# A GLOBAL SPACE-TIME ESTIMATE FOR DISPERSIVE OPERATORS THROUGH ITS LOCAL ESTIMATE 

CHU-HEE CHO, YOUNGWOO KOH, AND JUNGJIN LEE

#### Abstract

We will show that a local space-time estimate implies a global space-time estimate for dispersive operators. In order for this implication we consider a Littlewood-Paley type square function estimate for dispersive operators in a time variable and a generalization of Tao's epsilon removal lemma in mixed norms. By applying this implication to the fractional Schrödinger equation in $\mathbb{R}^{2+1}$ we obtain the sharp global space-time estimates with optimal regularity from the previous known local ones.

## 1. Intoduction

Let us consider a Cauchy problem of a dispersive equation in $\mathbb{R}^{n+1}$

$$
\left\{\begin{align*}
i \partial_{t} u+\Phi(D) u & =0  \tag{1.1}\\
u(0) & =f
\end{align*}\right.
$$

where $\Phi(D)$ is the corresponding Fourier multiplier to the function $\Phi$. We assume that $\Phi \in$ $C^{\infty}\left(\mathbb{R}^{n} \backslash\{0\}\right)$ is a real-valued function satisfying the following conditions:

## Condition 1.1.

- $|\nabla \Phi(\xi)| \neq 0$ for all $\xi \neq 0$.
- There is a constant $\mu \geq 1$ such that $\mu^{-1} \leq|\Phi(\xi)| \leq \mu$ for any $\xi$ with $|\xi|=1$.
- There is a constant $m \geq 1$ such that $\Phi(\lambda \xi)=\lambda^{m} \Phi(\xi)$ for all $\lambda>0$ and all $\xi \neq 0$.
- The Hessian $H_{\Phi}(\xi)$ of $\Phi$ has rank at least 1 for all $\xi \neq 0$.

The solution $u$ to (1.1) becomes the Schrödinger operator $e^{-i t \Delta} f$ if $\Phi(\xi)=|\xi|^{2}$ and the wave operator $e^{i t \sqrt{-\Delta}} f$ if $\Phi(\xi)=|\xi|$. When $\Phi(\xi)=|\xi|^{m}$ for $m>1$, the solution is called the fractional Schrödinger operator $e^{i t(\sqrt{-\Delta})^{m / 2}} f$.

Let $e^{i t \Phi(D)} f$ denote the solution to (1.1). Our interest is to find suitable pairs $(q, r)$ which satisfy the global space-time estimate

$$
\begin{equation*}
\left\|e^{i t \Phi(D)} f\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)} \leq C\|f\|_{\dot{H}^{s}\left(\mathbb{R}^{n}\right)} \tag{1.2}
\end{equation*}
$$

where $\dot{H}^{s}\left(\mathbb{R}^{n}\right)$ denotes the homogeneous $L^{2}$ Sobolev space of order $s$. By scaling invariance the regularity $s=s(r, q)$ should be defined as

$$
\begin{equation*}
s=n\left(\frac{1}{2}-\frac{1}{q}\right)-\frac{m}{r} . \tag{1.3}
\end{equation*}
$$

This problem for $\mu=1$ has been studied by many researchers. For the Schrödinger operator, Planchon [14] conjectured that the estimate (1.2) is valid if and only if $r \geq 2$ and $\frac{n+1}{q}+\frac{1}{r} \leq \frac{n}{2}$. Kenig-Ponce-Vega [10] showed the conjecture is true for $n=1$. In higher dimensions $n \geq 2$

[^0]it was proven by Vega [21] that (1.2) holds for $q \geq \frac{2(n+2)}{n}$ and $\frac{n+1}{q}+\frac{1}{r} \leq \frac{n}{2}$. When $n=2$ Rogers [15] showed it for $2 \leq r<\infty, q>\frac{16}{5}$ and $\frac{3}{q}+\frac{1}{r}<1$, and later the excluded endline $\frac{3}{q}+\frac{1}{r}=1$ was obtained by Lee-Rogers-Vargas [11]. When $n \geq 3$, Lee-Rogers-Vargas [11] improved the previous known result to $r \geq 2, q>\frac{2(n+3)}{n+1}$ and $\frac{n+1}{q}+\frac{1}{r}=\frac{n}{2}$. Recently it is shown by Du-Kim-Wang-Zhang [6] that the estimate (1.2) with $r=\infty$, that is, the maximal estimate fails for $n \geq 3$. For a case of the wave operator it is known that (1.2) holds for $(r, q)$ pairs such $2 \leq r \leq q, q \neq \infty$ and $\frac{1}{r}+\frac{n-1}{2 q} \leq \frac{n-1}{4}$ (see [8, 9, 13, 18]). Particularly, when $r=\infty$, Rogers-Villarroya [16] showed that (1.2) with regularity $s>n\left(\frac{1}{2}-\frac{1}{q}\right)-\frac{1}{r}$ is valid for $q \geq \frac{2(n+1)}{n-1}$. For the fractional Schrödinger operator the known range of $(r, q)$ for which the estimates hold is that $2 \leq r \leq q, q \neq \infty$ and $\frac{n}{2 q}+\frac{1}{r} \leq \frac{n}{4}$ (see [1, 2, 4, 12, 20]).

The case of $\mu>1$ has an interesting in its own right. The solution $u$ is formally written as

$$
u(t, x)=e^{i t \Phi(D)} f(x):=\frac{1}{(2 \pi)^{n}} \int_{\mathbb{R}^{n}} e^{i(x \cdot \xi+t \Phi(\xi))} \hat{f}(\xi) d \xi
$$

From this form we see that the space-time Fourier transform of $u$ is supported in the surface $S=\{(\xi, \Phi(\xi))\}$. It is known that the operator $u$ is related to the curvature of $S$ such as the sign of Gaussian curvature and the number of nonvanishing principle curvature. The Schrödinger operator corresponds to a paraboloid which has a positive Gaussian curvature, and the wave operator corresponds to a cone whose Gaussian curvature is zero. We are also interested in operators corresponding to a surface with negative Gaussian curvature. When $\mu>1$ there is a surface with negative Gaussian curvature. For instance, the surface $\left\{\left(\xi_{1}, \xi_{2}, \xi_{1}^{4}+2 \xi_{1}^{3} \xi_{2}-2 \xi_{1} \xi_{2}^{3}+\right.\right.$ $\left.\left.\xi_{2}^{4}\right)\right\}$ has negative Gaussian curvature on a neighborhood of the point $(1,0,1)$.

In this paper we will establish a local-to-global approach as follows.
Theorem 1.2. Let $\mathbb{I}=(0,1)$ be a unit interval and $\mathbb{B}=B(0,1)$ a unit ball in $\mathbb{R}^{n}$. Let $q_{0}, r_{0} \in$ $[2, \infty), s(r, q)$ defined as (1.3) and $\Phi$ satisfy Condition 1.1. Suppose that the local estimate

$$
\begin{equation*}
\left\|e^{i t \Phi(D)} f\right\|_{L_{x}^{q_{0}\left(\mathbb{B} ; L_{t}^{r_{0}}(\mathbb{I})\right)}} \leq C_{\epsilon}\|f\|_{H^{s\left(r_{0}, q_{0}\right)+\epsilon\left(\mathbb{R}^{n}\right)}} \tag{1.4}
\end{equation*}
$$

holds for all $\epsilon>0$. Then for any $q>q_{0}$ and $r>r_{0}$, the global estimate

$$
\begin{equation*}
\left\|e^{i t \Phi(D)} f\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)} \leq C\|f\|_{\dot{H}^{s(r, q)}\left(\mathbb{R}^{n}\right)} \tag{1.5}
\end{equation*}
$$

holds, where $H^{s}\left(\mathbb{R}^{n}\right)$ denotes the inhomogeneous $L^{2}$-Sobolev space of order s and $\dot{H}^{s}\left(\mathbb{R}^{n}\right)$ denotes homogeneous one.

The maximal estimate, which is (1.4) with $r_{0}=\infty$, is related to pointwise convergence problems. When $n=2$ it was proven that the maximal estimates with $m>1$ and $\mu=1$ are valid for $q_{0}=3$ and $s>\frac{1}{3}$ (see [3, 5]). By interpolating with a Strichartz estimate

$$
\left\|e^{i t \Phi(D)} f\right\|_{L_{x}^{6}\left(\mathbb{R}^{2} ; L_{t}^{2}(\mathbb{R})\right)} \leq\left\|e^{i t \Phi(D)} f\right\|_{L_{t}^{2}\left(\mathbb{R} ; L_{x}^{6}\left(\mathbb{R}^{2}\right)\right)} \leq C\|f\|_{\dot{H}^{(2-m) / 4}\left(\mathbb{R}^{2}\right)}
$$

we have (1.5) for the line $\frac{3}{q}+\frac{1}{r}=1$ with $r \geq 2$. By Theorem 1.2, we can obtain the following global space-time estimates which is the Planchon conjecture for $n=2$ except the endline.

Corollary 1.3. Let $m>1$ and $\mu=1$. For $2 \leq r<\infty$ and $\frac{3}{q}+\frac{1}{r}<1$, the global estimate

$$
\left\|e^{i t \Phi(D)} f\right\|_{L_{x}^{q}\left(\mathbb{R}^{2} ; L_{t}^{r}(\mathbb{R})\right)} \leq C\|f\|_{\dot{H}^{1-\frac{2}{q}-\frac{m}{r}}\left(\mathbb{R}^{2}\right)}
$$

Notation. Throughout this paper let $C>0$ denote various constants that vary from line to line, which possibly depend on $n, q, r, m$ and $\mu$. We use $A \lesssim B$ to denote $A \leq C B$, and if $A \lesssim B$ and $B \lesssim A$ we denote by $A \sim B$.

## 2. Proof of Theorem 1.2

In this section we prove Theorem 1.2 by using two propositions. In subsection 2.1 we consider a Littlewood-Paley type inequality by which the initial data $f$ can be assumed to be Fourier supported in $\{1 / 2 \leq|\xi| \leq 2\}$. In subsection 2.2 we prove a mixed norm version of Tao's $\varepsilon$ removable lemma by which the global estimates with a compact Fourier support are reduced to a local ones. In subsection 2.3 we show the two propositions imply Theorem 1.2,
2.1. A Littlewood-Paley type inequality. We discuss a Littlewood-Paley type inequality for the operator $e^{i t \Phi(D)}$ in a time variable.

Let a cut-off function $\phi \in C_{0}^{\infty}\left(\left[\frac{1}{2}, 2\right]\right)$ satisfy $\sum_{k \in \mathbb{Z}} \phi\left(2^{-k} x\right)=1$. We define Littlewood-Paley projection operators $P_{k}$ and $\widetilde{P_{k}}$ by

$$
\widehat{P_{k} f}(\xi)=\phi\left(2^{-k}|\xi|\right) \hat{f}(\xi) \quad \text { and } \quad \widehat{P_{k}} f(\tau)=\phi\left(2^{-m k}|\tau|\right) \hat{f}(\tau)
$$

for $\xi \in \mathbb{R}^{n}$ and $\tau \in \mathbb{R}$, respectively.
Lemma 2.1. Suppose that $\Phi$ satisfies Condition 1.1. Then for $1<r<\infty$,

$$
\left\|e^{i t \Phi(D)} f(x)\right\|_{L_{t}^{r}(\mathbb{R})} \leq C_{m, \mu}\left\|\left(\sum_{\substack{j, k \in \mathbb{Z}: \\|k-j| \leq \frac{\operatorname{loz} 2}{} \\ m}+2}\left|\widetilde{P_{j}} e^{i t \Phi(D)} P_{k} f(x)\right|^{2}\right)^{1 / 2}\right\|_{L_{t}^{r}(\mathbb{R})}
$$

for all functions $f$ and all $x \in \mathbb{R}^{n}$.
Proof. For simplicity,

$$
F(t):=e^{i t \Phi(D)} f(x) \quad \text { and } \quad F_{k}(t):=e^{i t \Phi(D)} P_{k} f(x) .
$$

Since the projection operators are linear, we have an identity

$$
F(t)=\sum_{j \in \mathbb{Z}} \widetilde{P}_{j} F(t)=\sum_{j \in \mathbb{Z}} \sum_{k \in \mathbb{Z}} \widetilde{P}_{j} F_{k}(t) .
$$

For any test function $\psi \in C_{0}^{\infty}([-2,2])$ with $\psi=1$ in $[-1,1]$, the Fourier transform $\widehat{f}$ of $f$ is defined by

$$
\widehat{f}(\tau)=\lim _{R \rightarrow \infty} \frac{1}{2 \pi} \int_{\mathbb{R}} e^{i t \tau} \psi\left(\frac{t}{R}\right) f(t) d t
$$

in the distributional sense.
We claim that $\widehat{P}_{j} F_{k}(t)=0$ if

$$
\begin{equation*}
|k-j|>\frac{\log _{2} \mu}{m}+2 . \tag{2.1}
\end{equation*}
$$

Indeed, using the above definition of the Fourier transform we can write

$$
\widehat{\widehat{P_{j} F_{k}}(\tau)=\frac{1}{(2 \pi)^{n+1}} \phi\left(\frac{|\tau|}{2^{m j}}\right) \lim _{R \rightarrow \infty} \int_{\mathbb{R}^{n}} e^{i x \cdot \xi}\left(\int_{\mathbb{R}} e^{i t \tau} e^{i t \Phi(\xi)} \psi\left(\frac{t}{R}\right) d t\right) \phi\left(\frac{|\xi|}{2^{k}}\right) \hat{f}(\xi) d \xi . . ~ . ~ . ~}
$$

In the right side of the above equation, we see that the range of $(\tau, \xi)$ is contained in

$$
2^{m(j-1)} \leq|\tau| \leq 2^{m(j+1)} \quad \text { and } \quad 2^{(k-1)} \leq|\xi| \leq 2^{(k+1)}
$$

From Condition 1.1 we have a bound

$$
\mu^{-1} 2^{m(k-1)} \leq|\Phi(\xi)| \leq \mu 2^{m(k+1)} .
$$

Then it follows that for $k$ and $j$ satisfying (2.1),

$$
|\tau+\Phi(\xi)|>0
$$

By the integration by parts it implies that there exists a constant $C_{0}>0$ such that

$$
\left|\int_{\mathbb{R}} e^{i t \tau} e^{i t \Phi(\xi)} \psi\left(\frac{t}{R}\right) d t\right| \leq \frac{1}{C_{0} R}
$$

From this estimate and the Lebesgue dominated convergence theorem we obtain $\widehat{\widehat{P_{j} F_{k}}}=0$, which implies the claim.

By the claim, the Littlewood-Paley theory and the Cauchy-Schwarz inequality,

$$
\begin{aligned}
\left\|e^{i t \Phi(D)} f(x)\right\|_{L_{t}^{r}(\mathbb{R})} & =\left\|\sum_{j \in \mathbb{Z}} \widetilde{P}_{j}\left(\sum_{k \in \mathbb{Z}} F_{k}(\cdot, x)\right)\right\|_{L_{t}^{r}(\mathbb{R})} \\
& \leq C\left\|\left(\left.\left.\sum_{j \in \mathbb{Z}}\right|_{k \in \mathbb{Z}:|k-j| \leq \frac{\log _{2} \mu}{m}+2} \widetilde{P}_{j} F_{k}(\cdot, x)\right|^{2}\right)^{1 / 2}\right\|_{L_{t}^{r}(\mathbb{R})} \\
& \leq C_{m, \mu}\left\|\left(\sum_{j \in \mathbb{Z}} \sum_{k \in \mathbb{Z}:|k-j| \leq \frac{\log _{2} \mu}{m}+2}\left|\widetilde{P}_{j} F_{k}(\cdot, x)\right|^{2}\right)^{1 / 2}\right\|_{L_{t}^{r}(\mathbb{R})}
\end{aligned}
$$

This is the desired inequality.
Using the above lemma we can have the following proposition.
Proposition 2.2. Let $2 \leq q, r<\infty$. Suppose that $\Phi$ satisfies Condition 1.1. If the estimate

$$
\begin{equation*}
\left\|e^{i \Phi \Phi(D)} f\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{L}(\mathbb{R})\right)} \leq C\|f\|_{L^{2}\left(\mathbb{R}^{n}\right)} \tag{2.2}
\end{equation*}
$$

holds for all $f$ with $\operatorname{supp} \hat{f} \subset\{1 / 2 \leq|\xi| \leq 2\}$, then the estimate

$$
\left\|e^{i t \Phi(D)} f\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)} \leq C_{m, \mu}\|f\|_{\dot{H}^{\frac{n}{2}-\frac{n}{q}-\frac{m}{r}}\left(\mathbb{R}^{n}\right)}
$$

holds for all $f$.
Proof. The Minkowski inequality and Lemma 2.1 allow that

$$
\left\|e^{i t \Phi(D)} f\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)} \leq C_{m, \mu}\left\|\left(\sum_{|k-j| \leq \frac{\log _{2} \mu}{m}+2}\left\|\widetilde{P}_{j}\left(e^{i t \Phi(D)} P_{k} f\right)\right\|_{L_{t}^{r}(\mathbb{R})}^{2}\right)^{1 / 2}\right\|_{L_{x}^{q}\left(\mathbb{R}^{n}\right)}
$$

Since $\widetilde{P_{j}}$ is bounded in $L^{p}$, it is bounded by

$$
C_{m, \mu}\left\|\left(\sum_{k \in \mathbb{Z}}\left\|e^{i t \Phi(D)} P_{k} f\right\|_{L_{t}^{r}(\mathbb{R})}^{2}\right)^{1 / 2}\right\|_{L_{x}^{q}\left(\mathbb{R}^{n}\right)}
$$

By the Minkowski inequality we thus have

$$
\left\|e^{i t \Phi(D)} f\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)} \leq C_{m, \mu}\left(\sum_{k \in \mathbb{Z}}\left\|e^{i t \Phi(D)} P_{k} f\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)}^{2}\right)^{1 / 2}
$$

Apply (2.2) to the right side of the above estimate after parabolic rescaling. Then we obtain

$$
\begin{aligned}
\left\|e^{i t \Phi(D)} f\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)} & \leq C_{m, \mu}\left(\sum_{k \in \mathbb{Z}} 2^{2 k\left(\frac{n}{2}-\frac{n}{q}-\frac{m}{r}\right)}\left\|P_{k} f\right\|_{2}^{2}\right)^{1 / 2} \\
& =C_{m, \mu}\|f\|_{\dot{H}^{\frac{n}{2}-\frac{n}{q}-\frac{m}{r}}\left(\mathbb{R}^{n}\right)}
\end{aligned}
$$

2.2. Local-to-global arguments. We will show that the global estimate (2.2) is obtained from its local estimate. Adopting the arguments in [19], we consider the dual estimate of (2.2).

Let $S=\left\{(\xi, \Phi(\xi)) \in \mathbb{R}^{n} \times \mathbb{R}: 1 / 2 \leq|x| \leq 2\right\}$ be a compact hypersurface with the induced (singular) Lebesgue measure $d \sigma$. We define the Fourier restriction operator $\mathfrak{R}$ for a compact surface $S$ by the restriction of $\hat{f}$ to $S$, i.e.,

$$
\mathfrak{R} f=\left.\hat{f}\right|_{S}
$$

Its adjoint operator $\mathfrak{R}^{*} f=\widehat{f d \sigma}$ can be viewed as $e^{i t \Phi(D)} \hat{g}$, where the Fourier transform $\hat{g}(\xi)$ of $g$ corresponds to $f(\xi, \Phi(\xi))$.

Let $\rho>0$ be the decay of $\widehat{d \sigma}$, i.e.,

$$
\begin{equation*}
|\widehat{d \sigma}(x)| \lesssim(1+|x|)^{-\rho}, \quad x \in \mathbb{R}^{n+1} \tag{2.3}
\end{equation*}
$$

It is known that $\rho$ is determined by the number of nonzero principal curvatures of the surface $S$, which is equal to the rank of the Hessian $H_{\Phi}$. Specifically, if $H_{\Phi}$ has rank at least $k$ then

$$
\rho=k / 2
$$

see [17, subsection 5.8, VIII]. From Condition 1.1 we have $k \geq 1$.
When a function $f$ has a compact Fourier support, the $\widehat{f d \sigma}$ decays away from the support of $\hat{f}$ because of the decay of $\widehat{d \sigma}$. Thus if $f$ and $g$ are compactly Fourier supported and their supports are far away from each other then the interaction between $\widehat{f d \sigma}$ and $\widehat{g d \sigma}$ is negligible.

Definition 2.3. A finite collection $\left\{Q\left(z_{i}, R\right)\right\}_{i=1}^{N}$ of balls in $\mathbb{R}^{n+1}$ with radius $R>0$ is called $(N, R)$-sparse if the centers $\left\{z_{i}\right\}$ are $(N R)^{\gamma}$-separated where $\gamma:=n / \rho(\geq 2)$.

From the definition of $(N, R)$-sparse we have a kind of orthogonality as follows. Let $\phi$ be a radial Schwartz function which is positive on the ball $B(0,3 / 2)$ and $\phi=1$ on the unit ball $B(0,1)$ and whose Fourier transform is supported on the ball $B(0,2 / 3)$.
Lemma 2.4 ([19, in the proof of Lemma 3.2]). Let $\left\{Q\left(z_{i}, R\right)\right\}_{i=1}^{N}$ be a $(N, R)$-sparse collection and $\phi_{i}(z)=\phi\left(R^{-1}\left(z-z_{i}\right)\right)$ for $i=1, \cdots, N$. Then there is a constnat $C$ independent of $N$ such that

$$
\begin{equation*}
\left\|\left.\sum_{i=1}^{N} f_{i} * \hat{\phi}_{i}\right|_{S}\right\|_{2} \leq C R^{1 / 2}\left(\sum_{i=1}^{N}\left\|f_{i}\right\|_{2}^{2}\right)^{1 / 2} \tag{2.4}
\end{equation*}
$$

for all $f_{i} \in L^{2}\left(\mathbb{R}^{n+1}\right)$.
A proof of the above lemma is given in Appendix.
Let $\mathbb{I}_{R}=(0, R)$ denote an $R$-interval and $\mathbb{B}_{R}$ the ball of radius $R$ centered at the origin in $\mathbb{R}^{n}$. Using Lemma 2.4 we have an intermediate result.
Proposition 2.5. Let $R>0$ and $1<q, r \leq 2$. Suppose that there is a constant $A(R)$ such that

$$
\begin{equation*}
\left\|\mathfrak{R}\left(\chi_{\mathbb{I}_{R} \times \mathbb{B}_{R}} f\right)\right\|_{L^{2}(d \sigma)} \leq A(R)\|f\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)} \tag{2.5}
\end{equation*}
$$

for all $f \in L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)$. Then for any $(N, R)$-sparse collection $\left\{Q\left(z_{i}, R\right)\right\}_{i=1}^{N}$ there is a constant $C$ independent of $N$ such that

$$
\begin{equation*}
\|\Re f\|_{L^{2}(d \sigma)} \leq C A(R)\|f\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)} \tag{2.6}
\end{equation*}
$$

for all $f$ supported in $\cup_{i=1}^{N} Q\left(z_{i}, R\right)$.
Proof. Let $f_{i}=f \chi_{Q\left(z_{i}, R\right)}$. Then,

$$
\mathfrak{R} f_{i}=\left.\hat{f}_{i}\right|_{S}=\left.\widehat{f_{i} \phi_{i}}\right|_{S}=\left.\left(\hat{f}_{i} * \hat{\phi}_{i}\right)\right|_{S}
$$

where $\phi_{i}(z)$ is defined as in Lemma [2.4. Since $\hat{\phi}_{i}$ is supported on the ball $B\left(0, \frac{2}{3 R}\right)$, we may restrict the support of $\hat{f}_{i}$ to a $O(1 / R)$-neighborhood of the surface $S$ and write

$$
\mathfrak{\Re} f_{i}=\left.\left(\left.\hat{f}_{i}\right|_{\mathcal{N}_{1 / R}(S)} * \hat{\phi}_{i}\right)\right|_{S}
$$

where $\mathcal{N}_{1 / R}(S)$ is a $O(1 / R)$-neighborhood of the surface $S$. Let $\tilde{\mathfrak{R}}$ be another restriction operator defined by $\tilde{\mathfrak{R}} f=\left.\hat{f}\right|_{\mathcal{N}_{1 / R}(S)}$. If $f$ is suppported in $\cup_{i=1}^{N} Q\left(z_{i}, R\right)$, we write

$$
\mathfrak{R} f=\left.\sum_{i=1}^{N}\left(\tilde{\mathfrak{R}} f_{i} * \hat{\phi}_{i}\right)\right|_{S}
$$

By Lemma 2.4,

$$
\|\Re f\|_{L^{2}(d \sigma)} \leq C R^{1 / 2}\left(\sum_{i=1}^{N}\left\|\tilde{\mathfrak{R}} f_{i}\right\|_{L^{2}\left(\mathcal{N}_{1 / R}(S)\right)}^{2}\right)^{1 / 2}
$$

Since the estimate (2.5) is translation invariant, by a slice argument we have

$$
\left\|\tilde{\mathfrak{R}} f_{i}\right\|_{L^{2}\left(\mathcal{N}_{1 / R}(S)\right)} \leq C R^{-1 / 2} A(R)\left\|f_{i}\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)}
$$

By combining the previous two estimates,

$$
\|\mathfrak{R} f\|_{L^{2}(d \sigma)} \leq C A(R)\left(\sum_{i=1}^{N}\left\|f_{i}\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)}^{2}\right)^{1 / 2}
$$

If $1 \leq r \leq q \leq 2$ then by $\ell^{r} \subset \ell^{q} \subset \ell^{2}$,

$$
\begin{aligned}
\left(\sum_{i=1}^{N}\left\|f_{i}\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)}^{2}\right)^{1 / 2} & \leq\left(\sum_{i=1}^{N}\left\|f_{i}\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)}^{q}\right)^{1 / q} \\
& =\left(\int_{\mathbb{R}^{n}} \sum_{i=1}^{N}\left\|f_{i}\right\|_{L_{t}^{r}(\mathbb{R})}^{q} d x\right)^{1 / q} \\
& \leq\left(\int_{\mathbb{R}^{n}}\left(\sum_{i=1}^{N}\left\|f_{i}\right\|_{L_{t}^{r}(\mathbb{R})}^{r}\right)^{q / r} d x\right)^{1 / q} \\
& =\|f\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)}
\end{aligned}
$$

If $1 \leq q \leq r \leq 2$ one can use the embedding $\ell^{r} \subset \ell^{2}$ and the Minkowski inequality to get

$$
\begin{aligned}
\left(\sum_{i=1}^{N}\left\|f_{i}\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)}^{2}\right)^{1 / 2} & \leq\left(\sum_{i=1}^{N}\left\|f_{i}\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)}^{r}\right)^{1 / r} \\
& \leq\left(\int_{\mathbb{R}^{n}}\left(\sum_{i=1}^{N}\left\|f_{i}\right\|_{L_{t}^{r}(\mathbb{R})}^{r}\right)^{q / r} d x\right)^{1 / q} \\
& =\|f\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)}
\end{aligned}
$$

Therefore we have (2.6).
We now extend the $(N, R)$-sparse sets to the whole space. For this we need the following decomposition lemma.

Lemma 2.6 ( 19$]$ ). Let $E$ be a subset in $\mathbb{R}^{n}$ with $|E|>1$. Suppose that $E$ is a finite union of finitely overlapping cubes of side-length $c \sim 1$. Then for each $K \in \mathbb{N}$, there are subsets $E_{1}, E_{2}, \cdots, E_{K}$ of $E$ with

$$
E=\bigcup_{k=1}^{K} E_{k}
$$

such that each $E_{k}$ has $O\left(|E|^{1 / K}\right)$ number of $\left(O(|E|),|E|^{O\left(\gamma^{k-1}\right)}\right)$-sparse collections

$$
\mathbf{S}_{1}, \mathbf{S}_{2}, \cdots, \mathbf{S}_{O\left(|E|^{1 / K}\right)}
$$

of which the union $\mathbf{S}_{1} \cup \mathbf{S}_{2} \cup \cdots \cup \mathbf{S}_{O\left(|E|^{1 / K)}\right.}$ is a covering of $E_{k}$.
This lemma is a precise version of Lemma 3.3 in [19. A detailed proof can be found in Appendix.

Using the above lemma we have the following proposition.
Proposition 2.7. Let $1<q_{0}, r_{0}<\infty$. Suppose that for any $\epsilon>0$ and any $(N, R)$-sparse collection $\left\{Q\left(z_{i}, R\right)\right\}_{i=1}^{N}$ in $\mathbb{R}^{n+1}$, the estimate

$$
\begin{equation*}
\|\mathfrak{R} f\|_{L^{2}(d \sigma)} \leq C_{\epsilon} R^{\epsilon}\|f\|_{L_{x}^{q_{0}}\left(\mathbb{R}^{n} ; L_{t}^{r_{0}}(\mathbb{R})\right)} \tag{2.7}
\end{equation*}
$$

holds for all $f$ supported in $\cup_{i=1}^{N} Q\left(z_{i}, R\right)$. Then for any $1 \leq q<q_{0}$ and $1 \leq r<r_{0}$, the estimate

$$
\|\Re f\|_{L^{2}(d \sigma)} \leq C\|f\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)}
$$

holds for all $f \in L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)$.
Proof. By interpolation (see [7]), it suffices to show that for $1 \leq q<q_{0}$ and $1 \leq r<r_{0}$, the restricted type estimate

$$
\left\|\Re \chi_{E}\right\|_{L^{2}(d \sigma)} \leq C\left\|\chi_{E}\right\|_{L^{q}\left(\mathbb{R}^{n} ; L^{r}(\mathbb{R})\right)}
$$

for all subset $E$ in $\mathbb{R}^{n+1}$. We may assume $|E|>1$, otherwise the estimate is trivial. Since the set $S$ is compact, $\chi_{E}$ can be replaced with $\chi_{E} * \varphi$, where $\varphi$ is a bump function supported on a cube of sidelength $c \sim 1$ such that $\hat{\varphi}$ is positive on $S$. Thus, we may further assume that $E$ is the union of $c$-cubes.

We denote by $\operatorname{proj}(E)$ the projection of $E$ onto the $x$-plane. For each grid point $x \in c \mathbb{Z}^{n} \cap$ $\operatorname{proj}(E)$, we define $E_{x}$ to be the union of $c$-cubes in $E$ that intersect $\mathbb{R} \times\{x\}$. Let $E^{j}$ be the union of $E_{x}$ which satisfies

$$
2^{j-1}<\text { the number of } c \text { - cubes contained in } E_{x} \leq 2^{j+1}
$$

for $j \in \mathbb{N}$, (see Figure (1). Then,

$$
E=\bigcup_{j \geq 1} E^{j}
$$

By using Lemma 2.6 with

$$
K:=\frac{\log (1 / \epsilon)}{2 \log \gamma}+1
$$

the $E^{j}$ is decomposed into $E_{k}^{j}$,s which are covered by $O\left(\left|E^{j}\right|^{1 / K}\right)$ number of $\left(O\left(\left|E^{j}\right|\right),\left|E^{j}\right|^{C \gamma^{k-1}}\right)$ )sparse collections. We apply (2.7) to these sparse collections and obtain

$$
\left\|\mathfrak{R} \chi_{E_{k}^{j}}\right\|_{L^{2}(d \sigma)} \leq C_{\epsilon}\left|E^{j}\right|^{1 / K}\left(\left|E^{j}\right|^{C \gamma^{k-1}}\right)^{\epsilon}\left\|\chi_{E_{k}^{j}}\right\|_{L_{x}^{q_{0}}\left(\mathbb{R}^{n} ; L_{t}^{r_{0}}(\mathbb{R})\right)} .
$$

Summing over k , we have

$$
\begin{aligned}
\left\|\Re \chi_{E^{j}}\right\|_{L^{2}(d \sigma)} & \leq \sum_{k=1}^{K}\left\|\Re \chi_{E_{k}^{j}}\right\|_{L^{2}(d \sigma)} \\
& \leq C_{\epsilon}\left|E^{j}\right|^{1 / K}\left(\left|E^{j}\right|^{C \gamma^{K-1}}\right)^{\epsilon}\left\|\chi_{E^{j}}\right\|_{L_{x}^{q_{0}}\left(\mathbb{R}^{n} ; L_{t}^{r_{0}}(\mathbb{R})\right)}
\end{aligned}
$$

Figure 1. The sets $E, \operatorname{proj} E, E_{x}$ and $E^{j}$ in the proof of Proposition 2.7.
where $K$ is absorbed into $C_{\epsilon}$. Since $\left|E^{j}\right| \leq 2^{j+1}\left|\operatorname{proj}\left(E^{j}\right)\right|$, we have

$$
\left\|\Re \chi_{E^{j}}\right\|_{L^{2}(d \sigma)} \leq C_{\epsilon} 2^{j\left(\frac{1}{r_{0}}+\delta(\epsilon)\right)}\left|\operatorname{proj}\left(E^{j}\right)\right|^{\frac{1}{q_{0}}+\delta(\epsilon)},
$$

where

$$
\delta(\epsilon):=\frac{1}{K}+C \gamma^{K-1} \epsilon
$$

Since $\lim _{\epsilon \rightarrow 0} \delta(\epsilon)=0$, we can take $\epsilon>0$ such that

$$
0<\delta(\epsilon)+\epsilon \leq \min \left(\frac{1}{q}-\frac{1}{q_{0}}, \frac{1}{r}-\frac{1}{r_{0}}\right)
$$

Thus,

$$
\begin{aligned}
\left\|\Re \chi_{E}\right\|_{L^{2}(d \sigma)} & \leq \sum_{j \geq 1}\left\|\Re \chi_{E^{j}}\right\|_{L^{2}(d \sigma)} \\
& \leq C_{\epsilon} \sum_{j \geq 1} 2^{j\left(\frac{1}{r_{0}}+\delta(\epsilon)\right)}\left|\operatorname{proj}\left(E^{j}\right)\right|^{\frac{1}{q_{0}}+\delta(\epsilon)} \\
& \leq C \sum_{j \geq 1} 2^{-\epsilon j} 2^{\frac{1}{r} j}\left|\operatorname{proj}\left(E^{j}\right)\right|^{\frac{1}{q}} \\
& \leq C \sum_{j \geq 1} 2^{-\epsilon j}\left\|\chi_{E}\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)} \\
& \leq C\left\|\chi_{E}\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)}
\end{aligned}
$$

Combining Proposition 2.5 and Proposition 2.7 we obtain an extension of Tao's epsilon removal lemma as follows.

Proposition 2.8. Let $1<q_{0}, r_{0} \leq 2$. Suppose that

$$
\left\|\mathfrak{R}\left(\chi_{\mathbb{I}_{R} \times \mathbb{B}_{R}} f\right)\right\|_{L^{2}(d \sigma)} \leq C_{\epsilon} R^{\epsilon}\|f\|_{L_{x}^{q_{0}}\left(\mathbb{R}^{n} ; L_{t}^{r_{0}}(\mathbb{R})\right)}
$$

for all $\epsilon>0, R>1$ and all $f \in L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)$. Then for any $1 \leq q<q_{0}$ and $1 \leq r<r_{0}$,

$$
\|\Re f\|_{L^{2}(d \sigma)} \leq C\|f\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)}
$$

for all $f \in L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)$.
Now we are ready to prove Theorem [1.2, The theorem follows from Proposition 2.2 and Proposition 2.8 as follows.
2.3. Proof of Theorem 1.2. Let $P_{0}$ be the Littlewood-Paley projection operator as in subsection 2.1. By rescaling $x \mapsto 2^{-k} x$ and $t \mapsto 2^{-m k} t$, the estimate (1.4) implies

$$
\left\|e^{i t \Phi(D)} P_{0} f\right\|_{L_{x}^{q_{0}}\left(\mathbb{B}_{R} ; L_{t}^{r_{0}}\left(\mathbb{I}_{R^{m}}\right)\right)} \leq C_{\epsilon} 2^{k \epsilon}\left\|P_{0} f\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}
$$

for all $k \geq 1$ and $\epsilon>0$. Since $m \geq 1$, we have

$$
\left\|e^{i t \Phi(D)} P_{0} f\right\|_{L_{x}^{q_{0}}\left(\mathbb{B}_{R} ; L_{t}^{r_{0}}\left(\mathbb{I}_{R}\right)\right)} \leq C_{\epsilon} 2^{k \epsilon}\left\|P_{0} f\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}
$$

By Proposition 2.8 and duality,

$$
\left\|e^{i t \Phi(D)} P_{0} f\right\|_{L_{x}^{q}\left(\mathbb{R}^{n} ; L_{t}^{r}(\mathbb{R})\right)} \leq C\left\|P_{0} f\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}
$$

By Proposition 2.2, we obtain the desired estimate.

## 3. Appendix

3.1. Proof of Lemma 2.4. We divide the left side of (2.4) into two parts

$$
\left\|\left.\sum_{i=1}^{N} f_{i} * \hat{\varphi}_{i}\right|_{S}\right\|_{2}^{2}=\sum_{i}\left\|\left.f_{i} * \hat{\varphi}_{i}\right|_{S}\right\|_{2}^{2}+\sum_{i \neq j} \int f_{i} * \hat{\varphi}_{i} \overline{f_{j} * \hat{\varphi}_{j}} d \sigma
$$

By a basic restriction estimate we have $\left\|\left.f_{i} * \hat{\varphi}_{i}\right|_{S}\right\|_{2} \lesssim R^{1 / 2}\left\|f_{i}\right\|_{2}$. Thus,

$$
\begin{equation*}
\sum_{i=1}^{N}\left\|\left.f_{i} * \hat{\varphi}_{i}\right|_{S}\right\|_{2}^{2} \lesssim R \sum_{i=1}^{N}\left\|f_{i}\right\|_{2}^{2} \tag{3.1}
\end{equation*}
$$

By Parseval's identity,

$$
\int f_{i} * \hat{\varphi}_{i} \overline{f_{j} * \hat{\varphi}_{j}} d \sigma=\int \overline{\tilde{f}_{j} \varphi_{j}}\left(\left(\check{f}_{i} \varphi_{i}\right) * \widehat{d \sigma}\right)
$$

where the denotes the inverse Fourier transform. It is bounded by

$$
\left(\sup _{z, w}\left|\varphi_{j}^{1 / 2}(z) \varphi_{i}^{1 / 2}(w) \widehat{d \sigma}(z-w)\right|\right)\left\|\check{f}_{i} \varphi_{i}^{1 / 2}\right\|_{1}\left\|\check{f}_{j} \varphi_{j}^{1 / 2}\right\|_{1}
$$

By the Cauchy-Schwarz inequality and Plancherel's theorem,

$$
\left\|\check{f}_{i} \varphi_{i}^{1 / 2}\right\|_{1} \lesssim R^{(n+1) / 2}\left\|f_{i}\right\|_{2}
$$

By (2.3),

$$
\sup _{z, w}\left|\varphi_{j}^{1 / 2}(z) \varphi_{i}^{1 / 2}(w) \widehat{d \sigma}(z-w)\right| \lesssim\left|z_{i}-z_{j}-2 R\right|^{-\rho}
$$

Since $\left|z_{i}-z_{j}\right| \geq(N R)^{\gamma}$ and $\gamma \geq 2$, we have that $\left|z_{i}-z_{j}-2 R\right|$ is comparable to $\left|z_{i}-z_{j}\right|$. Thus,

$$
\sup _{z, w}\left|\varphi_{j}^{1 / 2}(z) \varphi_{i}^{1 / 2}(w) \widehat{d \sigma}(z-w)\right| \lesssim\left|z_{i}-z_{j}\right|^{-\rho}
$$

Combining these estimates we have

$$
\begin{aligned}
\sum_{i \neq j} \int f_{i} * \hat{\varphi}_{i} \overline{f_{j} * \hat{\varphi}_{j}} d \sigma & \lesssim R^{n+1} \sum_{i=1}^{N} \sum_{j=1}^{N}\left|z_{i}-z_{j}\right|^{-\rho}\left\|f_{i}\right\|_{2}\left\|f_{j}\right\|_{2} \\
& \lesssim R^{n+1} N \max _{i, j}\left|z_{i}-z_{j}\right|^{-\rho} \sum_{i=1}^{N}\left\|f_{i}\right\|_{2}^{2}
\end{aligned}
$$

Since $\left|z_{i}-z_{j}\right| \geq(N R)^{\gamma} \geq N^{\frac{1}{\rho}} R^{\frac{n}{\rho}}$, it follows that

$$
\sum_{i \neq j} \int f_{i} * \hat{\varphi}_{i} \overline{f_{j} * \hat{\varphi}_{j}} d \sigma \lesssim R \sum_{i=1}^{N}\left\|f_{i}\right\|_{2}^{2}
$$

From the above estimate and (3.1) we obtain (2.4).
3.2. Proof of Lemma 2.6. Fix $K \in \mathbb{N}$. We define $R_{0}=1$ and $R_{k}$ for $k=1,2, \cdots, K$ recursively by

$$
\begin{equation*}
R_{k}=|E|^{\gamma} R_{k-1}^{\gamma} \tag{3.2}
\end{equation*}
$$

From this definition we have $R_{k}=|E|^{\frac{\gamma^{k+1}-\gamma}{\gamma-1}}$. Let $E_{0}=\emptyset$. We define $E_{k}$ for $k=1,2, \cdots, K$ to be the set of all $x \in E \backslash \cup_{j=0,1,2, \cdots, k-1} E_{j}$ such that

$$
\begin{equation*}
\left|E \cap B\left(x, R_{k}\right)\right| \leq|E|^{k / K} \tag{3.3}
\end{equation*}
$$

Then, $E=\bigcup_{k=1}^{K} E_{k}$. From this construction it follows that that for $x \in E_{k}, k=2,3, \cdots, K$,

$$
\begin{equation*}
\left|E \cap B\left(x, R_{k-1}\right)\right|>|E|^{(k-1) / K} \tag{3.4}
\end{equation*}
$$

We cover $E_{k}$ with finitely overlapping $R_{k}$-balls $\mathbf{C}_{E_{k}}:=\left\{B_{i}=B\left(x_{i}, R_{k}\right): x_{i} \in E_{k}\right\}$. Since $E$ is a finite union of cubes of side-length $c \sim 1$, it is obvious that $\# \mathbf{C}_{E_{k}} \lesssim|E|$. For each $B_{i} \in \mathbf{C}_{E_{k}}$ we cover $E_{k} \cap B_{i}$ with finitely overlapping $R_{k-1}$-balls $\mathbf{C}_{E_{k} \cap B_{i}}:=\left\{B_{i j}^{\prime}=B^{\prime}\left(y_{j}, R_{k-1}\right): y_{j} \in E_{k} \cap B_{i}\right\}$, that is,

$$
E_{k} \cap B_{i}=\bigcup_{B_{i j}^{\prime} \in \mathbf{C}_{E_{k} \cap B_{i}}} E_{k} \cap B_{i j}^{\prime}
$$

Since $\left(\left(E \backslash E_{k}\right) \cap B_{i j}^{\prime}\right) \subset\left(\left(E \backslash E_{k}\right) \cap B_{i}\right)$ for all $j$, we have

$$
\left(E_{k} \cap B_{i}\right) \cup\left(\left(E \backslash E_{k}\right) \cap B_{i}\right) \supset \bigcup_{B_{i j}^{\prime} \in \mathbf{C}_{E_{k} \cap B_{i}}}\left(E_{k} \cap B_{i j}^{\prime}\right) \cup\left(\left(E \backslash E_{k}\right) \cap B_{i j}^{\prime}\right)
$$

thus

$$
E \cap B_{i} \supset \bigcup_{B_{i j}^{\prime} \in \mathbf{C}_{E_{k} \cap B_{i}}} E \cap B_{i j}^{\prime}
$$

By finitely overlapping,

$$
\# \mathbf{C}_{E_{k} \cap B_{i}} \lesssim \max _{B_{i j}^{\prime} \in \mathbf{C}_{E_{k} \cap B_{i}}} \frac{\left|E \cap B_{i}\right|}{\left|E \cap B_{i j}^{\prime}\right|}
$$

By (3.3) and (3.4) the above is bounded by $C|E|^{1 / K}$, and we have $\# \mathbf{C}_{E_{k} \cap B_{i}} \leq C|E|^{1 / K}$ for all $i$. Thus,

$$
E_{k} \subset \bigcup_{i=1}^{O(|E|)} \bigcup_{j=1}^{O\left(|E|^{1 / K}\right)} B_{i j}^{\prime}
$$

We choose $O\left(R_{k}\right)$-separated balls $\left\{B_{i j(i)}^{\prime}\right\}_{i=1}^{O(|E|)}$. Then it becomes a $\left(O(|E|), R_{k-1}\right)$-sparse collection because of (3.2). Since $R_{k-1}=|E|^{O\left(\gamma^{k-1}\right)}$ and every $B_{i} \in \mathbf{C}_{E_{k}}$ has the covering
$\mathbf{C}_{E_{k} \cap B_{i}}$ of cardinality $O\left(|E|^{1 / K}\right)$, there are $O\left(|E|^{1 / K}\right)$ number of $\left(O(|E|),|E|^{O\left(\gamma^{k-1}\right)}\right)$-sparse collections $\mathbf{S}_{1}, \mathbf{S}_{2}, \cdots, \mathbf{S}_{O\left(|E|^{1 / K}\right)}$ such that

$$
E_{k} \subset \bigcup_{j=1}^{O\left(|E|^{1 / K}\right)} \bigcup_{B^{\prime} \in \mathbf{S}_{j}} B^{\prime}
$$
