BOUSSINESQ’S EQUATIONS FOR (2+1)-DIMENSIONAL GRAVITY-SURFACE WAVES

ANNA KARCZEWSKA AND PIOTR ROZMEJ

ABSTRACT. We study the problem of gravity surface waves for the ideal fluid model in (2+1)-dimensional case. We apply a systematic procedure for deriving the Boussinesq equations for a prescribed relationship between the orders of four expansion parameters, the amplitude parameters $\alpha$, the long-wavelength parameter $\beta$, the transverse wavelength parameter $\gamma$, and the bottom variation parameter $\delta$. Surface tension effects are taken into account, as well. For all considered cases, the (2+1)-dimensional Boussinesq equations can not be reduced to a single nonlinear wave equation for surface elevation function. On the other hand, they can be reduced to a single, highly nonlinear partial differential equation for an auxiliary $f(x, y, t)$ which determines the velocity potential but is not directly observed quantity. In principle, the solution $f$ of this equation, if known, determines the surface elevation function. We also show that limiting the obtained Boussinesq equations to (1+1)-dimensions one recovers well-known cases of the KdV, extended KdV, fifth-order KdV, and Gardner equations.

1. INTRODUCTION

The Korteweg-de Vries equation [1] is one of the most widely used nonlinear wave equations. It was derived by the perturbation calculus method from a model of an ideal fluid (inviscous and incompressible) in which the motion is irrotational in (1+1) dimensions and the bottom of the fluid container is flat. The simplest nonlinear wave equation in (2+1) dimensions is the Kadomtsev-Petviashvili (KP for short) equation [2]. Both the KdV and KP equations are integral and satisfy a number of conservation laws. Their analytical solutions are also known.

Since nonlinear waves on the surface of seas and oceans are very important in practice, there are many studies in the literature on (2+1)-dimensional equations of the KdV or KP type, see, e.g., [3, 4, 5, 6, 7, 8, 9, 10]. The equations used in these studies are also integral which allows their authors to construct analytical solutions of various types (solitons, periodic solutions, lumps, breathers, etc.).

The extension of the ideal fluid model to the (2+1) dimensional case leads to equations that are significantly more complicated. The only such attempt known to us is the work [11]. This particular paper is erroneous [12]. To our best knowledge, there are no correct (2+1)-dimensional studies that take into account the model of an ideal fluid in full detail. The reason is that the resulting equations are non-integrable.

Date: August 26, 2021.

Key words and phrases. Shallow water waves, Boussinesq system of equations, perturbation approach, uneven bottom.
In this paper, we generalize the perturbative approach described in [13] and [14] for (1+1)-dimensional case. The authors of [13] showed that for the flat bottom, the KdV, extended KdV, fifth-order KdV, and Gardner equations can be derived for different relations between small parameters determining nonlinearity ($\alpha$) and dispersion ($\beta$). In [14], we generalized this approach for the case with an uneven bottom, assuming that the bottom variations are much smaller than the fluid’s depth. Here, we follow [14] attempting to derive analogous wave equations for (2+1)-dimensional case. It turns out that while it is possible to derive a system of appropriate (2+1)-dimensional Boussinesq equations, it is rather intractable to reduce them to a wave equation on the surface of a fluid. However, it is possible to obtain a single nonlinear partial differential equation of the wave type in which the argument is a function related to the velocity potential. In principle, if known, the solution of such an equation determines the (2+1)-dimensional function representing the time-dependent surface profile.

The paper is organized as follows. In section 2 we recall the model, define small parameters $\alpha, \beta, \gamma, \delta$ and set up the set of Euler’s equations in scaled dimensionless variables. In section 3, the case when all small parameters are of the same order is considered. For $\gamma = \delta = 0$ and (1+1) dimensions, this case leads to the Korteweg-de Vries equation in the first order perturbation approach and the extended KdV equation when the perturbation approach is extended to second order. Section 4 is devoted to the case when $\alpha, \gamma$ are of the order of $\beta$, but $\delta$ is of the order of $\beta^2$. This case, for $\gamma = 0$ and (1+1) dimensions leads to the extended KdV equation generalized for an uneven bottom, derived by us in [14]. In section 5 we keep $\alpha, \beta, \delta$ of the same order, but $\gamma$ of the order of $\beta^2$. This case seems to be close to Kadomtsev-Petviashvili equation [2]. In section 7 we consider the case when parameters $\alpha, \gamma, \delta$ are of the order of $\beta^2$ and perturbation approach is extended to second order. Here, limitation to (1+1)-dimensions leads to fifth-order KdV equation generalized in [14] for an uneven bottom. Section 8 deals with the case when $\alpha$ is the leading parameter, $\beta, \gamma, \delta$ are of the order or $\alpha^2$, and derivations are performed up to second order. In this case limitation to (1+1) dimensions lead to the Gardner equation generalized for an uneven bottom [14]. Section 9 contains conclusions.

2. DESCRIPTION OF THE MODEL

Let us consider the inviscid and incompressible fluid model whose motion is irrotational in a container with an impenetrable bottom. In dimensional variables, the set of hydrodynamical equations has the following form

\begin{align}
\phi_{xx} + \phi_{yy} + \phi_{zz} &= 0, \quad \text{in the whole volume,} \\
\phi_z - (\eta_x \phi_x + \eta_y \phi_y + \eta_t) &= 0, \quad \text{at the surface,} \\
\phi_t + \frac{1}{2}(\phi_x^2 + \phi_y^2 + \phi_z^2) + g\eta + \frac{p_x}{\rho} &= 0, \quad \text{at the surface,} \\
\phi_z - h_x \phi_x - h_y \phi_y &= 0, \quad \text{at the impenetrable bottom.}
\end{align}
BOUSSINESQ’S EQUATIONS

Here \( \phi(x, y, z, t) \) denotes the velocity potential, \( \eta(x, y, t) \) denotes the surface profile function, \( g \) is the gravitational acceleration, \( \rho \) is fluid’s density, and \( p_s \) is additional pressure due to the surface tension [15]

\[
p_s = -T \nabla \cdot \left( \frac{\nabla \eta}{(1 + |\nabla \eta|^2)^{1/2}} \right) = T \frac{(1 + \eta_y^2) \eta_{xx} + (1 + \eta_x^2) \eta_{yy} - 2\eta_x \eta_y \eta_{xy}}{(1 + \eta_x^2 + \eta_y^2)^{3/2}},
\]

where \( T \) is fluid’s surface tension coefficient, and \( \nabla = (\partial_x, \partial_y) \) is two-dimensional gradient. The bottom can be non-flat and is described by the function \( h(x, y) \). Indexes denote partial derivatives, i.e. \( \phi_{xx} \equiv \partial^2 \phi / \partial x^2 \), and so on.

The next step consists in introducing a standard scaling to dimensionless variables (in general, it could be different in \( x \)-, \( y \)- and \( z \)-direction)

\[
\tilde{x} = x/L, \quad \tilde{y} = y/l, \quad \tilde{z} = z/H, \quad \tilde{t} = t/(L/\sqrt{gH}), \quad \bar{\eta} = \eta/A, \quad \bar{\phi} = \phi/(L A \sqrt{gH}),
\]

where \( A \) is the amplitude of surface distortions from equilibrium shape (flat surface), \( H \) is average fluid depth, \( L \) is the average wavelength (in \( x \)-direction), and \( l \) is a wavelength in \( y \)-direction. In general, \( l \) should be the same order as \( L \), but not necessarily equal. Then the set (1)-(4) takes in scaled variables the following form (tildas are now dropped)

\[
\beta \phi_{xx} + \gamma \phi_{yy} + \phi_{zz} = 0,
\]

\[
\eta_t + \alpha (\eta_x \phi_x + \gamma \eta_y \phi_y) - \frac{1}{\beta} \phi_z = 0, \quad \text{for} \quad z = 1 + \alpha \eta,
\]

\[
\phi_t + \frac{1}{2} \alpha \left( \phi_x^2 + \frac{\gamma}{\beta} \phi_y^2 + \frac{1}{\beta} \phi_z^2 \right) + \eta + \text{ST} = 0, \quad \text{for} \quad z = 1 + \alpha \eta,
\]

\[
\phi_z - \beta \delta h_x \phi_x - \gamma \delta h_y \phi_y = 0, \quad \text{for} \quad z = \delta h.
\]

Besides standard small parameters \( \alpha = \frac{a}{H} \), \( \beta = \left( \frac{H}{L} \right)^2 \) and \( \gamma = \left( \frac{H}{l} \right)^2 \), which are sufficient for the flat bottom case, we introduced another one defined as \( \delta = \frac{a_h}{H} \), where \( a_h \) denotes the amplitude of bottom variations [14, 16]. In the perturbation approach, all these parameters, \( \alpha, \beta, \gamma, \delta \), are assumed to be small but not necessarily of the same order. ST is the term originating from surface tension. The explicit form of this term and its useful approximation is given below, in (11). For details, see the Appendix.

\[
\text{ST} = -\tau \frac{\beta (1 + \alpha^2 \beta \eta_y^2) \eta_{xx} + \gamma (1 + \alpha^2 \beta \eta_x^2) \eta_{yy} - 2\alpha^2 \beta \gamma \eta_x \eta_y \eta_{xy}}{(1 + \alpha^2 \beta \eta_x^2 + \alpha^2 \gamma \eta_y^2)^{3/2}} = -\tau (\beta \eta_{xx} + \gamma \eta_{yy} + O(\beta^4)).
\]

The Bond number \( \tau = \frac{T \eta g H^3}{g^2 H} \). For shallow-water waves, when \( H \gtrsim 1 \) m, ST term can be safely neglected, since \( \tau < 10^{-7} \), but it becomes important for waves in thin fluid layers.
The standard perturbation approach to the system of Euler’s equations (7)-(10) consists of the following steps. First, the velocity potential is sought in the form of power series in the vertical coordinate
\begin{equation}
\phi(x, y, z, t) = \sum_{m=0}^{\infty} z^m \phi^{(m)}(x, y, t),
\end{equation}
where \( \phi^{(m)}(x, y, t) \) are yet unknown functions. The Laplace equation (7) determines \( \phi \) in the form which involves only two unknown functions with the lowest \( m \)-indexes, \( f(x, y, t) := \phi^{(0)}(x, y, t) \) and \( F(x, y, t) := \phi^{(1)}(x, y, t) \) and their space derivatives. Hence,
\begin{equation}
\phi(x, y, z, t) = \sum_{m=0}^{\infty} \frac{(-1)^m}{(2m)!} z^{2m} (\beta \partial_{xx} + \gamma \partial_{yy})^m f(x, y, t)
+ \sum_{m=0}^{\infty} \frac{(-1)^m}{(2m + 1)!} z^{2m+1} (\beta \partial_{xx} + \gamma \partial_{yy})^m F(x, y, t).
\end{equation}

The explicit form of this velocity potential reads as
\begin{equation}
\phi = f - \frac{1}{2} z^2 (\beta f_{2x} + \gamma f_{2y}) + \frac{1}{24} z^4 (\beta^2 f_{4x} + 2\beta \gamma f_{2x2y} + \gamma^2 f_{4y}) + \cdots
+ z F - \frac{1}{6} z^3 (\beta F_{2x} + \gamma F_{2y}) + \frac{1}{120} z^5 (\beta^2 F_{4x} + 2\beta \gamma F_{2x2y} + \gamma^2 F_{4y}) + \cdots
\end{equation}

Next, the boundary condition at the bottom (10) is utilized. For flat bottom case, it implies \( F = 0 \), simplifying substantially next steps. In particular, \( F = 0 \) makes it possible to derive the Boussinesq equations up to arbitrary order. For an uneven bottom, the equation (10) determines a differential equation relating \( F \) to \( f \). This differential equation can be resolved to obtain \( F(f, f_x, f_{xx}, h, h_x) \) but this solution can be obtained only up to some particular order in leading small parameter. Then, the velocity potential is substituted into kinematic and dynamic boundary conditions at the unknown surface (8)-(9). Retaining only terms up to a given order, one obtains the Boussinesq system of two equations for unknown functions \( \eta, f \) valid only up to a given order in small parameters. The resulting equations, however, depend substantially on the ordering of small parameters.

In 2013, Burde and Sergiyeyev [13] demonstrated that for the case of (1+1)-dimensional and the flat bottom, the KdV, the extended KdV, fifth-order KdV, and Gardner equations can be derived from the same set of Euler’s equations (7)-(10). Different final equations result from the different ordering of small parameters and consistent perturbation approach up to first or second order in small parameters.

In 2020, we extended their results to cases with an uneven bottom in [14], but still in (1+1)-dimensional theory. We showed that the terms originating from the bottom have the same universal form for all these four nonlinear equations. However, the validity of the obtained generalized wave equations is limited to the cases when the bottom functions are piecewise linear. On the other hand,
the corresponding sets of the Boussinesq equations are valid for the arbitrary form of the bottom functions.

In the present paper there are four small parameters, $\alpha, \beta, \gamma, \delta$. In order to make calculations easier, we will follow the idea from [13, 14], relating all small parameters to a single one, called leading parameter. This method allows us for easier control of the order of different terms, but the final forms of the obtained equations are presented in original parameters $\alpha, \beta, \gamma, \delta$. We discuss several cases, which are listed in Table 1. The table do not contain all possible second order cases, but mostly those that lead to well-known KdV-type and Gardner equations when reduced to (1+1)-dimensions.

### Table 1. Different ordering of small parameters considered in the paper.

3. **Case 1:** $\alpha = O(\beta), \quad \gamma = O(\beta), \quad \delta = O(\beta)$

Let us begin with the assumption that all small parameters are of the same order. For easier control of the orders of different terms let us denote

$$\alpha = A \beta, \quad \gamma = G \beta, \quad \delta = D \beta,$$

where $A, G, D$ are arbitrary but close to 1.

Insertion the velocity potential (14) into the boundary condition at the bottom (10) imposes the following relation

$$F = \beta^2 D \left(h_x f_x + G h_y f_y + h(f_{xx} + G f_{yy})\right)$$

$$+ \beta^3 D^2 \left(h h_x F_x + G h h_y F_y + \frac{1}{2} h^2 (F_{xx} + G F_{yy})\right) + O(\beta^3).$$

Equation (15), when only terms up to second order in small parameters are retained, that is

$$F = \beta^2 D \left(h_x f_x + G h_y f_y + h(f_{xx} + G f_{yy})\right)$$

allows us to express $F$ by $f$ and reduce the set of unknown functions to only $\eta$ and $f$. In higher order approximation equation (15) cannot be resolved for $F$. Then, retaining only terms up to second order,
one obtains the velocity potential, valid up to second-order approximation, expressed in terms of a single unknown function \( f(x, y, t) \) as

\[
\phi = f - \frac{1}{2} \beta z^2 (f_{xx} + G f_{yy}) + \frac{1}{24} \beta^2 z^4 (f_{xxxx} + 2G f_{xxyy} + G^2 f_{yyyy}) \\
+ \beta^2 z D (h_x f_x + Gh_y f_y + h(f_{xx} + G f_{yy})).
\] (17)

Now, we substitute the velocity potential (17) into (8) and (9), keeping terms only up to first order. Due to the term \( \frac{1}{\beta} \phi z \) in (8) and only second order valid expression for the potential (17) we can obtain valid Boussinesq’s equations only in first order in \( \alpha, \beta, \gamma, \delta \).

From (8) and (9) we get respectively

\[
\eta_t + f_{xx} + \frac{\gamma}{\beta} f_{yy} + \alpha \left( (\eta f_x)_x + \frac{\gamma}{\beta} (\eta f_y)_y \right) - \frac{1}{6} \beta \left( f_{4x} + 2\frac{\gamma}{\beta} f_{2x2y} + \left( \frac{\gamma}{\beta} \right)^2 f_{4y} \right) \\
- \delta \left( (h f_x)_x + \frac{\gamma}{\beta} (h f_y)_y \right) = 0 \quad \text{and} \quad (18)
\]

\[
\eta + f_t + \frac{1}{2} \alpha \left( f_{xx}^2 + \frac{\gamma}{\beta} f_{yy}^2 \right) - \frac{1}{2} \beta \left( f_{xxt} + \frac{\gamma}{\beta} f_{yxt} \right) = 0. \quad (19)
\]

Equations (18)-(19) are the first order Boussinesq equations for (2+1)-dimensional shallow water problem with an uneven bottom. When we reduce these equations to (1+1) dimensional (assuming translational invariance in \( y \) direction, that is, setting all \( y \)-derivatives equal zero), then we arrive at

\[
\eta_t + f_{xx} + \alpha (\eta f_x)_x - \frac{1}{6} \beta f_{4x} - \delta (h f_x)_x = 0, \quad (20)
\]

\[
\eta + f_t + \frac{1}{2} \alpha f_{xx}^2 - \frac{1}{2} \beta f_{xxt} = 0. \quad (21)
\]

Denoting \( w = f_x \) and taking \( x \)-derivative of (21) one gets this set of Boussinesq’s equation in the following form

\[
\eta_t + w_x + \alpha (\eta w)_x - \frac{1}{6} \beta w_{xxx} - \delta (h w)_x = 0, \quad (22)
\]

\[
w_t + \eta_x + \alpha w_x - \frac{1}{2} \beta w_{xxt} = 0, \quad (23)
\]

identical to the equations (17)-(18) derived by us in [14]. In [14], we also demonstrated that these two equations could be made compatible and reduced to the KdV equation generalized for uneven bottom [14, Eq. (29)], when the bottom profile \( h(x) \) is a piecewise linear function. This equation has the following form

\[
\eta_t + \eta_x + \frac{3}{2} \alpha \eta \eta_x + \frac{1}{6} \eta_{xxx} - \frac{1}{4} \delta (2 h \eta_x + h \eta) = 0. \quad (24)
\]
In [11], the authors presented the derivation of two new (2+1)-dimensional third- and fifth-order nonlinear evolution equations when $\alpha, \beta, \gamma$ are of the same order and the bottom is flat ($\delta = 0$). However, as we proved in [12], all results shown in [11] are false since the derivation lacks of consistency. When the method used by the authors is applied in a consistent way, the problem is reduced to well known KdV equation. For details, see [12].

The Boussinesq equations (18)-(19) look very complicated. It is hard to imagine how one can get a single equation for wave profile from them. On the other hand, one can reduce this set to a single equation by inserting $\eta = -\left[f_t + \frac{1}{2}\alpha \left(f_x^2 + \frac{\gamma}{\beta} f_y^2\right) - \frac{1}{2}\beta \left(f_{xxt} + \frac{\gamma}{\beta} f_{yxt}\right) \right]$ determined from (19) into (18) and retaining only terms up to first order. The result is

$$f_{xx} + \frac{\gamma}{\beta} f_{yy} - f_{tt} - \alpha \left[f_t \left(f_{xx} + \frac{\gamma}{\beta} f_{yy}\right) + \left(f_x^2 + \frac{\gamma}{\beta} f_y^2\right)_t\right]$$

$$- \beta \left[\frac{1}{6} \left(f_{4x} + 2 \frac{\gamma}{\beta} f_{2x2y} + \left(\frac{\gamma}{\beta}\right)^2 f_{4y}\right) - \frac{1}{2} \left(f_{xxx} + \frac{\gamma}{\beta} f_{yyt}\right)\right]$$

$$- \delta \left[(hf_x)_x + \frac{\gamma}{\beta} (hf_y)_y\right] = 0.$$

Equation (25) can be simplified utilizing zeroth-order solutions. In zeroth-order we have from (18)-(19)

$$\eta_t + f_{xx} + \frac{\gamma}{\beta} f_{yy} = 0 \quad \text{and} \quad \eta + f_t = 0.$$

So, $f_t = -\eta$ and $f_{tt} = -\eta_t = f_{xx} + \frac{\gamma}{\beta} f_{yy}$. Then we have

$$f_{xxtt} = \frac{\partial^2}{\partial x^2} \left(f_{xx} + \frac{\gamma}{\beta} f_{yy}\right) = f_{4x} + \frac{\gamma}{\beta} f_{xxyy}, \quad f_{yytt} = \frac{\partial^2}{\partial y^2} \left(f_{xx} + \frac{\gamma}{\beta} f_{yy}\right) = f_{xxyy} + \frac{\gamma}{\beta} f_{4y},$$

and the first-order term

$$- \frac{1}{2} \left(f_{xxtt} + \frac{\gamma}{\beta} f_{yytt}\right) = - \frac{1}{2} \left(f_{4x} + 2 \frac{\gamma}{\beta} f_{2x2y} + \left(\frac{\gamma}{\beta}\right)^2 f_{4y}\right)$$

receives the same form like the term with the factor $\frac{1}{6}$ in front. Then equation (25) receives the simpler form

$$f_{xx} + \frac{\gamma}{\beta} f_{yy} - f_{tt} - \alpha \left[f_t \left(f_{xx} + \frac{\gamma}{\beta} f_{yy}\right) + \left(f_x^2 + \frac{\gamma}{\beta} f_y^2\right)_t\right]$$

$$+ \beta \left[\frac{1}{3} \left(f_{4x} + 2 \frac{\gamma}{\beta} f_{2x2y} + \left(\frac{\gamma}{\beta}\right)^2 f_{4y}\right)\right] - \delta \left[(hf_x)_x + \frac{\gamma}{\beta} (hf_y)_y\right] = 0.$$

If the solution $f(x, y, t)$ to (26) is known, the equation (19) supplies the surface profile function

$$\eta(x, y, t) = - \left[f_t + \frac{1}{2}\alpha \left(f_x^2 + \frac{\gamma}{\beta} f_y^2\right) - \frac{1}{2}\beta \left(f_{xxt} + \frac{\gamma}{\beta} f_{yxt}\right)\right].$$
4. CASE 2: $\alpha = O(\beta), \quad \gamma = O(\beta), \quad \delta = O(\beta^2)$

Denote now

$$\alpha = A\beta, \quad \gamma = G\beta, \quad \delta = D\beta^2.$$ 

In this case, the boundary condition at the bottom (10) imposes the following relation

$$(27) \quad F = \beta^3 D [(h_f)_x + G(h_f)_y] + \frac{1}{2} \beta^3 D^2 [(h^2 F)_x + G(h^2 F)_y] + O(\beta^7),$$

which gives $F = \beta^3 D [(h_f)_x + G(h_f)_y]$ valid up to fourth order. Therefore, in this case, it is possible to obtain the Boussinesq equations valid up to third order in small parameters.

From (8) we get (up to second order)

$$(28) \quad \eta + f_{xx} + \frac{\gamma}{\beta} f_{yy} + \alpha \left[ (\eta f)_x + \frac{\gamma}{\beta} (\eta f)_y \right] - \frac{1}{6} \beta \left[ f_{4x} + 2\frac{\gamma}{\beta} f_{2x2y} + \left( \frac{\gamma}{\beta} \right)^2 f_{4y} \right]$$

$$- \frac{1}{2} \alpha \beta (\eta f_{3x})_x - \frac{1}{2} \alpha \gamma [\eta f_{x2y} + 2\eta f_{x2y} + \eta f_{xy}] - \frac{1}{120} \beta^2 f_{6x}$$

$$- \frac{1}{40} \beta \gamma \left[ f_{4x2y} + \frac{\gamma}{\beta} f_{2x4y} + \frac{1}{3} \left( \frac{\gamma}{\beta} \right)^2 f_{6y} \right] - \delta \left[ (h_f)_x + \frac{\gamma}{\beta} (h_f)_y \right] = 0,$$

whereas the result from (9), in the same second order, is

$$(29) \quad \eta + f_t + \frac{1}{2} \alpha \left( f_x + \frac{\gamma}{\beta} f_y \right)^2 - \frac{1}{2} \beta \left( f_{xx} + \frac{\gamma}{\beta} f_{yy} \right) + \alpha \beta \left[ \frac{1}{2} (f_{xx} - f_x f_3x) - \eta f_{xxt} \right]$$

$$+ \alpha \gamma \left[ f_{yy} + f_{xx} f_{yy} - \frac{1}{2} (f_x f_{xyy} + f_y f_{xxy}) + \frac{\gamma}{\beta} (f_{yy} - f_y f_{3y}) \right]$$

$$+ \frac{1}{24} \beta^2 \left[ f_{4xt} + 2\frac{\gamma}{\beta} f_{2x2yt} + \left( \frac{\gamma}{\beta} \right)^2 f_{4yt} \right] = 0.$$

Note that the term with $\delta$ in (28), originating from the uneven bottom, has identical form as such term in (18) although now it is of second order. Let us rewrite (29) in the form

$$(30) \quad \eta (1 - \alpha \beta f_{xxt} - \alpha \gamma f_{yy}) = - \left\{ f_t + \frac{1}{2} \alpha \left( f_x^2 + \frac{\gamma}{\beta} f_y^2 \right) - \frac{1}{2} \beta \left( f_{xxt} + \frac{\gamma}{\beta} f_{yy} \right) + \alpha \beta \left[ \frac{1}{2} (f_{xx}^2 - f_x f_{3x}) \right]$$

$$+ \alpha \gamma \left[ f_{xx} f_{yy} - \frac{1}{2} (f_x f_{xyy} + f_y f_{xxy}) + \frac{\gamma}{\beta} (f_{yy} - f_y f_{3y}) \right]$$

$$+ \frac{1}{24} \beta^2 \left[ f_{4xt} + 2\frac{\gamma}{\beta} f_{2x2yt} + \left( \frac{\gamma}{\beta} \right)^2 f_{4yt} \right] \right\}.$$
Multiplying both sides by \((1 + \alpha\beta f_{xxt} + \alpha\gamma f_{yyt})\) and retaining only terms up to second order we obtain

\[
\eta = - \left\{ f_t + \frac{1}{2} \alpha \left( f_x^2 + \frac{\gamma}{\beta} f_y^2 \right) - \frac{1}{2} \beta \left( f_{xxt} + \frac{\gamma}{\beta} f_{yyt} \right) + \alpha \beta \left[ \frac{1}{2} (f_{xx}^2 - f_x f_{3x}) \right] \\
+ \alpha \gamma \left[ f_{xx} f_{yy} - \frac{1}{2} (f_x f_{xyy} + f_y f_{xxy}) + \frac{\gamma}{\beta} (f_{yy}^2 - f_y f_{3y}) \right] \\
+ \frac{1}{24} \beta^2 \left[ f_{4xt} + 2 \frac{\gamma}{\beta} f_{2x2yt} + \left( \frac{\gamma}{\beta} \right)^2 f_{3yt} \right] \} + f_t (\alpha \beta f_{xxt} + \alpha \gamma f_{yyt}).
\]

Substituting \(\eta\) defined by (31) into (28) and keeping only the terms up to second order allows us to obtain a nonlinear (2+1)-dimensional differential equation for the function \(f(x, y, t)\). This equation
has the following form

\begin{align*}
(32) \\
& f_{xx} + Gf_{yy} - f_{tt} - AG(f_{tt}f_{yy} + f_t f_{2y2t}) - A(f_{tt}f_{2xt} + f_t f_{2x2t}) \\
& + \beta \left[ -GA^2 \left( f_{yyt}f_{xx} + f_t f_{xxt}f_{2y2t} + G^2 f_{yy}f_{xx} + f_t f_{y2yt}f_{2x2t} + f_t f_{yyt}f_{22xt} - f_t f_{yy}f_{2xt} + f_t f_{2yyt} \right) - \frac{1}{2} Gf_{2y2t} - \frac{1}{6} G^2 f_{4y} + \frac{1}{2} f_{2x2t} - \frac{1}{3} Gf_{2x2y} - \frac{1}{6} f_{4x} \right] \\
& + \beta^2 \left[ A^2 G^3 \left( f_{xy}f_{y2yt}f_{3y} + f_t f_{3y}f_{3yt} + f_t f_{yyt}f_{4y} \right) + \frac{1}{120} G^3 f_{6y} \\
& + A^2 G^2 \left( -\frac{3}{2} f_y f_{y2y} + \frac{1}{2} f_{yyt}f_{xx}f_{2y2t} + \frac{1}{2} f_t f_{x2yt}f_{2x2t} + \frac{1}{2} f_{xy}f_{3y}f_{22xt} + \frac{1}{2} f_t f_{4y}f_{2xt} \right) \\
& + \frac{1}{6} f_{xy}f_{yyt}f_{3y} + \frac{1}{2} f_t f_{3yt}f_{2x2y} + \frac{1}{2} f_t f_{3yt}f_{2x2y} + f_t f_{yyt}f_{22x2t} \right) \\
& + AG^2 \left( -\frac{1}{6} f_{yy}f_{yyt} + f_y f_{3y} + f_y f_{3yt} + \frac{1}{6} f_t f_{4y} \right) \\
& + A^2 G \left( -\frac{1}{6} f_{yy}f_x^2 f_{2yt} - \frac{1}{2} f_y f_{xx} + \frac{1}{2} f_{xy}f_{2x2y}f_{22xt} + \frac{1}{2} f_{xy}f_{22xt}f_{2x2t} + \frac{1}{2} f_t f_{2xy}f_{22yt} + \frac{1}{2} f_y f_{xxt}f_{3x} \right) \\
& + \frac{1}{2} f_t f_{x2yt}f_{3x} + \frac{1}{2} f_t f_{x2y}f_{3x} + \frac{1}{2} f_{yyt}f_{4x} + \frac{1}{2} f_t f_{2yt}f_{2x2y} + f_t f_{x2yt}f_{2x2y} - 2f_y f_{x2yt} \right) \\
& + G^2 \left( -\frac{1}{24} f_{4y2t} + \frac{1}{40} f_{2x4y} \right) + DG \left( -h_y f_y - h f_{yy} \right) - D \left( h f_x + h f_{xx} \right) \\
& + AG \left( +f_{xt} f_{x2y} + f_{x2yt}f_{2yt} - \frac{1}{2} f_{yyt}f_{xx} + \frac{1}{2} f_y f_{x2yt} + f_y f_{2x2y} + f_t f_{2x2y} \right) \\
& + G \left( -\frac{1}{12} f_{2x2y2t} + \frac{1}{40} f_{4x2y} \right) + A \left( -\frac{1}{2} f_{xx}f_{2xt} + f_x f_{3x} + f_x f_{3xt} + \frac{1}{2} f_t f_{4x} \right) \\
& + A^2 \left( \frac{1}{2} f_{xx}f_{2xt}f_{3x} + \frac{1}{2} f_t f_{3x}f_{3xt} + \frac{1}{2} f_t f_{2xt}f_{4x} \right) - \frac{1}{24} f_{4x2t} + \frac{1}{120} f_{6x} \right] = 0.
\end{align*}

In (32) we didn’t come back to original parameters $\alpha, \beta, \gamma, \delta$ for easier recognition of first order and second order terms.

In principle, if the solution $f(x, y, t)$ to (32) is known, the equation (31) supplies the surface profile function. However, the complexity of the equation (32) gives a little hope for finding the solution.
Let us check how the Boussinesq equations (28)-(29) look like when they are reduced to (1+1)-
dimensions. From (28) we get (denoting $w = f_x$)

$$\eta_t + w_x + \alpha (\eta w)_x - \frac{1}{6} \beta \omega_{3x} - \frac{1}{2} \alpha \beta (\eta w_{2x})_x - \frac{1}{120} \beta^2 w_{5x} - \delta (h w)_x = 0,$$

whereas from (29) after differentiation over $x$ we obtain

$$\eta_x + w_t + \alpha w w_x - \frac{1}{2} \beta w_{2xt} - \alpha \beta \left[ \frac{1}{2} (w_x w_{2x} - w w_{3x}) - (\eta w_{xt})_x \right] + \frac{1}{24} \beta^2 w_{4xt} = 0.$$

The (1+1)-dimensional Boussinesq equations (33)-(34) are identical with [14, Eqs. (37)-(38)], and
for the case of flat bottom ($\delta = 0$) are identical with [13, Eqs. (11)-(12)]. Then, the full (2+1)-
dimensional Boussinesq equations (28)-(29) seem to be correct.

5. Case 3: $\alpha = O(\beta), \quad \gamma = O(\beta^2), \quad \delta = O(\beta)$

Derivations of the Kadomtsev-Petviashvili (KP) equation suggest that variations of the surface waves should be slower in the $y$-direction perpendicular to the wave propagation ($x$-direction). Therefore it is worth studying the case when $\gamma = O(\beta^2)$. Denote now

$$\alpha = A \beta, \quad \gamma = G \beta^2, \quad \delta = D \beta,$$

where, as earlier, $A, G, D$ are arbitrary constants close to 1.

In this case, the boundary condition at the bottom (10) imposes the following relation

$$F = \beta^2 D (h f_x)_x + \beta^3 \left[ D G (h f_y)_y + D^2 \frac{1}{2} (h^2 F_x)_x \right] + O(\beta^4).$$

Therefore, the equation $F = \beta^2 D (h f_x)_x$ is valid only to second order in small parameters. So the explicit form of velocity potential, valid up to second order, is now

$$\phi = f - \frac{1}{2} z^2 (\beta f_{2x} + \gamma f_{2y}) + z \beta^2 D (h f_x)_x + \frac{1}{24} z^4 \beta^2 f_{4x}.$$

Now, if we substitute the velocity potential (37) into (8) and (9), the resulting equations are valid only up to first order. This fact contradicts the assumption that the parameter $\gamma$ is of the second order. Therefore, in this case, when $\alpha, \beta, \delta$ are of the first order, and $\gamma$ is of the second order, consistent Boussinesq equations can not be derived. However, when the bottom is flat, the Boussinesq equations can be derived. We show this in the subsequent subsection.
5.1. **Case 3a:** \( \alpha = O(\beta), \quad \gamma = O(\beta^2), \quad \delta = 0. \) For flat bottom case \( F = 0, \) it is always possible to derive the Boussinesq equations up to arbitrary order. Since we are interested in second order equations, we need the velocity potential up to third order. So, let us use the following form of velocity potential

\[
\phi = f - \frac{1}{2} z^2 (\beta f_{2x} + \gamma f_{2y}) + \frac{1}{24} z^4 (\beta^2 f_{4x} + 2\beta \gamma f_{2x2y} + \gamma^2 f_{4y}) - \frac{1}{720} z^6 (\beta^3 f_{6x} + 3\beta^2 \gamma f_{4x2y} + 3\beta \gamma^2 f_{2x4y} + f \gamma^3) + \cdots
\]

Then, substituting velocity potential (38) into kinematic (8) and dynamic (9) boundary conditions at the surface and limiting formulas to second order, we obtain the following set of the Boussinesq equations, respectively

\[
\eta_t + f_{xx} + \alpha(\eta f_x)_x - \frac{1}{6} \beta f_{4x} + \gamma f_{yy} + \frac{\alpha \gamma}{\beta} (\eta f_y)_y - \frac{1}{3} \gamma f_{2x2y} - \frac{1}{2} \alpha \beta (\eta f_{2x})_x + \frac{1}{120} \beta^2 f_{6x} = 0 \quad \text{and}
\]

\[
\eta + f_t + \frac{1}{2} \alpha f_x^2 - \frac{1}{2} \beta f_{xx} + \frac{1}{2} \alpha \gamma f_y^2 - \frac{1}{2} \gamma f_{yy} + \alpha \beta \left( \frac{1}{2} f_{xx}^2 - \eta f_{xxt} - \frac{1}{2} f_x f_{xxx} \right) + \frac{1}{24} \beta^2 f_{4xt} = 0.
\]

Note that all terms in second rows of (39)-(40) are second order. This system of equations (39)-(40), when restricted to \((1+1)\) dimensions, should be equivalent to the Boussinesq equation which leads to the extended KdV equation.

As a check, let us set \( \gamma = 0 \) in (39)-(40). Then, we obtain the Boussinesq equations for flat bottom case in the form

\[
\eta_t + f_{xx} + \alpha(\eta f_x)_x - \frac{1}{6} \beta f_{4x} - \frac{1}{2} \alpha \beta (\eta f_{3x})_x + \frac{1}{120} \beta^2 f_{6x} = 0 \quad \text{and}
\]

\[
\eta + f_t + \frac{1}{2} \alpha f_x^2 - \frac{1}{2} \beta f_{xxt} + \alpha \beta \left( \frac{1}{2} f_{xx}^2 - \eta f_{xxt} - \frac{1}{2} f_x f_{xxx} \right) + \frac{1}{24} \beta^2 f_{4xt} = 0.
\]

Denoting \( w = f_x \) and differentiating the second equation over \( x \), we obtain

\[
\eta_t + w_x + \alpha(\eta w)_x - \frac{1}{6} \beta w_{3x} - \frac{1}{2} \alpha \beta (\eta w_{2x})_x + \frac{1}{120} \beta^2 w_{5x} = 0 \quad \text{and}
\]

\[
\eta_x + w_t + \alpha w w_x - \frac{1}{2} \beta w_{xxt} + \alpha \beta \left( \frac{1}{2} (w_x w_{xx} - w w_{3x}) - (\eta w_x)_x \right) + \frac{1}{24} \beta^2 w_{4xt} = 0.
\]

Equations (43)-(44) are identical to equations (33)-(34) and to [16, Eqs. (8)-(9)] in which \( \delta = 0 \). Eliminating \( w \) from them one obtains in first order the KdV equation and in second order the extended KdV (KdV2) equation.
Rewrite (40), separating terms with \( \eta \)

\[
\eta(1 - \alpha \beta f_{xxt}) = - \left[ f_t + \frac{1}{2} \alpha f_x^2 - \frac{1}{2} \beta f_{xxt}ight.
\]

\[
+ \frac{1}{2} \alpha \gamma \beta f_y^2 - \frac{1}{2} \gamma f_{yyt} + \alpha \beta \left( \frac{1}{2} f_{xxt} - \frac{1}{2} f_x f_{xxx} + \frac{1}{24} \beta^2 f_{4xt} \right].
\]

(45)

Multiplying (45) by \((1 + \alpha \beta \eta f_{xxt})\) and retaining terms up to second order one gets

\[
\eta = - \left[ f_t + \frac{1}{2} \alpha f_x^2 - \frac{1}{2} \beta f_{xxt} + \frac{1}{2} \alpha \gamma \beta f_y^2 - \frac{1}{2} \gamma f_{yyt} + \alpha \beta \left( \frac{1}{2} f_{xxt} - \frac{1}{2} f_x f_{xxx} + f_t f_{xxt} \right) + \frac{1}{24} \beta^2 f_{4xt} \right].
\]

(46)

Inserting \( \eta \) from (46) into (40) and retaining terms up to second order one arrives with the final equation for the \( f(x, y, z, t) \) function

\[
f_{xx} - f_{tt} + \frac{\gamma}{\beta} f_{yy} - \alpha f_t (f_{xx} + f_{tt}) + f_x f_{xxt} - \frac{1}{6} \beta (f_{4x} - 3 f_{xxt}) - \alpha^2 (f_x f_{xt} + f_t f_{xx}) f_t
\]

\[- \alpha \beta \left( \frac{1}{2} f_{xxt} + f_{4x} f_t + f_t f_{xxt} + f_t f_{xxt} - f_{xt} f_{3x} - f_x f_{3xt} - \frac{1}{2} f_t f_{4x} \right)
\]

\[- \frac{\alpha \gamma}{\beta^2} (f_t f_{yy} + 2 f_y f_{yt}) + \gamma \left( \frac{1}{2} f_{yytt} - \frac{1}{3} f_{2x2y} \right) + \beta^2 \left( \frac{1}{120} f_{6x} - \frac{1}{24} f_{4x2t} \right) = 0.
\]

(47)

If the solution \( f(x, y, t) \) to (47) is known, the equation (46) provides the surface wave profile function \( \eta(x, y, t) \).

6. Case 4: \( \alpha = O(\beta), \quad \gamma = O(\beta^2), \quad \delta = O(\beta^2) \)

Denote now

\[
\alpha = A \beta, \quad \gamma = G \beta^2, \quad \delta = D \beta^2.
\]

Now, the boundary condition at the bottom (10) imposes the following relation

\[
F = \beta^3 D \left[ (h f_x)_x + G(h f_y)_y \right] + \beta^4 D G (h f_y)_y + \beta^5 \frac{1}{2} D (h^2 F_x)_x + O(\beta^6),
\]

(48)

which gives \( F = \beta^3 D \left[ (h f_x)_x + G(h f_y)_y \right] + \beta^4 D G (h f_y)_y \) and consequently the velocity potential valid up to fourth order. Therefore, in this case, it is possible to obtain the Boussinesq equations valid up to third order in small parameters. We will proceed up to second order which is enough complicated. From (8) we obtain

\[
\eta_t + f_{xx} + \alpha (\eta f_x)_x - \frac{1}{6} \beta f_{4x} + \frac{\gamma}{\beta} f_{yy}
\]

\[- \frac{1}{2} \alpha \beta (\eta_x f_{3x})_x + \frac{\alpha \gamma}{\beta} (\eta_y f_y)_y - \frac{1}{3} \gamma f_{xyyy} + \frac{1}{120} \beta^2 f_{6x} - \delta (h f_x)_x = 0.
\]

(49)
Equation (9) gives

\[ \eta + f_t + \frac{1}{2} \alpha f_x^2 - \frac{1}{2} \beta f_{xxt} + \alpha \beta \left( \frac{1}{2} f_{xx}^2 - f_x f_{3x} \right) - \eta f_{xxt} - \frac{1}{2} \gamma f_{yyt} + \frac{1}{2} \frac{\alpha \gamma f_y^2}{\beta} + \frac{1}{24} \beta^2 f_{4xt} = 0. \]  

Equations (49)-(50) are the Boussinesq equations for the case when \( \alpha \approx \beta \) and \( \gamma \approx \delta \approx \beta^2 \).

Like in other cases, from (50) we can calculate (up to second order)

\[ \eta = - \left[ f_t + \frac{1}{2} \alpha f_x^2 - \frac{1}{2} \beta f_{xxt} + \alpha \beta \left( \frac{1}{2} f_{xx}^2 - f_x f_{3x} \right) - \frac{1}{2} \gamma f_{yyt} + \frac{1}{2} \frac{\alpha \gamma f_y^2}{\beta} + \frac{1}{24} \beta^2 f_{4xt} \right] + \alpha \beta f_t f_{xxt}. \]  

Substituting this expression for \( \eta \) into (49) and retaining term up to second order, we obtain the single nonlinear differential equation for the function \( f(x, y, t) \)

\[ f_{xx} - f_{tt} - \alpha (2 Af_x f_x + f_t f_{xx}) - \frac{1}{6} \beta (f_{4x} - 3 f_{xxt}) + \frac{\gamma}{\beta} f_{yy}. \]  

Like in other (2+1)-dimensional cases, if the solution \( f(x, y, t) \) to (52) is known, then the equation (51) provides the surface profile function \( \eta(x, y, t) \).

Let us reduce equations (49)-(50) to (1+1)-dimensions. Then we obtain

\[ \eta_t + f_{xx} + \alpha (\eta f_x)_x - \frac{1}{6} \beta f_{4x} - \frac{1}{2} \alpha \beta (\eta_x f_{3x})_x - \frac{1}{120} \beta^2 f_{6x} - \delta (h f_x)_x = 0 \]  

and

\[ \eta + f_t + \frac{1}{2} \alpha f_x^2 - \frac{1}{2} \beta f_{xxt} + \alpha \beta \left( \frac{1}{2} f_{xx}^2 - f_x f_{3x} \right) - \eta f_{xxt} + \frac{1}{24} \beta^2 f_{4xt} = 0. \]  

Denoting \( w = f_x \) and differentiating (54) over \( x \) we have

\[ \eta_t + w_x + \alpha (\eta w)_x - \frac{1}{6} \beta w_{3x} - \frac{1}{2} \alpha \beta (\eta_x w_{2x})_x + \frac{1}{120} \beta^2 w_{5x} - \delta (h w)_x = 0 \]  

and

\[ \eta_x + w_t + \alpha w w_x - \frac{1}{2} \beta w_{xxt} + \alpha \beta \left( \frac{1}{2} (w_x w_{2x} - w w_{3x}) - (\eta w_x)_x \right) + \frac{1}{24} \beta^2 w_{4xt} = 0. \]  

The (1+1)-dimensional Boussinesq equations (55)-(56) are identical with [14, Eqs. (37)-(38)], which lead to derivation of the extended KdV equation generalised for an uneven bottom [14, Eq. (42)].
7. Case 5: \( \alpha = O(\beta^2), \quad \gamma = O(\beta^2), \quad \delta = O(\beta^2) \)

Denote now
\[
\alpha = A \beta^2, \quad \gamma = G \beta^2, \quad \delta = D \beta^2.
\]

Now, the boundary condition at the bottom (10) imposes the following relation
\[
F = \beta^3 D (h f_x)_x + \beta^4 D G (h f_y)_y - \beta^5 \frac{1}{2} D (h^2 F_x)_x + O(\beta^6),
\]
which gives \( F = \beta^3 D [(h f_x)_x] \) and consequently the velocity potential valid up to fourth order. Therefore, in this case it is possible to obtain the Boussinesq equations valid up to third order in small parameters. We will proceed up to second order which is enough complicated. From (8) we obtain
\[
\eta_t + f_{xx} - \frac{1}{6} \beta f_{4x} + \gamma \beta f_{yy} + \alpha (\eta f_x)_x - \frac{1}{120} \beta^2 f_{6x} - \frac{1}{3} \gamma f_{2x2y} - \delta (h f_x)_x = 0, \tag{58}
\]
whereas the result from (9) is
\[
\eta + f_t - \frac{1}{2} \beta f_{xx} - \frac{1}{2} \alpha f_{xt}^2 + \frac{1}{24} \beta^2 f_{4xx} - \frac{1}{2} \gamma f_{yyt} = 0. \tag{59}
\]
In (59), we didn’t take into account terms from surface tension \( (\tau = 0) \). Now, \( \eta \) determined from (59) is substituted into (58). Limiting this equation up to second order one obtains
\[
f_{xx} + \frac{\gamma}{\beta} f_{yy} - f_{tt} - \frac{1}{6} \beta f_{4x} + \frac{1}{2} \beta f_{xx} - \gamma f_{xx} f_{yy} - \beta^2 \left( \frac{1}{24} f_{4xt} + D \frac{1}{120} f_{6x} \right)
\]
\[
- \alpha (2 f_x f_{xt} + f_t f_{xx}) - \delta (h f_x)_x = 0. \tag{60}
\]

For a check, let us reduce the Boussinesq equations (58)-(59) to \((1+1)\)-dimensional case setting \( \gamma = 0 \). Then, after differentiating (59) over \( x \) and denoting \( w = f_x \) we obtain the set
\[
\eta_t + w_x - \frac{1}{6} \beta w_{3x} + \alpha (\eta w)_x - \frac{1}{120} \beta^2 w_{5x} - \delta (h f_x)_x = 0 \quad \text{and} \tag{61}
\]
\[
w_t + \eta_x - \frac{1}{2} \beta w_{xx} + \alpha w w_x + \frac{1}{24} \beta^2 w_{4xt} = 0. \tag{62}
\]

This set of equations, for \( \delta = 0 \), is identical to the equations (29)-30) in [13], limited to second order. Eliminating by the standard method the function \( w \), one obtains from them the well-known fifth-order KdV equation when \( \delta = 0 \), i.e., for the flat bottom. When \( \delta \neq 0 \), the final wave equation is the fifth-order KdV generalized for the uneven bottom [14, Eq. (68)], in which \( \tau = 0 \).
7.1. **Case 5a**: \( \alpha = O(\beta^2), \ \gamma = O(\beta^2), \ \delta = O(\beta^2), \ \gamma \neq 0 \). For thin fluid layers, surface tension may introduce significant changes into the dynamics. Using surface tension term in the form (11) in dynamical boundary condition at the surface (9), we obtain instead (59) more complicated equation

(63) \[
\eta + f_t - \beta \left( \frac{1}{2} f_{xx} + \gamma \eta_{xx} \right) + \frac{1}{2} \alpha f_x^2 + \frac{1}{24} \beta^2 f_{xx} - \gamma \left( \frac{1}{2} f_{yy} + \tau \eta_{yy} \right) = 0.
\]

In this case, we cannot reduce the Boussinesq equations (58)-(63) to a single equation. However, limiting to (1+1)-dimensions (as usual setting \( \gamma = 0 \), \( w = f_x \) and differentiating (63) over \( x \)) we obtain

(64) \[
\eta_t + w_x - \frac{1}{6} \beta w_{3x} + \alpha (\eta w)_x - \frac{1}{120} \beta^2 w_{5x} - \delta (h f_x)_x = 0 \quad \text{and}
\]

(65) \[
w_t + \eta_x - \beta \left( \frac{1}{2} w_{xx} + \tau \eta_{xx} \right) + \alpha w w_x + \frac{1}{24} \beta^2 w_{4xt} = 0.
\]

These equations are identical to [14, Eqs. (61)-(62)], which lead to the fifth-order KdV equation generalized for an uneven bottom [14, Eq. (68)].

8. **Case 6**: \( \beta = O(\alpha^2), \ \gamma = O(\alpha^2), \ \delta = O(\alpha^2) \)

Denote now

\[ \beta = B \alpha^2, \ \gamma = G \alpha^2, \ \delta = D \alpha^2. \]

Now, the boundary condition at the bottom (10) imposes the following relation

(66) \[
F = \alpha^4 (BD(h f_x)_x + DG(h f_y)_y) + \alpha^6 \frac{1}{2} (BD^2(h^2 F)_x + GD^2(h f_y)_y) + O(\alpha^8),
\]

which gives \( F = \alpha^4 (BD(h f_y)_y + DG(h f_y)_y) \) and consequently the velocity potential valid up to fourth order in the leading parameter. Therefore, in this case, it is possible to obtain the Boussinesq equations valid up to third order in small parameters. We will proceed up to second order, which is complicated enough. Then we can safely neglect higher order terms in surface tension term (11) and use dynamic boundary condition (9) in the following form

(67) \[
\phi_t + \frac{1}{2} \alpha \left( \phi_x^2 + \frac{\gamma}{\beta} \phi_y^2 + \frac{1}{\beta} \phi_z^2 \right) + \eta - \tau (\beta \eta_{xx} + \gamma \eta_{yy}) = 0, \quad \text{for} \quad z = 1 + \alpha \eta.
\]

From kinematic boundary condition at the surface (8), we obtain

(68) \[
\eta_t + f_{xx} + \frac{\gamma}{\beta} f_{yy} + \alpha \left( (\eta f_x)_x + \frac{\gamma}{\beta} (\eta f_y)_y \right) - \frac{1}{6} \beta \left( f_{4x} + \frac{\gamma^2}{\beta^2} f_{4y} \right) - \frac{1}{3} \gamma f_{2x2y} - \delta \left( (h f_x)_x + \frac{\gamma}{\beta} (h f_y)_y \right) = 0,
\]
whereas from dynamic boundary condition at the surface (67), the result is

\[ \eta + f_t + \frac{1}{2} \alpha \left( f_x^2 + \frac{\gamma}{\beta} f_y^2 \right) - \frac{1}{2} \beta f_{xx} + \gamma f_{yy} - \tau (\beta \eta_{xx} + \gamma \eta_{yy}) = 0. \]  

Equations (68)-(69) are the Boussinesq equations for the case when \( \beta \approx \gamma \approx \delta = O(\alpha^2) \).

When \( \tau \) is of the order of 1, what occurs for thin fluid layers, equation (69) can not be resolved to obtain \( \eta = G(f, f_x, f_y, f_t, \ldots) \), i.e. as a function of \( f \) and its derivatives only. Therefore, in this case, the Boussinesq set (68)-(69) can not be reduced to a single equation for \( f \) function.

Such reduction is, however, possible for cases when the depth of the fluid is of the order of meters. Then \( \tau \) is so small that terms \( -\tau (\beta \eta_{xx} + \gamma \eta_{yy}) \) in (69) can be safely neglected.

Substituting \( \eta = -\left[ f_t + \frac{1}{2} \left( f_x^2 + \frac{\gamma}{\beta} f_y^2 \right) - \frac{1}{2} (\beta f_{xx} + \gamma f_{yy}) \right] \) obtained from (69) with \( \tau = 0 \) into (68) we obtain a single nonlinear wave equation for the function \( f(x, y, t) \) in the form

\[ f_{xx} + \frac{\gamma}{\beta} f_{yy} - f_{tt} - \alpha \left[ (2 f_x f_{xx} + f_t f_{xx}) + \frac{\gamma}{\beta} (2 f_y f_{yy} + f_t f_{yy}) \right] - \delta [(h f_x)_x + (h f_y)_y] \]

\[ - \frac{1}{6} \beta \left[ f_{xx} + \left( \frac{\gamma}{\beta} \right)^2 f_y \right] + \frac{1}{2} \beta f_{xxtt} + \frac{1}{2} \gamma f_{yytt} - \frac{1}{3} \gamma f_{xxyy} \]

\[ - \alpha^2 \left[ \frac{3}{2} \left( f_x f_{xx} + \left( \frac{\gamma}{\beta} \right)^2 f_y f_{yy} \right) + \frac{1}{2} \gamma (f_x f_{yy} + f_y f_{xx}) + 4 f_x f_y f_{xt} \right] = 0. \]

Limiting equations (68)-(69) by setting \( \gamma = 0 \) we obtain from (68)

\[ \eta_t + w_x + \alpha (\eta w)_x - \frac{1}{6} \beta w_{xxx} - \delta (h w)_x = 0. \]

From (69), after setting \( \gamma = 0 \) and differentiating over \( x \) we have

\[ \eta_x + w_t + \alpha w w_x - \frac{1}{2} \beta w_{xxt} - \tau \beta \eta_{xxx} = 0. \]

Equations (71)-(72) are identical with equations (85)-(86) from [14], when the latter are limited to second order. Therefore, one can make them compatible and derive a single wave equation for wave profile function \( \eta(x, t) \). Such procedure leads to the equation identical with the equation (91) from [14], which is the Gardner equation generalized for an uneven bottom. For \( \delta = 0 \), that is for the flat bottom, this equation receives the form [14, Eq. (92)], the usual Gardner equation.

9. Conclusions

In the model of an ideal fluid, we have derived several sets of Boussinesq’s equations for (2+1)-dimensional nonlinear waves. When restricted to (1+1)-dimensions, the cases discussed include the Korteweg-de Vries equation, extended KdV, fifth-order KdV, and Gardner equations, both for a flat and an uneven bottom. Even though these Boussinesq’s equations are only first or second order in
small parameters, they are too complicated in (2+1)-dimensions to obtain single wave equations for surface profile function $\eta(x, y, t)$.

The Boussinesq equations, in each case, constitute a set of coupled partial differential equations for two functions, $\eta(x, y, t)$ - surface profile function and the function $f(x, y, t)$ which determines the velocity potential through the equation (13). For (1+1)-dimensions it is always possible to eliminate $f(x, y, t)$ from the Boussinesq set and arrive to a single wave equation of the KdV-type for the wave profile function $\eta(x, y, t)$. For (2+1)-dimensional cases it seems to be impossible due to the complexity of these equations. However, for each (2+1)-dimensional case, it is possible to eliminate the function $\eta(x, y, t)$ and obtain a single nonlinear wave equation for the function $f(x, y, t)$. The disadvantage of this result is that the function $f(x, y, t)$ is not a directly observed quantity. Only by knowing the $f(x, y, t)$ solution can one construct a solution of a wave profile $\eta(x, y, t)$.

APPENDIX

In the original, dimension variables the term originating from additional pressure due to the surface tension has the following form [15]

\begin{equation}
ST = -\frac{T}{\bar{g}} \nabla \cdot \left( \frac{\nabla \eta}{1 + |\nabla \eta|^2} \right) = -\frac{T}{\bar{g}} \left( (1 + \eta_x^2)\eta_{yy} + (1 + \eta_y^2)\eta_{xx} - 2\eta_x \eta_y \eta_{xy} \right) \frac{(1 + \eta_x^2 + \eta_y^2)^{3/2}}{(1 + \eta_x^2 + \eta_y^2)^{3/2}}.
\end{equation}

In (73), $\nabla = (\partial_x, \partial_y)$ is two-dimensional gradient operator, and $T$ is fluid’s surface tension coefficient. After transformation (6) to non-dimensional scaled variables we obtain (tildas are again dropped)

\begin{equation}
ST = -\frac{T}{\bar{g}H^2} \beta \left( 1 + \alpha^2 \beta \eta_y^2 \right) \eta_{xx} + \gamma \left( 1 + \alpha^2 \beta \eta_x^2 \right) \eta_{yy} - 2\alpha^2 \beta \gamma \eta_x \eta_y \eta_{xy} \frac{(1 + \alpha^2 \beta \eta_x^2 + \alpha^2 \gamma \eta_y^2)^{3/2}}{(1 + \alpha^2 \beta \eta_x^2 + \alpha^2 \gamma \eta_y^2)^{3/2}}
\end{equation}

In (74), we first expand the factor $1/ (1 + \alpha^2 \beta \eta_x^2 + \alpha^2 \gamma \eta_y^2)^{3/2}$ assuming that terms $\alpha^2 \beta \eta_x^2$ and $\alpha^2 \gamma \eta_y^2$ are small.

Since we are interested in Boussinesq’s equations up to second order in small parameters it is enough to use the surface term in the form

\begin{equation}
ST = -\tau \left( \beta \eta_{xx} + \gamma \eta_{yy} \right).
\end{equation}
