NEW FOURTH ORDER POSTPROCESSING TECHNIQUES FOR PLATE BUCKLING EIGENVALUES BY MORLEY ELEMENT

LIMIN MA AND SHUDAN TIAN

Abstract. In this paper, we propose and analyze the extrapolation methods and asymptotically exact a posterior error estimates for eigenvalues of the Morley element. We establish an asymptotic expansion of eigenvalues, and prove an optimal result for this expansion and the corresponding extrapolation method. We also design an asymptotically exact a posterior error estimate and propose new approximate eigenvalues with higher accuracy by utilizing this a posteriori error estimate. Finally, several numerical experiments are considered to confirm the theoretical results and compare the performance of the proposed methods.

Keywords. eigenvalue problem, Morley element, extrapolation method, asymptotically exact a posterior error estimates

AMS subject classifications. 65N30, 73C02.

1. Introduction

The biharmonic eigenvalue problem originates from the plate theory of elasticity, and also occurs in many physical areas, say the inverse scattering theory. In the Kirchhoff-Love plate model, the biharmonic eigenvalue problem describes the vibration and buckling of an elastic plate subject to some certain boundary condition. The Morley element method is one of the most popular methods for this problem in applied mechanics and engineering, and was widely studied in literature, see [38, 40, 8, 15, 13, 10, 24, 7, 22, 28] and the references therein.

The extrapolation method is an efficient approach to improve the accuracy of approximations of many problems. The key of the efficiency of extrapolation algorithm is an asymptotic expansion of the error. The classical analysis of asymptotic expansions is usually based on a superclose property of the canonical interpolation of the element under consideration, see for instance [32, 14, 36, 4, 29, 34, 33, 9, 26, 37, 35, 31, 30] and the references therein. For some nonconforming elements on triangular meshes, the lack of this crucial superclose property leads to a substantial difficulty of the asymptotic analysis. Until recently, [18] proved the first optimal asymptotic result for two nonconforming elements of second order elliptic
problem. Asymptotically exact a posteriori error estimates is another efficient technique to improve the accuracy of eigenvalues. The key of such a posteriori error estimates is to express the error in terms of some computable high accuracy approximations. For eigenvalues of the Laplacian operator, [39] [17] studied the asymptotically exact a posteriori error estimates for some conforming and nonconforming elements.

In this paper, we establish the first asymptotic analysis for eigenvalues by the Morley element and analyze the efficiency of the extrapolation algorithm. Inspired by [18], we overcome the difficulty caused by the lack of a crucial superclose property and get

\[(1.1) \quad \lambda - \lambda_M = \| (I - \Pi_{HHJ}) \nabla^2 u \|_{0, \Omega}^2 + 2I_1 + 2I_2 - 2I_3 + O(h^4 |u|_{2, \Omega}^2),\]

where \((\lambda_M, u_M)\) is an eigenpair of the Morley element and \(I_1, I_2, I_3\) are defined in (3.5). To achieve an optimal result, we conduct a new technical analysis for each term on the right hand side of (1.1). The analysis in this paper is quite different from the one in [18] because some natural orthogonal property is absent in this case. We establish an explicit expression with a vanishing subdominant term for the interpolation in [23]. By use of this expression, we can cancel some suboptimal terms in \(\| (I - \Pi_{HHJ}) \nabla^2 u \|_{0, \Omega}^2\) and get the desired optimal expansion. By employing the commuting property and the equivalence with the HHJ element, we express \(I_1\) in terms of the second order accuracy term \(u_{HHJ}\), instead of the first order accuracy term \(\sigma_{HHJ}\). In this way, we achieve an optimal estimate of \(I_1\). We express the consistency error term \(I_2\) in terms of jumps along interior edges, which allows some cancellation and is the key to a desired optimal analysis. For \(I_3\), we establish an explicit expression of the interpolation error of the Morley element, and cancel the suboptimal terms between adjacent elements forming a parallelogram, which is crucial in getting the optimal result.

We also design an asymptotically exact a posteriori error estimate and the corresponding approximate eigenvalues for the Morley element. By a simple postprocessing technique, the accuracy of the approximate eigenvalue can be improved to \(O(h^3)\). Numerical shows that this postprocessing technique is effective on both uniform and adaptive meshes, and achieves better performance than the extrapolation method.

The remaining paper is organized as follows. Section 2 presents fourth order elliptic eigenvalue problems and some notations. Section 3 explores optimal asymptotic expansions of approximate eigenvalues of the Morley element and analyzes the optimal convergence rate of eigenvalues by extrapolation methods. Section 4 proposes and analyzes an asymptotically exact a posteriori error estimate of eigenvalues of the Morley element. Section 5 the presents some numerical tests.
2. Notations and Preliminaries

2.1. Notations. Given a nonnegative integer $k$ and a bounded domain $\Omega \subset \mathbb{R}^2$ with boundary $\partial \Omega$, let $W^{k,\infty} (\Omega, \mathbb{R})$, $H^k (\Omega, \mathbb{R})$, $\| \cdot \|_{k,\Omega}$ and $| \cdot |_{k,\Omega}$ denote the usual Sobolev spaces, norm, and semi-norm, respectively. Denote the standard $L^2 (\Omega, \mathbb{R})$ inner product and $L^2 (K, \mathbb{R})$ inner product by $(\cdot, \cdot)$ and $(\cdot, \cdot)_{0,K}$, respectively.

Suppose that $\Omega \subset \mathbb{R}^2$ is a convex polygonal domain and the partition $T_h$ of domain $\Omega$ is assumed to be uniform in the sense that any two adjacent triangles form a parallelogram. Let $|K|$ denote the area of element $K$ and $|e|$ the length of edge $e$. Let $h_K$ denote the diameter of element $K \in T_h$ and $h = \max_{K \in T_h} h_K$. Denote the set of all interior edges and boundary edges of $T_h$ by $E^i_h$ and $E^b_h$, respectively, and $E_h = E^i_h \cup E^b_h$.

Let element $K$ have vertices $p_i = (p_{i1}, p_{i2})$, $1 \leq i \leq 3$ oriented counterclockwise, and corresponding barycentric coordinates $\{\psi_i\}_{i=1}^3$. Let $M_K = (M_1, M_2)$ denote the centroid of the element, $|e|^3_{i=1}$ the edges of element $K$, $\{d_i\}_{i=1}^3$ the perpendicular heights, $\{\theta_i\}_{i=1}^3$ the internal angles, $\{m_i\}_{i=1}^3$ the midpoint of edge $|e|_{i=1}$, and $\{n_i\}_{i=1}^3$ the unit outward normal vectors, $\{t_i\}_{i=1}^3$ the unit tangent vectors with counterclockwise orientation (see Figure 1). There holds the following relationships $d_i |e| = 2|K|$ and

$$
\nabla \psi_i = -\frac{n_i}{d_i}, \quad \sin \theta_i = n_{i-1} \cdot t_{i+1} = -n_{i+1} \cdot t_{i-1},
$$

(2.1)

$$
\cos \theta_k = -n_{i-1} \cdot n_{i+1} = \frac{|e_{i-1}|^2 + |e_{i+1}|^2 - |e_i|^2}{2|e_{i-1}| |e_{i+1}|}
$$

among the quantities $\{25\}$. For $K \subset \mathbb{R}^2$, $r \in \mathbb{Z}^+$, let $P_r (K, \mathbb{R})$ be the space of all polynomials of degree not greater than $r$ on $K$. Denote the piecewise Hessian operator by $\nabla^2_h$. For any $1 \leq i, j, k \leq 2$, denote the second order derivatives $\frac{\partial^2 \psi}{\partial x^i \partial x^j \partial x^k}$ by $\partial^i j k$. For any $\alpha = (\alpha_1, \alpha_2)$, denote

$$
|\alpha| = \alpha_1 + \alpha_2, \quad \alpha! = \alpha_1! \alpha_2!, \quad D^\alpha \psi = \partial_1^{\alpha_1} \partial_2^{\alpha_2} \psi.
$$

Figure 1. Parameters associated with a triangle $K$. 

For ease of presentation, the symbol $A \lesssim B$ will be used to denote that $A \leq CB$, where $C$ is a positive constant.

2.2. **Morley element for eigenvalue problems.** Consider the biharmonic eigenvalue problem for plate buckling, which is to find: $(\lambda, u) \in \mathbb{R} \times V$ such that $\|u\|_{0, \Omega} = 1$ and

$$a(u, v) = \lambda(u, v) \quad \text{for any } v \in V,$$

with $a(w, v) = \int_{\Omega} \nabla^2 w : \nabla^2 v \, dx$. Here $V \subset H^2(\Omega, \mathbb{R})$ is a Hilbert space with certain boundary condition. If a clamped plate is considered, let $H^2_0(\Omega, \mathbb{R})$ with $H^2_0(\Omega, \mathbb{R}) = \{ u \in H^2(\Omega, \mathbb{R}) : u|_{\partial\Omega} = \partial u/\partial n|_{\partial\Omega} = 0 \}$.

If a simply supported plate is under consideration, let $V = H^2(\Omega, \mathbb{R}) \cap H^1_0(\Omega, \mathbb{R})$ with $H^1_0(\Omega, \mathbb{R}) = \{ u \in H^1(\Omega, \mathbb{R}) : u|_{\partial\Omega} = 0 \}$.

The analysis in this paper focuses on the case $V = H^2_0(\Omega, \mathbb{R})$, and also works for $V = H^2(\Omega, \mathbb{R}) \cap H^1_0(\Omega, \mathbb{R})$.

The bilinear form $a(w, v)$ is symmetric, bounded, and coercive, namely for any $w, v \in V$,

$$a(w, v) = a(v, w), \quad |a(w, v)| \leq \|w\|_{2, \Omega} \|v\|_{2, \Omega}, \quad \|v\|_{2, \Omega}^2 \leq a(v, v).$$

The eigenvalue problem (2.2) has a sequence of eigenvalues

$$0 < \lambda^1 \leq \lambda^2 \leq \lambda^3 \leq ... \rightarrow +\infty,$$

and the corresponding eigenfunctions $u^1, u^2, u^3, ...$, with

$$(u^i, u^j) = \delta_{ij} \quad \text{with } \delta_{ij} = \begin{cases} 0 & i \neq j \\ 1 & i = j \end{cases}.$$

The nonconforming Morley element space $V_M$ over $\mathcal{T}_h$ is defined by $V_M := \{ v \in L^2(\Omega, \mathbb{R}) | v|_K \in P_2(K, \mathbb{R}) \text{ for any } K \in \mathcal{T}_h, v \text{ is continuous at each interior vertex and vanishes on each boundary vertex}, \int_e \left[ \frac{\partial v}{\partial n} \right] \, ds = 0 \text{ for any } e \in \mathcal{E}^i_{h'}, \int_e \frac{\partial v}{\partial n} \, ds = 0 \text{ for any } e \in \mathcal{E}^b_{h'} \}$.

The corresponding canonical interpolation operator $\Pi_M : V \to V_M$ is defined by

$$\int_e \frac{\partial \Pi_M v}{\partial n} \, ds = \int_e \frac{\partial v}{\partial n} \, ds, \forall e \in \mathcal{E}^i_{h'}, \quad \Pi_M v(p) = v(p) \quad \text{for any vertex } p.$$
The corresponding finite element approximation of (2.2) is to find \((\lambda_M, u_M) \in \mathbb{R} \times V_M\) such that \(\| u_M \|_{0,\Omega} = 1\) and
\[
(2.4) \quad a_h(u_M, v_h) = \lambda_M(u_M, v_h) \quad \text{for any } v_h \in V_M,
\]
with the discrete bilinear form \(a_h(w_h, v_h) := \sum_{K \in T_h} \int_K \nabla_h^2 w_h : \nabla_h^2 v_h \, dx\). Denote the approximate solution of (2.4) by \((\lambda^{i}_M, u^{i}_M)\) with
\[
0 < \lambda^{1}_M \leq \lambda^{2}_M \leq \cdots \leq \lambda^{N}_M,
\]
where \(N = \dim V_M\) and \((u^{i}_M, \lambda^{i}_M)\) is the eigenvector of Problem (2.2) corresponding to \(\lambda\).

Let \(\lambda\) be an eigenvalue of Problem (2.2) with multiplicity \(q\) and \(M(\lambda) = \{ w \in H^2_0(\Omega) : w\) is an eigenvector of Problem (2.2) corresponding to \(\lambda\}\). Without loss of generality, we assume the index of the eigenvalue \(\lambda\) are \(k_0 + 1, \cdots, k_0 + q\), that is,
\[
\lambda^{k_0} < \lambda = \lambda^{k_0+1} = \cdots = \lambda^{k_0+q} < \lambda^{k_0+q+1}.
\]
Denote
\[
M_h(\lambda) = \text{span}\{u^{k_0+1}_M, u^{k_0+2}_M, \cdots, u^{k_0+q}_M\} \subset V_M.
\]
Suppose that \((\lambda_M, u_M)\) is the solution of Problem (2.4) by the Morley element and \(\lambda_M\) is the \(i\)-th eigenvalue, it follows from the theory of nonconforming eigenvalue approximations, see for instance, \([2, 3, 5, 16, 40]\) and the references therein, that there exists \(u \in M(\lambda)\) with \(\lambda = \lambda^i\) such that
\[
(2.5) \quad h|\lambda - \lambda_M| + h^3|u - \Pi_M u|_{L^2} + h \| u - u_M \|_{0, \Omega} + h \| \nabla_h(u - u_M) \|_{0, \Omega} + h^2 \| \nabla_h^2(u - u_M) \|_{0, \Omega} \lesssim h^3 \| u \|_{3, \Omega}.
\]
provided that the domain is convex and \(M(\lambda) \subset H^2_0(\Omega) \cap H^3(\Omega)\). Whenever there is no ambiguity, \((\lambda, u)\) defined this way is called the corresponding eigenpair to \((\lambda_M, u_M)\) of Problem (2.4) if the estimate (2.5) holds.

For the Morley element, there holds the following commuting property for the canonical interpolation
\[
(2.6) \quad \int_K \nabla^2(w - \Pi_M w) : \nabla^2 v_h \, dx = 0 \quad \text{for any } w \in V, v_h \in V_M,
\]
see \([12, 16]\) for more details. Following the analysis in \([18, 17]\), this commuting property of the Morley element guarantees the following expansion
\[
(2.7) \quad \lambda - \lambda_M = \|\nabla_h^2(u - u_M)\|_{0, \Omega}^2 - 2\lambda(u - \Pi_M u, u) + O(h^4|u|_{3, \Omega}^2).
\]
The asymptotic expansions of eigenvalues of the Morley element in this paper are based on this crucial identity (2.7).
2.3. Hellan–Herrmann–Johnson element for source problems. For any source term \( f \), consider a source problem which seeks \( u \) in \( V \) such that

\[
a(u, v) = (f, v), \quad \forall v \in V.
\]

Suppose \( S := \text{symmetric } \mathbb{R}^{2 \times 2} \). Given \( K \in \mathcal{T}_h \) and \( \tau \in H^1(K, S) \), let

\[
M_{mn}(\tau) = n^T \tau n
\]

with the unit outnormal \( n \) of \( \partial K \). Define the following two spaces

\[
S = \{ \tau \in L^2(\Omega, S) : \tau|_K \in H^1(K, S) \}, \quad \text{and } M_{nn}(\tau) \text{ is continuous across interior edges},
\]

\[
D = \{ v \in H^1_0(\Omega, \mathbb{R}) : v|_K \in H^2(K, \mathbb{R}) \}.
\]

By introducing an auxiliary variable \( \sigma := \nabla^2 u \), the mixed formulation of \( (2.8) \) seeks \((\sigma, u) \in S \times D\), see

\[
(\sigma, \tau) + \sum_{K \in \mathcal{T}_h} - (\sigma, \nabla^2 u)_{0,K} + \int_{\partial K} M_{mn}(\tau) \frac{\partial u}{\partial n} \, ds = 0, \quad \forall \tau \in S,
\]

(2.9)

\[
\sum_{K \in \mathcal{T}_h} - (\sigma, \nabla^2 u)_{0,K} + \int_{\partial K} M_{mn}(\sigma) \frac{\partial v}{\partial n} \, ds = (f, v), \quad \forall v \in D.
\]

The first order HHJ element \( [27] \) of Problem \( (2.9) \) seeks \((\sigma_{HHJ}^f, u_{HHJ}^f) \in \Sigma(T_h) \times U(T_h)\) such that

\[
(\sigma_{HHJ}^f, \tau_h) + \sum_{K \in \mathcal{T}_h} \int_{\partial K} M_{mn}(\tau_h) \frac{\partial u_{HHJ}^f}{\partial n} \, ds = 0, \quad \forall \tau_h \in \Sigma(T_h),
\]

(2.10)

\[
\sum_{K \in \mathcal{T}_h} \int_{\partial K} M_{mn}(\sigma_{HHJ}^f) \frac{\partial v_h}{\partial n} \, ds = (f, v_h), \quad \forall v_h \in U(T_h),
\]

with

\[
\Sigma(T_h) := \{ \tau \in S : \tau|_K \in P_0(K, S) \text{ for any } K \in \mathcal{T}_h \},
\]

\[
U(T_h) := \{ v \in H^1_0(\Omega, \mathbb{R}) : v|_K \in P_1(K, \mathbb{R}) \text{ for any } K \in \mathcal{T}_h \}.
\]

It follows from the theory of mixed finite element methods \( [11] \) that

\[
(2.11) \quad u - u_{HHJ}^f \|_{0,\Omega} + h \| \sigma - \sigma_{HHJ}^f \|_{0,\Omega} + h|u - u_{HHJ}^f|_{1,\Omega} \leq h^2 \| u \|_{3,\Omega},
\]

provided that \( u \in V \cap H^2(\Omega, \mathbb{R}) \). In this paper, we consider two different source terms \( f = \lambda u \) and \( f = \lambda M_{nn}u \). Let \((\sigma_{HHJ}^{1u}, u_{HHJ}^{1u}) \) and \((\sigma_{HHJ}^{2u}, u_{HHJ}^{2u}) \) be the solutions of Problem \( (2.10) \) with source terms \( f = \lambda u \) and \( f = \lambda M_{nn}u \), respectively.

Define the interpolation operator \( \Pi_{HHJ} : S \rightarrow \Sigma(T_h) \) by

\[
(2.12) \quad \int_e M_{nn}(\Pi_{HHJ}\tau) \, ds = \int_e M_{nn}(\tau) \, ds \quad \text{for any } e \in E_h, \tau \in S.
\]
There exists the following identity in [20]

\[(\sigma_{\text{HHJ}}^{\lambda u} - \Pi_{\text{HHJ}}\sigma, \sigma_{\text{HHJ}}^{\lambda u} - \sigma) = 0.\]

According to [19], the HHJ element admits an important superconvergence property on uniform triangulations.

**Lemma 2.1.** Suppose that \((\sigma_{\text{HHJ}}^{\lambda u}, u_{\text{HHJ}}^{\lambda u})\) is the solution of Problem (2.10) on a uniform triangulation with \(f = \lambda u\) and \(u \in V \cap H^2(\Omega, \mathbb{R})\). It holds that

\[\|\sigma_{\text{HHJ}}^{\lambda u} - \Pi_{\text{HHJ}}\sigma\|_{0,\Omega} \lesssim h^2 \left(|u|_{2,\Omega} + \kappa \ln h |u|_{3,\Omega}^{1/2} + |u|_{3,\Omega}^{1/2}\right).\]

**2.4. Equivalence between the HHJ element and the Morley element.**

Given \(v \in V + V_M\), define the interpolation operator \(\Pi_D : V + V_M \to U(T_h)\) by

\[\Pi_D v(p) = v(p) \quad \text{for each vertex } p \text{ of } T_h.\]

Consider the modified Morley element for two discrete source problems: one seeks \(\tilde{u}_{\lambda M}^{\lambda u} \in V_M\) such that

\[(\nabla^2 h \tilde{u}_{\lambda M}^{\lambda u}, \nabla^2 h v_h) = (\lambda u, \Pi_D v_h) \quad \text{for any } v_h \in V_M,\]

and the other one seeks \(\tilde{u}_M \in V_M\) such that

\[(\nabla^2 h \tilde{u}_M, \nabla^2 h v_h) = (\lambda_M u_M, \Pi_D v_h) \quad \text{for any } v_h \in V_M.\]

The following lemma presents the equivalence between the HHJ element and the Morley element, see more details in [1].

**Lemma 2.2.** Let \((\sigma_{\text{HHJ}}^{\lambda u}, u_{\text{HHJ}}^{\lambda u}), (\sigma_{\text{HHJ}}, u_{\text{HHJ}})\) be the solutions of Problems (2.10) with \(f = \lambda u\) and \(f = \lambda_M u_M\), respectively. \(\tilde{u}_{\lambda M}^{\lambda u} \) and \(\tilde{u}_M\) be the solutions of Problems (2.15) and (2.16), respectively. It holds that

\[\sigma_{\text{HHJ}}^{\lambda u} = \nabla^2 h \tilde{u}_{\lambda M}^{\lambda u}, \quad u_{\text{HHJ}}^{\lambda u} = \Pi_D \tilde{u}_{\lambda M}^{\lambda u},\]

\[\sigma_{\text{HHJ}} = \nabla^2 h \tilde{u}_M, \quad u_{\text{HHJ}} = \Pi_D \tilde{u}_M.\]

3. **Optimal Analysis of Extrapolation Algorithm for the Morley Element**

In this section, we consider the extrapolation algorithm on the eigenvalues of the Morley element. An asymptotic expansion of eigenvalues is established, which gives an optimal theoretical analysis of the extrapolation algorithm on the eigenvalue problem.

Given the approximate eigenvalues of Morley element on triangulations \(T_h\) and \(T_{2h}\) by \(\lambda_M^h\) and \(\lambda_M^{2h}\), respectively. The extrapolation algorithm computes a new approximate eigenvalue by

\[\lambda_M^{\text{EXP}} = \frac{2^{\alpha} \lambda_M^h - \lambda_M^{2h}}{2^\alpha - 1},\]

where \(\alpha\) is the convergence rate of the eigenvalues. In the case that the eigenfunction is smooth enough, the convergence rate of eigenvalues \(\alpha = 2\).
Suppose that eigenvalues converge with a fixed coefficient $C$ in (2.5), namely, there exists such an asymptotic expansion of eigenvalues

$$
\lambda - \lambda_M^h = Ch^\alpha + \mathcal{O}(h^\beta) \quad \text{with } \beta > \alpha,
$$

where $C$ is independent on the mesh size $h$. It is easy to verify that the extrapolation algorithm (3.1) improves the accuracy of eigenvalues to $\mathcal{O}(h^\beta)$ if the assumption (3.2) holds.

In the rest of this section, we establish an expansion in the form of (3.2) with $C$ expressed explicitly by the function $u$. We also present a detailed analysis on this asymptotic expansion with an optimal rate $\beta = 4$, which proves the efficiency of the extrapolation algorithm.

### 3.1. Error expansions for eigenvalues

The classic asymptotic analysis does not work for the Morley element because of the lack of a crucial superclose property. Inspired by [18], we use the equivalence between the mixed HHJ element and the Morley element in Lemma 2.2 and the superconvergence property of the mixed HHJ element in Lemma 2.1 to establish an asymptotic expansion of eigenvalues.

To begin with, we analyze some superclose property of the Morley element and the mixed HHJ element. Let $u_{\lambda M} \in V_M$ be the Morley solution of the following source problem

$$
(\nabla^2 u_{\lambda M}, \nabla^2 v_h) = (\lambda u, v_h) \quad \text{for any } v_h \in V_M,
$$

where $(\lambda, u)$ is an eigenpair of Problem (2.2).

**Lemma 3.1.** Suppose that $(\lambda, u)$ is an eigenpair of (2.2), $(\sigma_{HHJ}^u, u_{HHJ}^u)$ and $(\sigma_{HHJ}, u_{HHJ})$ are the solutions of Problems (2.10) with $f = \lambda u$ and $f = \lambda_M u_M$, respectively. It holds that

$$
\| \nabla^2_h(u_{\lambda M}^M - \tilde{u}_{\lambda M}^M) \|_{0, \Omega} + \| \nabla^2_h(u_M - \tilde{u}_{M}) \|_{0, \Omega} + \| \nabla^2_h(u_{\lambda M}^M - u_{M}) \|_{0, \Omega} + \| \sigma_{HHJ}^u - \sigma_{HHJ} \|_{0, \Omega} \lesssim h^2 \| u \|_{3, \Omega},
$$

provided that $u \in V \cap H^3(\Omega, \mathbb{R})$.

**Proof:** To bound $\| \nabla^2_h(u_{\lambda M}^M - \tilde{u}_{\lambda M}^M) \|_{0, \Omega}$, let $v_h = u_{\lambda M}^M - \tilde{u}_{\lambda M}^M$ in (2.15) and (3.3). It holds that

$$
\| \nabla^2_h(u_{\lambda M}^M - \tilde{u}_{\lambda M}^M) \|_{0, \Omega}^2 = (\lambda u, (I - \Pi_D)(u_{\lambda M}^M - \tilde{u}_{\lambda M}^M)) \lesssim \lambda h^2 \| \nabla^2_h(u_{\lambda M}^M - \tilde{u}_{\lambda M}^M) \|_{0, \Omega},
$$

which implies that

$$
\| \nabla^2_h(u_{\lambda M}^M - \tilde{u}_{\lambda M}^M) \|_{0, \Omega} \lesssim h^2,
$$

and completes the estimate of the first term on the left-hand side of (3.4). A similar analysis leads to the following estimate of the second term

$$
\| \nabla^2_h(u_M - \tilde{u}_{M}) \|_{0, \Omega} \lesssim h^2.
$$
For the third term $\|\nabla_h^2 (u^M - u_M)\|_{0,\Omega}$, a similar analysis to the one for Lemma 3.1 in [18] gives
\[
\|\nabla_h^2 (u^M - u_M)\|_{0,\Omega} \leq h^2 \|u\|_{3,\Omega}.
\]
Consider the last term on the left-hand side of (3.4). By the equivalence (2.17) and (2.18) between the Morley element and the HHJ element,
\[
\sigma_{HHJ}^u - \sigma_{HHJ} = \nabla_h^2 (\tilde{u}_M - \tilde{u}_M) = \nabla_h^2 (\tilde{u}_M^u - u^M + u_M^u - u_M + u_M - \tilde{u}_M).
\]
It follows that
\[
\| \sigma_{HHJ}^u - \sigma_{HHJ} \|_{0,\Omega} \leq h^2 \|u\|_{3,\Omega},
\]
which completes the proof. \hfill \Box

For simplicity of presentation, we introduce the following notations
\begin{align}
I_1 &= (\sigma - \sigma_{HHJ}^u, \sigma_{HHJ}^u - \sigma_{HHJ}), \quad I_2 = (\sigma - \sigma_{HHJ}, \nabla_h^2 (\tilde{u}_M - u_M)), \\
I_3 &= \lambda (u - \Pi Mu, u).
\end{align}

The asymptotic expansions of eigenvalues of the Morley element are based on the decomposition in the following theorem.

**Theorem 3.1.** Suppose that $(\lambda, u)$ is the solution of Problem (2.2) with $u \in V \cap H^2(\Omega, \mathbb{R})$, and $(\lambda_M, u_M)$ is the corresponding discrete eigenpair of Problem (2.4) by the Morley element. If the triangulation is uniform, it holds that
\[
\lambda - \lambda_M = \| (I - \Pi HHJ) \nabla^2 u \|_{0,\Omega}^2 + 2I_1 + 2I_2 + 2I_3 + O(h^4 \|u\|_{3,\Omega}^2),
\]
where $I_1$, $I_2$ and $I_3$ are defined in (3.5).

**Proof.** Recall the expansion (2.7) of eigenvalues of the Morley element
\[
\lambda - \lambda_M = \| \nabla_h^2 (u - u_M) \|_{0,\Omega}^2 - 2\lambda (u - \Pi Mu, u) + O(h^4 \|u\|_{3,\Omega}^2).
\]

Thanks to the equivalence $\sigma_{HHJ} = \nabla_h^2 \tilde{u}_M$ in (2.18), $\nabla^2 u - \nabla_h^2 u_M = (\nabla^2 u - \Pi HHJ \nabla^2 u) + (\Pi HHJ \nabla^2 u - \sigma_{HHJ}^u) + (\sigma_{HHJ} - \sigma_{HHJ}) + \nabla_h^2 (\tilde{u}_M - u_M),$

with the HHJ solutions $\sigma_{HHJ}^u$ and $\sigma_{HHJ}$ of the source problem (2.10) with $f = \lambda u$ and $f = \lambda_M u_M$, respectively, and the Morley solutions $u_M$ and $\tilde{u}_M$ of the eigenvalue problem (2.4) and the modified problem (2.16), respectively. It holds that
\begin{align}
\lambda - \lambda_M &= \| (I - \Pi HHJ) \sigma \|_{0,\Omega}^2 + \| \Pi HHJ \sigma - \sigma_{HHJ}^u \|_{0,\Omega}^2 + \| \sigma_{HHJ}^u - \sigma_{HHJ} \|_{0,\Omega}^2 \\
&+ \| \nabla_h^2 (\tilde{u}_M - u_M) \|_{0,\Omega}^2 + 2(\sigma - \Pi HHJ \sigma, \Pi HHJ \sigma - \sigma_{HHJ}^u) \\
&+ 2(\sigma - \Pi HHJ \sigma, \sigma_{HHJ} - \sigma_{HHJ}) + 2(\sigma - \Pi HHJ \sigma, \nabla_h^2 (\tilde{u}_M - u_M)) \\
&+ 2(\Pi HHJ \sigma - \sigma_{HHJ}^u, \sigma_{HHJ} - \sigma_{HHJ}) + 2(\Pi HHJ \sigma - \sigma_{HHJ}^u, \nabla_h^2 (\tilde{u}_M - u_M)) \\
&+ 2(\sigma_{HHJ} - \sigma_{HHJ}, \nabla_h^2 (\tilde{u}_M - u_M)) - 2\lambda (u - \Pi Mu, u) + O(h^4 \|u\|_{3,\Omega}^2).
\end{align}
Recall the superconvergence (2.14) of the HHJ element in Lemma 2.1 and the superclose property (3.4) of both the Morley element and the HHJ element. Then,
\[ (3.9) \]
\[ \| \Pi_{HHJ} \sigma - \sigma_{HHJ}^{\lambda u} \|_{0, \Omega}^2 + \| \sigma_{HHJ}^{\lambda u} - \sigma_{HHJ} \|_{0, \Omega}^2 + \| V_h^2 (u_M - \tilde{u}_M) \|_{0, \Omega}^2 \]
\[ + 2 (\Pi_{HHJ} \sigma - \sigma_{HHJ}^{\lambda u}, \sigma_{HHJ}^{\lambda u} - \sigma_{HHJ}) + 2 (\Pi_{HHJ} \sigma - \sigma_{HHJ}^{\lambda u}, V_h^2 (\tilde{u}_M - u_M)) + 2 (\sigma_{HHJ}^{\lambda u} - \sigma_{HHJ}, V_h^2 (\tilde{u}_M - u_M)) \lesssim h^4 \ln h \| u \|_{\frac{2}{3}, \Omega}^2. \]

A combination of (2.13) and the superconvergence property (2.14) of the HHJ element yields
\[ (3.10) \]
\[ \left| (\sigma - \Pi_{HHJ} \sigma, \Pi_{HHJ} \sigma - \sigma_{HHJ}^{\lambda u}) \right| = \left| (\sigma_{HHJ}^{\lambda u} - \Pi_{HHJ} \sigma, \Pi_{HHJ} \sigma - \sigma_{HHJ}^{\lambda u}) \right| \lesssim h^4 \ln h \| u \|_{\frac{2}{3}, \Omega}^2. \]

A substitution of (3.9) and (3.10) into (3.8) leads to
\[ \lambda - \lambda_M = \| (I - \Pi_{HHJ}) V^2 u \|_{0, \Omega}^2 + 2 I_1 + 2 I_2 - 2 I_3 + O(h^4 \ln h \| u \|_{\frac{2}{3}, \Omega}^2), \]
which completes the proof. \( \square \)

In the rest of this section, we will conduct an asymptotic analysis of each term on the right hand side of the expansion (3.6) in the above theorem.

3.2. Asymptotic expansion of \( \| (I - \Pi_{HHJ}) V^2 u \|_{0, \Omega}^2 \). Define the three basis functions for the HHJ element
\[ \phi_{HHJ}^i(x) = - \frac{1}{2 \sin \theta_{i-1} \sin \theta_{i+1}} (t_{i-1} t_{i+1}^T + t_{i+1} t_{i-1}^T) \in P_0(K, S), \quad 1 \leq i \leq 3. \]

By (2.1), it is easy to verify that
\[ (3.11) \]
\[ \frac{1}{|e_i|} \int_{e_i} n_j^T \phi_{HHJ}^i n_j \, ds = \delta_{ij}. \]

Define four short-hand notations for the HHJ element
\[ (3.12) \]
\[ \phi_1(x) = \frac{1}{6|K|^{1/2}} (x_1 - M_1)^3, \quad \phi_2(x) = \frac{1}{2|K|^{1/2}} (x_1 - M_1)(x_2 - M_2), \]
\[ \phi_3(x) = \frac{1}{2|K|^{1/2}} (x_1 - M_1) x_2 - M_2)^2, \quad \phi_4(x) = \frac{1}{6|K|^{1/2}} (x_2 - M_2)^3. \]

Note that \( \{ \phi_i \}_{i=1}^4 \) are linear independent and
\[ (3.13) \]
\[ P_3(K, R) = P_2(K, R) \cup \text{span} \{ \phi_i : 1 \leq i \leq 4 \}, \]
\[ (3.14) \| \partial_{111} \phi_i \|_{0, K} = \delta_{11}, \| \partial_{112} \phi_i \|_{0, K} = \delta_{21}, \| \partial_{122} \phi_i \|_{0, K} = \delta_{22}, \| \partial_{222} \phi_i \|_{0, K} = \delta_{44}. \]

Define
\[ (3.15) \]
\[ \gamma_{HHJ}^{ij} = \frac{1}{|K|} \int_K ((I - \Pi_{HHJ}) V^2 \phi_i)^T (I - \Pi_{HHJ}) V^2 \phi_j \, dx, \quad 1 \leq i, j \leq 4. \]
**Lemma 3.2.** Constants $\gamma_{12}$ in (3.15) are the same on different elements of a uniform triangulation and independent of the mesh size $h$.

**Proof.** By the definition of $\Pi_{HHJ}$ and (3.11),

$$\Pi_{HHJ}V^2\phi_i = \sum_{j=1}^{3} a_{HHJ}^{ij} \phi_{HHJ}^{i}$$

with $a_{HHJ}^{ij} = \frac{1}{|e_j|} \int_{e_j} n_j^T V^2 \phi_i n_j ds$. Since $V^2 \phi_1 \in P_1(K,S)$,

$$a_{HHJ}^{ij} = n_j^T V^2 \phi_1(m_j) n_j = \frac{1}{|K|^{1/2}} n_j^T \left( 0 \right) n_j$$

is constant independent of the mesh size $h$, where $m_j = (m_{j1}, m_{j2})$ is the midpoint of edge $e_j$. Similarly, for any $1 \leq i \leq 4$ and $1 \leq j \leq 3$, constant $a_{HHJ}^{ij}$ is independent on the mesh size $h$. It follows from (3.15) and (3.16) that

$$\gamma_{12}^{ij} = \frac{1}{|K|} (V^2 \phi_i, V^2 \phi_i)_{0,K} - \frac{1}{|K|} \sum_{k=1}^{3} (\phi_{HHJ}^{k}, a_{HHJ}^{ik} V^2 \phi_j + a_{HHJ}^{jk} V^2 \phi_i)_{0,K}$$

$$+ \frac{1}{|K|} \sum_{k,l=1}^{3} a_{HHJ}^{ik} a_{HHJ}^{jl} (\phi_{HHJ}^{k}, \phi_{HHJ}^{l})_{0,K}.$$  

By the definition of $\phi_i \in P_3(K,R)$ and $\phi_{HHJ}^{i} \in P_0(K,R)$, each entry of $V^2 \phi_i$ is a linear combination of $x_1 - M_1$ and $x_2 - M_2$. Thus,

$$(\phi_{HHJ}^{i}, V^2 \phi_i)_{0,K} = 0, \quad \forall 1 \leq i \leq 4, \; 1 \leq k \leq 3.$$  

As the triangulation is uniform,

$$\frac{1}{|K|} (V^2 \phi_i, V^2 \phi_i)_{0,K}, \quad \frac{1}{|K|} (\phi_{HHJ}^{i}, \phi_{HHJ}^{i})_{0,K}$$

are constant independent of $h$ for any $1 \leq i, j \leq 4$. Thus, it follows from (3.17) that constants $\gamma_{12}^{ij}$ in (3.15) are the same on different elements and independent of mesh size $h$, which completes the proof. \qed

For any region $G$, define

$$F(u, G) = \gamma_{11}^{11} \| \partial_{111} u \|_{0,G}^2 + \gamma_{12}^{22} \| \partial_{112} u \|_{0,G}^2 + \gamma_{13}^{33} \| \partial_{113} u \|_{0,G}^2 + \gamma_{22}^{44} \| \partial_{122} u \|_{0,G}^2$$

$$+ 2\gamma_{11}^{12} \int_G \partial_{111} u \partial_{112} u dx + 2\gamma_{12}^{13} \int_G \partial_{112} u \partial_{113} u dx + 2\gamma_{12}^{14} \int_G \partial_{112} u \partial_{122} u dx$$

$$+ 2\gamma_{12}^{23} \int_G \partial_{112} u \partial_{122} u dx + 2\gamma_{12}^{24} \int_G \partial_{112} u \partial_{222} u dx + 2\gamma_{12}^{34} \int_G \partial_{122} u \partial_{222} u dx.$$  

The following lemma presents the Taylor expansion of the interpolation error of the HHJ element.
Lemma 3.3. For any \( w \in P_3(K, \mathbb{R}) \),

\[
(3.19) \quad \| (I - \Pi_{\text{HHJ}}) \nabla^2 w \|_{0,K}^2 = F(w, K)|K|.
\]

Proof. For any \( w \in P_3(K, \mathbb{R}) \), it follows from (3.13) and (3.14) that there exist \( p_2 \in P_2(K, \mathbb{R}) \) and \( \{a_i\}_{i=1}^4 \) such that

\[
(3.20) \quad w = \sum_{i=1}^{4} a_i \phi_i + p_2, \quad (I - \Pi_{\text{HHJ}}) \nabla^2 w = \sum_{i=1}^{4} a_i (I - \Pi_{\text{HHJ}}) \nabla^2 \phi_i,
\]

where

\[
(3.21) \quad a_1 = |K|^{1/2} \partial_{111} w, \quad a_2 = |K|^{1/2} \partial_{112} w, \quad a_3 = |K|^{1/2} \partial_{122} w, \quad a_4 = |K|^{1/2} \partial_{222} w.
\]

A combination of (3.15) to (3.20) leads to

\[
(3.22) \quad \| (I - \Pi_{\text{HHJ}}) \nabla^2 w \|_{0,K}^2 = \sum_{i,j=1}^{4} a_i a_j \gamma_{\text{HHJ}}^{ij} |K| = F(w, K)|K|,
\]

which completes the proof. \( \Box \)

Lemma 3.3 indicates that \( F(u, \Omega) \) is an expansion of \( \|(I - \Pi_{\text{HHJ}}) \nabla^2 u\|_{0,\Omega}^2 \) with the accuracy \( O(h^3) \). Next we improve this estimate to an optimal rate \( O(h^4) \). Define the interpolation \( \Pi_l^iv \in P_l(K, \mathbb{R}) \) in [23] for each positive integer \( l \) by

\[
(3.23) \quad \int_K D^\alpha \Pi_l^iv dx = \int_K D^\alpha v dx \quad \text{with} \quad |\alpha| \leq l,
\]

Let \( \Pi_l^iv|_K = \Pi_l^iv|K \). There exists the following error estimate of the interpolation error

\[
(3.24) \quad \| (I - \Pi_l^iv)|_{m,K} \leq h^{l-m+1} |v|_{m+1,K}, \quad \forall \ 0 \leq m \leq l + 1.
\]

Note that

\[
(3.25) \quad \| (I - \Pi_{\text{HHJ}}) \nabla^2 u\|_{0,K}^2 = \| (I - \Pi_{\text{HHJ}}) \nabla^2 \Pi_l^iv|_K \|_{0,K}^2 + \| (I - \Pi_{\text{HHJ}}) \nabla^2 (I - \Pi_l^iv)|_K \|_{0,K}^2
\]

\[+ 2(I - \Pi_{\text{HHJ}}) \nabla^2 (I - \Pi_l^iv)|_K \nabla^2 \Pi_l^iv|_K, (I - \Pi_{\text{HHJ}}) \nabla^2 \Pi_l^iv|_K, \]

where the second term on the right hand side is a higher order term. Thus, the key to prove the optimal estimate of \( \| (I - \Pi_{\text{HHJ}}) \nabla^2 u\|_{0,K}^2 \) is to prove a nearly orthogonal property of the cross term \( (I - \Pi_{\text{HHJ}}) \nabla^2 (I - \Pi_l^iv)|_K \nabla^2 \Pi_l^iv|_K \). To this end, define a set of polynomials

\[
(3.26) \quad \phi_0 = 1, \quad \phi_1(x) = x_1 - M_1, \quad \phi_2(x) = x_2 - M_2,
\]

\[
\phi_\alpha = \frac{1}{\alpha!}(x - M_K)^\alpha - \sum_{|\beta| < |\alpha|} C_\alpha^\beta \phi_\beta, \quad \text{for} \quad |\alpha| > 1,
\]

with constant

\[
(3.27) \quad C_\alpha^\beta = \frac{1}{\alpha!|K|} \int_K D^\beta (x - M_K)^\alpha dx.
\]
For any $|\alpha| = k$, $\phi_\alpha \in P_k(K, \mathbb{R})$ and it is the first term $\frac{1}{\alpha!}(x - M_K)^\alpha$ that determines the $k$-th derivatives of $\phi_\alpha$.

The following lemma gives an explicit expression of the interpolation $\Pi_K^l u$ with an important property $C^\beta_\alpha = 0$ for any $|\beta| = |\alpha| - 1$.

**Lemma 3.4.** For any nonnegative integer $l$ and $u \in H^l(K, \mathbb{R})$,

\begin{equation}
\Pi_K^l u = \sum_{|\alpha| \leq l} a^K_\alpha \phi_\alpha \quad \text{with} \quad a^K_\alpha = \frac{1}{|K|} \int_K D^\alpha u \, dx,
\end{equation}

and

\begin{equation}
\Pi_K^l u = \sum_{|\alpha| \leq l - 1} a^K_\alpha \phi_\alpha + \sum_{|\alpha| = l} a^K_\alpha \left( \frac{1}{\alpha!} (x - M_K)^\alpha - \sum_{|\beta| \leq l - 2} C^\beta_\alpha \phi_\beta \right),
\end{equation}

**Proof.** First we prove that basis functions $\phi_\alpha$ in (3.26) satisfy that

\begin{equation}
\frac{1}{|K|} \int_K D^\gamma \phi_\alpha \, dx = \delta_{\alpha\gamma} := \begin{cases} 1 & \alpha = \gamma \\ 0 & \alpha \neq \gamma \end{cases}
\end{equation}

by induction. It is obvious that $\phi_\alpha$ with $|\alpha| \leq 1$ satisfies (3.30). Suppose that (3.30) holds for any $\phi_\alpha$ with $|\alpha| \leq k$, consider $\phi_\alpha$ with $|\alpha| = k + 1$.

If $|\gamma| < k + 1$, a combination of (3.26), (3.27) and (3.30) gives

\begin{equation}
\frac{1}{|K|} \int_K D^\gamma \phi_\alpha \, dx = \frac{1}{\alpha!|K|} \int_K D^\gamma (x - M_K)^\alpha \, dx - C^\gamma_\alpha = 0.
\end{equation}

If $|\gamma| = k + 1$ and $\gamma \neq \alpha$, there must exist $i \in \{1, 2\}$ such that $\gamma_i > \alpha_i$, which implies that

$$\partial_i^{\gamma_i}(x_i - M_i)^{\alpha_i} = 0.$$ 

Consequently,

\begin{equation}
D^\gamma \phi_\alpha = \partial_1^{\gamma_1}(x_1 - M_1)^{\alpha_1} \partial_2^{\gamma_2}(x_2 - M_2)^{\alpha_2} = 0.
\end{equation}

Since $\phi_\beta \in P_{|\beta|}(K, \mathbb{R})$,

\begin{equation}
D^\gamma \phi_\beta = 0, \quad \text{if} \quad |\gamma| > |\beta|.
\end{equation}

A combination of (3.26), (3.32) and (3.33) gives

$$\int_K D^\gamma \phi_\alpha \, dx = 0, \quad \text{if} \quad |\gamma| = k + 1 \text{ and } \gamma \neq \alpha.$$ 

If $\gamma = \alpha$, by the definition (3.26), a direct computation yields

$$\frac{1}{|K|} \int_K D^\gamma \phi_\alpha \, dx = 1.$$ 

Since $\phi_\alpha \in P_{k+1}(K, \mathbb{R})$, it is trivial that $D^\gamma \phi_\alpha = 0$ for any $|\gamma| > k + 1$. A combination of all the results above leads to (3.30) for $|\alpha| = k + 1$, which completes the prove for (3.30). A combination of the definition of $\Pi_K^l$ in (3.23) and (3.30) gives (3.28) directly.
Note that $\int_K x - M_K \, dx = 0$ and
\[
D^\beta(x - M_K)^\alpha = c_1(x_1 - M_1) + c_2(x_2 - M_2), \quad \forall |\beta| = |\alpha| - 1.
\]

It follows from this fact and (3.27) that $C^\beta_\alpha = 0$. This, together with (3.26) and (3.28), completes the proof for (3.29). \hfill $\Box$

**Lemma 3.5.** It holds on uniform triangulations that
\[
|((I - \Pi_{HHJ})\nabla_h^2 \Pi^3_h u, (I - \Pi_{HHJ})\nabla_h^2 (I - \Pi^3_h u))| \lesssim h^4 |u|_{5,\Omega}^2
\]
provided $u \in H^5(\Omega, \mathbb{R})$.

**Proof.** The partition $\mathcal{T}_h$ of domain $\Omega$ includes the set of parallelograms $\mathcal{N}_1$ and the set of a few remaining boundary triangles $\mathcal{N}_2$, see Figure 2, for example. Let $\kappa = |\mathcal{N}_2|$ denote the number of the elements in $\mathcal{N}_2$. It holds

![Figure 2. A uniform triangulation of $\Omega$.](image)

that
\begin{equation}
(I - \Pi_{HHJ})\nabla_h^2 \Pi^3_h u, (I - \Pi_{HHJ})\nabla_h^2 (I - \Pi^3_h u) = I_{\mathcal{N}_1} + I_{\mathcal{N}_2}
\end{equation}

with $I_{\mathcal{N}_i} = \sum_{K \in \mathcal{N}_i} ((I - \Pi_{HHJ})\nabla_h^2 \Pi^3_h u, (I - \Pi_{HHJ})\nabla_h^2 (I - \Pi^3_h u))_{0,K}$.

It follows from the estimate (3.24) that
\begin{equation}
(I - \Pi_{HHJ})\nabla_h^2 \Pi^3_h u, (I - \Pi_{HHJ})\nabla_h^2 (I - \Pi^3_h u)_{0,K} = ((I - \Pi_{HHJ})\nabla_h^2 \Pi^3_h u, (I - \Pi_{HHJ})\nabla_h^2 (I - \Pi^3_h u))_{0,K} + O(h^4 |u|_{5,\Omega}^2).
\end{equation}

Consider the expansion of $(I - \Pi^3_h)\Pi^4_K u$. Let $l = 4$ in (3.29). It holds that
\[
(I - \Pi^3_h)\Pi^4_K u |_K = \sum_{|\alpha| = 4} a^3_K \frac{1}{\alpha!} (x - M_K)^\alpha - \sum_{|\beta| = 2} C^\beta_\alpha \phi_\beta.
\]

This implies that $(I - \Pi^3_h)\Pi^4_K u$ does not include any homogeneous third order terms. These vanishing homogeneous third order terms are crucial for the analysis here. By the definition of the interpolation $\Pi_{HHJ}$ and the fact that $\nabla^2 \phi_\beta$ is constant if $|\beta| = 2$,
\[
(I - \Pi_{HHJ})\nabla^2 (I - \Pi^3_h)\Pi^4_K u |_K = \sum_{|\alpha| = 4} a^3_K \frac{1}{\alpha!} (I - \Pi_{HHJ})\nabla^2 (x - M_K)^\alpha.
\]
Similarly, \((I - \Pi_{HHJ})V^2 \Pi_{K}^3 u|_K = \sum_{|\alpha|=3} a_{K}^{\alpha} \chi_{\alpha} (I - \Pi_{HHJ})V^2 (x - M_{K})^{\beta}\). Thus, by (3.35),

\[(3.36)\]

\[((I - \Pi_{HHJ})V^2 \Pi_{K}^3 u, (I - \Pi_{HHJ})V^2 (I - \Pi_{K}^3) u)_{0,K} = \sum_{|\alpha|=4} \sum_{|\beta|=3} \frac{a_{K}^{\alpha} d_{K}^{\beta}}{\alpha! \beta!} c_{K}^{\alpha \beta} + O(h^4 \|u\|^2_{2,K}),\]

with

\[c_{K}^{\alpha \beta} := \left( (I - \Pi_{HHJ})V^2 (x - M_{K})^{\beta}, (I - \Pi_{HHJ})V^2 (x - M_{K})^{\alpha} \right)_{0,K}.\]

Consider \(I_{K_{1}}\) in (3.34). Let \(c\) be the centroid of a parallelogram formed by two adjacent elements \(K_{1}\) and \(K_{2}\). Define a mapping \(T : x \rightarrow \tilde{x} = 2c - x\). It is obvious that \(T\) maps \(K_{1}\) onto \(K_{2}\) and

\[x - M_{K_{1}} = -(\tilde{x} - M_{K_{2}}).\]

Note that for any \(|\alpha| = 4\) and \(|\beta| = 3\), \(V^2(x - M_{K})^{\alpha}\) and \(V^2(x - M_{K})^{\beta}\) are homogeneous polynomials of \(x_{1} - M_{1}\) and \(x_{2} - M_{2}\) with degree 2 and 1, respectively. Thus, for any adjacent elements \(K_{1}\) and \(K_{2}\) form a parallelogram,

\[c_{K_{1}}^{\alpha \beta} = -c_{K_{2}}^{\alpha \beta}.\]

It follows that

\[(3.37)\]

\[((I - \Pi_{HHJ})V^2 \Pi_{K}^3 u, (I - \Pi_{HHJ})V^2 (I - \Pi_{K}^3) u)_{0,K_{1} \cup K_{2}} = \sum_{|\alpha|=4} \sum_{|\beta|=3} \frac{1}{\alpha! \beta!} (a_{K_{1}}^{\alpha} a_{K_{2}}^{\alpha} - a_{K_{2}}^{\alpha} a_{K_{1}}^{\alpha}) c_{K_{1}}^{\alpha \beta} + O(h^4 \|u\|^2_{5,\Omega})\]

Recall \(a_{K_{1}}^{\alpha} = \frac{1}{|K_{1}|} \int_{K_{1}} D^\alpha v dx\) in (3.28). Note that for all \(v \in P_{4}(K_{1} \cup K_{2})\), we have

\[
\frac{1}{|K_{1}|} \int_{K_{1}} D^\alpha v dx - \frac{1}{|K_{2}|} \int_{K_{2}} D^\alpha v dx = 0.
\]

The Bramble-Hilbert Lemma leads that

\[
\frac{1}{|K_{1}|} \int_{K_{1}} D^\alpha v dx - \frac{1}{|K_{2}|} \int_{K_{2}} D^\alpha v dx \leq |u|_{5,K_{1} \cup K_{2}}.
\]

A similar analysis for \(|\beta| = 3\) gives

\[(3.38)\]

\[|a_{K_{1}}^{\alpha} - a_{K_{2}}^{\alpha}| + |a_{K_{1}}^{\alpha} - a_{K_{2}}^{\alpha}| \leq |u|_{5,K_{1} \cup K_{2}}.\]

Note that

\[(3.39)\]

\[|c_{K_{1}}^{\alpha \beta}| \leq h^2 \|V^3(x - M_{K})^{\beta}\|_{0,K_{1}} \|V^3(x - M_{K})^{\alpha}\|_{0,K_{1}} \leq h^3 \|K_{1}| \text{ for } |\alpha| = 4, |\beta| = 3.\]
A substitution of (3.38) and (3.39) into (3.37) leads to
\[ I_{N_1} \lesssim \sum_{K \in N_1} h^4 \|u\|_{5,K}^2 |K|^2 + O(h^4 \|u\|_{5,\Omega}^2) \]
(3.40)
\[ \leq h^4 \left( \sum_{K \in N_1} \|u\|_{5,K}^2 \right)^{1/2} \left( \sum_{K \in N_1} |K| \right)^{1/2} + O(h^4 \|u\|_{5,\Omega}^2) \lesssim h^4 \|u\|_{5,\Omega}^2. \]

For any element $K \in N_2$, it follows from (3.36) and (3.39) that
\[ \left| (I - \Pi_{HHJ}) \nabla^2 \Pi_3^h u, (I - \Pi_{HHJ}) \nabla^2 (I - \Pi_3^h u) \right| \lesssim h^3 |K|. \]
Since $\sum_{K \in N_2} |K| \leq h$, it follows that
\[ I_{N_2} \lesssim h^4 \|u\|_{5,\Omega}^2. \]
A substitution of (3.40) and (3.41) into (3.34) leads to
\[ \left| (I - \Pi_{HHJ}) \nabla^2 \Pi_3^h u, (I - \Pi_{HHJ}) \nabla^2 (I - \Pi_3^h u) \right| \lesssim h^4 \|u\|_{5,\Omega}^2. \]
which completes the proof. \qed

Thanks to Lemmas 3.2, 3.3 and 3.5, there exists the following fourth-order accurate expansion of $\| (I - \Pi_{HHJ}) \nabla^2 u \|_{0,\Omega}^2$ in Theorem 3.1.

Lemma 3.6. For any $u \in V \cap H^3(\Omega, \mathbb{R})$,
\[ \| (I - \Pi_{HHJ}) \nabla^2 u \|_{0,\Omega}^2 = \frac{1}{N} F(u, \Omega) |\Omega| + O(h^4 \|u\|_{5,\Omega}^2), \]
where $F(u, \Omega)$ in (3.18) is independent of the mesh size $h$ and $N$ is the number of elements.

3.3. Error estimate of $I_1 = (\sigma - \sigma_{HHJ}^{\lambda} u, \sigma_{HHJ}^{\lambda} u - \sigma_{HHJ})$. The first order term $\sigma - \sigma_{HHJ}^{\lambda} u$ leads to a suboptimal result of $I_1$ if the Cauchy-Schwarz inequality is applied directly. To prove an optimal error estimate, we employ the commuting property of the interpolation of the Morley element and the equivalence between the HHJ element and the Morley element. This allows to express $I_1$ in terms of the error of $u_{HHJ}$ with a second order accuracy, which leads to the desired optimal estimate.

Lemma 3.7. Suppose that $(\lambda, u)$ is the solution of Problem (2.2) and $u \in V \cap H^3(\Omega, \mathbb{R})$. It holds that
\[ |I_1| \lesssim h^4 \|u\|_{5,\Omega}^2. \]
Proof. By the equivalence (2.17) and (2.18) between the HHJ element and the Morley element,
\[ (\sigma - \sigma_{HHJ}^{\lambda} u, \sigma_{HHJ}^{\lambda} u - \sigma_{HHJ}) = (\nabla_h^2(u - \tilde{u}_M^{\lambda} u), \nabla_h^2 (\tilde{u}_M^{\lambda} u - \tilde{u}_M)). \]
Since $\tilde{u}_M^{\lambda} u - \tilde{u}_M \in V_M$, the commuting property (2.6) of the Morley element leads to
\[ (\nabla_h^2(u - \tilde{u}_M^{\lambda} u), \nabla_h^2 (\tilde{u}_M^{\lambda} u - \tilde{u}_M)) = (\nabla_h^2 (M - \tilde{u}_M^{\lambda} u), \nabla_h^2 (\tilde{u}_M^{\lambda} u - \tilde{u}_M)). \]
Recall that \( \tilde{\tilde{\tilde{w}}}_M^{\lambda u} \) and \( \tilde{w}_M \) are the solutions of Problems (2.15) and (2.16), respectively. It follows that

\[
\| \Pi_D (\Pi_M u - \tilde{w}_M^{\lambda u}) \|_{0, \Omega} = \| \Pi_D (\Pi_M u - \tilde{w}_M^{\lambda u}) \|_{0, \Omega} \leq h^2 \| u \|_{3, \Omega}
\]

Thanks to the error estimate (2.5) of the Morley element and (2.11) of the HHJ element, the equivalence (2.17) between the Morley element and the HHJ element, and the triangle inequality,

\[
\| \Pi_D (\Pi_M u - \tilde{w}_M^{\lambda u}) \|_{0, \Omega} \leq \| \Pi_D (\Pi_M u - u) \|_{0, \Omega} + \| u - u_{\text{HHJ}}^{\lambda u} \|_{0, \Omega} \leq h^2 \| u \|_{3, \Omega}
\]

A combination of (2.5), (3.43), (3.44), (3.45) and (3.46) gives

\[
| \sigma - \sigma_{\text{HHJ}}^{\lambda u} | \leq h^2 (\| u \|_{3, \Omega} + \| \lambda - \lambda_{\text{HHJ}} \|_{3, \Omega} \| u \|_{3, \Omega} \leq h^4 \| u \|_{3, \Omega}^2
\]

which completes the proof.

\[\Box\]

3.4. **Error estimate of** \( I_2 = (\lambda - \sigma_{\text{HHJ}}^{\lambda u}, \nabla_h^2 (\tilde{u}_M - u_M)) \). This term is essentially a consistency error term of the Morley element with third order accuracy by a direct use of the Cauchy-Schwarz inequality. The main idea here is to employ the equivalence between the HHJ element and the Morley element and make use of the weak continuity of solutions in \( V_M \).

**Lemma 3.8.** Suppose that \( (\lambda, u) \) is the solution of Problem (2.2) and \( u \in V \cap H^3(\Omega, \mathbb{R}) \). It holds that

\[ |I_2| \leq h^4 \| u \|_{3, \Omega} \]

**Proof.** By the equivalence (2.18) between the HHJ element and the Morley element and the superclose property in Lemma 3.1,

\[ I_2 = (\nabla^2 (u - \tilde{w}_M), \nabla^2_h (\tilde{u}_M - u_M)) = (\nabla^2 (u - u_M), \nabla^2_h (\tilde{u}_M - u_M)) + O(h^4 \| u \|_{3, \Omega}^2) \]

By Problems (2.4) and (2.16),

\[ (\nabla^2 (\Pi_M u - \tilde{u}_M), \nabla^2_h (\tilde{u}_M - u_M)) = \lambda_M u_M, (I - \Pi_D) s_h \]

with \( s_h = \Pi_M u - u_M \). Note that

\[ \lambda_M u_M, (I - \Pi_D) s_h = (\lambda \Pi^0_h u, (I - \Pi_D) s_h) + (\lambda_M u_M - \lambda \Pi^0_h u, (I - \Pi_D) s_h) \]

It follows from the triangle inequality and the error estimates (2.5), (3.4) that

\[ |(\lambda_M u_M - \lambda \Pi^0_h u, (I - \Pi_D) s_h)| \leq h^4 \| u \|_{3, \Omega} \]

According to the expansion of the interpolation error in [25] for the linear element,

\[ (\lambda \Pi^0_h u, (I - \Pi_D) s_h) = -\frac{1}{2} \sum_{i=1}^{3} \frac{\partial^2 s_h}{\partial^2 t_i} \psi_{i-1} \psi_{i+1} |\epsilon_i|^2, \lambda \Pi^0_h u) = -\frac{\lambda}{24} \sum_{i=1}^{3} |\epsilon_i|^2 \left( \frac{\partial^2 s_h}{\partial^2 t_i}, \Pi^0_h u \right) \]
where $\psi_i$ are the barycentric coordinates. Integration by parts indicates that

\begin{equation}
(3.51) \quad \int_K \frac{\partial^2 s_h}{\partial t_i^2} \Pi_h^0 u \, dx = \int_{\partial K} \frac{\partial s_h}{\partial t_i} \Pi_h^0 u (n \cdot t_i) \, ds.
\end{equation}

As $s_h \in V_M$, it holds that

$$\int_c [\nabla s_h] \, ds = 0.$$ 

Note that $t_e$ is the unit tangent vector of edge $e$ with the same direction on two adjacent elements sharing the edge $e$, and $t_i$ is the one in an element with counterclockwise orientation. Since $n \cdot t_i$ is the same on two adjacent elements, it follows (2.5) that

$$\sum_{t \in T_h} \int_{|e|} |e| \frac{\partial s_h}{\partial t_i} \Pi_h^0 u (n \cdot t_i) \, ds = \sum_{t \in T_h} (n \cdot t_i) |e| \int_e \frac{\partial s_h}{\partial t_i} [(\Pi_h^0 - \Pi_h^0)u] \, ds \leq h^2 |s_h|_{1,h} ||u||_{1,\Omega} \lesssim h^4 ||u||^2_{5,\Omega}.$$ 

By the commuting property of the interpolation $\Pi_M$ in (2.6), a substitution of (3.48), (3.49), (3.50), (3.51) and (3.52) into (3.47) gives

$$|I_2| \lesssim h^4 ||u||^2_{5,\Omega},$$

which completes the proof. \qed

3.5. Error estimate of $I_3 = \lambda(u - \Pi_M u, u)$. This interpolation term $I_3$ can not be cancelled with other terms as the analysis in [18] for the Crouzeix-Raviart element. The key here to obtain an optimal estimate is to exploit the Taylor expansion of $(I - \Pi_M)u$ and make full use of the uniform triangulations.

Define

\begin{equation}
(3.53) \quad \phi^i_M = \psi_{i-1}^2 \psi_{i+1}, \quad \phi^4_M = \psi_1 \psi_2 \psi_3, \quad 1 \leq i \leq 3
\end{equation}

with the barycentric coordinates $\{\psi_i\}_{i=1}^3$. For two adjacent elements $K_1$ and $K_2$ forming a parallelogram, let the local index of vertices satisfy $\nabla \psi_i|_{K_2} = - \nabla \psi_i|_{K_1}, \quad i = 1, 2, 3$. By (2.1), there exist the following properties of these cubic polynomials

\begin{equation}
(3.54) \quad \frac{\partial^3 \phi^i_M}{\partial t_j^3} = -\frac{2}{|e_j|^3} \delta_{ij}, \quad \frac{\partial^3 \phi^4_M}{\partial t_{j-1}^2 \partial t_{j+1}} = \frac{2}{|e_{j+1}| |e_{j-1}|^2}, \quad 1 \leq i \leq 4, \quad 1 \leq j \leq 3,
\end{equation}

\begin{equation}
(3.54) \quad \frac{\partial^3 \phi^i_M}{\partial t_{j-1}^2 \partial t_{j+1}} = \left\{ \begin{array}{ll}
-\frac{2}{|e_{j+1}| |e_{j-1}|^2} & \text{if } i = j + 1 \\
0 & \text{if } i = j \\
\frac{2}{|e_{j+1}| |e_{j-1}|^2} & \text{if } i = j - 1
\end{array} \right., \quad 1 \leq i, j \leq 3.
\end{equation}

Note that

\begin{equation}
(3.55) \quad P_3(K, \mathbb{R}) = P_2(K, \mathbb{R}) + \text{span} \{\phi^i_M, \quad 1 \leq i \leq 4\}.
\end{equation}
For $1 \leq i \leq 3$, $\psi_i^2 \psi_{i-1} = \phi_{M}^{i+1}$ and

$$\psi_i^3 = -\phi_{M}^{i+1} + \phi_{M}^{i+1} + \phi_{M}^{4} - \psi_{i} \psi_{i+1} + \psi_{i}^2,$$

$$\psi_i^4 \psi_{i+1} = -\phi_{M}^{i+1} - \phi_{M}^{4} + \psi_{i} \psi_{i+1}.$$

**Lemma 3.9.** For any $w \in P_3(K, \mathbb{R})$,

$$(I - \Pi_M) \Pi_h^2 w = \sum_{i=1}^{4} c_i (I - \Pi_M) \phi_i^j,$$

with

$$c_j = \frac{|e_j|^3}{2} \sum_{j=1}^{3} \frac{\partial^3 w}{\partial t_j^3}, \quad 1 \leq j \leq 3,$$

$$(3.57)$$

$$c_4 = \frac{|e_{j+1}|^2}{2} \sum_{j=1}^{3} \frac{\partial^3 w}{\partial t_j^3 \partial t_{j+1}} - \frac{|e_{j+1}|^3}{2} \sum_{j=1}^{3} \frac{\partial^3 w}{\partial t_j^3 \partial t_{j+1}} + \frac{|e_{j-1}|^3}{2} \sum_{j=1}^{3} \frac{\partial^3 w}{\partial t_j^3 \partial t_{j+1}}.$$

**Proof.** By (3.55), there exists $c_i$ and $p_2 \in P_2(K, \mathbb{R})$ such that

$$(3.58)$$

$$\Pi_h^2 w = \sum_{i=1}^{4} c_i \phi_i^j + p_2.$$  

It implies that (3.56) with coefficients $c_i$ to be determined. Taking third derivatives on both sides of (3.58), it follows from (3.54) that

$$\frac{\partial^3 \Pi_h^2 w}{\partial t_j^3} = \frac{2}{|e_j|^3} c_j, \quad \frac{\partial^3 \Pi_h^2 w}{\partial t_j^3 \partial t_{j+1}} = \frac{2}{|e_{j+1}|^2} (c_{j-1} - c_{j+1} + c_4).$$

The fact $\partial^3 \Pi_h^2 w = \Pi_h^0 \partial^3 w$ with $|\alpha| = 3$ leads to (3.57) directly, and completes the proof. \hfill \Box

The expansion in Lemma 3.9 of the interpolation error of the Morley leads to the following optimal analysis of $I_3$ on uniform triangulations.

**Lemma 3.10.** Suppose that $(\lambda, u)$ is the solution of Problem (2.2) and $u \in V \cap H^4(\Omega, \mathbb{R})$. It holds on uniform triangulations that

$$|I_3| \leq h^4 ||u||_{4, \Omega}^2.$$

**Proof.** Note that

$$(3.59)$$

$$I_3 = \lambda ((I - \Pi_M) \Pi_h^3 u, \Pi_h^0 u) + \lambda ((I - \Pi_M)(I - \Pi_h^3 u, \Pi_h^0 u) + \lambda ((I - \Pi_M) u, (I - \Pi_h^0 u),$$

and

$$(3.60)$$

$$|((I - \Pi_M) u, (I - \Pi_h^0 u)|, \quad \lambda ((I - \Pi_M) u, (I - \Pi_h^0 u)|, \leq h^4 ||u||_{4, \Omega}^2.$$  

It follows from (3.56), (3.59) and (3.60) that

$$(3.61)$$

$$I_3 = \lambda ((I - \Pi_M) \Pi_h^3 u, \Pi_h^0 u) + O(h^4 ||u||_{4, \Omega}^2) = \lambda \sum_{K \in T_h} \sum_{i=1}^{4} s_i(c_i, \Pi_h^0 u) + O(h^4 ||u||_{4, \Omega}^2).$$
with \( s_i = \Pi_k^0(I - \Pi_{M})\hat{\phi}_M^i \) and \( c_i \) defined in (3.57). By the definition of \( \hat{\phi}_M^i \) in (3.53), constant \( s_i \) has the same value on different elements. Note that the directions of \( t_i \) for two adjacent elements are opposite. Thus, the definition of \( c_i \) in (3.57) indicates

\[
c_i|_{K_1} = -c_i|_{K_2} = O(h^3),
\]

where adjacent elements \( K_1 \) and \( K_2 \) forming a parallelogram. Similar to the analysis in Lemma 3.5

\[
\left| \sum_{i=1}^{4} s_i(c_i, \Pi_h^0 u) \right| \lesssim h^4 \|u\|_{L^2(\Omega)}^2.
\]

A substitution of the above estimate into (3.61) leads to

\[
|I_3| \lesssim h^4 \|u\|_{L^2(\Omega)}^2,
\]

which completes the proof. \( \square \)

The following asymptotic expansions of eigenvalues of the Morley element come from the combination of Lemmas 3.6, 3.7, 3.8, 3.10 and Theorem 3.1.

**Theorem 3.2.** Suppose that \((\lambda, u)\) is the eigenpair of Problem (2.2) with \( u \in V \cap H^3(\Omega, \mathbb{R}) \), and \((\lambda_M, u_M)\) is the corresponding eigenpair of Problem (2.4) by the Morley element on an uniform triangulation \( T_h \). It holds that

\[
\lambda - \lambda^M = \frac{1}{N} F(u, \Omega) + O(h^4 |\ln h||u||_{L^2(\Omega)}^2).
\]

with \( N \) the number of elements on \( T_h \) and \( F(u, \Omega) \) defined in (3.18).

The optimal convergence result of the extrapolation algorithm in the following theorem is an immediate consequence of Theorem 3.2.

**Theorem 3.3.** Suppose that \( \lambda \) is a simple eigenvalue of Problem (2.2) and a corresponding eigenfunction \( u \in V \cap H^3(\Omega, \mathbb{R}) \). Let \((\lambda_M, u_M)\) be the corresponding eigenpair of Problem (2.4) by the Morley element on an uniform triangulation \( T_h \). It holds that

\[
|\lambda - \lambda^M_{\text{EXP}}| \lesssim h^4 |\ln h||u||_{L^2(\Omega)}^2.
\]

with extrapolation eigenvalues \( \lambda^M_{\text{EXP}} \) defined in (3.1).

**Remark 3.1.** If \( \lambda \) is a multiple eigenvalue, eigenfunctions \( u_M \) on triangulations with different mesh size may approximate to different functions \( u \in M(\lambda) \). Then, the asymptotic expansion of eigenvalue \( \lambda_M \) in Theorem 3.2 cannot lead to a theoretical estimate of \( \lambda^M_{\text{EXP}} \) in (3.1). Some numerical tests in Section 5 show that extrapolation method can also improve the accuracy of multiple eigenvalues to \( O(h^4) \) if the eigenfunction is smooth enough.

**Remark 3.2.** Although the analysis in this paper focuses on the case that \( V = H^2_0(\Omega, \mathbb{R}) \), it also works for \( V = H^2(\Omega, \mathbb{R}) \cap H^1_0(\Omega, \mathbb{R}) \). Namely, a similar analysis can prove the efficiency of the extrapolation algorithms for simply supported plates.
4. Asymptotically exact a posterior error estimate and postprocessing scheme

In this section, we establish and analyze an asymptotically exact a posterior error estimate of eigenvalues by the Morley element. This estimate gives a high accuracy postprocessing scheme of eigenvalues.

To begin with, we introduce a gradient recovery technique [6, 21]. Given $q \in \Sigma(T_h)$, define $K_h q |_K \in \text{CR}(T_h, S)$ with

$$\text{CR}(T_h, S) := \{ v \in L^2(\Omega, S) : v|_K \in P_1(K, S) \text{ for any } K \in T_h, \int_e [v] \, ds = 0 \text{ for any } e \in E_h^i \}.$$

**Definition 1.**

1. For each interior edge $e \in E_h^i$, the elements $K^1_e$ and $K^2_e$ are the pair of elements sharing $e$. Then the value of $K_h q$ at the midpoint $m_e$ of $e$ is

$$K_h q(m_e) = \frac{1}{2} (q|_{K^1_e}(m_e) + q|_{K^2_e}(m_e)).$$

2. For each boundary edge $e \in E_h^b$, let $K$ be the element having $e$ as an edge, and $K'$ be an element sharing an edge $e' \in E_h^i$ with $K$. Let $e''$ denote the edge of $K'$ that does not intersect with $e$, and $m, m'$ and $m''$ be the midpoints of the edges $e, e'$ and $e''$, respectively. Then the value of $K_h q$ at the point $m$ is

$$K_h q(m) = 2 K_h q(m') - K_h q(m'').$$

The Morley element solution for source problems admits a first order superconvergence on uniform triangulations [19]. According to Lemma 3.1, the eigenfunction $u_M$ is superclose to the Morley element solution for a corresponding source problem. These two facts lead to the following superconvergence result

$$\| \nabla^2 u - K_h \nabla^2 u_M \|_{0, \Omega} \lesssim h^3 \ln h^{1/2} \| u \|_{3/2, \Omega},$$

provided that $u \in V \cap H^2(\Omega, \mathbb{R})$. Following the analysis for Lemma 2.2 in [18], this superconvergence property (4.1) leads to the following error estimate for third order derivatives of eigenfunctions, namely,

$$\| \nabla^3 u - \nabla_h \nabla^2 u_M \|_{0, \Omega} \lesssim C h \ln h^{1/2} \| u \|_{3/2, \Omega},$$

provided that $u \in V \cap H^2(\Omega, \mathbb{R})$.

Define the following asymptotically exact a posteriori error estimates

$$F_M = \| K_h \nabla^2 u_M - \nabla^2 u_M \|_{0, \Omega}.$$
where \( P_C(\nabla_h^3w) = \sum_{i=1}^{4} c_i(I - \Pi_M)\phi_M^i \) with \( c_i \) and \( \phi_M^i \) defined in (3.57) and (3.53), respectively. Given a discrete eigenvalue \( \lambda_M \) of the Morley element, the postprocessing scheme computes a new approximate eigenvalue

\[
\lambda_R^M = \lambda_M + F_M.
\]

By the expansion (2.7), a similar analysis to the one in [18] leads to the following theorem.

**Theorem 4.1.** Let \((\lambda, u)\) be an eigenpair of (2.2) with \( u \in V \cap H^2(\Omega, \mathbb{R}) \), and \((\lambda_M, u_M)\) be the corresponding approximate eigenpair of (2.4) in \( V_M \). The new eigenvalue \( \lambda_R^M \) by the postprocessing scheme satisfies

\[
|\lambda - \lambda_R^M| \lesssim h^3 \ln h \|u\|_{2,\Omega}^2,
\]

and the accuracy of the asymptotically exact a posterior error estimates \( F_M \) is \( O(h^3 \ln h) \).

**Proof.** Recall the expansion (3.7) of eigenvalues

\[
\lambda - \lambda_M = \|\nabla_h^2(u - u_M)\|_{0,\Omega}^2 - 2\lambda(u - \Pi_M u, u) + O(h^4\|u\|_{3,\Omega}^2).
\]

It follows from (4.1) and Cauchy Schwarz inequality that

\[
||\nabla_h^2(u - u_M)||_{0,\Omega}^2 - ||K_h \nabla_h^2 u_M - \nabla_h^2 u_M||_{0,\Omega}^2 \lesssim h^3 \ln h \|u\|_{2,\Omega}^2.
\]

It follows (2.5) that \( |(u - \Pi_M u, u)| \lesssim h^3\|u\|_{3,\Omega} \). This, together with (4.5), indicates that

\[
|\lambda - \lambda_R^M| \lesssim h^3 \ln h \|u\|_{2,\Omega}^2
\]

which completes the proof. \( \square \)

5. **Numerical examples**

This section presents some numerical tests to confirm the theoretical analysis in the previous sections.

5.1. **Example 1 (simply support plate and clamped plate).** We consider the plate problem (2.2) on the unit square \( \Omega = (0, 1)^2 \). The initial mesh \( T_1 \) consists of two right triangles, obtained by cutting the unit square with a north-east line. Each mesh \( T_i \) is refined into a half-sized mesh uniformly, to get a higher level mesh \( T_{i+1} \).
Simply support plate. Consider the simply support plate with boundary condition $u = \frac{\partial^2 u}{\partial n^2} = 0$, then

$$V = H^2(\Omega, \mathbb{R}) \cap H^1_0(\Omega, \mathbb{R})$$

It is known that the first eigenvalue of this problem is $\lambda_1 = 4\pi^4$, and the convergence rate of approximate eigenvalues of the Morley element is $\alpha = 2$. Figure 3 plots the errors of eigenvalues $\lambda_M$, $\lambda_{\text{EXP}}^M$, and $\lambda_{\text{R}}^M$ of the Morley element, the corresponding extrapolation methods and the postprocessing techniques, respectively. The convergence rate of eigenvalues of the Morley element is improved remarkably from second order to forth order, which verifies the analysis in Theorem 3.3 and Theorem 4.1. Figure 3 also shows that the postprocessing technique has a better performance than the extrapolation method, although the theoretical convergence rate is smaller than the extrapolation method.

Among the smallest six eigenvalues, it is known that $\lambda_2 = \lambda_3$ and $\lambda_5 = \lambda_6$. Table 1 lists the relative errors of eigenvalues by the Morley element for these multiple eigenvalues. It shows that extrapolation methods also improve the convergence rate of multiple eigenvalues to a rate of 4.00.

Clamped plate. Consider the clamped plate with boundary condition $u = \frac{\partial u}{\partial n} = 0$, then

$$V = H^2_0(\Omega, \mathbb{R})$$

The sum of the eigenvalue by the Morley element on the mesh $T_{11}$ and the corresponding a posteriori error estimate in (4.3) is taken as the reference.
Table 1. The relative errors of eigenvalues by the extrapolation method for the Morley element in Example 1.

Figure 4. The relative errors of the extrapolation eigenvalues for clamped plate in Example 1.

5.2. Example 2 (Piecewise uniform mesh). Consider a model problem (2.2) with $V = H^2_0(\Omega)$ on the domain $\Omega$ shown in Figure 5.2, where the coordinate of $A_1$ to $A_5$ are $(2, 0), (1, -2), (-1, -2), (-2, 0), (0, 2)$. The minimal and maximal angle of $\Omega$ are 90° and 121.3°, respectively. Figure 5.2 plots the initial mesh $T_1$ and each mesh $T_i$ is refined into a half-sized mesh uniformly, to get a
higher level mesh $T_{i+1}$. The eigenvalue by the Aygris element on $T_8$ is taken as the reference eigenvalue for this example.

Table 2 indicates an almost fourth order convergence rate of extrapolation eigenvalues $\lambda_M^{\text{EXP}}$ in (3.1) with $\alpha = 2$ and postprocessed eigenvalues $\lambda_M^R$ in (4.3). Although the meshes are no longer uniform, we can still observe the optimal estimate for asymptotic expansions of the Morley element on such piecewise uniform meshes. It implies that both the extrapolation methods and the postprocessing technique are effective on piecewise uniform meshes. Similar to Example 1, the accuracy of eigenvalues by the postprocessing technique is slightly better than that of eigenvalues by the extrapolation method.

Table 2. The relative errors of eigenvalues for Example 2.

5.3. Example 3 (Cracked domain). Consider the model problem (2.2) on a square domain with a crack

$$\Omega = (-1, 1)^2/[0, 1] \times \{0\}.$$

The boundary condition is $u = \frac{\partial u}{\partial n} = 0$. Let $T_0$ consist of two right triangles, obtained by cutting the domain $(-1, 1)^2$ with a north-east line. Each mesh $T_i$ is refined into a half-sized mesh uniformly, to get a higher level mesh $T_{i+1}$. Let $T_1$ be the initial mesh.
Figure 6. The first eigenfunctions on adaptive triangulations for Example 3 with 10246, 28909, 76779 and 459901 d.o.f, respectively.

Figure 7. The relative errors of the extrapolation eigenvalues on uniform triangulations and the adaptive method for Example 3.

The eigenfunction with respect to the smallest eigenvalue for this case is singular. Adaptive method is a popular and efficient way to deal with singular cases. For this eigenvalue problems by the Morley element, an efficient and reliable a posteriori error estimator of Morley elements was proposed in [41]. This a posteriori error estimator is adopted here to generate adaptive grids. Denote the smallest approximate eigenvalues by the Morley element on these adaptive grids by $\lambda_{M}^{A}$. For the approximate eigenvalues $\lambda_{M}^{A}$, compute the asymptotically exact a posterior error estimate in
(4.3) and denote the postprocessed approximate eigenvalues in (4.4) by \( \lambda^R_M \). Since the eigenvalues of the problem in consideration are unknown, we use the adaptive postprocessed eigenvalue \( \lambda^R_M \) on an adaptive mesh with 3454396 degrees of freedom as the reference eigenvalue. Figure 6 plots the approximate eigenfunction on adaptive meshes, and Figure 7 plots the errors of approximate eigenvalues \( \lambda^M_M, \lambda^{\text{EXP}}_M, \lambda^R_M, \lambda^A_M \). In this case, the discrete eigenvalue \( \lambda^M_M \) converges at the rate 1. We compute the extrapolation eigenvalue \( \lambda^{\text{EXP}}_M \) in (3.1) with \( \alpha = 1 \). Since the eigenfunction is singular, the postprocessing scheme improve the accuracy of eigenvalues on uniform meshes without improving the convergence rate, while the extrapolation method can improve the convergence rate to 2.00. Figure 7 also implies that the postprocessing scheme is also effective on adaptive meshes.

5.4. Example 4. Consider the model problem (2.2) on a Dumbbell-split domain with a slit \( \Omega = (-1, 1) \times (-1, 5) \setminus ([0, 1] \times \{0\} \cup [1, 3] \times [-0.75, 1]) \). The boundary condition is \( u = \partial u / \partial n = 0 \). The initial triangulation is shown in Figure 8.

\[
\begin{array}{c}

**Figure 8.** The initial triangulation of Dumbbell domain \( \Omega \) for Example 4.

Figure 9 and Figure 11 plot the first and the fourth eigenfunctions on adaptive meshes, respectively. Figure 10 plots the relative errors of the first and the fourth eigenvalues \( \lambda^M_M \) by the Morley element, the extrapolation eigenvalue \( \lambda^{\text{EXP}}_M \) in (3.1), the adaptive eigenvalue \( \lambda^A_M \), and the postprocessed eigenvalues \( \lambda^R_M \) and \( \lambda^{RA}_M \). The first eigenvalue \( \lambda^M_M \) converges at the rate 2.00, while the fourth eigenvalue \( \lambda^M_M \) only converges at the rate 1.00. This implies a relatively higher regularity of the first eigenfunction. This explains why the extrapolation method and postprocessing technique on uniform meshes even have better performance than adaptive methods. For the first eigenvalue, both the extrapolation method and the postprocessing technique can improve the convergence rate to 3.00. For the fourth eigenvalue, the convergence rate of eigenvalues by the postprocessing technique
stays 1.00, while that of eigenvalues by the extrapolation method (3.1) with \( \alpha = 1 \) increases to 2.00. For the case that the eigenfunction is not smooth enough, Figure 10 shows that the proposed postprocessing technique is effective on both uniform meshes and adaptive meshes.

Acknowledgments

The authors are greatly indebted to Professor Jun Hu from Peking University for many useful discussions and the guidance. The first author also wishes to thank the partial support from the Center for Computational Mathematics and Applications, the Pennsylvania State University.
