BCH-formula, rooted trees.

1. Introduction

The well-known Baker–Campbell–Hausdorff (BCH) formula \( \text{BCH}(x, y) \) is a formal power series, which lives in the completion of the free Lie algebra \( \mathcal{L}(x, y) \) generated (over a base field \( K \) of characteristic zero) by the two non-commutating variables \( x \) and \( y \). It is defined by:

\[
\exp(x) \exp(y) = \exp(\text{BCH}(x, y)) = \exp(x + y + \text{BCH}(x, y))
\]

or

\[
\text{BCH}(x, y) = \log(\exp(x) \exp(y)) = x + y + \text{BCH}(x, y).
\]
It plays a prominent role in modern mathematics\textsuperscript{[3, 7]}. A fruitful connection between the BCH-series and the notion of Rota–Baxter algebra has been explored in \textsuperscript{[13, 14, 15]}. The latter originated in the seminal 1960 article \textsuperscript{[5]} by the American mathematician G. Baxter, which in turn was motivated by F. Spitzer’s 1956 article \textsuperscript{[33]}. Baxter’s algebra was further developed foremost in the commutative realm in the 1960s and ’70s by P. Cartier, G.-C. Rota and F. V. Atkinson, among others, from algebraic, combinatorial and analytic viewpoints. We refer the reader to the review article \textsuperscript{[20]} as well as the monograph \textsuperscript{[23]} for details.

A weight-\(\lambda\) Rota–Baxter operator on an associative \(K\)-algebra \(\mathcal{A}\) is a \(K\)-linear map \(R : \mathcal{A} \rightarrow \mathcal{A}\), satisfying the Rota–Baxter identity of weight \(\lambda \in K\):

\[
R(x)R(y) = R(xR(y) + \lambda xy), \quad x, y \in \mathcal{A}.
\]

For example, the indefinite Riemann integral satisfies \textsuperscript{(1)} when the weight \(\lambda = 0\) (integration by parts). The linear map \(\widetilde{R} := -\lambda \text{id}_{\mathcal{A}} - R\) is also Rota–Baxter of weight \(\lambda\), and satisfies together with \(R\) the mixed identity

\[
R(x)\widetilde{R}(y) = \widetilde{R}(R(x)y) + R(x\widetilde{R}(y)), \quad x, y \in \mathcal{A}.
\]

Starting from a Rota–Baxter operator \(R\) of weight \(\lambda\), the BCH-recursion \textsuperscript{[15]} is defined by:

\[
\chi_{\lambda}(a) := a + \frac{1}{\lambda} \text{BCH}(R(\chi_{\lambda}(a)), \widetilde{R}(\chi_{\lambda}(a))), \quad a \in \mathcal{A}.
\]

It lies at the heart of the solution of an exponential factorisation problem \textsuperscript{[15]} and thereby permits the generalisation of a classical result for commutative Rota–Baxter algebras, known as Spitzer’s identity \textsuperscript{[33]}, to non-commutative Rota–Baxter algebras. The resulting non-commutative Spitzer identity says that for \(a \in \mathcal{A}\) the exponential

\[
X := \exp \left( R\left( \chi_{\lambda}\left( \frac{\log(1 + t\lambda a)}{\lambda} \right) \right) \right)
\]

solves the fixed point equation in \(\mathcal{A}[[t]]\)

\[
X = 1 + tR(aX).
\]

Here the formal parameter \(t\) commutes with all elements in \(\mathcal{A}\). More precisely, iterating the fixed point equation \textsuperscript{(3)} yields the rather non-trivial equality

\[
1 + tR(a) + t^2R(aR(a)) + t^3R(a(\mathcal{R}(aR(a)))) + \cdots = \exp \left( R\left( \chi_{\lambda}\left( \frac{\log(1 + t\lambda a)}{\lambda} \right) \right) \right).
\]

Thanks to the commuting parameter \(t\), the last equality can be seen as between formal power series and therefore encompasses at each order a specific relation between coefficients. For instance, at order two, that is, comparing the coefficients of \(t^2\), we have the identity

\[
2R(aR(a)) = R(a(\mathcal{R}(a) + \mathcal{R}(a), a) + \lambda a^2),
\]

which is easily verifiable in a Rota–Baxter algebra of weight \(\lambda\) by using the Rota–Baxter identity \textsuperscript{(1)} on the righthand side. We note that the fixed point equation \textsuperscript{(3)} is reminiscent of the integral fixed

\textsuperscript{1}The remainder Baker–Campbell–Hausdorff series, \(\text{BCH}(x,y)\), is denoted by \(\text{BCH}(x,y)\) in \textsuperscript{[15]}. We adopt here a more conventional notation.
point equation naturally associated to a linear matrix-valued initial value problem; the indefinite Riemann integral is a weight-zero Rota–Baxter map. Indeed, the series (2) turns out to be closely related to a well-known Lie algebra expansion due to W. Magnus [24]. This connection to the so-called Magnus expansion was studied in reference [15] in the case of the weight being zero ($\lambda = 0$). The adequate algebraic setting is provided through the notion of pre-Lie algebra, which is naturally defined on any non-commutative Rota–Baxter algebra. In [16] it was shown that the pre-Lie Magnus expansion can be expressed in terms of the BCH-recursion as follows:

$$\Omega_{\triangleright}(a) := a + \sum_{n>0} \frac{B_n}{n!} \{\Omega_{\triangleright}(a)\}(a) = \chi_{\lambda}\left(\frac{\log(1 + \lambda a)}{\lambda}\right).$$

Here $B_n$ is the n-th Bernoulli number and $L_{\triangleright}[x](y) = L^{(1)}_{\triangleright}[x](y) := x \triangleright y$ is the left-multiplication operator defined in terms of the aforementioned (left) pre-Lie product, denoted $\triangleright$, on a non-commutative Rota–Baxter algebra. Note that the weight $\lambda$ is absorbed in the definition of the pre-Lie product. In the weight-zero case of the indefinite Riemann integral, this pre-Lie product is defined for $\lambda$-matrix-valued functions $A, B$ as $(A \triangleright B)(t) := [\int_0^t A(s)ds, B(t)]$. When inserted in (4), one recovers Magnus’ original expansion [24].

In this work, we are revisiting the BCH-recursion (2) and its relation to the Magnus expansion. This time, in the context of post-Lie algebra defined in terms of a Rota–Baxter operator of non-zero weight [4]. We will recall the abstract definition of the so-called post-Lie Magnus expansion in the context of the universal enveloping algebra of a post-Lie algebra. Our main result shows that the post-Lie Magnus expansion and the BCH-recursion in (2) coincide in the context of a Rota–Baxter algebra endowed with its naturally associated post-Lie structure.

We close this introduction by noting that the Magnus expansion, in its various forms (classical [24, 27], pre-Lie [1, 10, 16] and post-Lie [17, 18, 19, 26]), has been studied in applied mathematics, control theory, physics and chemistry. See reference [6] for details on the classical Magnus expansion in applied mathematics. The reader can also find a brief summary in the recent work [12].

This paper consists of four sections accompanied by two appendices. In section 2, we review some basic topics related to post-Lie algebras and their universal enveloping algebras. The post-Lie structure defined on any Rota–Baxter algebra is recalled from [4]. Section 3 contains the description of the Baker–Campbell–Hausdorff recursion and its inverse, as well as their properties. Several important details on the post-Lie Magnus expansion and its inverse are included in section 4. Section 5 is the main part of this work, in which the identification of the post-Lie Magnus expansion with the BCH-recursion is proven. Finally, the two appendices A and B contain low-order computations of the post-Lie Magnus expansion and its inverse.

2. Post-Lie algebras

A post-Lie algebra is a Lie algebra \((L, [], \ldots)\) together with a bilinear mapping \(\triangleright : L \times L \to L\), which is compatible with the Lie bracket in the following sense:

\[
x \triangleright [y, z] = [x \triangleright y, z] + [y, x \triangleright z]
\]

\[
[x, y] \triangleright z = a_\triangleright(x, y, z) - a_\triangleright(y, x, z),
\]

for any \(x, y, z \in L\). Here, \(a_\triangleright(x, y, z)\) is the associator defined by:

\[
a_\triangleright(x, y, z) = x \triangleright (y \triangleright z) - (x \triangleright y) \triangleright z.
\]

Any Lie algebra can be seen as a post-Lie algebra by setting the second product \(\triangleright\) to zero. Another possibility is to take for the second product \(\triangleright\) the opposite of the Lie bracket.

A (left) pre-Lie algebra is an abelian post-Lie algebra, i.e., a post-Lie algebra with Lie bracket set to zero. The defining relation is the left pre-Lie identity

\[
0 = a_\triangleright(x, y, z) - a_\triangleright(y, x, z).
\]

We refer the reader to [25] for a short survey on pre-Lie algebras. The post-Lie operation \(\triangleright\) permits to produce two other operations:

\[
\llbracket x, y \rrbracket := x \triangleright y - y \triangleright x + [x, y],
\]

\[
x \mapsto y := x \triangleright y + [x, y],
\]

for all \(x, y \in L\). From (5) and (6), one can see that \((L, \llbracket, \ldots\rrbracket)\) forms a Lie algebra, denoted \(\hat{L}\). In the case of an abelian post-Lie algebra, this amounts to Lie admissibility of pre-Lie algebras. The triple \((L, -[, .], \triangleright)\) forms another post-Lie algebra [12] [28] sharing the same double Lie bracket, i.e.

\[
\llbracket x, y \rrbracket = x \triangleright y - y \triangleright x + [x, y] = x \mapsto y - y \mapsto x - [x, y].
\]

For more details on post-Lie algebras, we refer to [11 [17] [18] [28] and references therein.

2.1. The universal enveloping algebra of a post-Lie algebra. Inspired by the work of J.-M. Oudom and D. Guin in the pre-Lie context [22], the authors in [17] consider the enveloping algebra \(U(L)\) of the Lie algebra \((L, [\ldots])\) underlying a post-Lie algebra \((L, [\ldots], \triangleright)\). The post-Lie product \(\triangleright\) is then extended to \(L \otimes U(L) \to U(L)\) by requiring \(x \triangleright 1 := 0\) and

\[
x \triangleright (x_1 \cdots x_n) := \sum_{i=1}^{n} x_1 \cdots x_{i-1} (x \triangleright x_i) x_{i+1} \cdots x_n,
\]

for all \(x, x_1, \ldots, x_n \in L\). Here, \(1\) denotes the unit in \(U(L)\). Recall that the enveloping algebra \(U(L)\) together with the concatenation as product and the deshuffle coproduct has the structure of a non-commutative, co-commutative Hopf algebra. The deshuffle coproduct \(\Delta\) is defined for all letters \(x \in L \hookrightarrow U(L)\), by \(\Delta(x) := x \otimes 1 + 1 \otimes x\) and extended multiplicatively. We employ Sweedler’s notation, \(\Delta(X) := X_{(1)} \otimes X_{(2)}\), for the coproduct of any \(X \in U(L)\). The final definition of the extended post-Lie product on \(U(L)\), together with its properties, is given by the next two propositions.
Proposition 1. [17, Proposition 3.1] There is a unique extension of the post-Lie product $\triangleright$ from $L$ to $U(L)$ satisfying:

$1 \triangleright X = X,$

$xX \triangleright y = x \triangleright (X \triangleright y) - (x \triangleright X) \triangleright y,$

$X \triangleright YZ = (X(1) \triangleright Y)(X(2) \triangleright Z),$

for all $x, y \in L$, and $X, Y, Z \in U(L)$.

Proposition 2. [17, Proposition 3.2] The extended post-Lie product $\triangleright$ on $U(L)$ possesses the following properties:

$X \triangleright 1 = \epsilon(X),$

$\epsilon(X \triangleright Y) = \epsilon(X)\epsilon(Y),$

$\Delta(X \triangleright Y) = (X(1) \triangleright Y(1)) \otimes (X(2) \triangleright Y(2)),$

$xX \triangleright Y = x \triangleright (X \triangleright Y) - (x \triangleright X) \triangleright Y,$

$X \triangleright (Y \triangleright Z) = (X(1)(X(2) \triangleright Y)) \triangleright Z,$

for all $x \in L$ and $X, Y, Z \in U(L)$, where $\epsilon : U(L) \to K$ is the counit map.

From the last equality in Proposition 2, an associative product, known as Grossman–Larson product, can be defined on $U(L)$ as follows:

$X * Y := X(1)(X(2) \triangleright Y),$ (11)

for all $X, Y \in U(L)$. As an example, for any $x, y \in L$, we find $x * y = x \triangleright y + xy$, since any element of $L$ is primitive. The Grossman–Larson product (11) defines together with the coproduct $\Delta$ another structure of Hopf algebra on $U(L)$. The corresponding antipode will be denoted by $S_*$. The Hopf algebras $(U(L), *, \Delta)$ and $(U(\tilde{L}), ., \Delta)$ are isomorphic [15, Section 3], [22, Section 2].

Remark 3. Conversely, the product of the enveloping algebra can be expressed in terms of the Grossman–Larson product and the deshuffle coproduct as follows:

$XY = X(1) * (S_*X(2) \triangleright Y).$ (12)

This is seen by plugging (11) into the right-hand side of (12).

2.2. Free post-Lie Algebras. F. Chapoton and M. Livernet presented in [9] the free pre-Lie algebra in terms of (non-planar) decorated rooted trees. Similarly, H. Munthe-Kaas and A. Lundervold gave in [28] an explicit description of the free post-Lie algebra in terms of formal Lie brackets of planar decorated rooted trees. Let us briefly review this construction: a magma is a set $M$ together with a binary operation, without any further properties. For any (non-empty) set $E$, the set of all parenthesized words on the alphabet $E$ is the free magma over $E$, denoted $M(E)$. A practical presentation of it can be given in terms of planar rooted trees. Indeed, consider the set $T_{pl}^E$ of all planar rooted trees with vertices decorated by $E$, and let $\circ \downarrow$ denote the left Butcher product defined on $T_{pl}^E$ as:

$\sigma \circ \downarrow \tau = B_+(\sigma \tau_1 \tau_2 \cdots \tau_k),$ (13)
for \( \sigma, \tau_1, \tau_2, \ldots, \tau_k \in T_E^\text{pl} \) and \( \tau := B_e(\tau_1 \tau_2 \cdots \tau_k) \). Here, \( B_e^\tau \) is the operation defined by grafting a monomial \( \tau_1 \tau_2 \cdots \tau_k \) of \( E \)-decorated rooted trees on a common root decorated by some element \( e \) in \( E \), to obtain a new tree. For example (in the undecorated context):

\[
\circ \downarrow 1 = \mathbf{1}, \quad \circ \downarrow \mathbf{1} = \mathbf{1}, \quad 1 \circ \downarrow 1 = \mathbf{1}.
\]

Denote by \( T_E^\text{pl} \) the linear span of the set \( T_E^\text{pl} \). Besides the left Butcher product, \( \circ \downarrow \), this space has another magmatic product defined through left grafting, denoted \( \downarrow \), and defined by

\[
\sigma \downarrow \tau = \sum_v \sigma \downarrow_v \tau, \quad \quad (14)
\]

where \( \sigma \downarrow_v \tau \) is the tree obtained by grafting the root of the tree \( \sigma \) onto the vertex \( v \) of the tree \( \tau \), such that \( \sigma \) becomes the leftmost branch starting from vertex \( v \). See for example references \([2, 8]\).

Computing some examples (in the undecorated context) we find:

\[
\bullet \downarrow 1 = \mathbf{1} + \mathbf{1}, \quad 1 \downarrow \mathbf{1} = \mathbf{1} + \mathbf{1} + \mathbf{1}.
\]

By freeness universal property, there is a unique morphism of magmatic algebras

\[
\Psi : (T_E^\text{pl}, \circ \downarrow) \longrightarrow (T_E^\text{pl}, \downarrow)
\]

\[
\tau \longmapsto e_\tau := \Psi(\tau)
\]

such that \( \Psi(\bullet, a) = \bullet \cdot a \) for any \( a \in E \), which is a linear isomorphism. A detailed account of the map \( \Psi \) can be found in \([2]\).

Let \( L(T_E^\text{pl}) \) be the free Lie algebra generated by \( T_E^\text{pl} \). It can be endowed with a structure of post-Lie algebra by extending the aforementioned left grafting, \( \downarrow \), as follows:

\[
[\sigma \downarrow \tau, \tau'] = [\sigma \downarrow \tau, \tau'] + [\tau, \sigma \downarrow \tau'],
\]

\[
[\sigma, \tau] \downarrow \tau' = a_\downarrow(\sigma, \tau, \tau') - a_\downarrow(\tau, \sigma, \tau'),
\]

for all \( \sigma, \tau, \tau' \in T_E^\text{pl} \). The triple \((L(T_E^\text{pl}), [\ldots, \cdot], \downarrow)\) is the free post-Lie algebra generated by \( E \) ([31], see also \([28, 29]\)).

Recall that an \( E \)-decorated planar forest \( f = \tau_1 \cdots \tau_n \) is a (non-commutative) product of \( E \)-decorated planar rooted trees \( \tau_i \in T_E^\text{pl}, i = 1, \ldots, n \). Denote by \( F_E^\text{pl} \) the set of all \( E \)-decorated planar forests, and by \( T_E^\text{pl} \) its linear span. The space \( T_E^\text{pl} \) forms together with the concatenation product the free associative algebra generated by \( T_E^\text{pl} \). The left grafting, \( \circ \downarrow \), defined by \((14)\) on \( T_E^\text{pl} \) can be generalized to a grafting of forests as follows:

- **Left grafting a tree on a forest** is also defined by \((14)\). We thus have

\[
\sigma \circ \downarrow f f' = (\sigma \circ \downarrow f) f' + f(\sigma \circ \downarrow f'),
\]

for any tree \( \sigma \in T_E^\text{pl} \) and any two forests \( f, f' \in F_E^\text{pl} \).

- **The left grafting of a forest** \( f = \tau_1 \cdots \tau_n \) onto a forest \( f' \) is the sum of forests obtained by summing over all ways of successively left grafting the trees \( \tau_k, \ldots, \tau_1 \) to any node of \( f' \).
The well-known (planar) Grossman–Larson product on $\mathcal{F}_E^pl$ is defined by \(^{21}\):

\[
f \star f' := B_-\left(f \backslash \lambda B_+^\ast(f')\right),
\]

(15)

where $B_-\ast$ is the left inverse operation of $B_+\ast$, which removes the root of a tree and thus produces a forest. This product endows the space $\mathcal{F}_E^pl$ with a structure of a non-commutative associative unital algebra, called the Grossman–Larson algebra. This algebra acts naturally on $\mathcal{T}_E^pl$ by extended left grafting:

\[
(f \star f') \backslash \lambda \tau := f \backslash \lambda (f' \backslash \lambda \tau),
\]

for all $f, f' \in \mathcal{F}_E^pl$ and $\tau \in \mathcal{T}_E^pl$. The universal enveloping algebra $\mathcal{U}(\mathcal{L}(\mathcal{T}_E^pl))$ of the free post-Lie algebra $\mathcal{L}(\mathcal{T}_E^pl)$ can be identified with $\mathcal{F}_E^pl$. More precisely,

**Proposition 4.** \(^{17}\) Proposition 3.5] The universal enveloping algebra $(\mathcal{U}(\mathcal{L}(\mathcal{T}_E^pl)), \ast)$ is identical to the Grossman–Larson algebra $(\mathcal{F}_E^pl, \star)$.

2.3. **Post-Lie structure on a Rota–Baxter algebra.** Recall that a Rota–Baxter algebra of weight $\lambda \in K$ is a unital associative $K$-algebra $\mathcal{A}$ together with a linear operator $\mathcal{R} : \mathcal{A} \rightarrow \mathcal{A}$, which satisfies the Rota–Baxter identity\(^5\):

\[
\mathcal{R}(x)\mathcal{R}(y) = \mathcal{R}(\mathcal{R}(x)y + x\mathcal{R}(y) + \lambda xy),
\]

(16)

for all $x, y \in \mathcal{A}$. The identity (16) is called the Rota–Baxter identity of weight $\lambda$. There is another Rota–Baxter operator, of weight $\lambda$, defined on $\mathcal{A}$ by:

\[
\mathcal{R} := -\lambda \text{id}_\mathcal{A} - \mathcal{R}.
\]

(17)

The two maps satisfy the mixed identity $\mathcal{R}(x)\mathcal{R}(y) = \mathcal{R}(\mathcal{R}(x)y) + \mathcal{R}(x\mathcal{R}(y))$ for all $x, y \in \mathcal{A}$.

Recall that a unital algebra is said to be complete filtered if it is equipped with a separating complete filtration

\[
\mathcal{A} = \mathcal{A}_0 \supseteq \mathcal{A}_1 \supseteq \mathcal{A}_2 \supseteq \cdots \supseteq \mathcal{A}_n \supseteq \cdots
\]

by ideals \(^{13}\). Separation means that the intersection of the $\mathcal{A}_n$’s is equal to $\{0\}$, and completeness refers to the topology associated with the filtration, so that any series $a = \sum_{n\geq 1} a_n$ with $a_n \in \mathcal{A}_n$ converges in $\mathcal{A}$. The filtration is moreover supposed to be compatible with the product, i.e., $\mathcal{A}_{n_1}\mathcal{A}_{n_2} \subseteq \mathcal{A}_{n_1+n_2}$ for any $n_1, n_2 \geq 0$. A Rota–Baxter algebra is said to be complete filtered if it is equipped with a separating complete complete filtration by Rota–Baxter ideals, i.e., by ideals $\mathcal{A}_n$ stable by the Rota–Baxter operator.

The Rota–Baxter Algebra $(\mathcal{A}, \mathcal{R})$ of weight $\lambda$ has a structure of a post-Lie algebra defined by the following operations:

\[
[x, y]_{\lambda} := \lambda [x, y]
\]

(18)

\[
x \triangleright y := [\mathcal{R}(x), y],
\]

(19)

for all $x, y \in \mathcal{A}$. We leave it to the reader to show that the operations in (18), (19) satisfy the post-Lie identities \(^5\) and \(^6\) (see \(^4\) § 5.2]). As expected, the post-Lie algebra $(\mathcal{A}, [\ldots, \lambda, \triangleright])$ reduces to a (left) pre-Lie algebra in the case of a weight zero Rota–Baxter algebra. Indeed, if $\lambda = 0$, the product $\triangleright$ defined by (19) verifies the left pre-Lie identity (7).
We give here a brief account of the Baker–Campbell–Hausdorff recursion, which was defined and explored in [13, 14, 15]. Let \( \mathcal{A} = K \langle \langle x, y \rangle \rangle \) be the free complete (non-commutative) associative \( K \)-algebra of formal power series generated by non-commuting variables \( x \) and \( y \). The Baker–Campbell–Hausdorff expansion \( \text{BCH}(x, y) \) is the element in \( \mathcal{A} \) satisfying the following equation:

\[
\exp(x) \exp(y) = \exp(\text{BCH}(x, y)).
\]  

The first terms are given by

\[
\text{BCH}(x, y) = x + y + \frac{1}{2} [x, y] + \frac{1}{12} [x, [x, y]] - \frac{1}{12} [y, [x, y]] - \frac{1}{24} [x, [y, [x, y]]] + \cdots,
\]

where \([x, y] := xy - yx\) is the usual commutator of \( x \) and \( y \) in \( \mathcal{A} \). See, e.g., [7] for details.

**Proposition 5.** [15 Proposition 1] Let \( \mathcal{A} \) be a complete filtered \( K \)-algebra, and let \( R \) be a \( K \)-linear map preserving the filtration of \( \mathcal{A} \). There exists a unique (usually non-linear) map \( \chi : \mathcal{A}_1 \rightarrow \mathcal{A}_1 \), such that

\[
(\chi - \text{id} \mathcal{A})(\mathcal{A}_n) \subset \mathcal{A}_{2n}, \text{ for all } n \geq 1,
\]

and

\[
\text{BCH}(\mathcal{R}(\chi(x)), \mathcal{R}(\chi(x))) = x,
\]  

for all \( x \in \mathcal{A}_1 \), where \( \mathcal{R} := \text{id}_\mathcal{A} - R \). This map is bijective, and its inverse is:

\[
\chi^{-1}(x) = \text{BCH}(\mathcal{R}(x), \mathcal{R}(x)) = x + \text{BCH}(\mathcal{R}(x), \mathcal{R}(x)).
\]

As a consequence of (21), we have the exponential factorization

\[
\exp(\mathcal{R}(\chi(x))) \exp(\mathcal{R}(\chi(x))) = \exp(x),
\]  

for any \( x \in \mathcal{A}_1 \). Note also that (21) yields the non-linear BCH-recursion

\[
\chi(x) := x - \text{BCH}(\mathcal{R}(\chi(x)), \mathcal{R}(\chi(x))),
\]

for all \( x \in \mathcal{A}_1 \).

**Lemma 6.** [15] Let \( \mathcal{A} \) be a complete filtered (associative) algebra. According to the nature of the linear map \( R : \mathcal{A} \rightarrow \mathcal{A} \), we have the following cases:

1. If \( R \) preserves the filtration of \( \mathcal{A} \), then the map \( \chi \) given by (24), can be simplified:

\[
\chi(x) = x + \text{BCH}(-\mathcal{R}(\chi(x)), x), \quad \forall x \in \mathcal{A}_1.
\]

2. If \( R \) is an idempotent algebra homomorphism, which preserves the filtration of \( \mathcal{A} \), then the map \( \chi \) in (25) is further simplified, namely \( \chi(x) = x + \text{BCH}(-\mathcal{R}(x), x) \).

**Proof.** See [15 Lemmas 6, 7].

The BCH-recursion in the Rota–Baxter algebra framework is given as follows in the case where the weight \( \lambda \) is different from zero:
Proposition 7. [15] Proposition 11] Let \((\mathcal{A}, \mathcal{R})\) be a complete filtered Rota–Baxter algebra of weight \(\lambda \neq 0\), and set \(\overline{\mathcal{R}} := -\lambda \text{id}_\mathcal{A} - \mathcal{R}\). The \(\lambda\)-weighted BCH-recursion is written:

\[
\chi_\lambda(x) = x + \frac{1}{\lambda} \text{BCH}(\mathcal{R}(\chi_\lambda(x)), \overline{\mathcal{R}}(\chi_\lambda(x))),
\]

(26)

for all \(x \in \mathcal{A}_1\). It can be simplified to:

\[
\chi_\lambda(x) = x - \frac{1}{\lambda} \text{BCH}(\mathcal{R}(\chi_\lambda(x)), \lambda x).
\]

Its inverse is given by:

\[
\chi_\lambda^{-1}(x) = x - \frac{1}{\lambda} \text{BCH}(\mathcal{R}(x), \overline{\mathcal{R}}(x)).
\]

Moreover, the factorization obtained in (21) becomes:

\[
\exp(\mathcal{R}(\chi_\lambda(x))) \exp(\overline{\mathcal{R}}(\chi_\lambda(x))) = \exp(-\lambda x).
\]

(27)

The expansion \(\chi_\lambda\) can be written as the infinite sum:

\[
\chi_\lambda(x) = \sum_{n \geq 1} \chi_\lambda^{(n)}(x),
\]

where \(\chi_\lambda^{(n)} \in \mathcal{A}_n\) is the \(n\)-th homogenous component of the BCH-recursion. Here, we write the components \(\chi_\lambda^{(n)}\) up to order \(n = 4\) using the post-Lie algebra notation (18) and (19).

\[
\begin{align*}
\chi_\lambda^{(1)}(x) &= x, \\
\chi_\lambda^{(2)}(x) &= \frac{1}{2\lambda} \left[ \mathcal{R}(\chi_\lambda^{(1)}(x)), \overline{\mathcal{R}}(\chi_\lambda^{(1)}(x)) \right] \\
&= \frac{1}{2\lambda} \left[ \mathcal{R}(\chi_\lambda^{(1)}(x)), ( -\lambda \text{id}_\mathcal{A} - \mathcal{R})\chi_\lambda^{(1)}(x) \right] = -\frac{1}{2} \left[ \mathcal{R}(x), x \right] = -\frac{1}{2} x \triangleright x, \\
\chi_\lambda^{(3)}(x) &= \frac{1}{2\lambda} \left[ \mathcal{R}(\chi_\lambda^{(1)}(x)), \overline{\mathcal{R}}(\chi_\lambda^{(2)}(x)) \right] + \left[ \mathcal{R}(\chi_\lambda^{(2)}(x)), \overline{\mathcal{R}}(\chi_\lambda^{(1)}(x)) \right] \\
&\quad + \frac{1}{12\lambda} \left[ \left[ \mathcal{R}(\chi_\lambda^{(1)}(x)), \left[ \mathcal{R}(\chi_\lambda^{(1)}(x)), \overline{\mathcal{R}}(\chi_\lambda^{(1)}(x)) \right] \right] - \left[ \overline{\mathcal{R}}(\chi_\lambda^{(1)}(x)), \left[ \mathcal{R}(\chi_\lambda^{(1)}(x)), \overline{\mathcal{R}}(\chi_\lambda^{(1)}(x)) \right] \right] \right] \\
&= \frac{1}{4} (x \triangleright x) \triangleright x + \frac{1}{12} x \triangleright (x \triangleright x) + \frac{1}{12} [x \triangleright x, x], \\
\chi_\lambda^{(4)}(x) &= \frac{\lambda - 1}{24} x \triangleright ((x \triangleright x) \triangleright x) - \frac{\lambda + 1}{24} (x \triangleright x) \triangleright (x \triangleright x) + \frac{\lambda - 3}{24} ((x \triangleright x) \triangleright x) \triangleright x \\
&\quad - \frac{\lambda + 1}{24} (x \triangleright (x \triangleright x)) \triangleright x + \frac{1}{24} [x, x \triangleright (x \triangleright x) + (x \triangleright x) \triangleright x],
\end{align*}
\]

4. Magnus Expansion

W. Magnus [24] considered the problem of expressing the solution of the matrix-valued linear initial value problem \(\dot{Y}(t) = M(t)Y(t), Y(0) = Y_0\) as an exponential [6 27]

\[
Y(t) = \exp(\Omega(M)(t))Y_0.
\]

The Magnus expansion, \(\Omega(M)(t) = \log(Y(t))\), is determined by the particular differential equation

\[
\dot{\Omega}(M) := M + \sum_{n>0} \frac{B_n}{n!} \omega_n^{(n)}(M) := \text{dexp}^{-1}_{\Omega(M)}(M)
\]

(28)

\[
\Omega(M) = \sum_{n=0}^{\infty} \frac{B_n}{n!} \omega_n^{(n)}(M)
\]
where forests by:

\[ \Omega(M)(0) = 0. \]

Here, \( B_n \) are the Bernoulli numbers and \( ad^{(n)}_{M_1}(M_2) := ad^{(n-1)}(\Omega(M_1, M_2)), ad^{(0)}_{M_1}(M_2) = M_2. \) Defining the pre-Lie product, \((M_1 \triangleright M_2)(t) := [\int_0^t M_1(s)ds, M_2(t)]\), we can rewrite \( (29) \) using the left-multiplication operator defined in terms of the pre-Lie product

\[ \hat{\Omega}(M) = \frac{L_{\hat{\omega}}[\hat{\Omega}(M)]}{e^{L_{\hat{\omega}}} - 1}(M). \]

4.1. **Post-Lie Magnus Expansion.** We consider now the universal enveloping algebra \( U_T^\text{pl} := U(\mathcal{L}(T_E^\text{pl})) \) of the free post-Lie algebra \( (\mathcal{L}(T_E^\text{pl}), \cdot, \cdot , \cdot, \cdot) \), graded by the number of vertices of the forests. Denote by \( U(\mathcal{L}(T_E^\text{pl})) \) its completion with respect to the grading. Any element of the completion can be written as a so-called Lie-Butcher series \([17, 28, 29]\)

\[ \alpha = \sum_{f \in F_E^\text{pl}} \langle \alpha, f \rangle f, \]

where \( \langle \cdot, \cdot \rangle : U(\mathcal{L}(T_E^\text{pl})) \otimes U(\mathcal{L}(T_E^\text{pl})) \to K \) is the natural pairing defined on any pair \( (f, f') \) of forests by:

\[ \langle f, f' \rangle = \begin{cases} 0, & f \neq f' \\ 1, & f = f'. \end{cases} \]

The deshuffle coproduct, \( \Delta \), is naturally extended to the completion. The set \( \text{Prim}(F_E^\text{pl}) \) consists in primitive elements (infinitesimal characters), whereas \( G(F_E^\text{pl}) \) denotes the set of group-like elements (characters):

\[ \text{Prim}(F_E^\text{pl}) := \{ \alpha \in U(\mathcal{L}(T_E^\text{pl})) \mid \Delta(\alpha) = 1 \otimes \alpha + \alpha \otimes 1 \} = L(T_E^\text{pl}), \]

\[ G(F_E^\text{pl}) := \{ \alpha \in U(\mathcal{L}(T_E^\text{pl})) \mid \Delta(\alpha) = \alpha \otimes \alpha \}. \]

Both products on \( U(\mathcal{L}(T_E^\text{pl})) \) –the concatenation and the Grossman–Larson product \([15]\)– can also be extended to products on the completion \( U(\mathcal{L}(T_E^\text{pl})) \). As a result, two different exponential functions can be defined on \( U(\mathcal{L}(T_E^\text{pl})) \), namely:

\[ \exp^*(f) = \sum_{n=0}^{\infty} \frac{f^n}{n!} = 1 + f + \frac{1}{2} f \ast f + \frac{1}{6} f \ast f \ast f + \cdots, \]

\[ \exp(f) = \sum_{n=0}^{\infty} \frac{f^n}{n!} = 1 + f + \frac{1}{2} ff + \frac{1}{6} fff + \cdots. \]

Both these exponential functions map \( \text{Prim}(F_E^\text{pl}) \) bijectively onto \( G(F_E^\text{pl}) \). See \([17]\) for details. The post-Lie Magnus expansion \( \chi \) is the bijective map from \( \mathcal{L}(T_E^\text{pl}) \) onto itself defined by:

\[ \exp^*(\chi(f)) = \exp(f), \]

namely:

\[ \chi(f) = \log^*(\exp(f)). \]
Introducing a formal commuting indeterminate $t$, it can also be described as $\chi(ft) = \sum_{n \geq 1} \chi^{(n)}(f)t^n$, where $\chi^{(n)}(f)$ is the $n$-th order component of the post-Lie Magnus expansion $\chi$. The latter is defined recursively by $\chi^{(1)}(f) = f$, and \cite{17,18,19}:

$$
\chi^{(n)}(f) := \frac{f^n}{n!} - \sum_{k=2}^{n} \frac{1}{k!} \sum_{p_1 + \cdots + p_k = n \atop p_i > 0} \chi^{(p_1)}(f) \ast \chi^{(p_2)}(f) \ast \cdots \ast \chi^{(p_k)}(f).
$$

The computation of $\chi^{(n)}(f)$ for the first five values of $n$ is displayed in Appendix A below. Comparing with the computations at the end of Section 3, one observes that, up to order $n = 4$, the coefficient $\chi^{(n)}(f)$ coincides with the coefficient $\chi_f^{(n)}(f)$ of the BCH-recursion – if the weight $\lambda = 1$. We shall prove this fact at any order in Theorem 14 below.

**Remark 8.** By universal property of the free post-Lie algebra, the post-Lie Magnus expansion defined above gives rise to a post-Lie-Magnus expansion in any complete filtered post-Lie algebra. If the underlying Lie algebra is Abelian, then the post-Lie Magnus expansion is reduced to the so-called pre-Lie Magnus expansion.

**Remark 9.** We may deduce a Magnus-type differential equation similar to \cite{28} for the post-Lie Magnus expansion \cite{33}, by differentiating $\exp'(\chi(ft)) = \exp(ft)$ with respect to $t$. This results in

$$
\dot{\chi}(ft) = \exp^{-1}_*\left(\exp(-\chi(ft)) \triangleright f\right), \quad \chi(0) = 0.
$$

4.2. **Inverse Post-Lie Magnus Expansion.** The inverse post-Lie Magnus expansion $\theta$ is the bijective map from $\mathcal{L}(\mathcal{T}_E^{pl})$ onto itself given by the following formula:

$$
\theta(f) = \log(\exp^*(f))
$$

or

$$
\exp(\theta(f)) = \exp^*(f).
$$

The homogeneous component $\theta^{(n)} = \theta^{(n)}(f)$ of degree $n$ of the expansion

$$
\theta(ft) = \sum_{k \geq 1} \theta^{(k)}(f)t^k
$$

is given by $\theta^{(1)}(f) = f$ and the following recursive formula \cite{17}:

$$
\theta^{(n)}(f) = \frac{1}{n} \left( \sum_{j=1}^{n-1} \frac{1}{j!} \sum_{k_1 + \cdots + k_j = n-1 \atop k_i > 0} (\theta^{(k_1)}(f) \ast \cdots \ast \theta^{(k_j)}(f)) \triangleright f + \sum_{j=1}^{n-1} \frac{B_j}{j!} \sum_{k_1 + \cdots + k_j = n-1 \atop k_i > 0} \text{ad}_{\theta^{(k_1)}(f)} \cdots \text{ad}_{\theta^{(k_j)}(f)} f \right)
$$

$$
+ \sum_{j=2}^{n-1} \left( \sum_{q=1}^{j-1} \frac{B_q}{q!} \sum_{k_1 + \cdots + k_q = j-1 \atop k_i > 0} \text{ad}_{\theta^{(k_1)}(f)} \cdots \text{ad}_{\theta^{(k_q)}(f)} \left( \sum_{p=1}^{n-j} \frac{1}{p!} \sum_{k_1 + \cdots + k_p = n-j \atop k_i > 0} (\theta^{(k_1)}(f) \ast \cdots \ast \theta^{(k_p)}(f)) \triangleright f \right) \right),
$$

where $\text{ad}_{\theta^{(k)}(f)} := [\theta^{(k)}(f), f]$, and the $B_j$’s are the Bernoulli numbers. The computation of the first $\theta^{(n)}$’s is given in Appendix B.

**Remark 10.** The same fact, described in Remark 8, will be repeated again in the case of the inverse post-Lie Magnus Expansion. In other words, the formula in \cite{38} for the inverse post-Lie Magnus
expansion is reduced, in the case of commutative post-Lie algebras, to the inverse pre-Lie Magnus expansion formula [1] described below. See also [16, 25].

\[ W(x) := \frac{e^{L_{\infty}[x]} - 1}{L_{\infty}[x]} = \sum_{n=0}^{\infty} \frac{1}{(n+1)!} L_{n}[x](x). \]  

(39)

**Remark 11.** Similar to Remark 9, we may deduce a Magnus-type differential equation similar to (28) for the inverse post-Lie Magnus expansion [17, 19]

\[ \dot{\theta}(f(t)) = \exp^{-1}_{-\theta(f(t))}(\exp(\theta(f(t))) \triangleright f), \quad \theta(0) = 0. \]  

(40)

5. **Post-Lie Magnus Expansion and BCH-recursion**

We now show that the Baker–Campbell–Hausdorff recursion driven by a weight \( \lambda = 1 \) Rota–Baxter operator identifies with the Magnus expansion relative to the post-Lie structure naturally associated to the corresponding Rota–Baxter algebra.

**Theorem 12.** Let \((\mathcal{A}, \mathcal{R})\) be a complete filtered Rota–Baxter algebra of weight \( \lambda = 1 \). We have the following equality in \( \hat{\mathcal{U}}(\mathcal{A}) \) for any \( x \in \mathcal{A} \) and \( t \in K \):

\[ \exp^*(tx) = \exp(-t\hat{\mathcal{R}}(x)) \exp(-t\mathcal{R}(x)), \]  

(41)

where \( \hat{\mathcal{R}} = -id_{\mathcal{A}} - \mathcal{R}, \) and \( * \) is the associative product defined in (11), using the post-Lie product \( x \triangleright y = [\mathcal{R}(x), y] \).

The proof of this theorem will rely on the following proposition:

**Proposition 13.** In any complete filtered Rota–Baxter algebra \((\mathcal{A}, \mathcal{R})\) of weight \( \lambda = 1 \), we have the following identity in \( \hat{\mathcal{U}}(\mathcal{A}) \):

\[ \frac{d^n}{dt^n} \exp(-t\hat{\mathcal{R}}(x)) \exp(-t\mathcal{R}(x)) = \exp(-t\hat{\mathcal{R}}(x)) x^n \exp(-t\mathcal{R}(x)). \]  

(42)

**Proof.** The proof goes by induction. The base case \( k = 0 \) is trivial. For \( k = 1 \), we have in \( \hat{\mathcal{U}}(\mathcal{A}) \):

\[ \frac{d}{dt} \exp(-t\hat{\mathcal{R}}(x)) \exp(-t\mathcal{R}(x)) = \exp(t(id_{\mathcal{A}} + \mathcal{R})(x)) (id_{\mathcal{A}} + \mathcal{R})(x) \exp(-t\mathcal{R}(x)) \]

\[ - \exp(t(id_{\mathcal{A}} + \mathcal{R})(x)) \mathcal{R}(x) \exp(-t\mathcal{R}(x)) \]

\[ = \exp(-t\hat{\mathcal{R}}(x)) x \exp(-t\mathcal{R}(x)). \]

Now, suppose that the statement is true in the case \( k = n - 1 \), i.e.:

\[ \frac{d^{n-1}}{dt^{n-1}} \exp(-t\hat{\mathcal{R}}(x)) \exp(-t\mathcal{R}(x)) = \exp(-t\hat{\mathcal{R}}(x)) x^{n-1} \exp(-t\mathcal{R}(x)). \]

We then get:

\[ \frac{d^n}{dt^n} \exp(-t\hat{\mathcal{R}}(x)) \exp(-t\mathcal{R}(x)) = \frac{d}{dt} \frac{d^{n-1}}{dt^{n-1}} \exp(-t\hat{\mathcal{R}}(x)) \exp(-t\mathcal{R}(x)) \]

\[ = \frac{d}{dt} \exp(-t\hat{\mathcal{R}}(x)) x^{n-1} \exp(-t\mathcal{R}(x)) \]

\[ = \exp(-t\hat{\mathcal{R}}(x)) (id_{\mathcal{A}} + \mathcal{R})(x) x^{n-1} \exp(-t\mathcal{R}(x)) - \exp(-t\hat{\mathcal{R}}(x)) x^{n-1} \mathcal{R}(x) \exp(-t\mathcal{R}(x)) \]

\[ = \exp(-t\hat{\mathcal{R}}(x)) (x x^{n-1} + \mathcal{R}(x) x^{n-1} - x^{n-1} \mathcal{R}(x)) \exp(-t\mathcal{R}(x)). \]
\[
\exp(-t\tilde{R}(x)) (x \cdot x^{n-1} + x \triangleright x^{n-1}) \exp(-tR(x)) = \exp(-t\tilde{R}(x)) \exp(-tR(x)) = \exp(-t\tilde{R}(x)) x^n \exp(-tR(x)).
\]

Which means that (42) is true for \( k = n \), and it is true for all \( n \geq 0 \). This ends the proof. \( \Box \)

**Proof of Theorem 12** We have that:

\[
\frac{d^n}{dt^n} \exp^*(tx) = x^n \exp^*(tx),
\]

thus,

\[
\left. \frac{d^n}{dt^n} \exp^*(tx) \right|_{t=0} = \left. \frac{d^n}{dt^n} \exp(-t\tilde{R}(x)) \exp(-tR(x)) \right|_{t=0}, \text{ for all } n \geq 0.
\]

One can therefore conclude that both members of (41) do coincide as infinite formal series. \( \Box \)

**Theorem 14.** The post-Lie Magnus expansion \( \chi \), described in (33), coincides with the weighted BCH-recursion \( \chi_\lambda \) recursively given by (26), with weight \( \lambda = 1 \).

**Proof.** From Equation (27), specialized to \( \lambda = 1 \), and by setting \( \theta_{BCH} := \chi_1^{-1} \), we obtain that:

\[
\exp(-\theta_{BCH}(tx)) = \exp(tR(x)) \exp(t\tilde{R}(x)) \tag{43}
\]

in \( \mathcal{U}(\mathcal{A}) \), which is equivalent to

\[
\exp(\theta_{BCH}(tx)) = \exp(-\tilde{R}(x)) \exp(-tR(x)). \tag{44}
\]

From (36), (41) and (44) we have:

\[
\exp(\theta_{BCH}(tx)) = \exp^*(tx) = \exp(\theta(tx)). \tag{45}
\]

Then the two \( \theta \)'s, namely the inverse BCH-recursion in (44) and the inverse post-Lie Magnus expansion (45), do coincide. \( \Box \)
The first five elements of the post-Lie Magnus expansion are:

\[ \chi^{(1)}(f) = f \]
\[ \chi^{(2)}(f) = -\frac{1}{2} f \triangleright f \]
\[ \chi^{(3)}(f) = \frac{1}{12} f \triangleright (f \triangleright (f \triangleright f)) + \frac{1}{4} (f \triangleright f) \triangleright f + \frac{1}{12} [f \triangleright f, f] \]
\[ \chi^{(4)}(f) = -\frac{1}{12} [(f \triangleright f) \triangleright (f \triangleright f) + (f \triangleright (f \triangleright f)) \triangleright f + ((f \triangleright f) \triangleright (f \triangleright f)) \triangleright f] \]
\[ + \frac{1}{24} ([f, f \triangleright (f \triangleright f)] + [f, (f \triangleright f) \triangleright f]) \]
\[ \chi^{(5)}(f) = -\frac{1}{720} f \triangleright ((f \triangleright (f \triangleright f)) \triangleright f) - f \triangleright ((f \triangleright (f \triangleright f)) \triangleright f) - 5 (f \triangleright (f \triangleright f)) \triangleright (f \triangleright f) + 6 ((f \triangleright f) \triangleright (f \triangleright f)) \triangleright f + 3 ((f \triangleright f) \triangleright (f \triangleright f)) \triangleright f + 3 (f \triangleright (f \triangleright f)) \triangleright f + 3 (f \triangleright (f \triangleright f)) \triangleright f + 3 ((f \triangleright f) \triangleright (f \triangleright f)) \triangleright f + 3 \theta^4(f) \triangleright f \]
\[ + \frac{1}{180} [f, [f, f \triangleright (f \triangleright f)] - f \triangleright (f \triangleright (f \triangleright f))] - \frac{1}{120} \]
\[ [f \triangleright f, f \triangleright (f \triangleright f)] - \frac{1}{36} [f, (f \triangleright f) \triangleright (f \triangleright f)] - \frac{1}{72} [f, f \triangleright ((f \triangleright f) \triangleright f) + (f \triangleright (f \triangleright f)) \triangleright f + ((f \triangleright f) \triangleright f) \triangleright f] - \frac{1}{360} [f \triangleright f, [f, f \triangleright f]] + \frac{1}{720} [f, [f, [f, f \triangleright f]]] \]

Here, we calculate the first five inverse post-Lie Magnus elements:

\[ \theta^{(1)}(f) = f \]
\[ \theta^{(2)}(f) = \frac{1}{2} f \triangleright f \]
\[ \theta^{(3)}(f) = \frac{1}{6} f \triangleright (f \triangleright f) + \frac{1}{12} [f, f \triangleright f] \]
\[ \theta^{(4)}(f) = \frac{1}{24} (f \triangleright (f \triangleright (f \triangleright f)) + [f, f \triangleright (f \triangleright f)]) \]
\[ \theta^{(5)}(f) = \frac{1}{120} f \triangleright ((f \triangleright (f \triangleright f)) \triangleright f) + \frac{1}{80} [f, f \triangleright ((f \triangleright f) \triangleright f)] \]
\[ + \frac{1}{720} ([f, [f, f \triangleright (f \triangleright f)] - [f, [f, f \triangleright f]]] \]
\[ + \frac{1}{120} [f \triangleright f, f \triangleright (f \triangleright f)] - \frac{1}{240} [f \triangleright f, [f, f \triangleright f]] \]
