SET-INDEXED RANDOM FIELDS AND ALGEBRAIC EUCLIDEAN QUANTUM FIELD THEORY

SVETOSLAV ZAHARIEV

Abstract. We present a construction of non-Gaussian Borel measures on the space of continuous functions defined on the space of all balls in Euclidean space of arbitrary dimension. These measures induce nets of operator algebras satisfying a version of the Haag-Kastler axioms of algebraic quantum field theory and may be interpreted as (nonlinear) continuous transformations of the free scalar massive Euclidean quantum field.

1. Introduction

In the axiomatic approach to quantum field theory (QFT) due to A. Wightman quantum fields are represented by point-like localized objects, namely, operator-valued distributions on Minkowski space. Consequently, several low-dimensional scalar QFT models have been constructed in the Euclidean framework as probability measures on the space of distributions on Euclidean spacetime. The passage to relativistic QFT is provided by the well-known Osterwalder-Schrader reconstruction theorem.

The algebraic approach to QFT in which quantum fields are represented by nets, i.e. flabby pre-cosheaves, of operator algebras, transcends the necessity of using point-like localized objects. It is therefore natural to conjecture that models of algebraic QFT may be constructed from measures on more general topological vector spaces equipped with the structure of a flabby presheaf over the Euclidean spacetime \( \mathbb{R}^d \). It this article, we shall describe such a construction for any \( d > 1 \) utilizing probabilistic methods and a version of the axioms of algebraic Euclidean QFT developed by D. Schlingemann in [11].

More specifically, we shall first associate to the free scalar massive Euclidean quantum field a Gaussian measure on the space of all functions from the set of all balls in \( \mathbb{R}^d \) to the real numbers. Second, employing well-known results on the sample path continuity of Gaussian random fields due to R. Dudley, we shall show that the latter measure can be promoted to a Borel measure on the space of all continuous functions on space of of all balls in

Key words and phrases. Random field, Sample path continuity, White noise, Algebraic quantum field theory, Euclidean quantum field theory.
Finally, applying continuous (nonlinear) transformations to this measure, we shall obtain non-Gaussian measures on the same space and prove that these measures induce structures that satisfy the above mentioned axioms of algebraic Euclidean QFT.

While the non-Gaussian measures so obtained do not appear to bear direct relation to physically relevant QFT models, in a forthcoming paper we shall employ our method to construct interacting scalar QFT models such as the $\phi^4$-model via setting up and solving appropriate semilinear stochastic partial differential equations driven by the mollified white noise discussed in Section 3. It should be noted that since in our approach, heuristically speaking, the totality of all “scales” is considered at once (each “scale” being represented by the balls of fixed radius), no necessity of taking an ultraviolet limit and hence of a renormalization procedure arises. Thus, in particular, the above mentioned stochastic equations involve ordinary rather than generalized random fields.

This article is organized as follows. In Section 2 we present some facts from the theory of Gaussian random fields that will be used in the sequel. In Section 3 we discuss a general construction of Gaussian random fields indexed by the space of balls in $\mathbb{R}^d$ and their continuity properties. The axioms of algebraic Euclidean QFT as well as the relevant reconstruction theorem are briefly reviewed in Section 4. Section 5 is dedicated to the passage from random fields indexed by balls in $\mathbb{R}^d$ to objects satisfying the axioms of algebraic Euclidean QFT over $\mathbb{R}^d$. Finally, in Section 6 we construct the non-Gaussian measures representing transformations of the mollified scalar massive free Euclidean quantum field.

2. Preliminaries on Gaussian random fields

In this section we review some basic facts from the theory of Gaussian random fields. In what follows we have fixed a probability space $(\Omega, \mathcal{F}, \mu)$, where $\Omega$ is a set, $\mathcal{F}$ is a $\sigma$-algebra on $\mathcal{F}$, and $\mu$ is a probability measure on $\mathcal{F}$.

Let $T$ be an arbitrary set. By a random field indexed by $T$ we shall mean a map $X$ from $T$ to the space of the real-valued random variables on $(\Omega, \mathcal{F}, \mu)$. Given $t \in T$, we shall write $X_t$ for the random variable which is the image of $t$ under $X$. We say that $X$ is Gaussian if all $X_t$ are centered Gaussian random variables, i.e., the image/pushforward of $\mu$ under $X_t$ is a centered Gaussian measure on $\mathbb{R}$ for all $t \in T$. In the remainder of this section we assume that all random fields considered consist of random variables in $L^2(\Omega, \mathcal{F}, \mu)$, the space of square-integrable real-valued random variables on $(\Omega, \mathcal{F}, \mu)$.

Recall that a function $C : T \times T \rightarrow \mathbb{R}$ is called positive definite if for all finite sequences $t_1, \ldots, t_n \in T$ and $\lambda_1, \ldots, \lambda_n \in \mathbb{R}$ one has

$$\sum_{i,j=1}^{n} \lambda_i \lambda_j C(t_i, t_j) \geq 0.$$
The covariance of a random field \( X \) defined via
\[
\text{Cov}(X)(t_1, t_2) = \langle X_{t_1}, X_{t_2} \rangle_{L^2}, \quad t_1, t_2 \in T,
\]
is clearly positive definite and symmetric.

Conversely, one can construct a Gaussian random field indexed by \( T \) from any given symmetric positive function on \( T \times T \). Let us write \( \mathbb{R}^T \) for the set of all functions from \( T \) to \( \mathbb{R} \) and \( \mathcal{T} \) for the smallest \( \sigma \)-algebra on \( \mathbb{R}^T \) with respect to which the canonical projections from \( \mathbb{R}^T \) to \( \mathbb{R} \) are measurable.

**Theorem 2.1.** Let \( C : T \times T \to \mathbb{R} \) be positive definite and symmetric.

1. Then there exists a centered Gaussian probability measure \( \mu_C \) on \( (\mathbb{R}^T, \mathcal{T}) \) and a Gaussian random field \( X^C \) on \( (\mathbb{R}^T, \mathcal{T}, \mu_C) \) indexed by \( T \) whose covariance is \( C \).

2. Let \( \psi : T \to T \) be any map. Then the induced map \( \bar{\psi} : \mathbb{R}^T \to \mathbb{R}^T \) is \( \mathcal{T} \)-measurable and one has
\[
\bar{\psi} \ast \mu_C = \mu_C(\psi, \psi),
\]
where \( \bar{\psi} \ast \mu_C \) is the image of \( \mu_C \) under \( \bar{\psi} \) and \( \mu_C(\psi \times \psi) \) is the Gaussian measure constructed in Part (1) from the covariance \( C \circ (\psi \times \psi) \).

**Proof.** This is well-known, see e.g. [7, Theorem 8.2]. We briefly describe the construction as it will be needed in the sequel.

For every finite subset \( S \) of \( T \) one considers the centered Gaussian probability measure \( \mu_S \) on \( \mathbb{R}^S \) with covariance matrix \( C_{ij} = C(t_i, t_j), t_i \in S \). The Kolmogorov extension theorem (see e.g. [10, Theorem 14.36]) implies that the collection of these measures extends to a unique measure \( \mu_C \) on \( (\mathbb{R}^T, \mathcal{T}) \). The Gaussian random field \( X^C \) is then simply the canonical field associated with the probability space \( (\mathbb{R}^T, \mathcal{T}, \mu_C) \), i.e., one sets \( X^C(t)(f) = f(t) \) for any \( f \in \mathbb{R}^T \). \( \square \)

We next assume that \( T \) is a topological space and discuss certain continuity properties of random fields indexed by \( T \) on a probability space \( (\Omega, \mathcal{F}, \mu) \). We shall call a random field \( X \) continuous if it is continuous as a map from \( T \) to \( L^2(\Omega, \mathcal{F}, \mu) \) considered with the norm topology. We say that \( X \) has continuous sample paths if the real-valued function given by \( t \in T \mapsto X_t(\omega) \) is continuous for almost all \( \omega \in \Omega \) with respect to \( \mu \).

Now let \( d \) be a pseudo-metric on \( T \) and assume that \( T \) is compact with respect to the topology induced by \( d \). We write \( N_d(T, \varepsilon) \) for the minimum number of balls of radius \( \varepsilon \) who union covers \( T \) and set
\[
J(T, d) = \int_0^{\text{diam}(T)} (\log N_d(T, \varepsilon))^{1/2} d\varepsilon,
\]
where \( \text{diam}(T) \) stands for the diameter of \( T \). Given a Gaussian random field \( X \) indexed by \( T \), we define the canonical pseudo-metric \( d_X \) on \( T \) associated to \( X \) via
\[
d_X^2(t_1, t_2) = \int_{\Omega} |X_{t_1} - X_{t_2}|^2 d\mu.
\]
Recall that a random field \( \tilde{X} \) is called a modification of \( X \) if for every \( t \in T \) one has \( \tilde{X}_t = X_t \) a.s. with respect to \( \mu \). A proof of the following theorem due to Dudley may be found in \([8]\) Chapter 15, Section 4.

**Theorem 2.2.** If the integral \( J(T, d_X) \) is finite, the Gaussian random field \( X \) has a modification with continuous sample paths on \( (T, d_X) \).

Now let \( U \) be an open subset of \( \mathbb{R}^d \) and let \( X \) be a random field indexed by \( U \) that has a modification with continuous sample paths. We write \( C(U) \) for the space of all continuous real-valued functions on \( U \) equipped with the topology of uniform convergence on compact subsets of \( U \), and \( \mathcal{B}_U \) for the Borel \( \sigma \)-algebra on \( C(U) \). Proceeding as in \([10]\) Section 21.6, we shall explain how \( \mu \) and \( X \) induce a Borel probability measure on \( C(U) \).

By our assumption there exists \( \Omega \in \mathcal{F} \) with \( \mu(\Omega) = 1 \) such that for every \( \omega \in \Omega \) the function given by \( x \ni U \mapsto X_x(\omega) \) is in \( C(U) \). In other words, \( X \) induces a map from \( \Omega \) to \( C(U) \) which we denote by \( \tilde{X} \). Further, we write \( \tilde{\mathcal{F}} \) for the restriction (trace) of the \( \sigma \)-algebra to \( \tilde{\Omega} \) and \( \tilde{\mu} \) for the restriction of \( \mu \) to \( \tilde{\mathcal{F}} \).

Let \( \tilde{X}_x : C(U) \to \mathbb{R} \) be the evaluation of a function at \( x \in U \). It is standard (see e.g. \([7]\) p.125) that the \( \sigma \)-algebra on \( C(U) \) generated by the evaluations \( \tilde{X}_x \) coincides with \( \mathcal{B}_U \). Since \( \tilde{X}_x(\tilde{X}(\omega)) = X_x(\omega) \) for all \( x \in U \) and all \( \omega \in \tilde{\Omega} \), it follows that \( \tilde{X} \) is measurable map from \( (\tilde{\Omega}, \tilde{\mathcal{F}}) \) to \( (C(U), \mathcal{B}_U) \). Denoting by \( \tilde{\mu} \) the image of \( \mu \) under \( \tilde{X} \), we obtain the canonical random field \( \tilde{X} \) on the probability space \( (C(U), \mathcal{B}_U, \tilde{\mu}) \) given by the evaluations \( \tilde{X}_x \).

### 3. Constructing set-indexed random fields

Let us denote the set of all open balls in \( \mathbb{R}^d \) by \( B_d \). We identify \( B_d \) with \( \mathbb{R}^d \times (0, \infty) \) and equip it with the Euclidean metric on \( \mathbb{R}^d \times (0, \infty) \).

Given a strictly positive selfadjoint bounded operator \( A \) on \( L^2(\mathbb{R}^d) \), the space of the real-valued square integrable functions on \( \mathbb{R}^d \), we construct a Gaussian measure and a Gaussian random field indexed by \( B_d \) associated to \( A \) as follows. We write \( b(x, r) \) for the open ball with radius \( r \) centered at \( x \in \mathbb{R}^d \), \( 1_{b(x, r)} \) for its indicator function, and set

\[
A(x, r, y, s) := \langle v_r 1_{b(x, r)}, A v_s 1_{b(y, s)} \rangle_{L^2(\mathbb{R}^d)},
\]

where \( v_r \) is the reciprocal of the volume of a \( d \)-dimensional ball with radius \( r \).

Since \( \langle \cdot, \cdot \rangle_{L^2(\mathbb{R}^d)} \) is a symmetric positive definite bilinear form on \( L^2(\mathbb{R}^d) \), \( A(x, r, y, s) \) is symmetric and positive definite, considered as a function on \( B_d \times B_d \). Hence we can apply Theorem 2.1 to obtain a probability space \( (\mathbb{R}^{B_d}, \mathcal{B}, \mu_A) \) and a Gaussian random field \( X^A \) on it.

**Proposition 3.1.** The function \( A(x, r, y, s) \) is continuous on \( B_d \times B_d \) and \( X^A \) is a continuous random field. Moreover, \( X^A \) has a modification which has continuous sample paths.
Proof. We observe that
\[
\|X^A_{(x,r)} - X^A_{(y,s)}\|_{L^2(\mu_A)}^2 = A(x,r,x,r) + A(y,s,y,s) - 2A(x,r,y,s)
\]
\[
= \|\sqrt{A}(v_r b_{b(x,r)} - v_s b_{b(y,s)})\|_{L^2(\mathbb{R}^d)}^2 \leq K\|\sqrt{A}(v_r b_{b(x,r)} - v_s b_{b(y,s)})\|_{L^2(\mathbb{R}^d)}^2
\]  
(3.1)
for some $K > 0$. We fix a compact $V \subset B_d$ and let $(x_n, r_n)$ be a sequence in $V$ converging to $(x_0, r_0)$. Since $v_{r_n} b_{b(x_n, r_n)}$ converges pointwise to $v_{r_0} b_{b(x_0, r_0)}$, we conclude by the Lebesgue dominated convergence theorem and (3.1) that $X^A$ is continuous on $V$ and hence on $B_d$. It follows (see e.g. [7, Theorem 8.12]) that $A(x, r, y, s)$ is continuous on $B_d \times B_d$.

Now consider the positive definite symmetric function on $B_d \times B_d$ defined via
\[
W(x, r, y, s) := \langle b_{b(x,r)}, b_{b(y,s)} \rangle_{L^2(\mathbb{R}^d)} = \text{vol}(b(x,r) \cap b(y,s)).
\]
Applying Theorem 2.1, we construct from the function $W(x, r, y, s)$ a probability space $(\mathbb{R}^{B_d}, \mathcal{B}, \mu_W)$ and a Gaussian random field $X^W$ on it, known as the ($d$-dimensional) Brownian sheet indexed by balls.

Let us compare the canonical pseudo-metrics $d_{X^W}$ and $d_{X^A}$ associated to $X^W$ and $X^A$ on an arbitrary compact subset $V$ of $B_d$. We observe that $v_r$ is bounded from above, as well as bounded away from 0 when $(x, r)$ ranges within $V$, hence (3.1) implies
\[
d_{X^A}(b_1, b_2) \leq K_{V, 1} d_{X^A}(b_1, b_2)
\]
for all $b_1, b_2 \in V$ and some constant $K_{V, 1} > 0$. Similarly, since the operator $A$ is bounded from below, we find
\[
d_{X^W}(b_1, b_2) \leq K_{V, 2} d_{X^A}(b_1, b_2)
\]
for some $K_{V, 2} > 0$, hence the pseudo-metrics $d_{X^W}$ and $d_{X^A}$ are strongly equivalent on $V$.

Next we note that by [11, Theorem 1.4.7] (see also [11, Theorem 8.13]) the integral $J(B_d, d_{X^W})$ is finite and so is, by the above equivalence, the integral $J(B_d, d_{X^A})$. Thus by Theorem 2.2 the random field $X^A$ has a modification with continuous sample paths on $(V, d_{X^A})$. Since the compact $V$ is arbitrary and $B_d$ is $\sigma$-compact, the same holds for $X^A$ on $(B_d, d_{X^A})$ (cf. [11, p.13]). Finally, since convergence in $B_d$ with respect to the Euclidean metric implies convergence with respect to the pseudo-metric $d_{X^A}$, we conclude that $X^A$ has a modification with continuous sample paths on $B_d$ with respect to the Euclidean metric.

Applying the construction at the end of Section 2 with $U = B_d$ regarded as an open subset of $\mathbb{R}^{d+1}$, we obtain a probability space $(C(B_d), \mathcal{B}_{B_d}, \tilde{\mu}_A)$ and a canonical Gaussian random field $\tilde{X}^A$ indexed by $B_d$ on it.

The choice of the constants $v_r$ in the definition of $A(x, r, y, s)$ is justified by the following convergence result.
Proposition 3.2. Let $r_n$ be a sequence of positive numbers converging to 0. Then $A(x, r_n, y, r_n)$ converges to the bilinear form $\langle \cdot, A \cdot \rangle_{L^2(\mathbb{R}^d)}$ as $n \to \infty$ in the sense of distributions on $\mathbb{R}^d \times \mathbb{R}^d$.

Proof. We set $\psi_n(x,y) = v_{r_n} b(0,r_n)(x - y)$ so that $\psi_n(\cdot, y)$ converges to $\delta_y$ (the delta function centered at $y \in \mathbb{R}^d$) in the sense of distributions on $\mathbb{R}^d$ as $n \to \infty$. It follows that

$$A(x, r_n, y, r_n) = \langle \psi_n(\cdot, x), A\psi_n(\cdot, y) \rangle_{L^2(\mathbb{R}^d)}$$

converges to $\langle \cdot, A \cdot \rangle_{L^2(\mathbb{R}^d)}$ in the sense of distributions on $\mathbb{R}^d \times \mathbb{R}^d$. □

Example 3.3. Taking $A = I$, the identity operator, we find that $A(x, r_n, y, r_n)$ converges to $\delta(x - y)$, the covariance of the generalized random field known as white noise. Motivated by this, we shall refer to the associated random field $X^I$ as the **mollified white noise**.

Example 3.4. When $A = (-\Delta + I)^{-1}$, where $\Delta$ is the Laplacian on $\mathbb{R}^d$, we find that $A(x, r_n, y, r_n)$ converges to the covariance of the free scalar Euclidean quantum field of mass 1. We shall refer to the associated random field $X^{(-\Delta + I)^{-1}}$ as the **mollified free Euclidean field**.

4. The Axioms of Algebraic Euclidean QFT

In this section we present a version of the axioms and the reconstruction theorem of algebraic Euclidean QFT developed in [11]. We begin by introducing some notation. We write $(t, x_1, \ldots, x_{d-1})$ for the coordinates of $x \in \mathbb{R}^d$ and set

$$\mathbb{R}_+^d = \{ t, x_1, \ldots, x_{d-1} \in \mathbb{R}^d | t > 0 \},$$
$$\mathbb{R}_-^d = \{ t, x_1, \ldots, x_{d-1} \in \mathbb{R}^d | t < 0 \},$$
$$\mathbb{R}_0^d = \{ t, x_1, \ldots, x_{d-1} \in \mathbb{R}^d | t = 0 \}.$$

Further, we write $\theta$ for the reflection

$$(t, x_1, \ldots, x_{d-1}) \mapsto (-t, x_1, \ldots, x_{d-1}).$$

We denote by $E_d$ the group of Euclidean motions in $\mathbb{R}^d$ and by $E_d^0$ the subgroup of $E_d$ preserving $\mathbb{R}_0^d$.

Definition 4.1. Let $\mathcal{H}$ be a Hilbert space and let $\{ \mathcal{S}(V) \}$ be a family of closed subspaces of $\mathcal{H}$ indexed by the open sets $V$ of $\mathbb{R}^d$ satisfying the following:

1. (covariance) $U(g) \mathcal{S}(V) U^*(g) = \mathcal{S}(g \cdot V)$ for every $g \in E_d$ and every open $V \subset \mathbb{R}^d$,
2. (cyclicity) $\mathcal{S}(\mathbb{R}^d) = \mathcal{H}$,
3. (continuity) Given an open $V \subset \mathbb{R}^d$, denote by $\Pi_V$ the orthogonal projection onto $\mathcal{S}(V)$. Given an infinite sequence $V_1 \subset V_2 \subset V_3 \subset \cdots$ of open subsets of $\mathbb{R}^d$ with $\bigcup_{i=1}^\infty V_i = V$, the sequence $\Pi_{V_i}$ converges strongly to $\Pi_V$.  

A strongly continuous unitary representation $\mathbb{E}_d \ni g \mapsto U(g)$ of $\mathbb{E}_d$ on $\mathcal{H}$ is called reflection positive with respect to $\{\mathcal{G}(V)\}$ if one has $\langle h, U(\theta)h \rangle_{\mathcal{H}} \geq 0$ for every $h \in \mathcal{G}(\mathbb{R}_+^d)$.

The latter definition is motivated by the main result of [9] which shall be recalled below, in the proof of Theorem 4.3.

In what follows, by a net of unital algebras over a topological space $X$ indexed by a collection $\mathcal{V}$ of open subsets of $X$ we mean an assignment $\mathcal{V} \mapsto B(V)$ of a unital algebra to every $V \in \mathcal{V}$ such that there is an inclusion of unital algebras $B(V_1) \subset B(V_2)$ whenever $V_1 \subset V_2$. Unless otherwise specified, we shall assume that the nets we consider are indexed by the collection of all open sets on $X$. (Such nets are, in modern terminology, nothing but flabby pre-cosheaves on $X$.)

We shall write $L(H)$ for the algebra of all bounded operators on the Hilbert space $H$.

Definition 4.2. A triple $(\mathcal{H}, \mathfrak{A}, h_0)$, where $\mathcal{H}$ is a complex Hilbert space, $\mathfrak{A}$ is a net of commutative von Neumann algebras over $\mathbb{R}^d$ such that $\mathfrak{A}(\mathbb{R}^d) \subset L(\mathcal{H})$, and $h_0$ is a non-zero vector in $\mathcal{H}$, is called an algebraic Euclidean QFT over $\mathbb{R}^d$ if the following holds.

(1) The Hilbert space $\mathcal{H}$ is equipped with a strongly continuous unitary representation of $\mathbb{E}_d$ for which we write $\mathbb{E}_d \ni g \mapsto U(g)$.

(2) The vector $h_0$ is of norm 1 and is $\mathbb{E}_d$-invariant.

(3) The net $\mathfrak{A}$ satisfies:

(a) (covariance) $U(g)\mathfrak{A}(V)U^*(g) = \mathfrak{A}(g \cdot V)$ for every $g \in \mathbb{E}_d$ and every open $V \subset \mathbb{R}^d$, where $\mathfrak{A}(V)$ stands for the algebra in the net $\mathfrak{A}$ corresponding to $V$;

(b) (reflection positivity) The family of subspaces $\{\mathfrak{A}(V)h_0\}$ satisfies the assumptions of Definition 4.1 and the representation $\mathbb{E}_d \ni g \mapsto U(g)$ is reflection positive with respect to this family.

Next we describe the passage from algebraic Euclidean QFT to algebraic relativistic QFT satisfying a weak version of the Haag-Kastler axioms (cf. [6] and [2]). We denote by $\mathbb{M}^d$ the $d$-dimensional Minkowski space and by $\mathcal{P}^d$ the $d$-dimensional orthochronous Poincaré group.

Theorem 4.3. Every Euclidean algebraic QFT $(\mathcal{H}, \mathfrak{A}, h_0)$ over $\mathbb{R}^d$ gives rise to a triple $(\mathcal{H}, \tilde{\mathfrak{A}}, \tilde{h}_0)$, where $\mathcal{H}$ is a complex Hilbert space, $\tilde{\mathfrak{A}}$ is a net of unital Banach algebras acting on $\tilde{\mathcal{H}}$ indexed by the double cones in $\mathbb{M}^d$, $\tilde{h}_0$ is a non-zero vector in $\tilde{\mathcal{H}}$, and the following holds.

(1) The Hilbert space $\tilde{\mathcal{H}}$ is equipped with a strongly continuous unitary representation of $\mathcal{P}^d$ denoted by $\mathcal{P}^d \ni g \mapsto \tilde{U}(g)$, which satisfies the spectrum condition: the selfadjoint generators of the representation of the translation subgroup of $\mathcal{P}^d$ have spectrum contained in the closed forward light cone in $\mathbb{M}^d$.

(2) (vacuum) The vector $\tilde{h}_0$ is of norm 1 and is $\mathcal{P}^d$-invariant.
(3) The net \( \tilde{\mathcal{A}} \) satisfies:

(a) (covariance) \( \tilde{U}(g) \tilde{\mathcal{A}}(\mathcal{O}) \tilde{U}^*(g) = \tilde{\mathcal{A}}(g \cdot \mathcal{O}) \) for every \( g \in \mathcal{P}^d \) and every double cone \( \mathcal{O} \subset \mathcal{M}^d \).

(b) (causality) \( \tilde{\mathcal{A}}(\mathcal{O}_1), \tilde{\mathcal{A}}(\mathcal{O}_2) \) \( \{0\} \) whenever \( \mathcal{O}_1 \) and \( \mathcal{O}_2 \) are space-like separated double cones in \( \mathcal{M}^d \).

(c) (cyclicity) \( \tilde{\mathcal{A}}(\mathcal{O}) \tilde{h}_0 \) is dense in \( \tilde{\mathcal{H}} \) for every double cone \( \mathcal{O} \) in \( \mathcal{M}^d \).

Proof. We first construct a “physical” Hilbert space from \( \mathcal{H} \) as follows (cf. [9, Section I.1]). Let \( R_\theta = \Pi_{\mathcal{P}^d} U(\theta) \Pi_{\mathcal{P}^d} \) and set \( \mathcal{H}_0 = R_\theta(\mathcal{H}) = R_\theta(\mathcal{A}(\mathcal{R}_+^{d})h_0) \).

We define a sesquilinear form on \( \mathcal{H}_0 \) via

\[
\langle R_\theta h_1, R_\theta h_2 \rangle = \langle h_1, U(\theta)h_2 \rangle_{\mathcal{H}}, \quad h_1, h_2 \in \mathcal{A}(\mathcal{R}_+^{d})h_0.
\]

By the reflection positivity assumption (Definition [1,2](3)(b)) the latter form is in fact an inner product and denote the completion of \( \mathcal{H}_0 \) with respect to it by \( \tilde{\mathcal{H}} \).

Now applying the main result of [9, Section I] to the family of \( E_d \)-covariant subspaces \( \{\mathcal{A}(V)h_0\} \), we obtain a strongly continuous unitary representation of \( \mathcal{P}^d \) on \( \tilde{\mathcal{H}} \) satisfying the spectrum condition for which we write \( \mathcal{P}^d \ni g \mapsto \tilde{U}(g) \). Moreover, since \( h_0 \) is \( E_d \)-invariant, \( \tilde{h}_0 := R_\theta h_0 \) is non-zero and \( \mathcal{P}^d \)-invariant by construction.

Further, we note that the mapping \( \Psi : L(\mathcal{A}(\mathcal{R}_+^{d})h_0) \to L(\tilde{\mathcal{H}}) \) defined via

\[
\Psi(A)(R_\theta h) = R_\theta Ah, \quad h \in \mathcal{A}(\mathcal{R}_+^{d})h_0, \quad A \in L(\mathcal{A}(\mathcal{R}_+^{d})h_0),
\]

is an algebra homomorphism, hence \( \Psi(\mathcal{A}(\mathcal{R}_+^{d})) \) is an algebra of operators on \( L(\tilde{\mathcal{H}}) \).

Following [11, Section 3.2], we now construct a net of algebras acting on \( \tilde{\mathcal{H}} \). Given a double cone \( \mathcal{O} \) in \( \mathcal{M}^d \), we define \( \tilde{\mathcal{A}}(\mathcal{O}) \) to be the Banach algebra generated by the identity operator and all operators of the form

\[
\tilde{U}(g)\Psi(A)\tilde{U}(g)^*,
\]

where \( A \in \mathcal{A}(\mathcal{R}_+^{d}) \) and \( g \in \mathcal{P}^d \) is such that \( g(V) \subset \mathcal{O} \) for some open \( V \) in \( \mathcal{M}^d \), where \( \mathcal{M}^d \) stands for the \( t = 0 \) hyperplane in \( \mathcal{M}^d \).

The net \( \mathcal{O} \mapsto \tilde{\mathcal{A}}(\mathcal{O}) \) satisfies the covariance property (3)(a) by construction. Making use of the fact that \( \Psi(\mathcal{A}(\mathcal{R}_+^{d})) \) is closed under multiplication and the commutativity of \( \mathcal{A}(\mathcal{R}_+^{d}) \), we can apply verbatim the argument proving Theorem 3.7 in [11] to conclude that the net \( \tilde{\mathcal{A}} \) satisfies the causality property (3)(b). Finally, since \( \Psi(A)\tilde{h}_0 = R_\theta Ah_0 \) for every \( A \in \mathcal{A}(\mathcal{R}_+^{d}) \), we conclude that \( \Psi(\mathcal{A}(\mathcal{R}_+^{d}))\tilde{h}_0 \) is dense in \( \tilde{\mathcal{H}} \) which easily implies that property (3)(c) holds. \( \square \)

Remark 4.4. In the proof above, we have chosen to construct \( \tilde{\mathcal{A}} \) as a net of Banach algebras rather than \( \mathcal{C}^* \)-algebras as demanded by the standard Haag-Kastler axioms, since it appears that in our approach the causality property (3)(b) may be established only in this slightly more restrictive context.
5. FROM RANDOM FIELDS TO ALGEBRAIC EUCLIDEAN QFT

We now fix a probability space of the form \((C(B_d), \mathcal{B}_{B_d}, \mu)\), where \(B_d\) is as in Section 3, \(C(B_d)\) is the space of all continuous real-valued functions on \(B_d\) equipped with the topology of uniform convergence on compact subsets of \(B_d\), \(\mathcal{B}_{B_d}\) is the Borel \(\sigma\)-algebra on \(C(B_d)\) and \(\mu\) is a probability measure on \(\mathcal{B}_{B_d}\). We write \(\mathcal{H}_\mu\) for \(L^2_\mathbb{C}(C(B_d), \mathcal{B}_{B_d}, \mu)\), the complexification of \(L^2(C(B_d), \mathcal{B}_{B_d}, \mu)\).

Let \(X\) be a random field indexed by \(B_d\). Given an open \(V \subseteq \mathbb{R}^d\), we set \(B_d(V) = \{(x, r) \in B_d : b(x, r) \subseteq V\}\).

We define \(\mathfrak{A}_X(V)\) to be the von Neumann algebra generated by the operators
\[
\{M_{X(b,r)} : (x, r) \in B_d(V)\},
\]
where \(M_{X(b,r)}\) stands for the operator on \(\mathcal{H}_\mu\) given by multiplication by the bounded measurable function \(e^{iX(b,r)}\). Thus we obtain a net of von Neumann algebras over \(\mathbb{R}^d\) which we denote by \(\mathfrak{A}_X\). Several labels corresponding to elements of \(\mathfrak{A}(\mathbb{R}^2_+)\) are shown on Fig. 1 below.

![Figure 1](image_url)

**Figure 1.**

Given a random field \(X\) indexed by a set \(T\) and a subset \(V\) of \(T\), we write \(S(X, V)\) for the \(\mathbb{R}\)-linear span of the random variables \(\{X_t\}_{t \in V}\).

**Definition 5.1.** We say that a random field \(X\) indexed by \(B_d\) is reflection positive if for each finite sequence \(F_1, \ldots, F_n\) in \(S(X, B_d(\mathbb{R}^d_+))\) the matrix
\[
S_{ij} = \int_{C(B_d)} e^{iF_i - i\theta \cdot F_j} d\mu
\]
is positive definite.

We now equip \(B_d\) with the natural continuous action of \(E_d\) given by
\[
g \cdot (x, r) = (g \cdot x, r), \quad g \in E_d,
\]
which induces a continuous action on $C(B_d)$. Below we write $1_{\mathcal{H}_\mu}$ for the constant function 1 in $\mathcal{H}_\mu$.

**Theorem 5.2.** Assume that the measure $\mu$ is $E_d$-invariant, the random field $X$ is reflection positive and $E_d$-equivariant as a map from $B_d$ to the space of random variables on $(C(B_d), \mathcal{B}_d, \mu)$ and $\mathfrak{A}_X(\mathbb{R}^d) 1_{\mathcal{H}_\mu} = \mathcal{H}_\mu$.

Then the triple $(\mathcal{H}_\mu, \mathfrak{A}_X, 1_{\mathcal{H}_\mu})$ is an algebraic Euclidean QFT over $\mathbb{R}^d$ in the sense of Definition 4.2.

**Proof.** Since $\mu$ is $E_d$-invariant and the action of $E_d$ on $C(B_d)$ is continuous, the induced representation on $\mathcal{H}_\mu$ is unitary and strongly continuous, hence property (1) in Definition 4.2 holds. Property (3)(a) follows from the equivariance of $X$ and the fact that for any $g \in E_d$ and any open $V \subseteq \mathbb{R}^d$, $b(x, r) \subseteq V$ implies that $g \cdot b(x, r) \subseteq g(V)$.

Further, observe that property (3) in Definition 4.1 follows directly from the construction of the net $\mathfrak{B}_X$, hence the reflection positivity of $X$ implies that property (3)(b) in Definition 4.2 is satisfied. □

6. **Example: Transformations of the mollified Euclidean free field**

It will be convenient for our purposes in this section to recast the notion of reflection positivity in terms of positive-definite kernels and probability measures. As a preparation, we discuss a finite-dimensional version of reflection positivity.

Let $\mu_n$ be a centered Gaussian probability measure on $\mathbb{R}^{2n}$ with covariance matrix $C_{ij}^{\mu}$. Let $\theta_n$ be an involutive permutation of the set $\{1, 2, \ldots, 2n\}$ which maps $\{1, 2, \ldots, n\}$ to $\{n+1, n+2, \ldots, 2n\}$ and vice versa.

**Lemma 6.1.** If the matrix $\{C_{i,\theta_n(j)}^{\mu}\}_{i,j=1}^n$ is positive definite, then so is the matrix

$$S_{ij}^{\mu} = \int_{\mathbb{R}^{2n}} e^{ix_i - ix_{\theta_n(j)}} d\mu_n(x_1,\ldots,x_{2n}),$$

where $i, j = 1, \ldots, n$ and $(x_1,\ldots,x_{2n}) \in \mathbb{R}^{2n}$.

**Proof.** We observe that $S_{ij}^{\mu} = S_{\mu_n}(e_i - e_{\theta_n(j)})$, where $S_{\mu_n}$ is the characteristic function of $\mu_n$ and $e_1, \ldots, e_{2n}$ is the standard orthonormal basis of $\mathbb{R}^{2n}$. Thus the statement of the lemma is the finite-dimensional analogue of [5, Theorem 6.2.2]. □

Let $(C(B_d), \mathcal{B}_d, \mu)$ be as in Section 5 let $V$ be an open subset of $B_d$ and write $\mathcal{M}(V)$ for the vector space of all complex-valued bounded measurable functions on $C(B_d)$ which have the following property. For each $\Psi$ in $\mathcal{M}(V)$ there exists a bounded measurable function $\Psi'$ on $C(V)$ such that $\Psi = \Psi' \circ R_V$, where $R_V : C(B_d) \to C(V)$ is the restriction map. We introduce the short-hand notation $B_d^+ = B_d(\mathbb{R}_+^d)$
**Definition 6.2.** A probability measure $\mu$ on $(C(B_d), B_{B_d})$ is called **reflection positive** if

$$\int_{C(B_d)} \Psi(\theta \cdot \Psi) d\mu \geq 0 \quad (6.1)$$

for all $\Psi \in M(B_d^+)$.  

Now let $A$ be a strictly positive selfadjoint bounded operator on $L^2(\mathbb{R}^d)$. Let $\mu_A$ and $\tilde{\mu}_A$ be the Gaussian measures, and $X^A$ and $\tilde{X}^A$, the corresponding random fields associated to $A$ that were constructed in Section 3.

**Lemma 6.3.** (1) Assume that $A$ is $E_d$-invariant, i.e., $A$ commutes with the natural unitary representation of $E_d$ on $L^2(\mathbb{R}^d)$. Then the measure $\tilde{\mu}_A$ is $E_d$-invariant.

(2) Assume that $A$ is reflection positive, i.e., one has

$$\langle Af, \theta f \rangle_{L^2} \geq 0$$

for all $f \in C^\infty_c(\mathbb{R}^d_+)$. Then the measure $\tilde{\mu}_A$ is reflection positive.

**Proof.** (1) The $E_d$-invariance of $A$ implies

$$A(g \cdot x, r, g \cdot y, s) = A(x, r, y, s)$$

for all $g \in E_d, x, y \in \mathbb{R}^d, r, s \in (0, \infty)$. Thus by Theorem 2.1(2) the measure $\mu_A$ is $E_d$-invariant and therefore so is $\tilde{\mu}_A$.

(2) Given $(x_1, r_1), \ldots, (x_n, r_n) \in B_d^+$, the reflection positivity of $A$ implies that the matrix

$$A^\theta_{ij} := A(x_i, r_i, \theta \cdot x_j, r_j)$$

is positive definite.

![Figure 2](image_url)

We compute the integral

$$A^\mu_{ij} := \int_{C(B_d)} e^{iX^A_{(x_i, r_i)}} e^{-iX^A_{(\theta \cdot x_j, r_j)}} d\mu_A$$
via a change of variables with respect to the map from $\mathbb{R}^d$ to $\mathbb{R}^{2n}$ given by $(X^A_{(x_1,r_1)}, \ldots, X^A_{(x_n,r_n)}), (X^B_{(\theta x_1,r_1)}, \ldots, X^B_{(\theta x_n,r_n)})$, and utilize the construction of $\mu_A$ from Theorem $\text{[2.1]}$ as well as Lemma $\text{[6.1]}$ to conclude that the matrix $A^\mu_{ij}$ is positive definite. Since by construction the same holds if we replace $\mu_A$ with $\tilde{\mu}_A$ and $X^A$ with $\tilde{X}^A$, we conclude that $\tilde{\mu}_A$ satisfies (6.1) for all $\Psi$ of form $z_1 e^{i \tilde{X}^A_{(z_1,r_1)}} + \ldots + z_n e^{i \tilde{X}^A_{(z_n,r_n)}}$, where $z_1, \ldots, z_n$ are arbitrary complex numbers.

Now let us consider the probability space $(C(B^+_d), \mathcal{B}^+_d, \tilde{\mu}_A)$, where $\mathcal{B}^+_d$ is the Borel $\sigma$-algebra on $C(B^+_d)$ and $\tilde{\mu}_A$ is the image of $\mu_A$ under the restriction map $R_{B^+_d} : C(B_d) \to C(B^+_d)$. Let $\tilde{X}^{A,+}$ be the restriction of $\tilde{X}^A$ to $C(B^+_d)$. By $\text{[3]}$ Corollary $7.12.2$ the $\mathbb{C}$-linear span of $\{e^{iF} : F \in \mathcal{S}(\tilde{X}^{A,+}, B^+_d)\}$ is dense in $L^2(C(B^+_d), \mathcal{B}^+_d, \tilde{\mu}_A)$. It follows that any $\Psi \in \mathcal{M}(B^+_d)$ can be approximated in $L^2$ by a sequence of functions in the $\mathbb{C}$-linear span of $\{e^{iF} : F \in \mathcal{S}(\tilde{X}^A, B_d)\}$ and we conclude that $\tilde{\mu}_A$ satisfies (6.1) for all $\Psi$ in $\mathcal{M}(B^+_d)$.

We now take, as in Example $\text{[3.4]}$ $A$ to be the operator $(I - \Delta)^{-1}$, fix a continuous one-to-one function $\phi : \mathbb{R} \to \mathbb{R}$ and let $X^\phi$ be the transformation of the mollified free field $\tilde{X}^{(I - \Delta)^{-1}}$ via $\phi$, i.e., we set $X^\phi = \tilde{X}^{(I - \Delta)^{-1}} \circ \phi$. Setting $\mathcal{H}_s = L^2(C(B_d), \mathcal{B}_{B_d}, \tilde{\mu}_{(I - \Delta)^{-1}})$ and applying the construction from Section $\text{[5]}$ to the random field $X^\phi$, we obtain a triple $(\mathcal{H}_s, \mathfrak{A}_{X^\phi}, 1_{\mathcal{H}_s})$.

**Theorem 6.4.** The triple $(\mathcal{H}_s, \mathfrak{A}_{X^\phi}, 1_{\mathcal{H}_s})$ is an algebraic Euclidean QFT over $\mathbb{R}^d$.

**Proof.** Since the operator $(I - \Delta)^{-1}$ is $E_d$-invariant, by Lemma $\text{[6.3]}(1)$ so is the measure $\tilde{\mu}_{(I - \Delta)^{-1}}$, and the random field $X^\phi$ is $E_d$-equivariant. By $\text{[3]}$ Corollary $7.12.2$ one has $\mathfrak{A}_{X^\phi} 1_{\mathcal{H}_s} = \mathcal{H}_s$. Thus, by Theorem $\text{[5.2]}$ it remains to check that $X^\phi$ is reflection positive (cf. Definition $\text{[5.1]}$). To this end, we note that $(I - \Delta)^{-1}$ is known to be reflection positive (see e.g. $\text{[5]}$ Theorem $7.10.1$), hence by Lemma $\text{[6.3]}(2)$ the measure $\tilde{\mu}_{(I - \Delta)^{-1}}$ is reflection positive in the sense of Definition $\text{[6.2]}$ which in turn implies that $X^\phi$ is reflection positive as well.

**Remark 6.5.** Alternatively, one can consider $\tilde{\mu}^\phi_{(I - \Delta)^{-1}}$, the image of $\tilde{\mu}_{(I - \Delta)^{-1}}$ under the map given by

$$C(B_d) \ni f \mapsto \phi \circ f \in C(B_d),$$

and the canonical random field on $(C(B_d), \mathcal{B}_{B_d}, \tilde{\mu}^\phi_{(I - \Delta)^{-1}})$ given by evaluations to obtain an algebraic Euclidean QFT equivalent to $(\mathcal{H}_s, \mathfrak{A}_{X^\phi}, 1_{\mathcal{H}_s})$. Thus one can regard the triple $(\mathcal{H}_s, \mathfrak{A}_{X^\phi}, 1_{\mathcal{H}_s})$ as being induced by the measure $\tilde{\mu}^\phi_{(I - \Delta)^{-1}}$ which is in general non-Gaussian.
