On Faster Convergence of Scaled Sign Gradient Descent

Xiuxian Li, Kuo-Yi Lin, Li Li, Yiguang Hong, and Jie Chen

Abstract—Communication has been seen as a significant bottleneck in industrial applications over large-scale networks. To alleviate the communication burden, sign-based optimization algorithms have gained popularity recently in both industrial and academic communities, which is shown to be closely related to adaptive gradient methods, such as Adam. Along this line, this paper investigates faster convergence for a variant of sign-based gradient descent, called scaled SIGNGD, in three cases: 1) the objective function is strongly convex; 2) the objective function is nonconvex but satisfies the Polyak-Łojasiewicz (PL) inequality; 3) the gradient is stochastic, called scaled SIGNSGD in this case. For the first two cases, it can be shown that the scaled SIGNGD converges at a linear rate. For case 3), the algorithm is shown to converge linearly to a neighborhood of the optimal value when a constant learning rate is employed, and the algorithm converges at a rate of $O(1/k)$ when using a diminishing learning rate, where $k$ is the iteration number. The results are also extended to the distributed setting by majority vote in a parameter-server framework. Finally, numerical experiments on logistic regression are performed to corroborate the theoretical findings.

Index Terms—Optimization, gradient descent, sign compression, linear convergence, logistic regression.

I. INTRODUCTION

This paper studies an unconstrained optimization problem

$$\min_{x \in \mathbb{R}^d} f(x),$$

where the objective $f : \mathbb{R}^d \to \mathbb{R}$ is a proper differentiable function, and may be nonconvex, which has numerous applications in industry, such as electric vehicles [1], [2], smart grid [3], internet of things (IoT) [4], and so on. To solve this problem, a quintessential algorithm is the gradient descent (GD) method [5]–[7], which requires to access true gradients. However, it is usually expensive or difficult to compute the true gradients in reality, and thereby a typical stochastic gradient descent (SGD) algorithm has become prevalent in deep neural networks [8], [9], which depends upon a lower computing cost for stochastic gradients.

As for large-scale neural networks, the training efficiency can be substantially improved in general by introducing multiple workers in a parameter-server framework, where a group of workers can train their own mini-batch datasets in parallel. Nonetheless, the communication between workers and the parameter server has been a non-negligible handicap for its wide practical application. As such, as one of gradient compression techniques, sign-based methods have been popular in recent decades, not only because they can reduce the communication cost to one bit for each gradient coordinate, but because they have good performance and close relationship with adaptive gradient methods, such as Adam. Along this line, this paper is the first to address faster convergence of sign methods with more elaboration as follows.

Contributions. To our best knowledge, this paper is the first to address faster convergence of sign methods with more details as follows.

First, it is found that SIGNGD is not generally convergent even for strongly convex and smooth objectives when using constant learning rates, although it is indeed convergent for vanilla GD. Therefore, scaled versions in Algorithms [1] and [2] are investigated. It is proved that Algorithm [1] converges linearly to the minimal value for two cases: strongly convex objectives and nonconvex objectives yet satisfying the
Polyak-Łojasiewicz (PL) inequality. Meanwhile, Algorithm 2 converges linearly to a neighborhood of the minimal value when using a constant learning rate \(\alpha\) with an error being proportional to \(\alpha^2\) and the variance of stochastic gradients. When applying a kind of diminishing learning rate, a rate \(O(\ln^2(k)/k^2)\) can be ensured for \(15\), which is superior to the widely known rate \(O(1/k)\) \(20\).

Second, the obtained results are extended to the distributed setup, where a group of workers compute their own (stochastic) gradients using individual dataset and then transmit the sign gradient and the gradient \(\ell_1\)-norm to the parameter server who calculates the sign gradient by majority vote along with taking the average of the gradient \(\ell_1\)-norms and transmits back to all the workers.

Notations. Denote by \([n] := \{1, 2, \ldots, n\}\) for an integer \(n > 0\). Let \(\|\cdot\|, \|\cdot\|_1, \|\cdot\|_\infty\) and \(x^\top\) be the \(\ell_2\)-norm, \(\ell_1\)-norm, \(\ell_\infty\)-norm and the transpose of \(x \in \mathbb{R}^n\), respectively. 1 and 0 stand for column vectors of compatible dimension with all entries being 1 and 0, respectively. \(\nabla f\) represents the gradient of a function \(f\). \(E(\cdot)\) and \(P(\cdot)\) denote the mathematical expectation and probability, respectively.

II. Counterexamples for SignGD

For signGD, an interesting result can also be found in the continuous-time setup, which demonstrates obvious advantages of signGD compared with GD. Particularly, signGD converges linearly, while GD is only sublinearly convergent. More details are postponed to the Appendix as supplemental materials.

Motivated by the fact in the continuous-time setup, it seems promising to consider the discrete-time counterpart of \(23\), i.e., signGD \(4\) with \(\alpha_k = \alpha > 0\) being a constant learning rate. However, it is not the case. It is well known that GD is linearly convergent for small enough \(\alpha > 0\), while several counterexamples are presented below for illustrating that the sign counterpart \(2\) is generally not convergent even for strongly convex and smooth objectives.

Example 1. Consider \(f(x) = x_1^2 + x_2^2\) for \(x \in \mathbb{R}^2\), which is strongly convex and smooth with \(\nabla f(x) = (2x_1, 2x_2)^\top\). By choosing the initial point as \(x_0 = (\alpha/2, \alpha/2)^\top\), it is easy to verify for \(2\) that for \(l = 0, 1, 2, \ldots\),

\[
x_{2l} = \left(-\frac{\alpha}{2} - \frac{\alpha}{2}^\top\right), \quad x_{2l+1} = \left(\frac{\alpha}{2}, \frac{\alpha}{2}\right)^\top,
\]

which is obviously not convergent.

Example 1 shows that the exact convergence cannot be ensured for signGD even for strongly convex and smooth objectives. To fix it, one may attempt to consider the sign counterpart of adaptive gradient methods. However, it generally does not work as well. For instance, the AdaGrad-Norm \(21\)

\[
b_{k+1}^2 = b_k^2 + \|\nabla f(x_k)\|^2, \quad x_{k+1} = x_k - \frac{\eta}{b_{k+1}}\nabla f(x_k), \quad \eta > 0
\]

is shown to converge linearly without knowing any function parameters beforehand \(22\), while the linear convergence cannot be ensured in general for its sign counterparts, as illustrated below for its two sign variants.

Example 2. Consider the first sign variant as

\[
b_{k+1}^2 = b_k^2 + \|\nabla f(x_k)\|^2, \quad x_{k+1} = x_k - \frac{\eta}{b_{k+1}}\text{sign}(\nabla f(x_k)), \quad \eta > 0
\]

and \(f(x) = x^2/2\) (strongly convex and smooth) with \(x \in \mathbb{R}\). For simplicity, set \(b_0 = 0\) and \(x_0 \neq 0\). Then simple manipulations give rise to \(b_{k+1}^2 = \sum_{l=0}^k x_l^2\).

In what follows, we show that the convergence rate of \(6\) is not linear. To do so, it is easy to see that \(x_{k+1} = x_k - \frac{\eta}{b_{k+1}}\text{sign}(x_k)\), which leads to that

\[
x_{k+1}^2 = x_k^2 - \frac{2\eta}{b_{k+1}}|x_k| + \frac{\eta^2}{b_{k+1}^2}
\]

\[
= x_k^2 - \frac{\eta}{b_{k+1}}(2b_{k+1}|x_k| - \eta).
\]

By contradiction, if \(x_k\) or \(f(x_k)\) is linearly convergent, then one has that \(\sum_{k=0}^\infty x_k^2 \leq B\) for some constant \(B > 0\), which, together with \(7\) and \(b_{k+1}^2 = \sum_{l=0}^k x_l^2\), gives

\[
x_{k+1}^2 \geq x_k^2 - \frac{\eta}{b_{k+1}}(2\sqrt{B|x_k|} - \eta).
\]

After \(|x_k|\) decreases to where \(|x_k| \leq \frac{\eta}{2\sqrt{B}}\), invoking \(8\) leads to \(x_{k+1}^2 \geq x_k^2\), thus implying that \(f(x_k)\) will finally oscillate around the origin, which is a contradiction with the linear convergence of \(f(x_k)\). Hence, \(6\) is not linearly convergent.

Example 3. Consider now another sign variant as

\[
b_{k+1}^2 = b_k^2 + \|\text{sign}(\nabla f(x_k))\|^2, \quad x_{k+1} = x_k - \frac{\eta}{b_{k+1}}\text{sign}(\nabla f(x_k)), \quad \eta > 0
\]

and let \(f(x) = x^2\) (strongly convex and smooth) with \(x \in \mathbb{R}\) with initial \(x_0 = \eta/2\) and \(b_0 = 0\). In this case, it is straightforward to calculate that \(b_k = \sqrt{k}\) and

\[
x_k = \eta\left(\frac{1}{2} - \frac{1}{\sqrt{2}} - \frac{1}{\sqrt{3}} + \cdots + \frac{(-1)^k}{\sqrt{k}}\right),
\]

from which one can conclude that \(5\) amounts to

\[
x_{k+1} = x_k - \frac{\eta}{\sqrt{k+1}}\text{sign}(x_k),
\]

which can be viewed as GD for the convex objective \(g(x) = |x|\) with a learning rate \(\eta/\sqrt{k+1}\). Therefore, the convergence rate of classic GD can be invoked for \(4\), which is known to be sublinear \(23\).

Remark 1. The above examples demonstrate that although GD and AdaGrad-Norm are indeed linearly convergent for strongly convex and smooth objectives, their sign counterparts fail to converge linearly in general.
III. LINEAR RATE OF SCALED SIGNGD/SGD

With the above preparations, it is now ready to study faster convergence for solving problem (1). As shown in Section I the sign counterparts of GD and AdaGrad-Norm are not applicable for linear convergence. As such, the scaled versions of signGD/SGD are considered in this paper, as in Algorithms 1 and 2 which can be viewed as the steepest descent with respect to the maximum norm, but is still not fully understood.

A few assumptions are necessary for the following analysis.

**Assumption 1.** $f$ is $\mu$-strongly convex with respect to $\ell_\infty$-norm for some constant $\mu > 0$, i.e., $f(x) - f(y) \geq \nabla f(y)^T (x - y) + \frac{\mu}{2} \|x - y\|_\infty^2$ for all $x, y \in \mathbb{R}^d$.

**Assumption 2.** $f$ satisfies the Polyak-Łojasiewicz (PL) inequality, i.e., $\|\nabla f(x)\|_2^2 \geq 2\mu(f(x) - f^*)$, $\forall x \in \mathbb{R}^d$, where $f^*$ is the minimum value.

**Assumption 3.** $f$ is $L$-smooth with respect to $\ell_\infty$-norm, i.e., $\|\nabla f(x) - \nabla f(y)\|_1 \leq L\|x - y\|_\infty$ for all $x, y \in \mathbb{R}^d$.

The PL inequality does not require $f$ to be even convex, and the $\ell_\infty$- and $\ell_1$-norms employed in Assumptions 1 and 2 respectively, are slightly more relaxed than the Euclidean norm. Meanwhile, the smoothness condition is made with respect to $\ell_\infty$-norm, since it is more favorable than the Euclidean smoothness and separable smoothness.

**Remark 2.** It is noteworthy that another promising sign method is $\text{EF-SIGNGD}$ [16] using error feedback, given as

$$p_k = \lambda \nabla f(x_k) + e_k,$$
$$x_{k+1} = x_k - \frac{\|p_k\|}{d} \text{sign}(p_k),$$
$$e_{k+1} = p_k - \frac{\|p_k\|}{d} \text{sign}(p_k), (12)$$

where $\lambda > 0$ is the learning rate. In [16], it is shown that $\text{EF-SIGNGD}$ has a better performance than $\text{SIGNGD/SGD}$, actually enjoying the same convergence rate as $\text{GD/SGD}$. However, we point out that $\text{EF-SIGNGD}$ is, roughly speaking, equivalent to $\text{GD/SGD}$. Let us show this by slightly modifying (12) as

$$p_k = \lambda \nabla f(x_k) - e_k,$$
$$x_{k+1} = x_k - \frac{\|p_k\|}{d} \text{sign}(p_k),$$
$$e_{k+1} = p_k - \frac{\|p_k\|}{d} \text{sign}(p_k). (13)$$

By defining $z_k = x_k - e_k$, it is easy to verify that $z_{k+1} = z_k - \lambda \nabla f(z_k)$, that is, (13) amounts to $\text{GD}$ in terms of $z_k$. As a result, $\text{EF-SIGNGD/SGD}$ is not considered here.

In the following, the main results are divided into two scenarios, i.e., the deterministic and stochastic settings.

A. The Deterministic Setting

Consider the deterministic setting with full gradients, i.e., (14), for which we have the following results. Note that all proofs are given in the Appendix.

<table>
<thead>
<tr>
<th>Algorithm 1 Scaled signGD</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Input:</strong> learning rate $\alpha$, current point $x_k$</td>
</tr>
<tr>
<td>$x_{k+1} = x_k - \alpha |g_k| \text{sign}(g_k), \quad g_k := \nabla f(x_k)$ (14)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Algorithm 2 Scaled signSGD</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Input:</strong> learning rate $\alpha_k$, current point $x_k$</td>
</tr>
<tr>
<td>$\tilde{g}_k = \text{StochasticGradient}(x_k)$</td>
</tr>
<tr>
<td>$x_{k+1} = x_k - \alpha_k |\tilde{g}_k| \text{sign}(\tilde{g}_k)$ (15)</td>
</tr>
</tbody>
</table>

**Theorem 1.** The following statements are true for (14).

1) Under Assumptions 1 and 2 if $0 < \alpha < \frac{2}{L}$, then $f(x_k) - f^* \leq \zeta^k (f(x_0) - f^*)$, where $\zeta := 1 - 2\mu(1 - \frac{L}{2\mu}) \in [0, 1)$.

2) Under Assumptions 2 and 3 with $\alpha$ satisfying $0 < \alpha < \frac{2}{L}$, (15) still holds.

3) If Assumption 3 holds only, then

$$\min_{l \in \{0, 1, \ldots, k\}} \|g_l\|_2^2 \leq \frac{f(x_0) - f^*}{\gamma(k + 1)}, (17)$$

where $\gamma := \alpha(1 - \frac{L}{2\mu})$.

**Remark 3.** In view of Theorem 1, the algorithm (14) is proved to be linearly convergent, which is contrast to signGD and sign AdaGrad-Norm as discussed in Section I. Moreover, for the nonconvex but smooth with respect to the Euclidean norm, by leveraging the similar argument to Theorem 1, it is easy to obtain for signGD with a constant learning rate that

$$\min_{l \in \{0, 1, \ldots, k\}} \|g_l\|_2^2 \leq \frac{f(x_0) - f^*}{\gamma(k + 1)}$$

where $\gamma := \alpha(1 - \frac{L}{2\mu})$.

**Remark 4.** A similar result can be also obtained from the most related work by resorting to the $\delta$-approximate compressor. To be specific, $C(v) := \frac{\|v\|}{d} \text{sign}(v)$ can be viewed as a $\frac{1}{d}$-approximate compressor, and then applying Theorem 13 in [24] leads to the learning rate $\alpha \in [0, \frac{1}{d}]$ and convergence rate $(1 - \frac{\delta^2}{d})^k$. In contrast, Theorem 1 of this paper (need to replace $\alpha$ by $\frac{\alpha}{d}$ here) is for $\alpha \in (0, \frac{2}{L}]$ with the convergence rate $(1 - \frac{\alpha^2}{d})^k$. It is easy to verify that our learning rate is more relaxed and the convergence rate is faster due to $\frac{\alpha^2}{d} \leq \frac{2\mu}{d}(1 - \frac{\alpha^2}{d})$.

B. The Stochastic Setting

This section considers the stochastic gradient case, where the true gradient $g_k = \nabla f(x_k)$ is expensive to compute and instead a stochastic gradient $\tilde{g}_k$ is relatively cheap to evaluate as an estimate of $g_k$. To move forward, some standard assumptions are imposed on stochastic gradients [11, 13].
Assumption 4. The stochastic gradients \( \{ \tilde{g}_k \}_{k=0}^{\infty} \) are unbiased and have bounded variances with respect to \( \ell_1 \)-norm, i.e., there exists a constant \( \sigma > 0 \) such that
\[
\mathbb{E}(\tilde{g}_k) = g_k, \quad \mathbb{E}(\|\tilde{g}_k - g_k\|_2^2) \leq \sigma^2.
\] (18)

In this case, the algorithm becomes (15). For brevity, define \( p_{k,i} := \mathbb{P}(\text{sign}(\tilde{g}_{k,i}) = \text{sign}(g_{k,i})) \) for \( k \geq 0 \) and \( i \in [d] \), where \( \tilde{g}_{k,i} \) and \( g_{k,i} \) represents the \( i \)-th components of \( \tilde{g}_{k,i} \) and \( g_{k,i} \), respectively.

Remark 5. For stochastic gradient \( g_k \), when leveraging a mini-batch of size \( n_k \) at \( x_k \), the oracle gives us \( n_k \) gradient estimates and in this case, the stochastic gradient \( \tilde{g}_k \) can be chosen as the average of \( n_k \) following statements are true.

For (15), under Assumptions 1, 3, 4 or 2-4, the stochastic gradient \( \tilde{g}_k \) fails to work. And a multitude of cases can ensure where
\[
\sigma > \frac{L}{1 - \xi_2}.
\]
Additionally, it was shown in [19] that the success probability \( p_{k,i} \) should be greater than \( 1/2 \), and otherwise the sign algorithm generally fails to work. And a multitude of cases can ensure \( p_{k,i} > 1/2 \), for instance, each component \( \tilde{g}_{k,i} \) possesses a unimodal and symmetric distribution [17], [19].

We are now in a position to present the main result on (15).

Theorem 2. For (15), under Assumptions 7, 11, 3, 4 or 22 the following statements are true.
1) If \( \alpha_k = \alpha \in (0, \frac{2p_{\min} - 1}{L}) \), then
\[
\mathbb{E}(f(x_k)) - f^* \leq \frac{L\sigma^2}{4\mu}(2p_{\min} - 1 - L\alpha),
\] (19)
where \( p_{\min} := \min_{i \in [d]} p_{k,i} \) and \( \xi_1 := 1 - 2\mu \alpha (2p_{\min} - 1 - L\alpha) \in [\frac{1}{2}, 1] \).
2) If \( \alpha_k = \frac{3}{4p_{\min} - (k + 1)} \), then
\[
\mathbb{E}(f(x_k)) - f^* \leq \frac{9L\sigma^2}{4\mu^2(2p_{\min} - 1)} \left( \frac{32}{k} + \frac{1}{k^2} \right) f(x_0) - f^* + \frac{f(x_k) - f^*}{(k + 1)^3}.
\] (20)

Remark 6. The first result in Theorem 2 shows that algorithm (15) converges linearly at a rate \( \xi_1 \). This is comparable to vanilla SGD in [25], where the convergence rate is \( 1 - \alpha_k \mu \), which is slower than \( \xi_1 \) (i.e., \( \xi_1 \leq 1 - \alpha_k \mu \)) when \( \alpha \in (0, \frac{1}{2}) \). Moreover, the result in (20) is the exact convergence with rate \( O(1/k) \) for both strongly convex case and nonconvex case with PL inequality, which is the same as both vanilla SGD [26] and compression methods [20]. In addition, the same rate \( O(1/k) \) was established in [27]. However, the condition in [27] for convergence does not always hold, e.g., \( \ell_k = 1 \) in Theorem II.2 of [27], and our result (20) includes more faster rate \( O(1/k^2) \) except for \( O(1/k) \) in [27].

IV. THE DISTRIBUTED SETTING

Now, we extend the results in Section III to the distributed setting within a parameter server framework. For simplicity, we only focuses on scaled \( \text{sign}\text{SGD} \) in this section, but the results can be similarly obtained for scaled \( \text{sign}\text{GD} \).

To proceed, the distributed scaled \( \text{sign}\text{SGD} \) by majority vote is given in Algorithm 3 for which the following convergence result is obtained.

Algorithm 3 Distributed Scaled \( \text{sign}\text{SGD} \) by Majority Vote

**Input:** learning rate \( \alpha \), current point \( x_k \), \# workers \( M \) each with an i.i.d. gradient estimate \( \tilde{g}_m \), \( m \in [M] \)

**On server**

- Pull \( \text{sign}(\tilde{g}_m) \) and \( \|\tilde{g}_m\|_1 \) from each worker
- Push \( \text{sign}(\hat{g}_k) \) and \( M_k \) to each worker

\[
g_k := \frac{1}{M} \sum_{m=1}^{M} \text{sign}(\tilde{g}_m), \quad M_k := \frac{1}{M} \sum_{m=1}^{M} \|\tilde{g}_m\|_1
\]

**On each worker**

\[x_{k+1} = x_k - \alpha M_k \text{sign}(\hat{g}_k)\]

Theorem 3. For Algorithm 3 under Assumptions 11, 3, 4 or 22 if \( 0 < \alpha < \frac{M_{\min} (\kappa, \kappa - 1)}{L + \frac{1}{2}} \), then
\[
\mathbb{E}(f(x_k)) - f^* \leq \frac{L\sigma^2}{4\mu}(2p_{\min} - 1 - L\alpha),
\] (21)
where \( p_{\min} = \min_{i \in [d]} p_{k,i} \), \( \varsigma_2 := 1 - 2\mu \alpha (2p_{\min} - 1 - L\alpha) \in [\frac{1}{2}, 1] \), \( \kappa := \frac{M_{\min} (\kappa, \kappa - 1)}{L + \frac{1}{2}} \) with \( \lfloor \cdot \rfloor \) being the floor function, and \( I_p(a, b) \) is the regularized incomplete beta function, defined by

\[
I_p(a, b) := \int_0^p t^{a - 1} (1 - t)^{b - 1} dt, \quad a, b > 0, \quad p \in [0, 1]
\]

Remark 7. It is noteworthy that the exact convergence can be similarly established as (20) in Theorem 2, which is omitted in Theorem 3.

V. EXPERIMENTS

Numerical experiments are provided to corroborate the efficacy of the obtained theoretical results.

**Example 4 (A Toy Example).** Let us consider a simple example, where \( f(x) = x^2 + 3 \sin^2(x) \) for \( x \in \mathbb{R} \). It is easy to verify that \( f(x) \) is nonconvex, but satisfying the PL condition. To verify the performance of the proposed scaled \( \text{sign}\text{GD} \), several existing algorithms are compared in Fig. 1 by setting \( \alpha = 0.05 \) with an arbitrary initial state. The comparisons are performed with vanilla gradient descent (GD), \( \text{sign}\text{GD} \), \( \text{sign}\text{GDm} \) (i.e., \( \text{SIGNUM} \)), and \( \text{ef}\text{-sign}\text{GD} \) [10]. It can be observed from Fig. 1 that the proposed algorithm has the same linear convergence as GD and \( \text{ef}\text{-sign}\text{GD} \), while \( \text{sign}\text{GD} \) and \( \text{SIGNUM} \) cannot converge, behaving oscillations near
the optimal variable. In summary, this example shows the efficiency of the scaled signGD, and supports the observation in Example 7.

**Example 5.** Consider the logistic regression problem, where the objective is \( f(x) = \frac{1}{n} \sum_{i=1}^{n} \log(1 + \exp(-b_i a_i^\top x)) + \frac{1}{2n} \|x\|^2 \) with a standard L2-regularizer \([22]\), and \( a_i \in \mathbb{R}^d \) and \( b_i \in \{-1, +1\} \) are the data samples.

![Fig. 2. Scaled SIGN SGD](image)

**Fig. 2.** Scaled SIGN SGD. (a) \( \alpha = 2 \); (b) \( \alpha_k = \frac{6m}{k+1} \). Setting \( \alpha = 2 \) helps achieve a faster convergence rate, as shown in Fig. 2 on a platform with the Intel Core i7-4300U CPU. Fig. 2 indicates that signSGD has a similar performance to SGD and performs better than signSGD and signSGDm. It can be also observed that EF-SIGN SGD is comparable to SGD and performs better than signSGD and signSGDm. Moreover, the case in Fig. 2(a) with a constant learning rate converges faster than that in Fig. 2(b) with a diminishing learning rate. Meanwhile, Fig. 3 shows that more workers can improve the performance. Therefore, the numerical results support our theoretical findings.

![Fig. 3. Distributed scaled SIGN SGD for M = 1, 3.](image)

**Fig. 3.** Distributed scaled SIGN SGD for \( M = 1, 3 \).

To test the performance of scaled signGD, the epsilon dataset with \( n = 400000 \) and \( d = 2000 \) is exploited \([28]\), and the baseline is calculated using the standard optimizer LogisticSGD of scikit-learn \([29]\). To marginalize out the effect of initial choices, the numerical result is averaged over repeated runs with \( x_0 \approx N(0, I) \). We compare scaled signGD with vanilla SGD, signSGD, signSGDm, and EF-SIGN SGD \([16]\), as shown in Fig. 3.

VI. CONCLUSION

This paper has investigated faster convergence of scaled signGD/SGD, which can relieve the communication cost compared with vanilla SGD. To further motivate the study of sign methods, continuous-time algorithms have been addressed, indicating that sign GD can significantly improve the convergence speed of SGD. Subsequently, it has been proven that scaled signGD is linearly convergent for both strongly convex and nonconvex (satisfying PL inequality) objectives. Also, the convergence for signGD has been analyzed in two cases with constant and decaying learning rates. The results are also extended to the distributed setting in the parameter server framework. The efficacy of scaled sign methods has been validated by numerical experiments for the logistic regression problem.

**APPENDIX**

**A. Further Motivations for signGD**

Let us provide more evidences for studying sign-based GD from the continuous-time perspective. In doing so, consider the continuous-time dynamics corresponding to the discrete-time GD and signGD, i.e.,

\[
\dot{x} = -\beta \nabla f(x),
\]

\[
\dot{x} = -\beta \text{sign}(\nabla f(x)),
\]

where \( \beta > 0 \) is a constant learning rate.

To proceed, let us construct a Lyapunov candidate as

\[
V(t) := f(x) - f^{*}, \quad \forall \ t \geq 0
\]

where \( f^{*} \) denotes the minimum value attained by \( f \).

For algorithms \((22)\) and \((23)\), the following results can be obtained.

**Proposition 1.** For algorithm \((22)\),

1) if \( f \) is convex, then \( V(t) \leq \frac{D_1^2 V(0)}{D_1^2 + V(0) \beta t} \), where \( D_1 := \max_{x: f(x) \leq f(x_0)} \min_{x^* \in X^*} \|x - x^*\| \) with \( X^* \) being the set of minimizers;

2) if \( f \) is nonconvex, then \( \min_{s \in [0, t]} \|\nabla f(x(s))\| \leq \frac{\sqrt{I(x(0)) - f^{*}}}{\sqrt{\beta t}} \).

**Proposition 2.** For algorithm \((23)\),

1) if \( f \) is convex, then \( V(t) \leq V(0)e^{-\frac{\beta t}{2D_2}} \), where \( D_2 := \max_{x: f(x) \leq f(x_0)} \min_{x^* \in X^*} \|x - x^*\|_{\infty} \); 

2) if \( f \) is nonconvex, then \( \min_{s \in [0, t]} \|\nabla f(x(s))\|_{1} \leq \frac{f(x(0)) - f^{*}}{\beta t} \).
In view of the above results, it can be easily observed that GD in the continuous-time domain, indicating that the performance of gradient descent can be largely improved by sign gradient compression. For instance, in the scenario with convex objectives, GD is sublinearly convergent while SGNGD is linearly convergent. As a result, the above results provide a new perspective for showing advantages of SGNGD compared with GD.

B. Proof of Proposition 1

Consider the case with convex objectives. In light of (22), it can be calculated that

\[ V(t) = \nabla f(x(t))^T \dot{x} = -\beta \|\nabla f(x(t))\|^2 \leq 0, \]  

which implies \( f(x(t)) \leq f(x(0)) \).

Meanwhile, invoking the convexity of \( f \) yields

\[
V(t) \leq \nabla f(x(t))^T (x - x^*) \\
\leq \|\nabla f(x(t))\| \cdot \|x - x^*\| \\
\leq D_1\|\nabla f(x(t))\|,
\]

which, together with (25), gives rise to \( \dot{V}(t) \leq -\beta V(t)^2 \), further implying the claimed result.

For the case with nonconvex objectives, by integrating (25) from 0 to \( t \), one can obtain that

\[
\beta \int_0^t \|\nabla f(x(s))\|^2 ds = V(0) - V(t) \\
= f(x(0)) - f(x(t)) \\
\leq f(x(0)) - f^*.
\]

where the inequality has employed the fact that \( f(z) \geq f^* \) for all \( z \in \mathbb{R}^d \). Then taking the minimum of \( \|\nabla f(x(s))\| \) over \( [0, t] \) ends the proof.

C. Proof of Proposition 2

Consider first the convex case. Similar to (28), it can be obtained that

\[ \dot{V}(t) = -\beta \|\nabla f(x(t))\|_1. \]

Akin to (26), one has that

\[
V(t) \leq \nabla f(x(t))^T (x - x^*) \\
\leq \|\nabla f(x(t))\|_1 \cdot \|x - x^*\|_\infty \\
\leq D_2\|\nabla f(x(t))\|_1,
\]

where the second inequality has used Holder’s inequality. Combining (28) with (29) yields \( \dot{V}(t) \leq -\beta D_2 V(t) \), from which it is easy to verify the claimed result.

Consider now the nonconvex case. The desired result can be obtained by (28) and the similar argument to that in convex case. This completes the proof.

D. Proof of Theorem 1

To facilitate the subsequent analysis, define

\[ V_k := f(x_k) - f^*, \quad \forall k \geq 0. \]

In view of (14) and Assumption 3, it can be concluded that

\[
V_{k+1} - V_k = f(x_{k+1}) - f(x_k) \\
\leq \nabla f(x_k)^T (x_{k+1} - x_k) + \frac{L}{2} \|x_{k+1} - x_k\|^2_\infty \\
= -\alpha \|g_k\|^2_2 + \frac{L\alpha^2}{2} \|g_k\|^2_2 \cdot \|\text{sign}(g_k)\|_\infty^2 \\
\leq -\alpha \|g_k\|^2_2 + \frac{L\alpha^2}{2} \|g_k\|^2_2 \\
= -\gamma \|g_k\|^2_2.
\]

In what follows, let us prove this theorem one by one.

First, for case 1, invoking Assumption B yields

\[
V_k \leq g_k^T (x_k - x^*) - \frac{\mu}{2} \|x_k - x^*\|_\infty^2 \\
\leq \frac{1}{2} \left( \|g_k\|^2_2 + \mu \|x_k - x^*\|_\infty^2 \right) - \frac{\mu}{2} \|x_k - x^*\|_\infty^2 \\
\leq \|g_k\|^2_2 - 2\mu \gamma \|g_k\|^2_2,
\]

where the second inequality has employed the Holder inequality. Then one has that \( \|g_k\|^2_2 \geq 2\mu V_k \). Therefore, in combination with (31), one can obtain that \( V_{k+1} - V_k \leq -2\mu \gamma V_k \), further leading to \( V_{k+1} \leq \zeta V_k \). Consequently, by iteration, this completes the proof of case 1.

Second, for case 2, Assumption A leads to \( 2\mu V_k \leq \|g_k\|^2_2 \), which, together with the similar argument to case 1, follows the conclusion in this case.

Third, for case 3, invoking (31) gives \( \gamma \|g_k\|^2_2 \leq V_k - V_{k+1} \), which, by summation over \( l = 0, 1, \ldots, k \), implies that

\[
\gamma \sum_{l=0}^k \|g_l\|^2_2 \leq V_0 - V_{k+1} = f(x_0) - f(x_{k+1}) \\
\leq f(x_0) - f^*,
\]

where the last inequality has used the fact that \( f(x_{k+1}) \geq f^* \). Then taking the minimum of \( \|g_l\|^2_2 \) over \( l = 0, 1, \ldots, k \) ends the proof.

E. Proof of Theorem 2

Recalling \( V_k \) in (30). Invoking Assumption B gives rise to

\[
V_{k+1} - V_k \leq g_k^T (x_{k+1} - x_k) + \frac{L}{2} \|x_{k+1} - x_k\|^2_\infty \\
= -\alpha \|g_k\|^2_2 \text{sign}(g_k) + \frac{L\alpha^2}{2} \|g_k\|^2_2 \text{sign}(g_k)\|_\infty^2 \\
\leq -\alpha \|g_k\|^2_2 \text{sign}(g_k) + \frac{L\alpha^2}{2} \|g_k\|^2_2.
\]

By taking the conditional expectation, one has

\[
\mathbb{E}(V_{k+1}|x_k) - V_k \leq -\alpha \|g_k\|^2_2 \mathbb{E}(|\text{sign}(g_k)|x_k) \\
+ \frac{L\alpha^2}{2} \mathbb{E}(\|g_k\|^2_2|x_k).
\]
Consider now the coordinate $\tilde{g}_{k,i}$ for $i \in [d]$. One has that
\[
\mathbb{E}(\|\tilde{g}_{k,i}\|_1 \text{sign}(\tilde{g}_{k,i})|x_k) = \mathbb{E}[\mathbb{E}(\|\tilde{g}_{k,i}\|_1 \text{sign}(\tilde{g}_{k,i})|\tilde{g}_k)|x_k] = \mathbb{E}[\mathbb{E}(\|\tilde{g}_{k,i}\|_1 \text{sign}(\tilde{g}_{k,i})|\tilde{g}_k)]
\]
which, together with (33), implies that
\[
\mathbb{E}(\|\tilde{g}_{k,i}\|_1|x_k) = \mathbb{E}[\mathbb{E}(\|\tilde{g}_{k,i}\|_1|\tilde{g}_k)|x_k] = \mathbb{E}[\|\tilde{g}_{k,i}\|_1|\tilde{g}_k] + \mathbb{E}[\text{sign}(\tilde{g}_{k,i})|\tilde{g}_k] = \mathbb{E}[\|\tilde{g}_{k,i}\|_1|\tilde{g}_k].
\]

By Jensen’s inequality, it follows that $\mathbb{E}(\|\tilde{g}_{k,i}\|_1|x_k) \geq \mathbb{E}(\|\tilde{g}_{k,i}\|_1)|x_k|_1 = \|\tilde{g}_{k,i}\|_1$. Because $p_{k,i} \geq \nu_{\text{min}}$ for $i \in [d]$, taking the expectation implies that
\[
\mathbb{E}(V_{k+1}) - \mathbb{E}(V_k) \leq -\alpha(2\nu_{\text{min}} - 1)\mathbb{E}(\|g_k\|^2)
\]
\[
+ \frac{L_\alpha^2}{2}\mathbb{E}(\|\tilde{g}_k\|^2) + \mathbb{E}(\|g_k\|^2).
\]

Iteratively applying the above inequality leads to (19). It remains to prove (20). Invoking the similar analysis for (36) yields that
\[
\mathbb{E}(V_{k+1}) \leq c_k \mathbb{E}(V_k) + \mathbb{E}(\|g_k\|^2),
\]
where $c_k := 1 - \alpha_k \mu(2\nu_{\text{min}} - 1)$, further implying that
\[
\mathbb{E}(V_k) \leq \Pi_{t=0}^{k-1} c_t V_0 + \frac{L_\alpha^2}{2}(c_k - \cdots c_k \alpha_0^2 + \cdots + c_k - 1) + \mu^2(2\nu_{\text{min}} - 1)^2.
\]
\[
\leq \Pi_{t=0}^{k-1} c_t V_0 + \mu^2(2\nu_{\text{min}} - 1)^2,
\]

where the second inequality has employed the expression of $\alpha_k$.

For the last two terms in (37), in light of the fact that $\Pi_{t=0}^{k-1}(1 - a_t) \leq e^{-\sum_{t=0}^{k-1} a_t}$ for $a_t \in [0, 1]$, one has that
\[
\Pi_{t=0}^{k-1} c_t \leq e^{-\mu(2\nu_{\text{min}} - 1)\sum_{t=0}^{k-1} a_t} \leq \frac{1}{(k+1)^{\frac{3}{2}}},
\]
and
\[
\sum_{m=1}^{k-1} e^{-\sum_{t=m}^{k-1} \frac{1}{m^2}} \leq \sum_{m=1}^{k-1} \frac{(m + 1)^3}{(k + 1)^3 \sqrt{m^2}} \leq \sum_{m=1}^{k-1} \frac{8m^3}{(k + 1)^3 m^2} \leq \frac{4}{k}.
\]

Then inserting (38) and (39) to (37) leads to the conclusion (20). The proof is complete.

\section{Proof of Theorem 3}

To ease the exposition, define $\tilde{g}_k := \{\tilde{g}_k^m, m \in [M]\}$. Invoking Assumptions 3 and Algorithm 4 yields
\[
V_{k+1} - V_k \leq -\alpha M_k \mathbb{E}(\tilde{g}_k^m) + \frac{L_\alpha^2}{2} M_k^2,
\]
which, by taking the conditional expectation, implies that
\[
\mathbb{E}(V_{k+1}|x_k) - \mathbb{E}(V_k) \leq -\alpha g_k^m \mathbb{E}(M_k \text{sign}(\tilde{g}_k^m)|x_k)
\]
\[
+ \frac{L_\alpha^2}{2} M_k^2|x_k).
\]

For $g_k^m \mathbb{E}(M_k \text{sign}(\tilde{g}_k^m)|x_k)$ in (40), one has
\[
g_k^m \mathbb{E}(M_k \text{sign}(\tilde{g}_k^m)|x_k) = g_k^m \mathbb{E}(M_k \text{sign}(\tilde{g}_k^m)|\tilde{g}_k)|x_k)
\]
\[
= \mathbb{E}(M_k \sum_{i=1}^{d} g_{k,i} \mathbb{E}(\text{sign}(\tilde{g}_k^m)|\tilde{g}_k)|x_k)
\]
\[
= \mathbb{E}(M_k \sum_{i=1}^{d} |g_{k,i}| \mathbb{E}(\text{sign}(\tilde{g}_k^m)|\tilde{g}_k)|x_k)
\]
\[
= \mathbb{E}(M_k \sum_{i=1}^{d} |g_{k,i}|(2I_{p_{k,i}}(\kappa, \kappa) - 1)|x_k)
\]
\[
\geq (2I_{p_{min}}(\kappa, \kappa) - 1)\|g_k\|_1 \mathbb{E}(M_k|x_k),
\]
where the last equality has exploited Lemma 7 in [19], and the inequality comes from the fact that $p_{k,i} \geq \nu_{\text{min}}$ for $i \in [d], k \geq 0$.

As for the last term in (41), it can be concluded that
\[
\mathbb{E}(M_k|x_k) \geq \mathbb{E}(\|\frac{1}{M} \sum_{m=1}^{M} \tilde{g}_k^m\|_1|x_k)
\]
\[
\geq \mathbb{E}(\|\frac{1}{M} \sum_{m=1}^{M} \tilde{g}_k^m\|_1),
\]

which, combining with (20) and (41), leads to
\[
E(V_{k+1}) - E(V_k) \leq -\alpha(2I_{p_{\text{min}}}(\kappa, \kappa) - 1)\mathbb{E}(\|g_k\|_1^2)
\]
\[
+ \frac{L_\alpha^2}{2} \mathbb{E}(M_k^2). \tag{42}
\]

Now, for the last term in (42), one has
\[
\mathbb{E}(M_k^2) \leq \frac{1}{M} \sum_{m=1}^{M} \mathbb{E}(\|g_k^m\|_1^2)
\]
\[
\leq \frac{2}{M} \sum_{m=1}^{M} \mathbb{E}(\|g_k^m - g_k\|^2) + 2\mathbb{E}(\|g_k\|^2)
\]
\[
\leq 2\sigma^2 + 2\mathbb{E}(\|g_k\|^2),
\]

which, together with (42), yields
\[
E(V_{k+1}) - E(V_k)
\]
\[
\leq -\alpha(2I_{p_{\text{min}}}(\kappa, \kappa) - 1 - L_\alpha)\mathbb{E}(\|g_k\|_1^2) + L_\alpha^2 \sigma^2.
\]

The rest of proof is similar to that after (35). This ends the proof.
