Geometric Stochastic Filter with Guaranteed Performance for Autonomous Navigation based on IMU and Feature Sensor Fusion

Hashim A. Hashim, Mohammed Abouheaf, and Mohammad A. Abido

Abstract—This paper concerns the estimation problem of attitude, position, and linear velocity of a rigid-body autonomously navigating with six degrees of freedom (6 DoF). The navigation dynamics are highly nonlinear and are modeled on the matrix Lie group of the extended Special Euclidean Group $\mathbb{SE}(3)$. A computationally cheap geometric nonlinear stochastic navigation filter is proposed on $\mathbb{SE}(3)$ with guaranteed transient and steady-state performance. The proposed filter operates based on a fusion of sensor measurements collected by a low-cost inertial measurement unit (IMU) and features (obtained by a vision unit). The closed loop error signals are guaranteed to be almost globally uniformly ultimately bounded in the mean square from almost any initial condition. The equivalent quaternion representation is included in the Appendix. The filter is proposed in continuous form, and its discrete form is tested on a real-world dataset of measurements collected by a quadrotor navigating in three dimensional (3D) space.

I. INTRODUCTION

ROBUST and accurate navigation solutions for autonomous vehicles are essential [1]–[6]. Indoor and outdoor applications, such as household cleaning devices, pipelines, terrain mapping, reef monitoring, exemplify situations when GPS might be unreliable and only low-cost measurement units (e.g., inertial measurement unit (IMU)) might be available. In such a case GPS-independent navigation solutions are indispensable. A typical low-cost IMU module is composed of an accelerometer and a gyroscope which provide measurements of rigid-body’s acceleration and angular velocity, respectively. In the absence of GPS, a cost-effective autonomous vehicle requires navigation solutions that rely on low-cost IMU and feature measurements collected by a vision unit. Consequently, linear velocity cannot be measured and its integration is impracticable due to the unbounded error growth resulting from sensor noise and bias [7]. Hence, autonomous navigation in space requires estimation of orientation (known as attitude), position, and linear velocity. Attitude can be successfully extracted given a low-cost IMU module using Gaussian filters [8]–[10], nonlinear deterministic filters on the Special Orthogonal Group $\mathbb{SO}(3)$ [11]–[13] or nonlinear stochastic filters on $\mathbb{SO}(3)$ [14]. The nonlinear deterministic filters in [11], [12], [15]–[17] have been proven to be almost globally asymptotically stable, while nonlinear stochastic filters in [14] are guaranteed to be almost globally asymptotically stable with a probability of one in mean square.

An inertial vision unit composed of a stereo vision unit and an IMU can be employed to extract rigid-body’s pose - a combination of attitude and position. Pose estimation is commonly approached using Gaussian filters (Kalman-type filters) [18]. Nonetheless, nonlinear deterministic filters [16], [17], [19] and nonlinear stochastic filters [3] evolved on the Special Euclidean Group $\mathbb{SE}(3)$ have been deemed more suitable. Nonlinear deterministic pose filters have been shown to be almost globally asymptotically stable [15]–[17], while nonlinear stochastic pose filters are guaranteed to be semi-globally uniformly ultimately bounded in mean square [3]. It should be remarked that although the use of low-cost IMU and vision units facilitates the development of cost-effective autonomous vehicles, it requires robust solutions that accommodate for the measurement uncertainties.

The true six degrees of freedom (6 DoF) vehicle navigation dynamics are composed of attitude, position, and linear velocity dynamics modeled on the Lie group of $\mathbb{SE}(3)$. The true dynamics are highly nonlinear, and are neither right nor left invariant. Navigation problem has been addressed using Kalman-type filters (KF) [20], [21], extended Kalman filters (EKF) [22], unscented Kalman filters (UKF) [23], multiplicative extended Kalman filter (MEKF) [24], and particle filters (PFs) [25]. However, the navigation solutions involving KF, EKF, UKF, MEKF, and PFs are not posed on $\mathbb{SE}(3)$. In view of the nonlinearity of the navigation dynamics, several solutions have been developed on the Lie group of $\mathbb{SE}(3)$, including invariant extended Kalman filter (IEKF) [1], a Riccati observer [26], and a nonlinear stochastic observer [27]. Stochastic filters have been useful in several applications, for instance distributed delays [28] and simultaneous localization and mapping [29]. The main shortcomings of these solutions are 1) the disregard for the IMU measurement noise and 2) the lack of transient and steady-state performance measures. Guaranteed convergence...
can be achieved by applying a prescribed performance function (PPF) [30]. PPF manipulates the error to initiate within a known large set and to decay systematically ultimately settling within a known small set [30].

To summarize, the true navigation dynamics are 1) highly nonlinear, 2) posed on $\mathbb{SE}_2(3)$, and 3) reliant on angular velocity and acceleration. Addressing all of the above-mentioned navigation dynamics characteristics,

1) this paper introduces a geometric nonlinear stochastic filter for inertial navigation posed on $\mathbb{SE}_2(3)$ reliant on measurements supplied by a typical low-cost IMU module, namely angular velocity and acceleration measurements commonly corrupted by noise.

2) the proposed stochastic filter is characterized by guaranteed transient and steady-state performance of the attitude and position error.

3) the closed loop error signals are shown to be almost semi-globally uniformly ultimately bounded in the mean square.

4) although the stochastic filter is developed in a continuous form, its discrete representation is included, and

5) the computational inexpensiveness of the proposed stochastic filter is demonstrated using a real-world three dimensional (3D) quadrotor dataset tested at a low sampling rate.

The proposed navigation filter is applicable to unmanned aerial vehicles as well as ground robots.

The paper is composed of seven sections: Section II presents important notation and preliminaries. Section III discusses the true navigation problem in a stochastic sense, available measurements, and error criteria. Section IV reformulates the stochastic dynamics to follow systematic measures. Section V proposes a novel nonlinear stochastic filter. Section VI reveals experimental results. Lastly, Section VII concludes the work.

II. Preliminary Material

A set of real numbers, nonnegative real numbers, and an $n$-by-$m$ real dimensional space are defined by $\mathbb{R}$, $\mathbb{R}_+$, and $\mathbb{R}^{n \times m}$, respectively. The Euclidean norm of $x \in \mathbb{R}^n$ is $||x|| = \sqrt{x^T x}$, while the Frobenius norm of $M \in \mathbb{R}^{n \times m}$ is $||M||_F = \sqrt{\text{Tr}(MM^T)}$ where $^*$ denotes a conjugate transpose. $I_n$ is an $n$-by-$n$ identity matrix. For $M \in \mathbb{R}^{n \times n}$, the set of eigenvalues is $\lambda(M) = \{\lambda_1, \lambda_2, \ldots, \lambda_n\}$ where $\lambda_{\max} = \lambda(M)$ and $\lambda_{\min} = \lambda(M)$ are the maximum and the minimum of $\lambda(M)$, respectively. $0_{n \times m}$ is a zero matrix and $I_{n \times n}$ is an $n$-by-$n$ matrix of ones. $\mathbb{P}\{}$ and $\mathbb{E}\{}$ denote a probability and an expected value of a component, respectively. The fixed inertial- and body-frame are represented by $\{I\}$ and $\{B\}$, respectively. The vehicle’s attitude is denoted by $R \in \mathbb{SO}(3)$ with $\mathbb{SO}(3)$ defined by

$$\mathbb{SO}(3) = \{ R \in \mathbb{R}^{3 \times 3} | R R^T = R^T R = I_3, \det(R) = +1 \}$$

where $\det(\cdot)$ is a determinant. $\mathbb{SO}(3)$ is the Lie algebra of $\mathbb{SO}(3)$ given by

$$\mathfrak{so}(3) = \{ [x]_\times \in \mathbb{R}^{3 \times 3}| [x]_\times^T = -[x]_\times, x \in \mathbb{R}^3 \}$$

where $[x]_\times$ is a skew symmetric matrix defined by

$$[x]_\times = \begin{bmatrix} 0 & -x_3 & x_2 \\ x_3 & 0 & -x_1 \\ -x_2 & x_1 & 0 \end{bmatrix} \in \mathfrak{so}(3), \quad x = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}$$

$vex: \mathfrak{so}(3) \to \mathbb{R}^3$ describes the inverse mapping of $[x]_\times$ such that $vex([x]_\times) = x, \forall x \in \mathbb{R}^3$. $\mathcal{P}_a$ denotes the anti-symmetric projection on the $\mathfrak{so}(3)$ given by

$$\mathcal{P}_a(M) = \frac{1}{2}(M - M^T) \in \mathfrak{so}(3), \forall M \in \mathbb{R}^{3 \times 3}$$

Let $\Upsilon = vex \circ \mathcal{P}_a$ denote the composition mapping such that

$$\Upsilon(M) = vex(\mathcal{P}_a(M)) \in \mathbb{R}^3, \forall M \in \mathbb{R}^{3 \times 3}$$

Consider $||R||_1$ as the Euclidean distance of $R \in \mathbb{SO}(3)$ expressed by

$$||R||_1 = \frac{1}{3} \text{Tr}(I_3 - R) \in [0, 1] \quad (1)$$

It is worth noting that $-1 \leq \text{Tr}(R) \leq 3$ and $||R||_1 = \frac{1}{8}||I_3 - R||_2^2$, visit [14]. Let the attitude, position, and linear velocity of a vehicle navigating in 3D space be $R \in \mathbb{SO}(3)$, $P \in \mathbb{R}^3$, and $V \in \mathbb{R}^3$, respectively, for all $R \in \{I\}$ and $P, V \in \{I\}$. The Special Euclidean Group contains $R$ and $P$ defined by $\mathbb{SE}(3) = \mathbb{SO}(3) \times \mathbb{R}^3 \subset \mathbb{R}^{4 \times 4}$, visit [3]. The extended form of $\mathbb{SE}(3)$ is $\mathbb{SE}_2(3) = \mathbb{SO}(3) \times \mathbb{R}^3 \times \mathbb{R}^3 \subset \mathbb{R}^{5 \times 5}$ defined by

$$\mathbb{SE}_2(3) = \{ X \in \mathbb{R}^{5 \times 5}| R \in \mathbb{SO}(3), P, V \in \mathbb{R}^3 \} \quad (2)$$

$$X = \Psi(R, P, V) = \begin{bmatrix} R & P \\ 0_{1 \times 3} & V \end{bmatrix} \in \mathbb{SE}_2(3) \quad (3)$$

where $X \in \mathbb{SE}_2(3)$ is a homogeneous navigation matrix composed of rigid-body’s attitude, position and linear velocity. Define $\mathbb{U}_m = \mathbb{so}(3) \times \mathbb{R}^3 \times \mathbb{R} \subset \mathbb{R}^{5 \times 5}$ as follows:

$$\mathbb{U}_m = \{ u(\Omega)_\times, V, \alpha, \kappa) | \Omega \times \in \mathbb{so}(3), V, \alpha \in \mathbb{R}^3, \kappa \in \mathbb{R} \} \quad (4)$$

where $\Omega \in \mathbb{R}^3$, $V \in \mathbb{R}^3$, and $\alpha \in \mathbb{R}^3$ denote the vehicle’s true angular velocity, linear velocity, and apparent acceleration comprised of all non-gravitational forces affecting the vehicle, respectively, for all $\Omega, \alpha \in \{B\}$.

III. Problem Formulation

From (3), the true dynamics of a rigid-body navigating in 3D space are given by

$$\begin{bmatrix} \dot{R} \\ \dot{P} \\ \dot{V} \end{bmatrix} = \begin{bmatrix} R \Omega\times \\ V \end{bmatrix}$$

$$\begin{bmatrix} R \tilde{g} \end{bmatrix} \quad (5)$$

where $R \in \mathbb{SO}(3)$, $P \in \mathbb{R}^3$, and $V \in \mathbb{R}^3$ represent attitude, position, and linear velocity of a vehicle navigating in 3D space, respectively, and $\tilde{g}$ is a gravity vector. Also, $\Omega \in \mathbb{R}^3$ denotes the vehicle’s true angular velocity, $V \in \mathbb{R}^3$ denotes the vehicle’s true linear velocity, and $\alpha \in \mathbb{R}^3$ denotes the apparent acceleration comprised of all non-gravitational forces affecting
achieve adaptive stabilization, define $\mathcal{R}$ Brownian motion process is characterized by $[14], [31]–[33]$:

\[ \text{covariance of } \mathcal{Q} \text{ is an unknown positive time-variant diagonal matrix. The } Q \in \mathbb{R}^{n} \text{ a low-cost IMU module. Due to the fact that the derivati-} \]

\[ \Omega = \mathcal{Q} \text{ and } \Omega = u(0) \in \mathbb{R}^{n} \text{ and } \mathcal{Q} = u(0) \in \mathbb{R}^{n} \text{ and } \mathcal{Q} \in \mathbb{R}^{n} \text{ and } \mathcal{Q} \in \mathbb{R}^{n} \text{ for control.}
\]

The estimation can be performed using a set of sensor measurements. The measurements of $\Omega$ and $a$ are as follows:

\[
\begin{align*}
\Omega_m &= \Omega + n_\Omega \in \mathbb{R}^3 \\
a_m &= a + n_a \in \mathbb{R}^3
\end{align*}
\]

where $n_\Omega$ and $n_a$ denote unknown bounded zero-mean noise contaminating $\Omega$ and $a$, respectively, and $\mathbb{E}[n_\Omega] = \mathbb{E}[n_a] = 0_{3\times 1}$. Measurements of $\Omega$ and $a$ can be easily obtained by a low-cost IMU module. Due to the fact that the derivative of a Gaussian process results in a Gaussian process, $n_\Omega = \mathcal{Q}d\Omega/dt$ and $n_a = \mathcal{Q}d\beta_a/dt$ as defined relative to the Brownian motion process vector $[31]$ where $\mathcal{Q} \in \mathbb{R}^{3\times 3}$ is an unknown constant time-variant diagonal matrix. The covariance of $n_\Omega$ and $n_a$ is $\mathcal{Q}^2 = \mathcal{Q}Q$. Note that the Brownian motion process is characterized by $[14], [31]–[33]$:

\[
\begin{align*}
\mathbb{P}\{\beta_\Omega(0) = \beta_a(0) = 0\} &= 1 \\
\mathbb{E}[d\beta_\Omega/dt] &= \mathbb{E}[d\beta_a/dt] = 0_{3\times 1} \\
\mathbb{E}[\beta_\Omega] &= \mathbb{E}[\beta_a] = 0_{3\times 1}
\end{align*}
\]

Thus, in the light of (1), the navigation dynamics in (5) can be expressed as a stochastic differential equation:

\[
\begin{align*}
\frac{d}{dt}||R|| &= (1/2)\text{vech}(\mathcal{P}_a(R))^\top(\Omega_m \cdot dt - d\beta_\Omega) \\
\frac{dP}{dt} &= \mathcal{V}^\top dt \\
\frac{dV}{dt} &= (R\mathcal{Q} + \mathcal{Q})^\top dt - \mathcal{Q}d\beta_a
\end{align*}
\]

where $dR = R[\Omega_m \cdot dt - R[\mathcal{Q}d\beta_a]_x \times$ and $\text{Tr}[R] = \mathcal{Q} \times \mathcal{Q} \times \mathcal{Q} \times \mathcal{Q} \times \mathcal{Q} = -2\text{vech}(\mathcal{P}_a(R))\top \Omega_m$, visit $[14]$. To achieve adaptive stabilization, define

\[
\sigma = \sup_{t \geq 0} \mathcal{Q}_{(1,1)}, \sup_{t \geq 0} \mathcal{Q}_{(2,2)}, \sup_{t \geq 0} \mathcal{Q}_{(3,3)}
\]

Let $n$ features be observed in the inertial-frame $p_i \in \mathcal{I}$ and measured in the body-frame such that

\[
\begin{align*}
\hat{y}_i &= X^{-1}\hat{p}_i + [(n_i^p)^\top, 0, 0]^\top \in \mathbb{R}^5 \\
y_i &= R^\top(p_i - P) + n_i^p \in \mathbb{R}^3
\end{align*}
\]
with $\hat{R} \in \mathbb{S}O(3)$, $\hat{P} \in \mathbb{R}^3$, and $\hat{V} \in \mathbb{R}^3$ being the estimates of $R$, $P$, and $V$, respectively. Let the estimation error between $X$ and $\hat{X}$ be

$$
\hat{X} = X \hat{X}^{-1} = \begin{bmatrix}
\hat{R} & \hat{P} & \hat{V} \\
0_{3 \times 3} & 1 & 0 \\
0_{3 \times 3} & 0 & 1
\end{bmatrix} \in \mathbb{SE}_2(3)
$$

where $\hat{X}^{-1} = \Psi(\hat{R}^T, -\hat{R}^T \hat{P}, -\hat{R}^T \hat{V})$, $\hat{R} = \hat{R}\hat{R}^T$, $\hat{P} = P - \hat{R}\hat{P}$, and $\hat{V} = V - \hat{R}\hat{V}$. The navigation estimation problem aims to drive $X \to \hat{X}$ such that $\hat{X} \to I_3$, $\hat{R} \to I_3$, $\hat{P} \to 0_{3 \times 1}$, and $\hat{V} \to 0_{3 \times 1}$. Define the error

$$
\tilde{y}_i = [\tilde{y}_i^T, 0, 0]^T
$$

where $\tilde{y}_i = [\tilde{y}_i^T, 0, 0]^T$, $\hat{p}_i = \hat{p}_i - \hat{R}\hat{p}_i$, and $\hat{P} = \hat{P} - \hat{R}\hat{P}$. Let $s_i > 0$ represent the sensor confidence level of the $i$th feature. Define the following components with respect to the available vector measurements:

$$
s_T = \sum_{i=1}^n s_i, \quad p_c = \frac{1}{s_T} \sum_{i=1}^n s_ip_i, \quad M = \sum_{i=1}^n s_i(p_i - \bar{p}_c)(p_i - \bar{p}_c)^T
$$

such that $\dot{M} = \sum_{i=1}^n s_i(p_i - \bar{p}_c)(p_i - \bar{p}_c)^T$, $\sum_{i=1}^n s_i \hat{y}_i^T \hat{R}^T = \sum_{i=1}^n s_i(p_i - \bar{p}_c)(p_i - \bar{p}_c)^T \hat{R} = M\hat{R}$, and $\sum_{i=1}^n s_i \hat{y}_i = \sum_{i=1}^n s_i(p_i - \hat{R}\hat{y}_i - \hat{P}) = s_T \hat{R}^T \hat{P}_c$ with $\hat{P}_c = P - \hat{P}$. It can be deduced that $\hat{R} \to I_3$ indicates that $\hat{P}_c \to P$. Let us sum up the vector measurements:

$$
\begin{align*}
\dot{p}_c &= \frac{1}{s_T} \sum_{i=1}^n s_ip_i, \\
\dot{M} &= \sum_{i=1}^n s_ip_i^T - s_T p_c \hat{p}_c^T, \\
\dot{M}\hat{R} &= \sum_{i=1}^n s_i(p_i - \bar{p}_c)g_i^T \hat{R}^T, \\
\dot{R}^T \hat{P}_c &= \frac{1}{s_T} \sum_{i=1}^n s_i(p_i - \hat{R}\hat{y}_i - \hat{P})
\end{align*}
$$

The vector measurements in (17) will be used to facilitate an explicit observer implementation.

**Lemma 2.** Consider $\hat{R} \in \mathbb{S}O(3)$ and $M = M^T \in \mathbb{R}^{3 \times 3}$ as in (17). Let $\bar{M} = \text{Tr}(\hat{M})I_3 - M$ where $\lambda_{\mathbb{M}}$ and $\bar{M}$ are the minimum and the maximum values of $\bar{M}$, respectively. For $||M\hat{R}||_1 = \frac{1}{2} \text{Tr}(M(I_3 - \hat{R}))$ and $\chi(M\hat{R}) = \text{vecc}(\mathbf{P}_a(M\hat{R}))$,

$$
\frac{\lambda_{\mathbb{M}}}{2} (1 + \text{Tr}(\hat{R})) ||M\hat{R}||_1 \leq ||\chi(M\hat{R})||^2
$$

$$
2\bar{M} ||M\hat{R}||_1 \geq ||\chi(M\hat{R})||^2
$$

**Proof.** See ([14], Lemma 1). □

Let $\lambda(M) = \{\lambda_1, \lambda_2, \lambda_3\}$ where $\lambda_3 \geq \lambda_2 \geq \lambda_1$ and $\bar{M} = \text{Tr}(\hat{M})I_3 - M$. Based on Assumption 1, a minimum of two eigenvalues of $\lambda(M)$ are greater than zero. Hence, ([35] page 553): 1) $\bar{M}$ is positive-definite, and 2) $\lambda(\bar{M}) = \{\lambda_3 + \lambda_2, \lambda_3 + \lambda_1, \lambda_2 + \lambda_1\}$ with $\lambda_{\mathbb{M}} = \lambda_2 + \lambda_1 > 0$.

**Definition 3.** ([14]) Define the unstable set $U_s \subset \mathbb{S}O(3)$ as

$$
U_s = \left\{ \hat{R}(0) \in \mathbb{S}O(3) \mid \text{Tr}(\hat{R}(0)) = -1 \right\}
$$

where $\hat{R}(0)$ is in $U_s$ if $\hat{R}(0) = \text{diag}(1, -1, -1)$, $\hat{R}(0) = \text{diag}(-1, 1, -1)$, or $\hat{R}(0) = \text{diag}(-1, -1, 1)$. **Based on (1), $\hat{R}(0) \in U_s$ indicates that $||\hat{R}(0)||_1 = +1$.**

**IV. GUARANTEED PERFORMANCE**

Define the error vector as follows:

$$
e = [e_1, e_2, e_3, e_4]^T = [||M\hat{R}||_1, \hat{P}_c^T \hat{R}]^T \in \mathbb{R}^4
$$

This section demonstrates how to guide the error $e$ to reduce systematically and smoothly from a known large set to a known small set following the guaranteed measures of transient and steady-state performance. Hence, define the following prescribed performance function (PPF) [30]:

$$
\xi_i(t) = (\xi_i^0 - \xi_i^\infty) \exp(-\ell_i t) + \xi_i^\infty, \quad \forall i = 1, 2, \ldots, 4
$$

where $\xi_i : \mathbb{R}_+ \to \mathbb{R}_+$, $\xi_i(0) = \xi_i^0 \in \mathbb{R}_+$ is the upper bound of the known large set, $\xi_i^\infty \in \mathbb{R}_+$ is the upper bound of the small set with $\lim_{t \to \infty} \xi_i(t) = \xi_i^\infty$, and $\ell_i > 0$ is the convergence rate of $\xi_i(t)$ from $\xi_i^0$ to $\xi_i^\infty$ for all $i = 1, 2, 3, 4$. Define $e_i := e_i(t)$, $\xi_i := \xi_i(t)$, $\xi = [\xi_1, \ldots, \xi_4]^T$, $\xi^0 = [\xi_1^0, \ldots, \xi_4^0]^T$, $\xi^\infty = [\xi_1^\infty, \ldots, \xi_4^\infty]^T$, and $\ell = [\ell_1, \ldots, \ell_4]^T$ for all $\xi, \xi^0, \xi^\infty, \ell \in \mathbb{R}^4$. $e_i$ follows the PPF in (22):

$$
-\delta_i e_i < \xi_i(t) < \xi_i, \quad \text{if } e_i(t) \geq 0
$$

$$
-\xi_i < e_i < \delta_i e_i, \quad \text{if } e_i(t) < 0
$$

where $\delta \in (0, 1]$. Figure 2 illustrates the concept of PPF for the two scenarios presented in (23) and (24).
Let $e_i$ be defined as

$$e_i = \xi_i N(E_i)$$  \hfill (25)\

where $N(E_i)$ is a smooth function and $E_i$ is a transformed error (unconstrained error). To extract $E_i$, $N(E_i)$ must follow Assumption 2:

**Assumption 2.** [5], [15], [30]

1) $N(E_i)$ is continuously differentiable and strictly increasing.

2) $N(E_i)$ is bounded such that

$$-\delta_i < N(E_i) < \delta_i, \forall e_i(0) \in \mathbb{R}$$

where $\delta_i$ is a positive constant.

3) 

$$\lim_{E_i \to \pm \infty} N(E_i) = \pm \delta_i, \forall e_i(0) \in \mathbb{R}$$

where $\delta_i$ is a positive constant.

The following function satisfies Assumption 2:

$$N(E_i) = \frac{\delta_i \exp(E_i) - \delta_i \exp(-E_i)}{\exp(E_i) + \exp(-E_i)}$$  \hfill (26)

Define $\delta = [\delta_1, \delta_2, \delta_3, \delta_4]^T$, $E = [E_R, E_P]^T$ for all $\delta$, $E \in \mathbb{R}^4$ where $E_R = E_1 \in \mathbb{R}$ and $E_P = [E_2, E_3, E_4]^T \in \mathbb{R}^3$. The inverse transformation of (26) is $E_i = N^{-1}(e_i/\xi_i)$ where

$$E_i = \frac{1}{2} \ln \frac{\delta_i + e_i/\xi_i}{\delta_i - e_i/\xi_i}$$  \hfill (27)\

**Remark 1.** [5], [15], [30] Let the unconstrained error be as in (27). The transient and steady-state performance of $e_i$ follow the PPF $\xi_i$, if and only if $E_i \in \mathcal{L}_\infty$.

**Remark 2.** Note that by definition $e_i = \|\tilde{M}\|_1 = \frac{1}{2} \text{Tr}([I_3 - \tilde{R}] \geq 0$ for all $\forall t \geq 0$. Also, $e_i \leq \xi_i$ indicates that $(\delta_i + e_i/\xi_i)/(\delta_i - e_i/\xi_i) \neq 1$ for all $e_i \neq 0$.

and $(\delta_i + e_i/\xi_i)/(\delta_i - e_i/\xi_i) = 1$ if $e_i = 0$. Therefore, $E_i \neq 0 \forall e_i \neq 0$ and $E_i = 0$ if and only if $e_i = 0$.

Define

$$\Delta_i = \frac{1}{2\xi_i} \frac{\partial N^{-1}(e_i/\xi_i)}{\partial (e_i/\xi_i)} = \frac{1}{2\xi_i} \left( \frac{1}{\delta_i + e_i/\xi_i} + \frac{1}{\delta_i - e_i/\xi_i} \right)$$  \hfill (28)\

Therefore, the dynamics of $\dot{E}_i$ can be obtained as

$$\dot{E}_i = \Delta_i \left( \frac{d}{dt} e_i - \mu_i e_i \right)$$  \hfill (29)\

Consider defining $\mu_R = \xi_1/\xi_i$, $\mu_P = \text{diag}(\xi_2/\xi_i, \xi_3/\xi_i, \xi_4/\xi_i)$, $\Delta_R = \Delta_i$, and $\Delta_P = \text{diag}(\Delta_2, \Delta_3, \Delta_4)$ for all $\mu_R, \Delta_R \in \mathbb{R}$ and $\mu_P, \Delta_P \in \mathbb{R}^{3 \times 3}$.

**V. NONLINEAR STOCHASTIC NAVIGATION FILTER**

This section pursues three main objectives: 1) providing a comprehensive discussion of a nonlinear stochastic complementary navigation filter evolved on $\mathbb{SE}(2,3)$, 2) constraining the error vector defined in (21) to behave following the predefined transient and steady state measures specified by the user, and 3) designing a robust filter that is able to produce accurate results irrespective of the noise level in measurements. The proposed filter can be utilized for unmanned aerial vehicles and ground robots. Let $\hat{\sigma}$ denote the estimate of $\sigma$ defined in (10). Define the error between $\sigma$ and $\hat{\sigma}$ as

$$\sigma = \sigma - \hat{\sigma} \in \mathbb{R}^3$$

Based on the set of measurements in (17), the error in (21), and the transformed error in (27), consider the following nonlinear stochastic navigation filter evolved directly on the Lie Group of $\mathbb{SE}(2,3)$:

$$\dot{\hat{X}} = \hat{X}U_m - W\hat{X}$$  \hfill (30)\

where $\hat{X} \in \mathbb{SE}(2,3)$, $U_m = u(\Omega_m)\times 0_{3 \times 1}, a_m, 1 \in U_m$ and $W = u(|w_\Omega|, |w_\nu|, |w_\alpha|, 1 \in U_m$. The equivalent detailed representation of (30) is as follows:

$$\begin{cases}
\dot{\tilde{R}} = \tilde{R} |\Omega|_x - |w_\Omega|_x \tilde{R} \\
\dot{\tilde{P}} = \tilde{P} - |w_\nu|_x \tilde{P} - w_\nu \\
\dot{\tilde{V}} = \tilde{R}a + \tilde{g} - |w_\Omega|_x \tilde{V} - w_\alpha \\
\dot{w_\Omega} = -k_w(\Delta_R E_R + 1) \text{ skew}(\tilde{X}) \\
\dot{w_\nu} = -k_v (|w_\nu| + 1) \Delta_P E_P - \mu_P \tilde{P} \tilde{R} \\
\dot{w_\alpha} = -k_a (\Delta_P + I_3) \Delta_P E_P \\
k_R = \gamma_\sigma \|w_\Omega|_x^2 \Delta_R \text{ skew}(E_R) \\
\dot{\hat{\sigma}} = k_R \text{ skew}(\tilde{X}^\top \text{ skew}(\tilde{X})) \tilde{R}^\top \text{ skew}(\tilde{X} - k_\sigma \gamma_\sigma \hat{\sigma})
\end{cases}$$  \hfill (31)
Consider the following Lyapunov function candidate $V = \phi(MR)$ and $\hat{V} = \dot{\phi}(\hat{M} \hat{R})$. The first part of (33) has the map $V^a : \mathbb{R} \times \mathbb{R} \times \mathbb{R}^3 \to \mathbb{R}^+$ and is selected as

$$V^a = \exp(E_R)||M\hat{R}|| + \frac{1}{2 \gamma_a}||\hat{\sigma}||^2$$

where $\gamma_a$ is a positive constant, $E_R \neq 0$ for all $||M\hat{R}|| \neq 0$, and $E_R = 0$ only at $||M\hat{R}|| = 0$ as discussed in Section IV. The first and the second partial derivatives of $\exp(E_R)||M\hat{R}||$ are $||M\hat{R}|| + 1)\exp(E_R)$ and $(||M\hat{R}|| + 2)\exp(E_R)$, respectively. In view of (13), (33), and (34), one has

$$\mathcal{L}V^a = \exp(E_R)||M\hat{R}|| + 1)\Delta_R(\frac{1}{2}Y(M\hat{R})^\top w_\alpha - \mu_R||M\hat{R}||)$$

$$+ k_R Y(M\hat{R})^\top \hat{R}Q^2\hat{R}^\top Y(M\hat{R}) - \frac{1}{\gamma_a}||\hat{\sigma}||^2$$

$$\leq \exp(E_R)||M\hat{R}|| + 1)\Delta_R(\frac{1}{2}Y(M\hat{R})^\top w_\alpha - \mu_R||M\hat{R}||)$$

$$+ k_R Y(M\hat{R})^\top \hat{R}\text{diag}(\sigma)\hat{R}^\top Y(M\hat{R}) - \frac{1}{\gamma_a}||\hat{\sigma}||^2$$

where $Q^2$ has been replaced by $\text{diag}(\sigma)$ in (10). Replacing $w_\Omega$ and $\hat{\sigma}$ with their definitions in (31) and recalling (18) in Lemma 2, one has

$$\mathcal{L}V^a \leq -\left( 1 + \frac{1}{Q^2} \right)\left( k_{w_a} - c_a \right) \frac{\lambda_M \Delta^2_a}{4} \exp(E_R)||M\hat{R}||$$

$$+ k_a ||\hat{\sigma}||^2$$

Since $||\mu_R|| \leq \ell_1$, one has $k_a = \frac{1}{\lambda_M(1 + TR)}$ and select $k_w > c_m$. Also, in view of Young’s inequality, one has $k_a ||\hat{\sigma}|| \leq \frac{c_m}{2} ||\hat{\sigma}||^2 + (k_a/2) ||\hat{\sigma}||^2$. Define $c_R = \frac{4\ell_k}{\lambda_M(1 + TR)}$, one has

$$\mathcal{L}V^a \leq -\left( k_w - c_m \right) \frac{c_m \Delta^2_a}{4} \exp(E_R)||M\hat{R}||$$

$$+ \frac{1}{2} \left[ \frac{c_m}{2} ||\hat{\sigma}||^2 + (k_a/2) ||\hat{\sigma}||^2 \right]$$

Turning our attention to the second part of (35), define the following Lyapunov function candidate:

$$V^b = \frac{1}{4}||E_P||^4 + \frac{1}{2K_k}||\hat{R}^\top \hat{V}^\top ||^2 + \frac{1}{\mu}||\hat{R}^\top \hat{V}||^2||E_P||$$

In view of (13), (33), and (34), one has

$$\mathcal{L}V^b = \left[ ||E_P||^2 E_P^\top - \frac{1}{\mu}||\hat{R}^\top \hat{V}||^2 \right] f_P$$

$$+ \frac{1}{2} \left[ \frac{1}{k_a} ||\hat{R}^\top \hat{V}||^2 + \frac{1}{\mu}||\hat{R}^\top \hat{V}||^2||E_P||^2 \right] f_P$$

$$+ \frac{1}{2} \text{Tr} \left\{ ||E_P||^2 I_3 + 2E_P E_P^\top \Delta_P h_P^2 h_P^2 \Delta_P \right\}$$

$$+ \frac{1}{2k_a} \text{Tr} \left\{ ||\hat{R}^\top \hat{V}||^2 I_3 + 2E_P \hat{V}^\top \hat{R} h_N^2 \hat{V}^\top \hat{R} \right\}$$

The equation in (41) can be presented in an inequality form as below:

$$\mathcal{L}V^b \leq -\left( \xi_1 - \frac{3}{4} \right) \frac{4k_{\xi}}{2k_a^2} ||E_P||^2$$

$$+ \left( \xi_2 + \xi_3 \right) \frac{4k_{\xi}}{2k_a^2} \frac{||\hat{\sigma}||^2}{||\hat{\sigma}||^2}$$

$$+ \left( \xi_2 + \xi_3 \right) \frac{4k_{\xi}}{2k_a^2} \frac{||\hat{\sigma}||^2}{||\hat{\sigma}||^2}$$

$$+ \left( \xi_2 + \xi_3 \right) \frac{4k_{\xi}}{2k_a^2} \frac{||\hat{\sigma}||^2}{||\hat{\sigma}||^2}$$

where $\xi_1 = \min\{\Delta_P\}, \xi_2 = \max\{\Delta_P\}, \xi_3 = \min\{\Delta_P\}, \xi_2 = \max\{\Delta_P\}, \xi_4 = \sup_{P \geq 0} (1 + ||V||^2)$, and $c_P = \sup_{P \geq 0} ||P - P||^2$. Let $c_{\xi} = \max\{\xi_1, \xi_2, \xi_3, |\hat{\sigma}||X_M||\}$ and $c_{\xi} = \max\{2|||\hat{\sigma}||X_M||, 2|||\hat{\sigma}||X_M||\}$. Consequently, one obtains
\[
\mathcal{L}^b \leq -c_2(k_v - \frac{3}{4})||E_P||^4 - \left(\frac{c_4}{k_a} - \frac{c_v}{4}\right)||\bar{R}^T\bar{V}||^4 \\
+ \frac{5c_5}{4\mu}||\bar{R}^T\bar{V}||^2||E_P||^2 + 2c_{d2}||\bar{R}^T\bar{V}||^2||I_3 - \hat{R}||_F \\
+ \left(\frac{3c_P}{2c_{d2}} + \frac{c_v}{4k_a\epsilon_1}\right)||\sigma||^2 \\
\text{(43)}
\]
such that \[
\mathcal{L}^b \leq 2c_{d2}||\bar{R}^T\bar{V}||^2||I_3 - \hat{R}||_F + \left(\frac{3c_P}{2c_{d2}} + \frac{c_v}{4k_a\epsilon_1}\right)||\sigma||^2 \\
- \varepsilon_{PV}^{T} \left[ \begin{array}{cc}
\zeta_2 & \frac{c_4 - 3}{3c_4} \\
\frac{c_4 - 3}{4c_4} & \frac{c_4}{8c_4}
\end{array} \right] \varepsilon_{PV}
\text{(44)}
\]
where \(\varepsilon_{PV} = \begin{bmatrix} ||E_P||, ||\bar{R}^T\bar{V}|| \end{bmatrix}^T\). It can be deduced that \(A_1\) can be made positive by selecting \(k_v > \max\{3/4, \mu c_2/\epsilon_1, c_4\mu^2/(\mu c_2 - c_4)\}\). Recalling (35), (39), and (43), one obtains
\[
\mathcal{L}^V \leq -\left(\frac{k_w - c_m}{4}\right) c_R \Delta R^2 \exp(E_R)||\bar{M}\bar{R}||_1 - \Delta A_1 ||\varepsilon_{PV}||^4 \\
+ 2c_{d2}||\bar{R}^T\bar{V}||^2||I_3 - \hat{R}||_F + \frac{k_a}{2}||\sigma||^2 \\
+ \left(\frac{3c_P}{2c_{d2}} + \frac{c_v}{4k_a\epsilon_1}\right)||\sigma||^2 \\
\text{(45)}
\]
which is
\[
\mathcal{L}^V \leq -\varepsilon_T^{T} \left[ \frac{c_4 - 3}{4c_4} \right] c_1 I_2 \varepsilon_T - \frac{k_a}{2}||\sigma||^2 \\
+ \left(\frac{3c_P}{2c_{d2}} + \frac{c_v}{4k_a\epsilon_1}\right)||\sigma||^2 \\
\leq -\Delta A_1 ||\varepsilon_T||^2 - \frac{k_a}{2}||\sigma||^2 + \eta_2||\sigma||^2 \\
\text{(46)}
\]
where \(\varepsilon_T = \sqrt{\exp(E_R)||\bar{M}\bar{R}||_1, ||E_P||^2, ||\bar{R}^T\bar{V}||^2}\) and \(\eta_2 = \frac{3c_P}{2c_{d2}} + \frac{c_v}{4k_a\epsilon_1} + \frac{k_a}{2}\). \(A_2\) is made positive by selecting \((k_w - c_m)c_R\epsilon_2\Delta R^2 > c_4\). Based on (46), one finds
\[
\mathcal{L}^V \leq -\Delta A_2 \exp(E_R)||\bar{M}\bar{R}||_1 + ||E_P||^4 + ||\bar{R}^T\bar{V}||^4 \\
- \frac{k_a}{2}||\sigma||^2 + \eta_2||\sigma||^2 \\
\text{(47)}
\]
which means that
\[
\frac{dE[V]}{dt} = E[\mathcal{L}^V] \leq -\eta_1 E[V] + \eta_2 \\
\text{(48)}
\]
with \(\eta_1 = \min\{\Delta A_2, k_a/2\}\). In view of Lemma 1, the inequality in (48) shows that
\[
0 \leq E[V(t)] \leq V(0)\exp(-\eta_1 t) + \frac{\eta_2}{\eta_1}, \forall t \geq 0.
\]

**Algorithm 1** Discrete nonlinear filter with guaranteed performance

Fig. 3. Block diagram of the proposed nonlinear stochastic observer for inertial navigation.
Therefore, the vector $[\varepsilon^T, ||\tilde{\sigma}||]$ is almost globally uniformly ultimately bounded which completes the proof.

The filter in (31) is proposed in a continuous form. For the purposes of low-cost electronic kit implementation, a discrete version practicable at a low sampling rate is necessary. Let $\Delta t$ denote a small sample time. The complete discrete implementation steps are detailed in Algorithm 1.

VI. EXPERIMENTAL RESULTS

This section experimentally demonstrates the performance of the proposed nonlinear stochastic filter for inertial navigation with guaranteed performance on the Lie group of $SE_2(3)$. The proposed stochastic filter in its discrete form (Algorithm 1) has been tested on the real-world data obtained from the EuRoC dataset [36]. The dataset is comprised of the ground truth, IMU measurements provided by ADIS16448 at a sampling rate of 200 Hz, and stereo images collected by MT9V034 at a sampling rate of 20 Hz. The camera parameters were calibrated using the Stereo Camera Calibrator Application ensuring that the images are not distorted. Figure 4 presents right and left feature detection. The detection of each photo in the EuRoC dataset [36] was tracked based on minimum eigenvalue feature detection using Kanade-Lucas-Tomasi (KLT) [37]. The noise inherent to low-cost IMUs has been supplemented with additional noise of $n_\Omega = \mathcal{N}(0, 0.11)$ (rad/sec) for the measurements of angular velocity while $n_a = \mathcal{N}(0, 0.1)$ (m/sec$^2$) for the measurements of acceleration. Note that $\mathcal{N}(0, 0.11)$ is a notation of normally distributed noise with a zero mean and a standard deviation of 0.11. Owing to the lack of real-world features in the dataset, feature locations are selected arbitrarily. The maximum number of features were set to 30. The downloadable datasets can be accessed at the following URL. The initial covariance estimate is set to $\hat{\Sigma}(0) = [0, 0, 0]^T$, and the design parameters are selected as $k_w = 3, k_v = 3, k_a = 20, \gamma_\sigma = 3, k_\sigma = 0.1, \mu = 0.8, \varepsilon = 0.8, \ell = [1, 1, 1, 1]^T, \xi^\infty = [0.03, 0.1, 0.1, 0.1]^T$, and

$$\xi^0_\ell = \delta = \left\lfloor \begin{array}{c} 1.2||M\hat{R}(0)||_1 + 0.5 \\ 2\hat{R}(0)^TP_\varepsilon(0) + 2 \times 1_{3 \times 1} \end{array} \right\rfloor$$

For large error in initialization, set the initial estimates of attitude, position, and linear velocity to

$$\hat{R}_0 = \hat{R}(0) = I_3, \quad \hat{P}(0) = \hat{V}(0) = [0, 0, 0]^T$$

The left portion of Figure 5 illustrates rapid adaptation from large initial error in attitude and position and strong tracking capabilities of the filter to the true trajectory. The right portion of Figure 5 reveals impressive convergence of the error components $||R\hat{R}^T||_1$, $||P - \hat{P}||$, and $||V - \hat{V}||$ from large initial error to the close neighborhood of the origin. Also, Figure 5 confirms the robustness of the filter against the high levels of measurement noise. Figure 6 shows remarkable tracking performance of the filter estimated orientation in terms of Euler angles ($\phi, \theta, \psi$) in comparison with the true vehicle’s orientation ($\hat{\phi}, \hat{\theta}, \hat{\psi}$). Likewise, Figure 7 illustrates impressive tracking performance of the filter estimated position ($\hat{x}, \hat{y}, \hat{z}$) against the true vehicle’s position ($x, y, z$). To access experiment demonstration visit the Video Link. The real-world dataset experiment demonstrates the ability of the proposed stochastic filter to produce good results at low sampling rates and in presence of large initial error and measurement uncertainties. The performed testing indicates that the proposed filter is computationally cheap. As such, the proposed solution can be implemented using an inexpensive kit.

VII. CONCLUSION

This paper addressed the problem of attitude, position, and linear velocity estimation of a rigid-body navigating with six degrees of freedom (6 DoF). A geometric nonlinear stochastic navigation filter on the matrix Lie group of $SE_2(3)$ with guaranteed transient and steady-state performance has been proposed. The closed loop error signals have been shown to be almost semi-globally uniformly ultimately bounded in the mean square. The proposed filter produces good results given measurements supplied by low-cost inertial measurement and vision units. Experiments with real-world data obtained from quadrotor have demonstrated the strong tracking capabilities of the proposed filter as it rapidly and accurately estimates the unknown pose and linear velocity in presence of large initial attitude, position, and linear velocity error and high level of measurement uncertainties.
Consider $Q = [q_0, q^T] \in S^3$ as a unit-quaternion vector where $S^3 = \{ Q \in \mathbb{R}^4 ||Q|| = \sqrt{q_0^2 + q^T q} = 1 \}$ with $q_0 \in \mathbb{R}$ and $q \in \mathbb{R}^3$. Let $\hat{Q} \in S^3$ be the estimate of $Q \in S^3$ and consider the mapping from $S^3$ to $SO(3)$ to be $\hat{R}_Q = (\hat{q}_0^2 - ||\hat{q}||^2) I_3 + 2\hat{q} \hat{q}^T + 2q_0 \hat{q} \hat{q}^T \in SO(3)$. Recall the vector measurements in (17):

$$\begin{align*}
\delta_R &= \frac{1}{2} \ln \frac{\delta_i + e_i[k]/\xi_i[k]}{\delta_i - e_i[k]/\xi_i[k]} \\
\Delta_i &= \frac{1}{2} \left[ (a_i + e_i[k]/\xi_i[k]) + (a_i - e_i[k]/\xi_i[k]) \right]
\end{align*}$$

for all $i = 1, \ldots, 4$. Let $E = [E_R, E_P]^T$, $\Delta_R = \Delta_1$, and $\Delta_P = \text{diag}(\Delta_2, \Delta_3, \Delta_4)$. The equivalent quaternion-based
navigation filter in (31) is given below:

\[
\begin{align*}
\Theta_m &= \begin{bmatrix} 0 & -\Omega_m^T \\ \Omega_m & -[\Omega_m]^x \end{bmatrix}, \\
\dot{\Psi} &= \begin{bmatrix} 0 & -w_\Omega^T \\ w_\Omega & [w_\Omega]^x \end{bmatrix}, \\
\dot{Q} &= \frac{1}{2} \Theta_m \dot{Q} - \frac{1}{2} \Psi \dot{Q}, \\
\dot{P} &= \dot{V} - [w_\Omega]^x \dot{P} - w_V, \\
\dot{V} &= R \dot{Q} \Omega_m + \tilde{g} - [w_\Omega]^x \dot{V} - w_a, \\
w_\Omega &= -k_\sigma (\Delta P E_p + 1) \Psi (M \tilde{R}) - \frac{\Delta \Psi}{4} [\|M\tilde{R}\|_1^2]^2 \tilde{R} \text{diag}(\tilde{R}^T \Psi (M \tilde{R}) \sigma, \\
w_V &= \frac{[p_c]^x}{\| \tilde{g} \|} - \frac{\Delta \Psi}{\| \tilde{g} \|} \Delta P E_p - \ell \tilde{P}^T \tilde{P} \tilde{\sigma}, \\
w_a &= -\tilde{g} - k_\sigma \left( \frac{\Delta \Psi}{\| \tilde{g} \|} \Delta P E_p \right), \\
k_R &= \gamma_\sigma \|M\tilde{R}\|_1^2 \Delta \Psi^2 \exp(E_R), \\
k_{\tilde{\sigma}} &= k_\sigma \text{diag}(\tilde{R}^T \Psi (M \tilde{R}) \tilde{R} \Psi (M \tilde{R}) - k_\sigma \gamma_\sigma \tilde{\sigma})
\end{align*}
\]
