SPLIT EXTENSIONS AND KK-EQUIVALENCES FOR QUANTUM PROJECTIVE SPACES

FRANCESCO ARICI, SOPHIE EMMA MIKKELSEN

Abstract. We study the noncommutative topology of the $C^*$-algebras $C(CP^n_q)$ of the quantum projective spaces within the framework of Kasparov’s bivariant K-theory. In particular, we construct an explicit KK-equivalence with the commutative algebra $C^{n+1}$. Our construction relies on showing that the extension of $C^*$-algebras relating two quantum projective spaces of successive dimensions admits a splitting, which we can describe explicitly using graph algebra techniques.

1. Introduction

Gelfand duality, which lies at the base of noncommutative geometry, establishes an equivalence of categories between commutative $C^*$-algebras and locally compact Hausdorff spaces. For this reason, when studying general noncommutative $C^*$-algebras, even though there is no longer an underlying space, one often thinks of them as algebras of continuous functions on a non-existing virtual space.

This approach is particularly effective when working with so-called quantum deformations of spaces: many classical topological spaces have a $q$-deformed analogues, obtained from quantum groups and their homogeneous spaces.

The $C^*$-algebra of the quantum $(2n+1)$-sphere by Vaksman and Soibelman [22], denoted $C(S^q_{2n+1})$, is perhaps one of the most studied noncommutative spaces within this class. It is constructed as a quantum homogeneous space for the special unitary group, and can also be proven to be isomorphic to a universal $C^*$-algebra in $(n+1)$ generators subject to a set of commutation relations. In those relations, a parameter $q \in (0,1)$ plays a central role, making the resulting $C^*$-algebra noncommutative. When writing $C(S^q_{2n+1})$ for the $C^*$-algebra of the quantum sphere, one often thinks of $S^q_{2n+1}$ as a virtual space.

If one lets the parameter $q = 1$, then the $C^*$-algebra $C(S^1_{2n+1})$ is commutative and isomorphic to the $C^*$-algebra $C(S^{2n+1})$ of continuous functions on the $(2n+1)$-sphere.

Like their classical counterparts, the odd quantum spheres are endowed with a canonical $U(1)$-action, allowing one to define, in total analogy with the commutative setting, the quantum complex projective space $C(CP^n_q)$ as the fixed point algebra for that action. In [13], Hong and Szymański showed that both $C(S^q_{2n+1})$ and $C(CP^n_q)$ are graph $C^*$-algebras. Through the graph-algebraic picture, one can obtain useful information about the structure of those $C^*$-algebra, including topological invariants, by only considering properties of the underlying graph. In particular, using graph $C^*$-algebra techniques, the K-theory groups of $C(CP^n_q)$ can be found to agree with the ones of their classical counterparts:

$$K_0(C(CP^n_q)) \cong \mathbb{Z}^{n+1}, \quad K_1(C(CP^n_q)) \cong \{0\}.$$  

In [13], the authors show that for $n \geq 1$, the algebras of two projective spaces of successive dimension fit into an extension of $C^*$-algebras of the from

$$0 \longrightarrow K \longrightarrow C(CP^n_q) \longrightarrow C(CP^{n-1}_q) \longrightarrow 0 ,$$  

with the convention that $C(CP^{n-1}_q) \cong \mathbb{C}$. It is worth stressing that the exact sequence for $n = 1$,

$$0 \longrightarrow K \longrightarrow C(CP^1_q) \longrightarrow \mathbb{C} \longrightarrow 0 ,$$  

is known to split, which implies that the algebra $C(CP^1_q)$ is isomorphic to the minimal unitisation of the compacts. Note also that one can also compute the K-theory groups of quantum projective spaces inductively, using the above exact sequence (1).

Key words and phrases. Quantum projective space, KK-theory, KK-equivalence, Graph algebras.
In the present work, we bring the analysis of the topological invariants of quantum projective spaces further and study these algebras within the framework of Kasparov’s bivariant K-theory [17]. In particular, we construct an explicit KK-equivalence between the algebras $C(\mathbb{P}_q^n)$ and $\mathbb{C}^{n+1}$.

Since the two $C^*$-algebras have the same K-theory, such a KK-equivalence follows provided $C(\mathbb{P}_q^n)$ is contained in the class of $C^*$-algebras that satisfy the Universal Coefficient Theorem (UCT) of Rosenberg and Schochet. Indeed, by [20, Corollary 7.5] (see also, [5, Corollary 23.10.2]), two $C^*$-algebras in the UCT class are KK-equivalent if and only if they have isomorphic K-theory groups.

To see that the algebra $C(\mathbb{P}_q^n)$ is in the UCT class, one observes that the UCT class is closed under extensions and contains the algebra of compact operators and the complex numbers. Hence, one can first conclude that $C(\mathbb{P}_q^n)$ is in the UCT class, and by induction this yields that $C(\mathbb{P}_q^n)$ is in the UCT class for any $n$, by virtue of the exact sequences (1).

Our strategy for obtaining an explicit KK-equivalence between $C(\mathbb{P}_q^n)$ and $\mathbb{C}^{n+1}$ consists of proving that (1) splits. For any split exact sequence one obtains a KK-class implementing the desired KK-equivalence through the so-called splitting homomorphism (see, for instance, [5, Exercise 19.9.1]).

The existence of a splitting is, once more, a direct consequence of the Universal Coefficient Theorem [20]. Knowing that a splitting exists is however not enough for practical applications, and, in general, constructing such a splitting explicitly is a non-trivial task. When considering $C(\mathbb{P}_q^n)$ as a graph $C^*$-algebra, the structure of the graph makes it easier to unravel the form of such a splitting. To our knowledge, such a splitting has not been described in the literature before.

The structure of the paper is as follows: In Section 2 we recall definitions and results on graph $C^*$-algebras, focusing on K-theory and ideal structure, which we then specialise to quantum projective spaces in Section 3. Section 4 contains the construction of a splitting for the extension (1). We then recall how our KK-equivalence result in Section 6. Finally, in Section 7 we relate the classes in $KK_*(\mathbb{C}, C(\mathbb{P}_q^n))$ obtained from the splitting to classes of projections in $C(\mathbb{P}_q^n)$ which generate $K_0(C(\mathbb{P}_q^n))$.

**Acknowledgements.** We would like to thank our colleagues Bram Mesland and Wojciech Szymański for inspiring conversations on KK-theory and on graph $C^*$-algebras. 2. Preliminaries on graph algebras

2.1. Graph $C^*$-algebras. We start out by recalling the definition of the $C^*$-algebra associated to a directed graph $\Gamma$, together with results about its K-theory and ideal structure.

A directed graph $E = (E^0, E^1, r, s)$ consists of a countable set $E^0$ of vertices, a countable set $E^1$ of edges and two maps $r, s : E^1 \to E^0$ called the range map and the source map respectively. For an edge $e \in E^1$ from $v$ to $w$ we have $s(e) = v$ and $r(e) = w$. A path $\alpha$ in a graph is a finite sequence $\alpha = e_1e_2\ldots e_n$ of edges satisfying $r(e_i) = s(e_{i+1})$ for $i = 1, \ldots, n-1$.

A vertex $v \in E^0$ is called regular if the set $s^{-1}(v) := \{e \in E^1 \mid s(e) = v\}$ is finite and nonempty. A vertex $v$ is called a sink if it emits no edges i.e. $s^{-1}(v)$ is empty. A graph $E$ is row-finite if every vertex in $E^0$ is either regular or a sink.

**Definition 2.1.** Let $E = (E^0, E^1, r, s)$ be a directed graph. The graph $C^*$-algebra $C^*(E)$ is the universal $C^*$-algebra generated by families of projections $\{P_v \mid v \in E^0\}$ and partial isometries $\{S_e \mid e \in E^1\}$ satisfying, for all $v, w \in E^0$ and $e, f \in E^1$, the relations

(i) $P_vP_w = 0$, for $v \neq w$;
(ii) $S_e^*S_f = 0$, for $e \neq f$;
(iii) $S_e^*S_f = P_r(e)$;
(iv) $S_eS_e^* \leq P_{s(e)}$;
(v) $P_v = \sum_{s(e)=v} S_e S_e^*$, for every $v \in E^0$ regular.

The conditions (iii)-(v) are known as the Cuntz–Krieger relations.

By universality, we can define a circle action on $C^*(E)$, called the gauge action $\gamma : \mathbb{T} \to \text{Aut}(C^*(E))$, for which

$$\gamma_z(P_v) = P_v \text{ and } \gamma_z(S_e) = zS_e$$

for all $v \in E^0, e \in E^1$ and $z \in \mathbb{T}$.
2.1.1. K-theory. The K-theory of graph $C^*$-algebras has over the time been been described under various assumptions on the graph: first for Cuntz–Krieger algebras in [18], then in the case of row-finite graphs [19]. We present here the description of the K-theory groups for a general graph $E$ from [19].

Let $V_E \subseteq E^0$ denote the collection of all the regular vertices. Let $\mathbb{Z}V_E$ and $\mathbb{Z}E^0$ be the free abelian groups on free generators $V_E$ and $E^0$, respectively. We define a map $K_E : \mathbb{Z}V_E \to \mathbb{Z}E^0$ as follows

$$K_E(v) = \left( \sum_{e \in E^1 : s(e) = v} r(e) \right) - v. \quad (3)$$

Then [10] Theorem 3.1 (see also [21] Proposition 2) yields

$$K_0(C^*(E)) \cong \ker(K_E), \quad K_1(C^*(E)) \cong \operatorname{coker}(K_E). \quad (4)$$

If $E$ is a row finite graph with no sinks, the above corresponds to taking the cokernel and the kernel of $A_E^T - 1$, where $A_E$ is the adjacency matrix of the graph, see [19] Theorem 3.2.

2.1.2. Gauge-invariant ideals. The ideal structure of a graph $C^*$-algebra can also be read off from the underlying graph. We will now describe the gauge-invariant ideals of $C^*(E)$ which arise from hereditary and saturated subsets. A subset $H \subseteq E^0$ is called hereditary and saturated if the following two conditions are satisfied, respectively:

1. If $v \in H$ and $w \in E^0$ is such that there exists a path from $v$ to $w$ then $w \in H$.
2. If $w \in E^0$ with $0 < |s^{-1}(w)| < \infty$ and for each $e \in E^1$, for which $s(e) = w$, we have $r(e) \in H$, then $w \in H$.

It was shown in [3] that gauge-invariant ideals of the $C^*$-algebra correspond to hereditary and saturated subsets of the vertex set. Let $\Sigma_E$ denote the collection of all hereditary and saturated subset $H \subseteq E^0$. For any $H \in \Sigma_E$ we obtain a gauge-invariant ideal: the ideal generated by $J_H$. We denote this ideal by $I_H$. Given a row-finite graph $E$, [4, Theorem 4.1] establishes a one-to-one correspondence between $\Sigma_E$ and the gauge-invariant ideals of $C^*(E)$. The correspondence is given by the following maps:

$$H \mapsto I_H, \quad J \mapsto \{ v \in E^0 \mid P_v \in J \},$$

for $H \in \Sigma_E$ and $J$ a gauge-invariant ideal. A word of caution is needed here: if some of the vertices in the graph emit infinitely many edges, not every gauge-invariant ideal need to take the form $I_H$ for a $H \in \Sigma_E$. This phenomenon is thoroughly described in [3] Theorem 3.6], where the authors also provide a complete description of all gauge-invariant ideals of an infinite graph.

Moreover, if $E$ is row-finite and $H \in \Sigma_E$, then the quotient $C^*(E)/I_H$ is a graph algebra, isomorphic to $C^*(F)$, where $F$ is the directed graph defined by setting

$$F^0 = E^0 \setminus H, \quad F^1 = \{ e \in E^1 \mid r(e) \notin H \},$$

and with range and source maps obtained from the ones from the graph $E$ [4, Theorem 4.1].

For graph $C^*$-algebras that are not row-finite, like the quantum complex projective spaces, one needs the more advanced description of the quotient $C^*(E)/I_H$ as a graph $C^*$-algebra from [3]. Let $H \in \Sigma_E$ and define

$$H^\text{fin} = \{ v \in E^0 \setminus H : |s^{-1}(v)| = \infty \text{ and } 0 < |s^{-1}(v) \cap r^{-1}(E^0 \setminus H)| < \infty \}.$$ Let $E/H$ be the directed graph for which

$$(E/H)^0 = (E^0 \setminus H) \cup \{ \beta(v) \mid v \in H^\text{fin} \},$$

$$(E/H)^1 = r^{-1}(E^0 \setminus H) \cup \{ \beta(e) \mid e \in E^1, r(e) \in H^\text{fin} \},$$

where the symbols $\beta(v)$ and $\beta(e)$ denote the vertices and edges which have been added to the graph $F$ from before. Note that all $\beta(v)$ will be sinks. The range and the source maps are extended from $E$ by setting $s(\beta(e)) = s(e)$ and $r(\beta(e)) = \beta(r(e))$. If $E$ is row-finite, then $H^\text{fin} = \emptyset$, and we get $F = E/H$, as above. By [3, Corollary 3.5] we have that $C^*(E)/I_H$ is isomorphic to $C^*(E/H)$.

This has the important consequence that for any $H \in \Sigma_E$, one gets a short exact sequence of $C^*$-algebras:

$$0 \longrightarrow I_H \longrightarrow C^*(E) \longrightarrow C^*(E/H) \longrightarrow 0.$$ As we will describe in the next Section, exactness of the sequence [11] follows from considerations of this kind.
3. Quantum Complex Projective Spaces

We will now introduce our main object of study, namely the C*-algebras of quantum projective spaces, and describe their K-theory and ideal structure.

For $q \in (0,1)$, the quantum $(2n + 1)$-sphere $C(S_{q}^{2n+1})$ of Vaksman and Soibelman \cite{22} is defined as universal C*-algebra generated by $z_{0}, z_{1}, ..., z_{n}$ subject to the following relations:

$$z_{i}z_{j} = q^{-1}z_{j}z_{i}, \text{ for } i < j, \quad z_{i}z_{j}^{*} = qz_{j}^{*}z_{i}, \text{ for } i \neq j,$$

$$z_{i}^{*}z_{i} = z_{i}z_{i}^{*} + (1 - q^{2})\sum_{j=0}^{n} z_{j}z_{j}^{*}, \text{ for } i = 0, ..., n,$$

$$\sum_{j=0}^{n} z_{j}z_{j}^{*} = 1.$$  \hspace{1cm} (5)

The complex projective space $C(\mathbb{C}P^{n}_{q})$ is obtained as the fixed point algebra under the circle action on $C(S_{q}^{2n+1})$ given on generators by $z_{i} \mapsto wz_{i}, w \in U(1)$, and extended by universality. The fixed point algebra is generated by elements $p_{ij} := z_{i}^{*}z_{j}$ for $i, j = 0, 1, ..., n$, which satisfy commutation relations that can be obtained from those of the quantum sphere $C(S_{q}^{2n+1})$:

$$p_{ij}p_{kl} = q^{\text{sign}(k-i)\text{sign}(j-l)} p_{kl}p_{ij} \quad \text{if } i \neq l \text{ and } j \neq k, N \hspace{1cm} (6)$$

$$p_{ij}p_{jk} = q^{\text{sign}(j-i)\text{sign}(j-k)+1} p_{jk}p_{ij} - (1 - q^{2})\sum_{l=0}^{n} p_{il}p_{lk} \quad \text{if } i \neq k, N \hspace{1cm} (7)$$

$$p_{ij}p_{ji} = q^{2\text{sign}(j-i)} p_{ji}p_{ij} + (1 - q^{2}) \left(\sum_{l=0}^{n} q^{2\text{sign}(j-i)} p_{ji}p_{lj} - \sum_{l=0}^{n} p_{il}p_{lj}\right) \quad \text{if } i \neq j, \hspace{1cm} (8)$$

with $\text{sign}(0) := 0$. The elements $p_{ij}$ are the matrix entries of an $(n + 1) \times (n + 1)$ projection $P = (p_{ij})$, and satisfy $\sum_{j=0}^{n} p_{ij}p_{jk} = p_{ik}$ and $p_{ij}^{*} = p_{ji}$.

3.1. Quantum sphere and complex projective spaces as graph C*-algebras. In this subsection, we will recall the main results from \cite{13} and describe how odd quantum spheres and projective spaces can be studied within the framework of graph C*-algebras. Let $L_{2n+1}$ be the directed graph with $n + 1$ vertices, denoted $\{v_{1}, v_{2}, ..., v_{n+1}\}$, and edges

$$\bigcup_{i=1}^{n+1} \{e_{ij} \mid j = i, ..., n + 1\}.$$ 

The source and the range maps are given by

$$s(e_{ij}) = v_{i}, \quad r(e_{ij}) = v_{j}.$$ 

As an example, if $n = 2$, the graph $L_{5}$ will be as follows.

$$L_{5} \quad \text{Diagram}$$

By \cite{13} Theorem 4.4, $C(S_{q}^{2n+1})$ is isomorphic to the graph C*-algebra $C^*(L_{2n+1})$.

Under the isomorphism of $C(S_{q}^{2n+1})$ and $C^*(L_{2n+1})$, the $U(1)$-action on $C(S_{q}^{2n+1})$ defining $C(\mathbb{C}P^{n}_{q})$ becomes

$$S_{e_{ij}} \mapsto wS_{e_{ij}} \quad P_{v_{i}} \mapsto P_{v_{i}}, \quad w \in U(1),$$

which is precisely the gauge action, $\gamma$, on the graph C*-algebra $C^*(L_{2n+1})$.

In order to realise $C(\mathbb{C}P^{n}_{q})$ as a graph C*-algebra, consider the directed graph $F_{n}$ with vertices $\{w_{1}, ..., w_{n+1}\}$ and infinitely many edges from $w_{i}$ to $w_{j}$ if $i < j$ for $i, j = 1, ..., n + 1$. 

Indeed, by [3, Lemma 3.2] we have
\[ C\] the
\[ \ast\] Ideal structure and extensions.
use this fact to construct a different basis of generators for the K-theory of quantum projective spaces.
and
\[ \rho \]
Hence
\[ I \]
\[ \gamma \]
invariant under the gauge action
The proof essentially relies on considering all the paths \( \alpha \) and \( \beta \) in the graph \( L_{2n+1} \) such that \( S_\alpha S_\beta \) is invariant under the gauge action \( \gamma \).

3.1.1. Representations of \( C(S^{2n+1}_q) \) and \( C(CP^n_q) \). A faithful representation of the Vaksman and Soibelman \( C(S^{2n+1}_q) \) is obtained in [22],
\[ \pi: C(S^{2n+1}_q) \to B(l^2(\mathbb{N}^n)) \]
given on the generators by:
\[
\begin{align*}
\pi(z_0)\xi(k_1,\ldots,k_n) &= \sqrt{1-q^{2(k_{i+1})}}\xi(k_1+1,\ldots,k_n), \\
\pi(z_j)\xi(k_1,\ldots,k_n) &= q^{k_{i+1}-k_1}\sqrt{1-q^{2(k_{i+1})}}\xi(k_1,\ldots,k_{j-1},k_j+1,k_{j+2},\ldots,k_n), \\
\pi(z_n)\xi(k_1,\ldots,k_n) &= q^{k_{i+1}-k_n}\xi(k_1,\ldots,k_n),
\end{align*}
\]
for \( j = 1,\ldots,n \) and \( k_1,\ldots,k_n \in \mathbb{N} \).

A faithful representation of the corresponding graph \( C^* \)-algebra \( C^*(L_{2n+1}) \) is given in [14] by
\[ \rho: C^*(L_{2n+1}) \to B(l^2(\mathbb{N}^n)) \]
such that
\[
\begin{align*}
\rho(P_{n+1})\xi(k_1,\ldots,k_n) &= \delta_{k_1,0}\cdots\delta_{k_n,0}\xi(k_1,\ldots,k_n), \\
\rho(P_{2n})\xi(k_1,\ldots,k_n) &= \delta_{k_1,0}\cdots\delta_{k_n,0}(1-\delta_{k_{i+1},0})\xi(k_1,\ldots,k_n), \\
\rho(S_{n+1})\xi(k_1,\ldots,k_n) &= \delta_{k_1,0}\cdots\delta_{k_n,0}\xi(k_1,\ldots,k_n), \\
\rho(S_{2n})\xi(k_1,\ldots,k_n) &= \delta_{k_1,0}\cdots\delta_{k_n,0}(1-\delta_{k_{i+1},0})\xi(k_1,\ldots,k_{i+1},k_{i+2},\ldots,k_n),
\end{align*}
\]
for \( j = 1,\ldots,n,i = 1,\ldots,j \) and \( k_1,\ldots,k_n \in \mathbb{N} \). Here \( \delta \) is the Kronecker symbol.

We then obtain faithful representations of \( C(CP^n_q) \) and \( C^*(F_n) \) by restricting the representations \( \pi \) and \( \rho \) respectively. Later in Section 4 we will show how these two representation relate to each-other and use this fact to construct a different basis of generators for the K-theory of quantum projective spaces.

3.2. Ideal structure and extensions. We will now exploit the description of the ideal structure of a graph \( C^* \)-algebra in terms of hereditary and saturated subsets presented in Subsection 2.1.2 to obtain the \( C^* \)-algebra extension [1].

In \( F_n \), we consider the hereditary and saturated subset \( H = \{ w_{n+1} \} \). In this case \( H_\infty = \emptyset \) since \( w_{n+1} \) is a sink. Then \( C^*(F_n)/IH \cong C^*(F_n/\{ w_{n+1} \}) \) which is \( C^*(F_{n-1}) \). The ideal \( I_{\{ w_{n+1} \}} \) is isomorphic to \( \mathcal{K} \).

Indeed, by [3, Lemma 3.2] we have
\[
I_{\{ w_{n+1} \}} = \text{span}\{ s_{\alpha} s^*_{\beta} | \alpha, \beta \in E^*, r(\alpha) = r(\beta) = w_{n+1} \}.
\]
It can be shown that \( f_{\alpha,\beta} = s_{\alpha} s^*_{\beta} \) for \( \alpha, \beta \in E^*, r(\alpha) = r(\beta) = w_{n+1} \) forms a set of matrix units \( I_{\{ w_{n+1} \}} \).

Hence \( I_{\{ w_{n+1} \}} \cong \mathcal{K}^0(\{ \alpha \in E^* | r(\alpha) = w_{n+1} \}) \).

We then obtain a short exact sequence:
\[
0 \to \mathcal{K} \xrightarrow{j_n} C(CP^n_q) \xrightarrow{\pi_n} C(CP^{n-1}_q) \to 0.
\]
In Section 3.1 we will prove that the exact sequence is split exact. This is a crucial step in our construction of an explicit KK-equivalence between \( C(\mathbb{P}^n_q) \) and \( \mathbb{C}^{n+1} \).

### 3.3. K-theory and K-homology of quantum projective spaces

As mentioned in the introduction, the K-theory groups for the \( C^* \)-algebras of quantum projective spaces \( C(\mathbb{P}^n_q) \) are given by

\[
K_0(\mathbb{C}(\mathbb{P}^n_q)) \cong \mathbb{Z}^{n+1}, \quad K_1(\mathbb{C}(\mathbb{P}^n_q)) \cong \{0\}.
\]

This fact can be proved by viewing the \( C^* \)-algebra \( C(\mathbb{P}^n_q) \) as the graph \( C^* \)-algebra \( C^*(F_n) \). Since \( V_{F_n} = \emptyset \), using (41) and (29), we obtain \( K_{F_n} : (0) \to \mathbb{Z}^{n+1} \) which has cokernel \( \mathbb{Z}^{n+1} \) and the kernel is 0.

The dual result for the K-homology of quantum projective spaces is obtained similarly and leads to

\[
K^0(\mathbb{C}(\mathbb{P}^n_q)) = \mathbb{Z}^{n+1}, \quad K^1(\mathbb{C}(\mathbb{P}^n_q)) = \{0\}.
\]

**Remark 3.1.** One should compare those results with their analogues in the commutative case, where one also has a KK-equivalence between the algebras \( C(\mathbb{P}^n_0) \) and \( \mathbb{C}^{n+1} \). Let \( \mathbb{CP}^{n-1} \) and \( \mathbb{CP}^n \) denote the complex projective space of \( \mathbb{CP}^n \) and \( \mathbb{CP}^{n+1} \), respectively. Since \( \mathbb{CP}^{n-1} \) is a closed subspace of the compact topological space \( \mathbb{CP}^n \), the corresponding \( C^* \)-algebras of continuous functions fit into an extension of the form

\[
0 \longrightarrow C_0(\mathbb{C}^n) \longrightarrow C(\mathbb{CP}^n) \longrightarrow C(\mathbb{CP}^{n+1}) \longrightarrow 0,
\]

which induces a corresponding six-term exact sequence in K-theory generalising the relative K-theory exact sequence in topological K-theory [16, Corollary II.3.23]. It follows that the K-groups of all \( C(\mathbb{CP}^n) \) can be computed inductively, obtaining that they are equal to those of \( \mathbb{C}^{n+1} \). A crucial step in the computation is the observation that by Bott periodicity \( K_i(C_0(\mathbb{C}^n)) \cong K_i(\mathbb{C}) \) for \( i = 0, 1 \). Here again, the KK-equivalence follows from the fact that all commutative \( C^* \)-algebras are in the UCT class.

As described in the introduction, \( C(\mathbb{CP}^n_0) \) is in the UCT class and hence \( C(\mathbb{CP}^n_0) \) is KK-equivalent to \( \mathbb{C}^{n+1} \). Remark 3.1 then implies that it is also KK-equivalent to its commutative counterpart \( C(\mathbb{P}^n_0) \).

### 4. A Splitting for the Defining Extension of Quantum Projective Spaces

In this section, we construct a splitting of the exact sequence (11) from which we will obtain an explicit KK-equivalence between \( C(\mathbb{P}^n_q) \) and \( \mathbb{C}^{n+1} \). Let \( \mathbb{CP}^{n-1} \) and \( \mathbb{CP}^n \) denote the complex projective space of \( \mathbb{CP}^n \) and \( \mathbb{CP}^{n+1} \), respectively. Since \( \mathbb{CP}^{n-1} \) is a closed subspace of the compact topological space \( \mathbb{CP}^n \), the corresponding \( C^* \)-algebras of continuous functions fit into an extension of the form

\[
0 \longrightarrow C_0(\mathbb{C}^n) \longrightarrow C(\mathbb{CP}^n) \longrightarrow C(\mathbb{CP}^{n+1}) \longrightarrow 0,
\]

which induces a corresponding six-term exact sequence in K-theory generalising the relative K-theory exact sequence in topological K-theory [16, Corollary II.3.23]. It follows that the K-groups of all \( C(\mathbb{CP}^n) \) can be computed inductively, obtaining that they are equal to those of \( \mathbb{C}^{n+1} \). A crucial step in the computation is the observation that by Bott periodicity \( K_i(C_0(\mathbb{C}^n)) \cong K_i(\mathbb{C}) \) for \( i = 0, 1 \). Here again, the KK-equivalence follows from the fact that all commutative \( C^* \)-algebras are in the UCT class.

As described in the introduction, \( C(\mathbb{CP}^n_0) \) is in the UCT class and hence \( C(\mathbb{CP}^n_0) \) is KK-equivalent to \( \mathbb{C}^{n+1} \). Remark 3.1 then implies that it is also KK-equivalent to its commutative counterpart \( C(\mathbb{P}^n_0) \).

**Lemma 4.1.** Let \( A \) be a separable \( C^* \)-algebra in the UCT-class, with \( K_0(A) \) free abelian and vanishing \( K_1(A) \). Let \( m \geq 1 \) and denote by \( K \) the algebra of compact operators. Then any extension of \( A \) by \( K^{\otimes m} \) splits.

**Proof.** Extensions of the form

\[
0 \longrightarrow K^{\otimes m} \longrightarrow E \longrightarrow A \longrightarrow 0,
\]

are classified by the Kasparov group \( KK^1(A, K^{\otimes m}) \cong KK^1(A, K) \otimes K^m \), which we can describe in terms of the K-groups of \( A \) thanks to the UCT and the Morita equivalence between \( K \) and \( \mathbb{C} \).

Since \( K_0(A) \) is a free abelian group, the group \( Ext_1(K_0(A), \mathbb{Z}) \) vanishes, yielding

\[
KK_1(A, K^m) = \text{Hom}_{\mathbb{Z}}(K_1(A), \mathbb{Z}) \otimes K^m \cong \text{Hom}_{\mathbb{Z}}(K_0(A), \{0\}) \otimes K^m = \{0\},
\]

by virtue of our assumption on \( K_1(A) \). It follows that there are no non-trivial extension of the form above, that is, all such extensions must necessarily split. \( \square \)

As a consequence, all the defining extensions for quantum projective spaces split. This is also true for a class of weighted projective spaces satisfying a suitable assumption on the weight vector, like those studied in [7] and [1], but we shall postpone the treatment of that case to later work, as the question regarding which graphs underlie such algebras has not been settled yet. It is worth noting that an explicit KK-equivalence in the one-dimensional case, that is for quantum teardrops, can be found in [2].

We will now describe our splitting explicitly in the graph algebra picture. Since we have to consider two complex projective spaces at once, we will denote vertices and edges of their graphs with different letters. We label the vertices of \( F_n \) with \( w \) and the edges with \( f \), like in Figure [1] while for the graph \( F_{n-1} \) we chose the label \( e_i \) for \( i = 1, ..., n \) for the vertices and \( e_i^{m_j} \), \( 1 \leq i, j \leq 2, ..., n, \) and \( m \in \mathbb{N} \) for the
edges. Then $C(CP_{q-1})$ is isomorphic to the universal $C^*$-algebra $C^*(F_{n-1})$, generated by projections $P_m, i = 1, \ldots, n$ and partial isometries $S_{ij}^m, 1 \leq i \leq j, j = 2, \ldots, n$, and $m \in \mathbb{N}$, subject to the relations
\begin{align}
P_m P_{m'} & = 0, i \neq j, \quad i, j = 1, \ldots, n \quad (13) \\
S_{ij}^m S_{kl}^m & = 0, \quad (i, j) \neq (k, l), \quad (14) \\
S_{ij}^m S_{ik}^m & = P_{ij}, \quad k = 2, \ldots, n, i = 1, \ldots, k - 1, \quad (15) \\
S_{ik}^m S_{ij}^m & \leq P_{ik}, \quad k = 1, \ldots, n - 1, i = k + 1, \ldots, n. \quad (16)
\end{align}

Similarly, $C(CP_{q}^n)$ is isomorphic to the universal $C^*$-algebra, $C^*(F_n)$, generated by projections $P_{w_i}, i = 1, \ldots, n + 1$ and partial isometries $S_{ij}^{w_m}, 1 \leq i \leq j, j = 2, \ldots, n + 1, m \in \mathbb{N}$ subject to the relations
\begin{align}
P_{w_i} P_{w_j} & = 0, i \neq j, \quad (17) \\
S_{ij}^{w_m} S_{kl}^{w_m} & = 0, \quad (i, j) \neq (k, l), \quad (18) \\
S_{ij}^{w_m} S_{ik}^{w_m} & = P_{ij}, \quad k = 2, \ldots, n + 1, i = 1, \ldots, k - 1, \quad (19) \\
S_{ik}^{w_m} S_{ij}^{w_m} & \leq P_{ik}, \quad k = 1, \ldots, n, i = k + 1, \ldots, n + 1. \quad (20)
\end{align}

Let us now look at the exact sequence in (11), which we know to be split exact by virtue of Lemma 4.1. In this setting, and following the convention described above, the quotient map $q_n$ is given by
\begin{align}
P_{w_{n+1}} & \mapsto 0, \\
P_{w_i} & \mapsto P_{w_i}, i = 1, \ldots, n - 1, \\
P_{v_n} & \mapsto P_{w_n} + P_{w_{n+1}}, \\
S_{ij}^{w_m} & \mapsto S_{ij}^{w_m}, j \neq n, \\
S_{ij}^{v_n} & \mapsto S_{ij}^{w_m} + S_{ij}^{v_n}, i = 1, \ldots, n - 1.
\end{align}

**Theorem 4.2.** The map $s_n : C(CP_{q-1}) \rightarrow C(CP_{q}^n)$ defined on generators by
\begin{align}
P_{v_i} & \mapsto P_{w_i}, i = 1, 2, \ldots, n - 1, \\
P_{v_n} & \mapsto P_{w_n} + P_{w_{n+1}}, \\
S_{ij}^{v_n} & \mapsto S_{ij}^{w_m} + S_{ij}^{v_n}, i = 1, \ldots, n - 1
\end{align}
is a splitting for the short exact sequence in (11).

**Proof.** To prove that $s_n$ is a $*$-homomorphism we will show that its target elements satisfy the graph algebra relations (13)-(20). It will then follow by universality that $s_n$ is a $*$-homomorphism.

First, we clearly have that $F_n$ are all mapped to mutually orthogonal projections, that the unit of $C^*(F_{n-1})$ is mapped to the unit of $C^*(F_n)$, and that relation (13) is satisfied. It is also clear that the partial isometries $S_{v_{ij}}$ are all mapped to partial isometries in $C^*(F_n)$ when $j \neq n$. When $j = n$ we have that $S_{w_{ij}} + S_{v_{ij}n}$ is indeed a partial isometry since
\begin{align}
(S_{w_{ij}} + S_{v_{ij}n})(S_{w_{ij}} + S_{v_{ij}n})^* & = (S_{w_{ij}} + S_{v_{ij}n})(S_{w_{ij}} + S_{v_{ij}n}^*) \\
& = (S_{w_{ij}} + S_{v_{ij}n})(P_{w_n} + P_{w_{n+1}}) \\
& = (S_{w_{ij}} + S_{v_{ij}n})(P_{w_n} + P_{w_{n+1}}) \\
& = (S_{w_{ij}} + S_{v_{ij}n}).
\end{align}

Relation (15) is clearly satisfied for all $S_{ij}^{v_m}$ with $j \neq n$. For $j = n$ we have
\begin{align}
S_{v_{ij}}^{w_m} S_{v_{ij}}^{v_m} & \mapsto (S_{w_{ij}} + S_{v_{ij}n})(S_{w_{ij}} + S_{v_{ij}n})^* = P_{w_n} + P_{w_{n+1}} \leftrightarrow P_{v_n}
\end{align}
and relation (15) is then satisfied in this case.

Relation (19) is also clearly obtained for all $S_{ij}^{v_m}$ with $j \neq n$. For $j = n$ we have
\begin{align}
P_{v_i} & \leftrightarrow P_{v_i} S_{v_{ij}}^{v_m} \mapsto (S_{w_{ij}} + S_{v_{ij}n})(S_{w_{ij}} + S_{v_{ij}n})^*.
\end{align}

Hence we have to show
\begin{align}
B_i := (S_{w_{ij}} + S_{v_{ij}n})(S_{w_{ij}} + S_{v_{ij}n})^* \leq P_{w_i},
\end{align}
We have
\begin{align}
(P_{w_i} - B_i)(P_{w_i} - B_i) = P_{w_i} - P_{w_i} B_i - B_i P_{w_i} + B_i
\end{align}
\[ P_{w_i}B_i = P_{w_i}(S_{f_i}^m \cdot S_{f_i}^r \cdot S_{f_i}^r + S_{f_{i+1}}^m + S_{f_{i+1}}^r \cdot S_{f_{i+1}}^m) = B_i \]

for all \( i \), since \( S_{f_i}^m \cdot S_{f_i}^r \cdot S_{f_i}^r \leq P_{w_i} \) and \( S_{f_{i+1}}^m + S_{f_{i+1}}^r \cdot S_{f_{i+1}}^m \leq P_{w_i} \). Similar \( B_iP_{w_i} = B_i \). Then

\[ (P_{w_i} - B_i)(P_{w_i} - B_i) = P_{w_i} - B_i \]

hence \( P_{w_i} - B_i \geq 0 \) and we obtain \( P_{w_i} \geq B_i \).

It follows from an easy computation that \( q_n \circ s_n \) is the identity on the generators of \( C^*(F_{n-1}) \) and therefore \( q_n \circ s_n = \text{id}_{C^*(F_{n-1})} \). \( \Box \)

To summarise our result, for every \( n \geq 1 \), we have a split exact sequence

\[ 0 \longrightarrow K \xrightarrow{\cdot j_n} C(CP^n_q) \xrightarrow{s_n} C(CP^{n-1}_q) \longrightarrow 0. \quad (17) \]

**Remark 4.1.** In the rest of this work, especially in Section 6, we will mostly be working with the graph \( C^* \)-algebra picture. We choose to identify \( C(CP^n_q) \) with \( C^*(F_n) \), and use the former notation.

5. **KK-equivalences for split exact sequences**

We will now recall how any split extension of \( C^* \)-algebras gives a \( KK \)-equivalence between the algebra in the middle and the \( C^* \)-algebraic direct sum of the other two. This relies on the following result, which in [5] is stated as an exercise.

**Theorem 5.1 ([15 Exercise 19.9.1]).** For any split exact sequence of graded separable \( C^* \)-algebras

\[ 0 \longrightarrow J \xrightarrow{\cdot j} E \xrightarrow{\cdot s} q \longrightarrow B \longrightarrow 0 \]

the element \([j] \oplus [s] \in KK(J \oplus B, E)\) is a \( KK \)-equivalence.

An explicit inverse to the class \([j] \oplus [s] \in KK(J \oplus B, E)\) is also provided in [5], through a construction known as the *splitting homomorphism*. We will illustrate this result using Cuntz’s quasi-homomorphism picture of \( KK \)-theory [8], in which all the involved \( C^* \)-algebras are assumed to be trivial graded and \( \sigma \)-unital. Our main references are the article [12] and the monograph [15].

5.1. **KK\(_h\)-theory.** For the sake of simplicity, we will further assume all \( C^* \)-algebras to be separable.

**Definition 5.1.** ([14 Def. 4.1.1]). A \( KK_h(A, B) \)-cycle is a pair \((\phi_+, \phi_-)\) of \( * \)-homomorphisms from \( A \) to \( M(K \otimes B) \), such that

\[ \phi_+(a) - \phi_-(a) \in K \otimes B. \]

The set of \( KK_h(A, B) \)-cycles will be denoted by \( F(A, B) \).

Note that a pair of \( * \)-homomorphisms \((\phi_+, \phi_-)\) satisfying the condition above is also called a quasi-homomorphism from \( A \) to \( B \).

Homotopy of \( KK_h \)-cycles can be defined in a similar way as homotopy of Kasparov modules, see [15 Def. 4.1.2]. Then \( KK_h(A, B) \) is defined as the homotopy classes of \( KK_h(A, B) \)-cycles. Likewise, one can endow \( KK_h(A, B) \) with the structure of an abelian group, as described in [15 Proposition 4.1.5].

In [12], Higson proved that the \( KK_0(A, B) \) group is isomorphic to the original Kasparov group \( KK_0(A, B) \), whenever \( A \) and \( B \) are considered as trivially graded \( C^* \)algebras (see also [15 Theorem 4.1.8]).

The \( KK \) groups are functorial: if \( f : A' \to A \) and \( g : B \to B' \) are homomorphisms of \( C^* \)algebras, one has corresponding maps \( f_* : F(A, B) \to F(A', B) \) and a map \( g^* : F(A, B) \to F(A, B') \) at the level of cycles. Both maps pass to the quotient \( KK_h \).

Last but not least, there is a bilinear pairing, known as the Kasparov product,

\[ \Theta : KK_h(A, B) \times KK_h(B, C) \to KK_h(A, C) \]

satisfying the conditions of Theorem 4.2.1 in [15].

8
5.2. **The splitting homomorphism.** Let us consider a split exact sequence of $C^*$-algebras

$$0 \rightarrow J \xrightarrow{j} E \xrightarrow{q} B \rightarrow 0$$

We will now recall how to construct an inverse to the class $[j] \oplus [s] \in KK_h(J \oplus B, E)$.

First of all, consider the $^\ast$-homomorphism

$$e_E : E \rightarrow K \otimes E, \quad e_E(b) = e \otimes b$$

where $e$ is a minimal projection in $K$.

Denote by $r_j$ the canonical map given by

$$r_j : M(K \otimes E) \rightarrow M(K \otimes J)$$

$$r_j(T)(x) := (id_K \otimes j^{-1})(m(id_K \otimes j)(x))$$

for all $x \in K \otimes E$, $m \in M(K \otimes E)$, where $j^{-1}$ is the inverse when we restrict to the image of $j$, [13 Exercise 1.1.9]. The map satisfies

$$(id_K \otimes j)(r_j(m)x) = m(id_K \otimes j)(x)$$

for all $m \in M(K \otimes E)$ and $x \in K \otimes E$.

Denote by $[\pi] \in KK_h(E,J)$ the class of the quasi-homomorphism $(1,s \circ q)$, which we rewrite as $[\pi] := [(r_j \circ e_E, r_j \circ e_E \circ s \circ q)]$ (see also [12 Lemma 2.13]).

Then we have

$$j_{\ast}(\pi) + s_{\ast} \circ q_{\ast} \circ (1_E) = 1_E,$$

$$(j^* + s^*)([\pi] + q^{1}(1_B)) = 1_J + 1_B = 1_{J \otimes B}.$$  

By [5 Proposition 18.7.2], we conclude that $[j] \oplus [s] \in KK_h(J \oplus B, E)$ is a KK-equivalence with inverse $[\pi] \oplus [q] \in KK_h(E,J \oplus B)$.

6. **An explicit KK-equivalence between $C(\mathbb{C}P^n_q)$ and $\mathbb{C}^{n+1}$**

We will now apply Theorem [5.1] to construct an explicit KK-equivalence between $C(\mathbb{C}P^n_q)$ and $\mathbb{C}^{n+1}$ up to Morita equivalence.

Consider the split exact sequence in (17). For each $n \in \mathbb{N}$ we have the following $KK_h$-classes:

$$[j_n] \in KK_h(\mathbb{C}(\mathbb{C}P^n_q)), \quad [q_n] \in KK_h(C(\mathbb{C}P^n_q), C(\mathbb{C}P^{n-1}_q)), \quad [s_n] \in KK_h(C(\mathbb{C}P^{n-1}_q), C(\mathbb{C}P^n_q))$$

$$[\pi_n] = [(1, s_n \circ q_n)] \in KK_h(C(\mathbb{C}P^n_q), \mathbb{C}).$$

If we now apply Theorem 5.1 to our setting, we obtain that $[j_n] \oplus [s_n] \in KK_h(\mathbb{C}(\mathbb{C}P^{n-1}_q), C(\mathbb{C}P^n_q))$ is a KK-equivalence with inverse $[\pi_n] \oplus [q_n] \in KK_h(C(\mathbb{C}P^n_q), \mathbb{C} \otimes C(\mathbb{C}P^{n-1}_q))$. More concretely, for $n = 1$ we have

$$[j_1] \otimes C(\mathbb{C}P^1_q) \pi_1 = 1_{\mathbb{C}}, \quad [s_1] \otimes C(\mathbb{C}P^1_q) [q_1] = 1_{\mathbb{C}},$$

$$[\pi_1] \otimes_{\mathbb{C}} [j_1] + [q_1] \otimes_{\mathbb{C}} [s_1] = 1_{C(\mathbb{C}P^1_q)}.$$  

(19)

and for $n \geq 2$

$$[j_n] \otimes C(\mathbb{C}P^n_q) [\pi_n] = 1_{\mathbb{C}}, \quad [s_n] \otimes C(\mathbb{C}P^n_q) [q_n] = 1_{C(\mathbb{C}P^{n-1}_q)}$$

$$[\pi_n] \otimes_{\mathbb{C}} [j_n] + [q_n] \otimes_{\mathbb{C}} C(\mathbb{C}P^{n-1}_q) = 1_{C(\mathbb{C}P^n_q)}.$$  

(20)

We are now ready to prove our KK-equivalence result. First note that if we let $I_1 := [j_1] \oplus [s_1]$ and $I_1 := [\pi_1] \oplus [q_1]$ then

$$I_1 \otimes C(\mathbb{C}P^1_q) \Pi_1 = 1_{\mathbb{C} \otimes \mathbb{C}}, \quad \Pi_1 \otimes_{\mathbb{C}} I_1 = 1_{C(\mathbb{C}P^1_q)},$$

which follows directly by Theorem 5.1 and is already well-known.

**Theorem 6.1.** For $n \geq 2$ we define

$$\Pi_n := [\pi_n] \oplus ([q_n] \otimes C(\mathbb{C}P^{n-1}_q) [\pi_n]) \oplus ([q_{n-1} \circ q_n] \otimes C(\mathbb{C}P^{n-2}_q) [\pi_n])$$

$$\oplus \cdots \oplus ([q_2 \circ \cdots \circ q_{n-1} \circ q_n] \otimes C(\mathbb{C}P^1_q) [\pi_1]) \oplus [q_1 \circ q_2 \circ \cdots \circ q_n]$$

and

$$I_n := [j_n] \oplus [s_n \circ j_{n-1}] \oplus [s_n \circ s_{n-1} \circ j_{n-2}] \oplus \cdots \oplus [s_n \circ s_{n-1} \cdots \circ s_2 \circ j_1] \oplus [s_n \circ s_{n-1} \cdots \circ s_1].$$

Then $\Pi_n \in KK_h(C(\mathbb{C}P^n_q), \mathbb{C}^{n+1} \otimes \mathbb{C})$ is a KK-equivalence with inverse $I_n \in KK_h(\mathbb{C}^{n+1} \otimes \mathbb{C}, C(\mathbb{C}P^n_q))$. 

Proof. The proof follows by induction on $n$. For $n = 2$ we obtain the following by (20):

$$I_2 \otimes C(CP^q_2) \Pi_2 = [j_2] \otimes C(CP^q_2) [\pi_2] + [s_2 \circ j_1] \otimes C(CP^q_2) ([q_2] \otimes C(CP^q_2) [\pi_1]) + [s_2 \circ s_1] \otimes C(CP^q_2) [q_1 \circ q_2]$$

$$= 1_K + [j_1] \otimes C(CP^q_2) ([s_2] \otimes C(CP^q_2) [q_2]) \otimes C(CP^q_2) [\pi_1] + [q_1 \circ q_2 \circ s_2 \circ s_1]$$

$$= 1_K + [j_1] \otimes C(CP^q_2) 1_C(CP^q_2) \otimes C(CP^q_2) [\pi_1] + [q_1 \circ id(C(CP^q_2) \circ s_1]$$

$$= 1_K + 1_K + 1_C$$

$$= 1_{K^2 \otimes C}.$$  

When taking the product in the other direction we obtain

$$\Pi_2 \otimes_{K^2 \otimes C} I_2 = [\pi_2] \otimes_K [j_2] + ([q_2] \otimes C(CP^q_2) [\pi_1]) \otimes_K [s_2 \circ j_1] + [q_1 \circ q_2 \circ [s_2 \circ s_1]$$

$$= [\pi_2] \otimes_K [j_2] + ([q_2] \otimes C(CP^q_2) [\pi_1]) \otimes_K ([j_1] \otimes C(CP^q_2) [s_2])$$

$$+ ([q_2] \otimes C(CP^q_2) [q_1]) \otimes C([s_1] \otimes C(CP^q_2) [s_2])$$

$$= [\pi_2] \otimes_K [j_2] + [q_2] \otimes C(CP^q_2) [\pi_1] \otimes_K [j_1] + [q_1 \circ C([s_1] \otimes C(CP^q_2) [s_2])$$

$$= [\pi_2] \otimes_K [j_2] + [q_2] \otimes C(CP^q_2) 1_C(CP^q_2) \otimes C(CP^q_2) [s_2]$$

$$= [\pi_2] \otimes_K [j_2] + [q_2] \otimes C(CP^q_2) [s_2]$$

$$= 1_C(CP^q_2).$$

Let us assume that the statement is true for $n - 1$, i.e.,

$$I_{n-1} \otimes C(CP^q_{n-1}) \Pi_{n-1} = 1_{K^{n-1} \otimes C}, \quad \Pi_{n-1} \otimes_{K^{n-1} \otimes C} I_{n-1} = 1_C(CP^q_{n-1}).$$  

(21)

Then we can rewrite

$$I_n \otimes C(CP^q_n) \Pi_n = [j_n] \otimes C(CP^q_n) [\pi_n] + [s_n \circ j_{n-1}] \otimes C(CP^q_n) ([q_n] \otimes C(CP^q_{n-1}) [\pi_{n-1}])$$

$$+ [s_n \circ s_{n-1} \circ j_{n-2}] \otimes C(CP^q_n) ([q_{n-1} \circ q_n] \otimes C(CP^q_{n-2}) [\pi_{n-2}])$$

$$+ \cdots + [s_n \circ s_{n-1} \circ \cdots \circ s_2 \circ j_1] \otimes C(CP^q_n) ([q_2 \circ \cdots \circ q_{n-1} \circ q_n] \otimes C(CP^q_1) [\pi_1])$$

$$= [j_n] \otimes C(CP^q_n) [\pi_n] + [j_{n-1}] \otimes C(CP^q_{n-1}) ([s_n] \otimes C(CP^q_n) [q_n]) \otimes C(CP^q_{n-1}) [\pi_{n-1}])$$

$$+ [j_{n-2}] \otimes C(CP^q_{n-2}) ([s_{n-1} \circ s_{n-2}] \otimes C(CP^q_n) [q_{n-1} \circ q_n]) \otimes C(CP^q_{n-2}) [\pi_{n-2}])$$

$$+ \cdots + [j_1] \otimes C(CP^q_1) ([s_2 \circ s_1 \circ \cdots \circ s_2] \otimes C(CP^q_n) [q_2 \circ \cdots \circ q_{n-1} \circ q_n]) \otimes C(CP^q_1) [\pi_1])$$

$$+ [s_n \circ s_{n-1} \circ \cdots \circ s_1] \otimes C(CP^q_n) [q_1 \circ q_2 \circ \cdots \circ q_n]$$

$$= \sum_{m=1}^n [j_m] \otimes C(CP^q_m) [\pi_m] + 1_C$$

$$= 1_{K^n \otimes C}.$$  

On the other hand by the induction hypothesis in (21) we have

$$\Pi_n \otimes_{K^n \otimes C} I_n = [\pi_n] \otimes_K [j_n] + ([q_n] \otimes C(CP^q_{n-1}) [\pi_{n-1}]) \otimes_K [s_n \circ j_{n-1}$$

$$+ ([q_{n-1} \circ q_n] \otimes C(CP^q_{n-2}) [\pi_{n-2}]) \otimes_K [s_n \circ s_{n-1} \circ j_{n-2}$$

$$+ \cdots + ([q_2 \circ \cdots \circ q_{n-1} \circ q_n] \otimes C(CP^2_1) [\pi_1]) \otimes_K [s_n \circ s_{n-1} \circ \cdots \circ s_2 \circ j_1]$$

$$+ [q_1 \circ q_2 \circ \cdots \circ q_n] \otimes C([s_n \circ s_{n-1} \circ \cdots \circ s_1]$$

$$= [\pi_n] \otimes_K [j_n] + [q_n] \otimes C(CP^q_{n-1}) + ([\pi_{n-1}] \otimes_K [j_{n-1}]$$

$$+ ([q_{n-1}] \otimes C(CP^q_{n-2}) [\pi_{n-2}]) \otimes_K [s_{n-1} \circ j_{n-2}$$

$$+ \cdots + ([q_2 \circ \cdots \circ q_{n-1}] \otimes C(CP^2_1) [\pi_1]) \otimes_K [s_{n-1} \circ \cdots \circ s_2 \circ j_1]) \otimes C(CP^q_{n-1}) [s_n]$$

$$= [\pi_n] \otimes_K [j_n] + [q_n] \otimes C(CP^q_{n-1}) (\Pi_{n-1} \otimes_{K^{n-1} \otimes C} I_{n-1}) \otimes C(CP^q_{n-1}) [s_n]$$

$$= [\pi_n] \otimes_K [j_n] + [q_n] \otimes C(CP^q_{n-1}) [s_n]$$

$$= 1_C(CP^q_n).$$

Then $C(CP^q_n)$ and $K^n \otimes C$ are KK-equivalent by the explicit KK-equivalence $\Pi_n$ with inverse $I_n$.  

\[\square\]
Remark 6.1. Let $[\ell^2(N_0)] \in KK(K, \mathbb{C})$ denote the class of the natural Morita equivalence. Let $\varphi : \mathbb{C} \to KK(\ell^2(N_0))$ the $*$-homomorphism given by the choice of a rank-one projection, and denote by $[\varphi]$ the corresponding class in $KK(\mathbb{C}, K)$. Note that different choices of rank-one projection yield the same class in KK-theory. The two classes are known inverse to each other. This allows us to write an explicit KK-equivalence between $C(CP^n_q)$ and $C^{n+1}$ by

$$[\Pi_n] \otimes_{K^*} \mathbb{C} \left( \bigoplus_n [\ell^2(N_0)] \otimes [1_C] \right) \in KK(C(CP^n_q), C^{n+1}),$$

with inverse

$$\left( \bigoplus_n [\varphi] \otimes [1_C] \right) \otimes_{K^*} \mathbb{C} [\Pi_n] \in KK(C^{n+1}, C(CP^n_q)).$$

7. Splittings and projections

In this last section we relate the elements $[j_n] = [s_n \circ s_{n-1} \circ \cdots \circ s_n \circ j_{n+1}^{-1}] \in KK(K, C(CP^n_q))$ from our Theorem 6.1 to classes of projections in $C(CP^n_q)$ which generate the group $K_0(C(CP^n_q))$. To show that the projections are generators of the K-theory, we apply the index pairing with the Fredholm modules defined in [9]:

$$\mu_k = (A(CP^n_q), \mathcal{H}(k), \pi(k), \gamma(k), F(k)), \quad 0 \leq k \leq n,$$

which are known to be generators of the K-homology group $K^0(C(CP^n_q))$.

Theorem 7.1. Let $P_0 = 1$, there exists projections $P_l$, $l = 1, \ldots, n$ in $C(CP^n_q)$ such that

$$\pi_k^n(P_l) = 0, k \neq l$$

$$\pi_k^n(P_l) = \text{The projection onto the subspace spanned by } \{0, \ldots, 0, m_{l+1}, \ldots, m_n\} \cap V^n_k,$$

where the representation $\pi_k^n$ and the subspace $V^n_k$ is as defined in [9]. The classes of the projections $P_l$, $l = 0, 1, \ldots, n$ form a basis $K_0(C(CP^n_q))$.

Proof. We first want to show existence of the projections, they are obtained in a similar way as in [6] as limits

$$q^{-2m} \prod_{r=1}^{m} \frac{2^n \pi_k^n(z_1 z_1^* + z_{l+1} z_{l+1}^* + \cdots + z_n z_n^*) - q^{-2(r+1)}}{1 - q^{2r}} \to \pi_k^n(P_l).$$

It is clear that if $l < k$ then $\pi_k^n(z_1 z_1^* + z_{l+1} z_{l+1}^* + \cdots + z_n z_n^*) = 0$. For $k \geq l$ we have

$$\pi_k^n(z_1 z_1^* + z_{l+1} z_{l+1}^* + \cdots + z_n z_n^*) \mid m_1, \ldots, m_n\rangle = q^{m_1} (1 - q^{2(m_{l+1} - m_0)}) + \cdots + q^{2(m_{k-1} - 1)} (1 - q^{2(m_{k-1} - m_0)}) + q^{2m_k} \mid m_1, \ldots, m_n\rangle$$

when $\mid m_1, \ldots, m_n\rangle \in V^n_k$ otherwise 0. Then

$$q^{-2m} \prod_{r=1}^{m} \frac{2^n \pi_k^n(z_1 z_1^* + z_{l+1} z_{l+1}^* + \cdots + z_n z_n^*) - q^{2(r+1)}}{1 - q^{2r}} \mid m_1, \ldots, m_n\rangle$$

$$\to \begin{cases} [m_1, \ldots, m_n], & m_l = 0 \text{ and } \mid m_1, \ldots, m_n\rangle \in V^n_k, \\ 0, & \text{otherwise} \end{cases}.$$
which follows since for every \( \pi^{(t)}_k \) there are two other representation namely \( \pi^{(t)}_{k-1} \) and \( \pi^{(t)}_{k+1} \) defined on orthogonal subspaces which are also nonzero on some part of \( V^a_n \). We then get a degenerated module hence the product is 0. For \( l = t \) and \( l \) even we have

\[
[P_l] \otimes_{C(CP_q)} [\tau_l] = [(l^2(n^l_0), \alpha^{(0)}_{\tau_l} \circ \psi_l, F, \gamma)] = [\pi^{(0)}_{l}(P_l)I_2(n^l_0) \oplus 0, M_{C}, F, \gamma)] = [(\mathcal{C}, I_dC, 0)] = [1_{C}]
\]

we get a similar result if \( l \) is odd. Hence \([P_l] \otimes_{C(CP_q)} [\tau_l] = [1_{C}]\) if \( l = t \) otherwise it is 0. Since the matrix with entries \( a_{lt} = [P_l] \otimes_{C(CP_q)} [\tau_l] \) is the identity matrix and is then invertible we get that \( P_l, l = 0, 1, ... , n \) generate the K-theory. \( \Box \)

**Remark 7.1.** We remark that the projections constructed here are very similar in fashion to the faithful irreducible representations of quantum teardrop presented in [6, Section 2]. Those were later used in [2, Section 7.4] to prove an explicit KK-equivalence result.

**Proposition 7.2.** Let \( \pi : C(S^{2n+1}) \to B(l^2(N^n)) \) be the irreducible representation of the Vaksman–Soibelman sphere defined in [9], and \( \rho : C^*(L_{2n+1}) \to B(l^2(N^n)) \) the faithfual graph algebra representation in [10]. The projections \( P_{w_n-k} \) satisfy

\[
\pi(P_{w_n-k}) = \rho(P_{w_n-k} + P_{w_n-k+1} + P_{w_n-k+2} + \ldots + P_{w_n+t}),
\]

for \( k = 0, 1, \ldots, n-1 \). Moreover, up to Morita equivalence, they define the same classes in KK-theory as \( [s_n \circ s_{n-1} \circ \ldots \circ s_{n-k} \circ j_{n-k-1}] \). In other words, if \( \varphi : C \to K \) is the \( * \)-homomorphism from Remark 7.1 we have the following equalities of classes in \( KK(C, CP_q^n) \):

\[
[P_n] = [\varphi] \otimes_K [j_n], \quad \text{and} \quad [P_{n-k-1}] = [\varphi] \otimes_K [s_n \circ s_{n-1} \circ \ldots \circ s_{n-k} \circ j_{n-k-1}], \quad k = 0, \ldots, n-1.
\]

**Proof.** We start our proof by recalling our labelling convention on the graph \( F_n \) underlying the algebra \( C(CP_q^n) \): vertices will be denoted by \( w \), and edges by \( f \). We will do so independently of the dimension \( n \) of the space.

Let \( 0 \leq k < n \), we denote by \( I_{(w_n-k)} \) the 2-sided closed ideal generate by the projection \( P_{w_n-k} \). Then

\[
J_{n-k-1} : I_{(w_n-k)} \to C^*(F_{n-k-1})
\]

and

\[
s_n \circ s_{n-1} \circ \ldots \circ s_{n-k} \circ j_{n-k-1}(P_{w_n-k}) = s_n \circ s_{n-1} \circ \ldots \circ s_{n-k-1}(P_{w_n-k} + P_{w_n-k+1}) = s_n \circ s_{n-1} \circ \ldots \circ s_{n-k-2}(P_{w_n-k} + P_{w_n-k+1} + P_{w_n-k+2}) = P_{w_n-k} + P_{w_n-k+1} + P_{w_n-k+2} + \ldots + P_{w_n-t} \in C(CP_q^n),
\]

Any element in \( I_{(w_n-k)} \) takes the form \( S_{\alpha} S_{\beta}^* \) where \( \alpha \) and \( \beta \) are finite paths in \( F_{n-k-1} \) such that \( r(\alpha) = r(\beta) = w_n-k \) by [5, Lemma 3.2].

By the structure of the graph and the splitting in [11], we have

\[
s_{n-k}(S_{\alpha} S_{\beta}^*) = s_{n-k}(S_{\alpha'} P_{w_n-k} S_{\beta}^*) = S_{\alpha'}(w_{2n-k} + P_{w_n-k+1})^* S_{\beta}^*.
\]

where \( \alpha = \alpha' f_{n-k}^{m_1}, \beta = \beta' f_{n-k}^{m_2} \). Then the image of \( I_{(w_n-k)} \) under \( s_{n-k} \) consists of all \( S_{\mu} S_{\nu}^* \) such that \( r(\mu) = r(\nu) \in \{ w_{2n-k}, w_{2n-k+1} \} \) which is precisely the ideal generated by the sum \( P_{w_n-k} + P_{w_n-k+1} \) in \( C(CP_q^n) \) by [8, Lemma 3.2]. Continuing like this we obtain that the image of \( I_{(w_n-k)} \) under \( s_n \circ s_{n-1} \circ \ldots \circ s_{n-k} \circ j_{n-k-1} \) is the ideal generated by \( P_{w_n-k} + P_{w_n-k+1} + P_{w_n-k+2} + \ldots + P_{w_n-t} \) in \( C(CP_q^n) \).

Consider the projections \( P_l, l = 0, \ldots, n \) in the representation \( \pi \) of \( C(S^{2n+1}) \), restricted to \( C(CP_q^n) \).

Then

\[
q^{-2n} \prod_{r=1}^{n} q^2 \xi(k_1, \ldots, k_n) = \frac{q^2 q^{2(k_1+\ldots+k_l)} - q^{2(r+1)}}{1-q^{2r}}
\]

\[
= \begin{cases} \xi(k_1, \ldots, k_n) & \text{if } k_1 + \ldots + k_l = 0 \\ 0 & \text{otherwise} \end{cases}
\]

Then \( \pi(P_l) \) is the projection onto the subspace spanned by \( \{ \xi(0, 0, \ldots, 0, k_{l+1}, \ldots, k_n) \mid k_i \in \mathbb{N} \} \). On the other hand, under the representation \( \rho \) of the graph \( C^* \)-algebra \( C^*(L_{2n+1}) \), which descends to \( C^*(F_n) \),
we have
\[\rho(1 - (P_{w_1} + P_{w_2} + \cdots + P_{w_t}))\xi(k_1, \ldots, k_n) = (1 - ((1 - \delta_{k_1,0}) + \delta_{k_1,0}(1 - \delta_{k_2,0}) + \delta_{k_1,0}\delta_{k_2,0}(1 - \delta_{k_3,0}) + \cdots + \delta_{k_1,0}\delta_{k_2,0}\cdots\delta_{k_{n-1},0}(1 - \delta_{k_n,0})))\xi(k_1, \ldots, k_n)
= \delta_{k_1,0}\delta_{k_2,0}\cdots\delta_{k_{n-1},0}\xi(k_1, \ldots, k_n).\]

Hence \(\rho(1 - (P_{w_1} + P_{w_2} + \cdots + P_{w_t})) = \pi(\mathcal{H})\) and
\[\rho(P_{w_{n-k}+1} + P_{w_{n-k+1}} + P_{w_{n-k+2}} + \cdots + P_{w_{n+1}}) = \rho(1 - (P_{w_1} + \cdots + P_{w_{n-k}})) = \pi(P_{n-k-1}).\]

In order to prove (23) for \(P_n\), we note that \(P_{w_{n+1}} \in C^*(F_n)\) is a rank one projection by considering the representation \(\rho \) in (10). Hence we can set \(\varphi(1) = P_{w_{n+1}}\) since, as mentioned earlier, the choice of rank-one projection does not affect the class in KK-theory. Moreover, by (22), we have
\[\rho(j_n \circ \varphi(1)) = \rho(P_{w_{n+1}}) = \pi(P_n).\]

Since \([\varphi] \otimes [j_n] = [(C(\mathbb{C}P^n_q), j_n \circ \varphi, 0)] \in KK(C(\mathbb{C}P^n_q))\) we obtain (23).

Similarly we have that \(P_{w_{n-k}}\) is a rank one projection in \(C^*(F_{n-k-1})\). Hence for each \(k = 0, 1, \ldots, n-1\) we can set \(\varphi(1) = P_{w_{n-k}}\). Then
\[\rho(s_n \circ s_{n-1} \circ \cdots \circ s_{n-k} \circ j_{n-k-1} \circ \varphi(1)) = \rho(P_{w_{n-k}} + P_{w_{n-k+1}} + P_{w_{n-k+2}} + \cdots + P_{w_{n+1}}) = \pi(P_{n-k-1})\]
by (22). Hence
\[[\varphi] \otimes [s_n \circ s_{n-1} \circ \cdots \circ s_{n-k} \circ j_{n-k-1}] = [s_n \circ s_{n-1} \circ \cdots \circ s_{n-k} \circ j_{n-k-1} \circ \varphi] = [P_{n-k-1}],\]
as desired. \(\square\)

Note that it follows directly from the identification in (22), that \(P_{l} = 0, 1, \ldots, n\) generates \(K_0(C(\mathbb{C}P^n_q))\) which was shown in Theorem 7.1 using the index pairing with Fredholm modules.
