Abstract

Uncertainty principle plays a vital role in quantum physics. The Wigner-Yanase skew information characterizes the uncertainty of an observable with respect to the measured state. We generalize the uncertainty relations for two quantum channels to arbitrary N quantum channels based on Wigner-Yanase skew information. We illustrate that these uncertainty inequalities are tighter than the existing ones by detailed examples. Especially, we also discuss the uncertainty relations for N unitary channels, which could be regarded as variance-based sum uncertainty relations with respect to any pure state.

I. INTRODUCTION

As a fundamental characteristic of quantum theory, uncertainty principle has been widespread concerned since Heisenberg proposed the notions of uncertainties for measuring non-commuting observables [1]. The well-known Robertson uncertainty relation says that for arbitrary two observables A and B [2], $\Delta A \Delta B \geq \frac{1}{2} |\langle \psi[A, B] \psi \rangle|$, where the commutator [A, B] = AB - BA and $\Delta \Omega = \sqrt{\langle \Omega^2 \rangle - \langle \Omega \rangle^2}$ is the standard deviation of an observable Ω with respect to the measured state $|\psi\rangle$. With the development of quantum information theory, many kinds of characterizations and quantifications of uncertainty relations have been established, such as the ones based on entropy [3–10], Wigner-Yanase skew information [11–13], under successive measurements [14–18], and with majorization techniques [19–21].

In modern formalism of quantum theory, the most general description of quantum measurement is given in terms of quantum channels [22, 23]. Quantum channels play a pivotal role in quantum information processing. Many aspects related to the quantum channels have been extensively investigated, such as the coherence of quantum channels [24, 25], the operational resource theory of quantum channels [26, 27], the capacity of quantum channels [28, 29], and the abilities of quantum channels in producing or destroying quantum resources [30–33]. Recently, the uncertainty relations for quantum channels have been also widely studied in terms of the Wigner-Yanase skew information and variance [11, 13, 34, 35]. The Wigner-Yanase skew information $I_{\rho}(A)$ with respect to a quantum state ρ and an arbitrary operator A is defined by [36–39],

$$I_{\rho}(A) = \frac{1}{2} tr([\sqrt{\rho}, A]^{\dagger}[\sqrt{\rho}, A]) = \frac{1}{2} \| [\sqrt{\rho}, A] \|^{2},$$
(1)

where $\| \bullet \|$ denotes the Frobenius norm. Let Φ be a quantum channel with Kraus representation, $\Phi(\rho) = \sum_{i=1}^{n} K_i \rho K_i^{\dagger}$. The Wigner-Yanase skew information of ρ with respect to the channel is given by

$$I_{\rho}(\Phi) = \sum_{i=1}^{n} I_{\rho}(K_i),$$
(2)

where $I_{\rho}(K_i) = \frac{1}{2}Tr([\sqrt{\rho}, K_i]^{\dagger}[\sqrt{\rho}, K_i])[38]$. The quantity $I_{\rho}(\Phi)$ is well-defined because it is independent of the choice of the Kraus of Φ . It is demonstrated that $I_{\rho}(\Phi)$ can be regarded as a bona fide measure, for coherence as well as quantum uncertainty of ρ with respect to quantum channel Φ . For a pure state, the skew information for channel has a similar physical meaning to the variance [40]. Pass through a given quantum channel Φ with Kraus operators K_i , a pure state $|\psi\rangle$ can be transformed into:

$$\rho = \Phi(\rho) = \sum_{i=1}^{n} K_i |\psi\rangle \langle \psi | K_i^{\dagger}.$$

The Fidelity between $|\psi\rangle$ and ρ is defined as [23]:

$$F = \langle \psi | \rho | \psi \rangle = \sum_{i=1}^{n} |\langle \psi | K_i | \psi \rangle|^2.$$

The skew information of $|\psi\rangle$ for quantum channel Φ

$$I_{|\psi\rangle}(\Phi) = \sum_{i} I_{|\psi\rangle}(K_{i}) = 1 - \sum_{i=1}^{n} |\langle \psi | K_{i} | \psi \rangle|^{2} = 1 - F,$$

that is to say,

$$I_{|\psi\rangle}(\Phi) + F = 1.$$

The above equality shows a strict complementarity between fidelity and uncertainty of quantum channel [13]. The complementary relation reveals that any restriction on the uncertainty in the channel will impose a restriction on the fidelity between the input and output states.

Fu *et al.* established the uncertainty relation for two quantum channels Φ_1 and Φ_2 in terms of Wigner-Yanase skew information [41],

$$I_{\rho}(\Phi_1) + I_{\rho}(\Phi_2) \ge \max_{\pi \in S_n} \frac{1}{2} \sum_{i=1}^n I_{\rho}(K_i^1 \pm K_{\pi(i)}^2),$$
(3)

where $\Phi_s = \sum_{i=1}^n K_i^s \rho(K_i^s)^{\dagger}$, $s = 1, 2, \pi \in S_n$ is an arbitrary *n*-element permutation.

Very recently, generalizing the results in [41] to the case of N quantum channels, Zhang *et al.* provided two elegant uncertainty relations [13],

$$\sum_{s=1}^{N} I_{\rho}(\Phi_{s}) \geq \max_{\pi_{s}, \pi_{t} \in S_{n}} \frac{1}{N-2} \sum_{i=1}^{n} \left\{ \sum_{1 \leq s < t \leq N} I_{\rho}(K_{\pi_{s}(i)}^{s} + K_{\pi_{t}(i)}^{t}) - \frac{1}{(N-1)^{2}} \left[\sum_{1 \leq s < t \leq N} \sqrt{I_{\rho}(K_{\pi_{s}(i)}^{s} + K_{\pi_{t}(i)}^{t})} \right]^{2} \right\},$$

$$(4)$$

and

$$\sum_{s=1}^{N} I_{\rho}(\Phi_{s}) \geq \max_{\pi_{s}, \pi_{t} \in S_{n}} \frac{1}{N} \sum_{i=1}^{n} \left\{ I_{\rho}(\sum_{s} K_{\pi_{s}(i)}^{s}) + \frac{2}{N(N-1)} \left[\sum_{1 \leq s < t \leq N} \sqrt{I_{\rho}(K_{\pi_{s}(i)}^{s} - K_{\pi_{t}(i)}^{t})} \right]^{2} \right\},$$
(5)

where $\pi_s, \pi_t \in S_n$ are arbitrary *n*-element permutations. For convenience, we denote the right hands of (4) and (5) as $\overline{\text{LB}}_1, \overline{\text{LB}}_2$, respectively.

In this paper, we formulate several new uncertainty relations based on Wigner-Yanase skew information for N quantum channels. The lower bounds of our uncertainty inequalities are tighter than the existing ones [13]. Detailed examples are presented to illustrate the superiority. Especially, we also discuss the uncertainty relations for unitary channels.

II. SKEW INFORMATION-BASED SUM UNCERTAINTY RELATIONS FOR QUANTUM CHANNELS

Let Φ be a quantum channel with Kraus representation, $\Phi(\rho) = \sum_{i=1}^{n} K_i \rho K_i^{\dagger}$. The skew information of the channel can be written as

$$I_{\rho}(\Phi) = \frac{1}{2} tr(a^{\dagger}a) = \frac{1}{2} ||a||^2,$$
(6)

where $a^{\dagger} = ([\sqrt{\rho}, K_1]^{\dagger}, [\sqrt{\rho}, K_2]^{\dagger}, \dots, [\sqrt{\rho}, K_n]^{\dagger})$. $I_{\rho}(\Phi)$ characterizes some intrinsic features of both the quantum state and the quantum channel. For arbitrary N quantum channels, we have the following conclusion.

Theorem 1 Let $\Phi_1, \Phi_2, \ldots, \Phi_N$ be N quantum channels with Kraus representations $\Phi_s(\rho) = \sum_{i=1}^n K_i^s \rho(K_i^s)^{\dagger}$, s = 1, 2, ..., N. We have

$$\sum_{s=1}^{N} I_{\rho}(\Phi_s) \ge \operatorname{Max}\{\operatorname{LB1}, \operatorname{LB2}, \operatorname{LB3}\},\tag{7}$$

where

$$LB1 = \max_{\pi_s, \pi_t \in S_n} \frac{1}{N-2} \Biggl\{ \sum_{1 \le s < t \le N} \sum_{i=1}^n I_\rho(K^s_{\pi_s(i)} + K^t_{\pi_t(i)}) - \frac{1}{(N-1)^2} \Biggl[\sum_{1 \le s < t \le N} \sqrt{\sum_{i=1}^n I_\rho(K^s_{\pi_s(i)} + K^t_{\pi_t(i)})} \Biggr]^2 \Biggr\},$$
(8)

$$LB2 = \max_{\pi_s, \pi_t \in S_n} \frac{1}{N} \Biggl\{ \sum_{i=1}^n I_\rho(\sum_{s=1}^N K^s_{\pi_s(i)}) + \frac{2}{N(N-1)} \Biggl[\sum_{1 \le s < t \le N} \sqrt{\sum_{i=1}^n I_\rho(K^s_{\pi_s(i)} - K^t_{\pi_t(i)})} \Biggr]^2 \Biggr\},$$
(9)

$$LB3 = \max_{\pi_s, \pi_t \in S_n} \frac{1}{2N - 2} \Biggl\{ \sum_{1 \le s < t \le N} \sum_{i=1}^n I_\rho(K^s_{\pi_s(i)} \mp K^t_{\pi_t(i)}) + \frac{2}{N(N - 1)} \Biggl[\sum_{1 \le s < t \le N} \sqrt{\sum_{i=1}^n I_\rho(K^s_{\pi_s(i)} \pm K^t_{\pi_t(i)})} \Biggr]^2 \Biggr\},$$
(10)

 $\pi_s, \pi_t \in S_n$ are arbitrary n-element permutations.

[Proof] To prove the inequality (7), we employ the following equality,

$$\|\sum_{s=1}^{N} a_s\|^2 + (N-2)\sum_{s=1}^{N} \|a_s\|^2 = \sum_{1 \le s < t \le N} \|a_s + a_t\|^2.$$

Note that

$$\|\sum_{s=1}^{N} a_s\| = \|\frac{1}{N-1} \sum_{1 \le s < t \le N} (a_s + a_t)\| \le \frac{1}{N-1} \sum_{1 \le s < t \le N} \|a_s + a_t\|,$$

we get

$$\sum_{s=1}^{N} \|a_s\|^2 \ge \frac{1}{N-2} \left[\sum_{1 \le s < t \le N} \|a_s + a_t\|^2 - \frac{1}{(N-1)^2} \left(\sum_{1 \le s < t \le N} \|a_s + a_t\|\right)^2 \right].$$

From (6), we have $||a_s||^2 = 2I_{\rho}(\Phi_s)$ and $||a_s + a_t||^2 = 2\sum_{i=1}^N I_{\rho}(K_i^s + K_i^t)$, which proves $\sum_{s=1}^N I_{\rho}(\Phi_s) \ge \text{LB1}.$

By using the identity,

$$N\sum_{s=1}^{N} \|a_s\|^2 = \|\sum_{s=1}^{N} a_s\|^2 + \sum_{1 \le s < t \le N} \|a_s - a_t\|^2$$

and the Cauchy-Schwarz inequality, we obtain

$$\sum_{1 \le s < t \le N} \|a_s - a_t\|^2 \ge \frac{2}{N(N-1)} (\sum_{1 \le s < t \le N} \|a_s - a_t\|)^2,$$

and

$$\sum_{s=1}^{N} \|a_s\|^2 \ge \frac{1}{N} [\|\sum_{s=1}^{N} a_s\|^2 + \frac{2}{N(N-1)} (\sum_{1 \le s < t \le N} \|a_s - a_t\|)^2].$$

Taking account into that $\|\sum_{s=1}^{N} a_s\|^2 = 2\sum_{i=1}^{n} I_{\rho}(\sum_s K_i^s)$ and $\|a_s - a_t\|^2 = 2\sum_{i=1}^{N} I_{\rho}(K_i^s - K_i^t)$, we prove the inequality $\sum_{s=1}^{N} I_{\rho}(\Phi_s) \ge LB2$.

At last, by using the parallelogram law,

$$(2N-2)\sum_{s=1}^{N} \|a_s\|^2 = \sum_{1 \le s < t \le N} \|a_s - a_t\|^2 + \sum_{1 \le s < t \le N} \|a_s + a_t\|^2$$

and the Cauchy-Schwarz inequality, we get

$$\sum_{1 \le s < t \le N} \|a_s - a_t\|^2 \ge \frac{2}{N(N-1)} (\sum_{1 \le s < t \le N} \|a_s - a_t\|)^2$$

and

$$\sum_{1 \le s < t \le N} \|a_s + a_t\|^2 \ge \frac{2}{N(N-1)} (\sum_{1 \le s < t \le N} \|a_s + a_t\|)^2.$$

Therefore we have

л т

$$\sum_{s=1}^{N} \|a_s\|^2 \ge \frac{1}{2N-2} \left[\frac{2}{N(N-1)} \left(\sum_{1 \le s < t \le N} \|a_s \mp a_t\|\right)^2 + \sum_{1 \le s < t \le N} \|a_s \pm a_t\|^2\right]$$

which proves the inequality $\sum_{s=1}^{N} I_{\rho}(\Phi_s) \ge LB3$. \Box

As examples, let us consider the mixed state given by Bloch vector $\vec{r} = (\frac{\sqrt{3}}{2}cos\theta, \frac{\sqrt{3}}{2}sin\theta, 0)$ [13],

$$\rho = \frac{I_2 + \vec{r} \cdot \vec{\sigma}}{2},\tag{11}$$

where $\vec{\sigma} = (\sigma_x, \sigma_y, \sigma_z)$ is given by the standard Pauli matrices, I_2 is the 2×2 identity matrix. We respectively consider three quantum channels: the phase damping channel ϕ ,

$$\phi(\rho) = \sum_{i=1}^{2} A_i \rho(A_i)^{\dagger}, \quad A_1 = |0\rangle \langle 0| + \sqrt{1-q} |1\rangle \langle 1|, \quad A_2 = \sqrt{q} |1\rangle \langle 1|,$$

the amplitude damping channel ϵ ,

$$\epsilon(\rho) = \sum_{i=1}^{2} B_i \rho(B_i)^{\dagger}, \quad B_1 = |0\rangle \langle 0| + \sqrt{1-q} |1\rangle \langle 1|, \quad B_2 = \sqrt{q} |0\rangle \langle 1|$$

and the bit flip channel Λ ,

$$\Lambda(\rho) = \sum_{i=1}^{2} C_i \rho(C_i)^{\dagger}, \quad C_1 = \sqrt{q} |0\rangle \langle 0| + \sqrt{q} |1\rangle \langle 1|, \quad C_2 = \sqrt{1-q} (|0\rangle \langle 1| + |1\rangle \langle 0|)$$

with $0 \le q < 1$.

For the case q = 0.1 and $\theta = \pi/2$, we have $I_{\rho}(\phi) + I_{\rho}(\epsilon) + I_{\rho}(\Lambda) = 0.475658$. The lower bound LB1 is 0.449135, the lower bounds $\overline{\text{LB}1}$ and $\overline{\text{LB}2}$ are 0.475658 and 425827, respectively. Obviously, LB1 is tighter than $\overline{\text{LB}2}$ in [13]. Here the lower bound LB1 is also greater than 0.42873 from LB2 and 0.440462 from LB3.

We also consider the case q = 0.5, the comparison among the lower bounds $\overline{\text{LB}1}$, $\overline{\text{LB}2}$, LB1, LB2 and LB3 is shown in Figure. 1. Especially, we take some special θ , see Table. I. These results show that our Theorem 1 improve the existing ones given in [13].

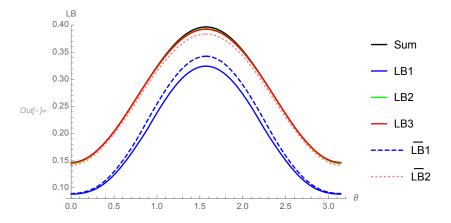

FIG. 1: The comparison among the lower bounds $\overline{\text{LB}1}$, $\overline{\text{LB}2}$, LB1, LB2 and LB3 for the state ρ with Bloch vector $\vec{r} = (\frac{\sqrt{3}}{2}cos\theta, \frac{\sqrt{3}}{2}sin\theta, 0)$, and three quantum channels, the phase damping channel, the amplitude damping channel and the bit flip channel. Let $\text{Sum} = I_{\rho}(\phi) + I_{\rho}(\epsilon) + I_{\rho}(\Lambda)$.

| | TABLE I: | Comparison | among the | uncertainty | lower bounds |
|--|----------|------------|-----------|-------------|--------------|
|--|----------|------------|-----------|-------------|--------------|

| | | - | - | | - | |
|------------------|-------------------------|-------------------------|----------|----------|----------|---|
| q = 0.5 | $\overline{\text{LB}}1$ | $\overline{\text{LB}}2$ | LB1 | LB2 | LB3 | $I_{\rho}(\phi) + I_{\rho}(\epsilon) + I_{\rho}(\Lambda)$ |
| $\theta = \pi/6$ | 0.133979 | 0.204181 | 0.127677 | 0.208898 | 0.20891 | 0.208947 |
| $\theta=\pi/4$ | 0.194803 | 0.264726 | 0.182753 | 0.271447 | 0.271447 | 0.271447 |
| $\theta = \pi/2$ | 0.342466 | 0.383224 | 0.324177 | 0.393068 | 0.393913 | 0.396447 |

In addition, by using the generalized Hlawka's inequality [12, 42, 43],

$$\sum_{s=1}^{N} \|a_s\| \ge \frac{1}{N-2} (\sum_{1 \le s < t \le N} \|a_s + a_t\| - \|\sum_{i=1}^{N} a_s\|),$$

we can similarly prove the following theorem.

Theorem 2 Let $\Phi_1, \Phi_2, \ldots, \Phi_N$ be N quantum channels with Kraus representations $\Phi_s(\rho) = \sum_{i=1}^n K_i^s \rho(K_i^s)^{\dagger}$, we have

$$\sum_{s=1}^{N} \sqrt{I_{\rho}(\Phi_s)} \ge \max_{\pi_s, \pi_t \in S_n} \frac{1}{N-2} \Biggl\{ \sum_{1 \le s < t \le N} \sqrt{\sum_{i=1}^{n} I_{\rho}(K_{\pi_s(i)}^s + K_{\pi_t(i)}^t)} - \sqrt{\sum_{i=1}^{n} I_{\rho}(\sum_{s=1}^{N} K_{\pi_s(i)}^s)} \Biggr\},$$
(12)

where $\pi_s, \pi_t \in S_n$ are arbitrary n-element permutations.

Unitary channels are also used a lot in quantum computation and quantum information theory[23]. Consider an arbitrary channel $U(\rho) = U\rho U^{\dagger}$, the Wigner-Yanase skew information of ρ with respect to the channel is given by

$$I_{\rho}(U) = \frac{1}{2} tr([\sqrt{\rho}, U]^{\dagger}[\sqrt{\rho}, U]).$$

Next we consider the skew information-based uncertainty relations for N unitary channels U_1, U_2, \ldots, U_N . Directly from Theorom 1, the following uncertainty relations hold:

$$\sum_{s=1}^{N} I_{\rho}(U_s) \ge \frac{1}{N-2} \left\{ \sum_{1 \le s < t \le N} I_{\rho}(U_s + U_t) - \frac{1}{(N-1)^2} \left[\sum_{1 \le s < t \le N} \sqrt{I_{\rho}(U_s + U_t)} \right]^2 \right\}, \quad (13)$$

$$\sum_{s=1}^{N} I_{\rho}(U_s) \ge \frac{1}{N} \left\{ I_{\rho}(\sum_{s=1}^{N} U_s) + \frac{2}{N(N-1)} \left[\sum_{1 \le s < t \le N} \sqrt{I_{\rho}(U_s - U_t)} \right]^2 \right\},$$
(14)

$$\sum_{s=1}^{N} I_{\rho}(U_s) \ge \frac{1}{2N-2} \left\{ \sum_{1 \le s < t \le N} I_{\rho}(U_s \mp U_t) + \frac{2}{N(N-1)} \left[\sum_{1 \le s < t \le N} \sqrt{I_{\rho}(U_s \pm U_t)} \right]^2 \right\}.$$
 (15)

For convenience, we denote the right hands of (13), (14) and (15) as Lb1, Lb2 and Lb3, respectively.

Theorem 2 implies the following inequality holds for N Unitary channels:

$$\sum_{s=1}^{N} \sqrt{I_{\rho}(U_s)} \ge \frac{1}{N-2} \left\{ \sum_{1 \le s < t \le N} \sqrt{I_{\rho}(U_s + U_t)} - \sqrt{I_{\rho}(\sum_{s=1}^{N} U_s)} \right\}.$$
 (16)

Noticed that quantum variance is defined as: $(\Delta_{|\psi\rangle}U)^2 = \frac{1}{2}\langle UU^{\dagger} + U^{\dagger}U \rangle - \langle U \rangle \langle U^{\dagger} \rangle$ with any quantum pure state $|\psi\rangle$, then the following equality holds:

$$(\Delta_{|\psi\rangle}U)^2 = I_{|\psi\rangle}(U). \tag{17}$$

The above inequalities (13) to (16) can be regarded as variance-based sum uncertainty relations for N unitary operators.

We take an example to illustrate these uncertainty relations. Let us consider the pure state $\rho = \frac{1}{2}(I + \vec{r} \cdot \vec{\sigma})$ with $\vec{r} = (\frac{1}{\sqrt{2}}\cos\theta, \frac{1}{\sqrt{2}}\sin\theta, \frac{1}{\sqrt{2}})$, where $\sigma_x, \sigma_y, \sigma_z$ are Pauli matrices.

Consider three unitary operators,

$$U_{1} = e^{\frac{i\pi\sigma_{x}}{8}} = \begin{pmatrix} \cos\frac{\pi}{8} & i\sin\frac{\pi}{8} \\ i\sin\frac{\pi}{8} & \cos\frac{\pi}{8} \end{pmatrix},$$
$$U_{2} = e^{\frac{i\pi\sigma_{y}}{8}} = \begin{pmatrix} \cos\frac{\pi}{8} & \sin\frac{\pi}{8} \\ -\sin\frac{\pi}{8} & \cos\frac{\pi}{8} \end{pmatrix},$$
$$U_{3} = e^{\frac{i\pi\sigma_{z}}{8}} = \begin{pmatrix} e^{i\frac{\pi}{8}} & 0 \\ 0 & e^{-i\frac{\pi}{8}} \end{pmatrix},$$

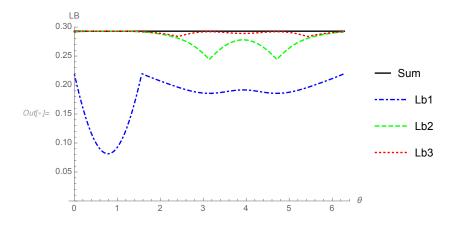

FIG. 2: The black (solid) line is $\text{Sum} = I_{\rho}(U_1) + I_{\rho}(U_2) + I_{\rho}(U_3) = 1 - \sqrt{2}/2$. The blue (dot-dashed) line Lb1, green (dashed) line Lb2 and red (dotted) line Lb3 represent the right hands of (13), (14) and (15), respectively.

which correspond to Bloch sphere rotations of $-\pi/4$ about the x axis, the y axis and z axis, respectively. Then the lower bounds of inequalities (13), (14) and (15) associated with ρ can be computed. Figure 2 shows that lower bound of (15) is strictly greater than (13) and (14) in this case.

III. CONCLUSION

Based on Wigner-Yanase skew information for quantum channels, we have derived several uncertainty relations for arbitrary N quantum channels. By detailed examples we have shown that our uncertainty relations improve the existing ones. We also get several uncertainty relations for N unitary channels. It can be regarded as variance-based sum uncertainty relations for N unitary operators as we take the pure state. These results and the simple approaches used in this article may highlight further investigations on related uncertainty relations.
