

INFINITE UTILITY: COUNTERPARTS AND ULTIMATE LOCATIONS

ADAM JONSSON

ABSTRACT. The locations problem in infinite ethics concerns the relative moral status of different categories of potential bearers of value, the primary examples of which are people and points in time. The challenge is to determine which category of value bearers are of ultimate moral significance: the *ultimate locations*, for short. This paper defends the view that the ultimate locations are *people at times*. A person at a time is not a specific person, but the person born at a specific point in time (*de dicto*). The main conclusion of the paper is that the unsettling implications of the time- and person-centered approaches to infinite ethics can be avoided by taking people at times as the ultimate locations. Most notably, a broad class of worlds that are incomparable using the person-centered approach can be strictly ranked.

1. THE LOCATIONS PROBLEM

The locations problem in infinite ethics concerns the moral status of people relative to points in time, states of nature, and other categories of potential bearers of value. Following Broome (1991), the literature refers to such potential value bearers as the *locations*. The challenge is to determine which category of value bearers are of ultimate moral significance: the *ultimate locations*, for short.¹ One way to formulate this challenge is to ask over which locations the Pareto axiom is most appropriately imposed.² For utilitarians, the challenge is to describe the objects whose utilities should be included in the sum that determines which act brings about the greatest total utility.

Some utilitarians see people as containers for well-being. On this view, what matters is not people, but rather the intensity and duration of subjective experiences. Torbjörn Tännsjö, for instance, takes points in time as the ultimate locations in his hedonistic version of act-utilitarianism.³ Other authors, including Peter Vallentyne, John Broome, Nick Bostrom and Amanda Askill, take the opposite view. As Vallentyne writes, ‘the spirit of traditional utilitarianism goes with the

Date: 21st May 2023.

Key words and phrases. infinite utility; counterpart relations; locations of value; non-identity.

¹This term was introduced by Vallentyne and Kagan (1997), who reserve it for those locations that are decisive for moral theory. As Mulgan (2002b: 166) puts it, the ultimate locations are ‘those that really matter’. The precise meaning of the term, and its usefulness, will become clearer as the discussion progresses.

²The Pareto axiom says that for worlds w_1 and w_2 with the same locations, if every location has more utility in w_1 and no location has less utility in w_1 , then w_1 is better than w_2 . It is well known that, in infinite worlds, Pareto over times conflicts with Pareto over persons; see §2.1.

³He claims that ‘what matters is the hedonistic situation of a given individual at a given time’ (Tännsjö, 2013: 19).

person-centered approach rather than the time-centered approach'.⁴ Finally, some authors remain neutral as to whether the ultimate locations are people, points in time, or something else. For example, neither Lauwers and Vallentyne (2004) nor Arntzenius (2014) take a stance on what the ultimate locations are.

It is long known that, in infinite worlds, it makes a crucial difference what we take the ultimate locations to be. As Cain (1995) demonstrates, there are worlds populated by infinitely many people where total utility is negative at all times, but each person has a life worth living. If we insist that people are important, as many people do, the time-centered approach thus becomes untenable. The person-centered approach leads to plausible prescriptions when it applies. However, person-centeredness results in generic incomparability: 'most' pairs of infinite worlds cannot be ranked (Askell, 2018). One might react to this result by concluding that infinite ethics is fundamentally undecidable. But one might also ask if it is possible to place significance on people in such a way that generic incomparability is not entailed.

In this paper I defend the view that the ultimate locations are *people at times*.⁵ Informally, a person at a time is not a specific person, but the person born at a specific point in time (*de dicto*). In §5 I give a formal definition of people at times using a counterpart relation that identifies individuals born at the same time in different futures. I show that under certain assumptions (stated in §4), this counterpart relation can be deduced from Parfit's (1984) *No-Difference View*. In §6–9 I explore the implications of taking people at times as the ultimate locations through the study of a collection of examples. My conclusion from this study is that the unsettling implications of the time- and person-centered approaches can be avoided. Most notably, a broad class of infinite worlds that are incomparable using the person-centered approach can be strictly ranked.

2. AGAINST TIMES AND PEOPLE AS ULTIMATE LOCATIONS

I begin by describing some criticisms of the time- and person-centered approaches to infinite ethics.

2.1. Against times. The most influential critique of time-centeredness is due to Cain (1995). The following is a variant of one of his examples.⁶

Ordeal. At times $t = 1, 2, 3, \dots$, a person is born and lives for two equally long periods. Each person's life is an ordeal where utility is negative in the first period and positive in the second period. As a whole, each person has a life worth living. Table 1 displays the utility profile of an infinite world that obtains in this way. I will refer to this world as *Ordeal*.

In *Ordeal*, the utility realized in every period is negative. Thus, if times are ultimate locations, then *Ordeal* is worse than the world where everyone has utility 0. But intuition suggests that a world in which all lives are worth living is better

⁴See Vallentyne (1995: 417). Bostrom (2011: 19) and Askell (2018: 14) make similar remarks. Broome (2006: Ch. 7) addresses a version of the locations problem in finite worlds. He rejects the time-based (or 'snap-shot') view in favor of the person-centered view.

⁵As indicated above, most works on infinite ethics endorse the person-centered approach in one form or another. A recent exception is Wilkinson (2021). He argues that Pareto over persons should be rejected in favor of Pareto over times.

⁶Cf. Cain (1995: 401).

person							sum
1	-2	4					2
2		-8	16				8
3			-32	64			32
4				-128	256		128
5					-512	⋱	512
⋮						⋱	⋮
sum	-2	-4	-16	-64	-256	...	

TABLE 1. Each column represents one time period of length one unit. The utility realized in every period is negative, but the life-time utility of every person is positive.

than a world in which everyone has utility 0. This is one version of what has become the standard objection to letting times be ultimate locations.

2.2. Against people. One criticism of person-centered approaches say that such approaches are inappropriate when we consider *future* people. The following thought experiment from Parfit (1984: 361) is a well-known illustration of this point.

Depletion. As a society, we must choose between conservation and depletion of a certain natural resource. If we choose to deplete the resource, then the quality of life over the next few centuries will be slightly higher than what it would be if chose to conserve the resource. However, if we choose depletion, then the quality of life will later, and then for many centuries, be much lower than what it would have been if we had chosen conservation.

Since the choice between depletion and conservation affects *which* individuals will be born, depletion is not bad for any one specific person. In fact, if individuals are what ultimately matter, we have the following argument for depleting the natural resource: if we do, then some individuals will be better off (those now living and those about to be born) and no-one will be worse off. Thus, at least some person-centered views seem to wrongly suggest that depletion is permissible. This problem persists (for such views) in what I will refer to as *Eternal Depletion*, which is the twist to Depletion that we obtain by replacing ‘for many centuries’ above with ‘for eternity’. We will see (in §3 and §7.2) that the possibility of an infinite future actually poses further problems for person-centered views.

3. COUNTERPARTS AND INFINITE UTILITY

As the Depletion case illustrates, we need to separate three types of comparisons of possible worlds. In the first class of problem cases, the worlds that we compare have no locations in common. In the second class, the worlds that we compare have the *same* locations. It can also happen that the location sets of the worlds that we compare have partial overlap.

Sameness occasionally has a clear meaning. If we consider a world in which a single person has coffee tomorrow morning, then we can easily imagine a single-person world where that person has tea—typically, the claim that such worlds contain the same person does not cause much confusion. However, since the meaning of transworld identity is often not as clear, it is useful to consider a generalisation of the case where the locations are the same. In this more general case, each location in one world has a *counterpart* in another.⁷ For instance, a version of myself that has coffee tomorrow morning is a counterpart to a version of myself that has tea. In general, a counterpart relation should be such that it is relevant to compare the utility at a location with the utility of its counterpart.

For utilitarians, the existence of a plausible counterpart relation does not make a decisive difference in case the number of value bearers is finite. In the infinite case, it makes all the difference. To illustrate, consider two worlds, say w_2 and w'_2 , whose populations have the same cardinality. In w_2 , each individual has utility 2. In w'_2 , everyone has utility 2, except for one individual that has utility 1.

Suppose first that w_2 and w'_2 both contain n individuals, where n is an integer greater than 1. If w_2 and w'_2 contain the same individuals we can argue that w_2 is better than w'_2 since one individual is better off in w_2 and the others are indifferent. This argument extends to the case when a plausible counterpart relation exists, but is not valid in general. Nevertheless, since the total utility in w_2 is $2 \cdot n$ and the total utility in w'_2 is $2 \cdot n - 1$, classic utilitarianism ranks w_2 above w'_2 .

Now suppose that the populations of w_2 and w'_2 are countably infinite. In the case of identical populations (or if a plausible counterpart relation exists), we may still argue that w_2 is better than w'_2 since one individual is better off in w_2 and the others are indifferent. However, in some cases it is implausible that w_2 is better than w'_2 . To see this, let w''_2 be the world obtained from w'_2 by deleting the individual in w'_2 with utility 1. Then w''_2 is a world where everyone has utility 2, and w''_2 is not better than w'_2 .⁸ Hence, in the context of countably infinite worlds, it is not generally plausible that a world where everyone has utility 2 is better than a world where some individuals have utility 1 and the others have utility 2.

The difficulty of ranking infinite worlds without a counterpart relation goes deeper. For example, it is not, in general, plausible that w_2 is better than an infinite world where *everyone* has utility 1. As noted already by Vallentyne (1995), the problem is, to begin with, that the world where everyone has utility 1 may contain all individuals from w_2 , plus a hundred clones of each. On these grounds, he concludes that traditional utilitarianism should not, in general, judge the act of bringing about an infinite world where everyone has utility 2 as being better than the act of bringing about an infinite world where everyone has utility 1.⁹ Similar

⁷Some philosophers doubt that it is ever meaningful to speak of objects in different worlds as being the same. From this perspective, the concept of a counterpart can be used a substitute for transworld identity. Readers who sympathise with this perspective may interpret my saying that ‘ p and q are the same’ to mean that p and q are counterparts in the least controversial sense possible. For an uncontroversial case, the reader is asked to think of a single-person world where the reader has coffee, and another single-person world where the reader has tea.

⁸Unless, that is, it is possible to improve a world by deleting an individual with positive utility. In the finite case, this possibility is ruled out by the Mere Addition Principle from the population ethics literature (see, e.g., Arrhenius (2000: 250)). In the infinite case, it is ruled out by Hamkins and Montero’s (2000: 93) Adding Goodness Principle.

⁹See Vallentyne (1995: 419).

observations lead Vallentyne and Kagan (1997: 20) to reject the notion that worlds where the level of utility is high are in general better than worlds where it is low. In short, without sameness or a plausible counterpart relation, the mere fact that the utility level in one infinite world is higher than in another does not in itself say much about if and how the two worlds should be strictly ranked.

In Eternal Depletion, we face a choice between two possible worlds. By what we have just noted, the fact that conservation eventually leads to higher well-being does not in itself provide a strong reason for preferring conservation to depletion. Thus, if we prefer conservation, then it seems this must be so because we believe that a plausible notion of counterparts exists in the Depletion case, or because the structure of that case in some other way provides reasons for preferring conservation to depletion. The counterpart relation that I will defend identifies people born at the same time in different futures. I begin by discussing this relation in a setting where there is one person living at each point in time.

4. TIME AND COUNTERPARTS

In this section, I am concerned with the following setting: At time $t = 1$, a person comes into existence, lives for one unit of time and then dies. A new person comes into existence at time $t = 2$, lives for one unit of time and then dies. And so on, without end. By a *future*, I mean a sequence $w = ((u_1, p_1), (u_2, p_2), \dots)$, where u_t is the lifetime utility of p_t , the person born at time t . I am primarily interested in the problem of how utilitarians and other consequentialists should rank possible futures and the acts that generate them. The study of this problem goes back at least to Segerberg (1976).

Consider, for instance, a school that each year admits a single student to a one-year program. The problem of managing the school ‘optimally’ can be conceived as an instance of the above stated problem if certain idealizations are made (e.g., the students are equally prepared when they arrive). In the case of a perpetual school, we might take u_t to be a cardinal measure of the amount of knowledge acquired by the t th student by the time of his or her graduation. Another example could be a medical clinic that admits one patient each day. For a perpetual clinic, we interpret u_t as the utility of the t th patient at the end of day t .

Due to the *non-identity effect*, it would be implausible to assume that different futures contain the exact same people.¹⁰ In fact, since almost everything we do affects who will be born, go to a particular school, or seek care from a particular clinic a few centuries from now, we can expect that any two futures eventually have no individuals in common. As Parfit (1984) writes of acts as that of choosing between different social or economic policies:

We can plausibly assume that, after one or two centuries, there will be no one living in our community who would have been born whichever policy we choose. (Parfit, 1984: 361)

¹⁰Like Broome (2012), I distinguish between the non-identity problem, of which the puzzle that Depletion presents is an instance, and the non-identity effect, which is its main driving force. The non-identity effect refers to the indirect or random way in which efforts made today affect who their future beneficiaries will be. For the time being I assume whatever is needed to rule out the possibility of non-random effects; I will consider such effects in §9.2.

And as Greaves (2016) writes of acts as unoffending as that of helping an elderly person cross a busy road:

Nor is it at all likely that the number of identities my action affects in generation r will decrease as r increases; on the contrary, it will increase. (Greaves, 2016: 350)

For simplicity, I will assume that any two futures have no individuals in common at all. I also assume, to begin with, that the non-identity effect is the only reason why individuals in different futures are not the same. In particular, I assume that we cannot control which individuals will come into existence or affect the order in which individuals appear. These assumptions are all quite reasonable in the kind of situations that I have sketched. I will discuss the implications of relaxing them in §9.2.

The *No-Difference View* (NDV) tells us to reason as if our acts were *not* identity-affecting. Mulgan (2002b: 168) formulates this view in the following way.

(NDV) If we believe we are facing a same-people choice, and discover that it is actually a different-people choice, then this should make no difference to our moral deliberations.

In a same-people choice, the worlds that we compare contain the exact same individuals; in different-people choices, they may have no individuals in common (see Parfit, 1984: 356).

In general, there may be no good reason to treat a different-people choice as a same-people choice. Mulgan's formulation therefore needs a qualifier which clarifies that the reason why we initially believed that we were facing a same-people choice, but then 'discovered' that we actually have a different-people choice, is that the choice itself is identity-affecting.¹¹ With this qualifier, the No-Difference View might be expressed as follows.

If we believe we are facing a same-people choice, and then, after having taken the non-identity effect into account, find that it is actually a different-people choice, then this should make no difference to our moral deliberations.¹²

Understood in this way, the implications of NDV are widely accepted in cases involving finitely many future people.¹³ The motivation for NDV is in one sense stronger when the future is infinite. I will elaborate this point in §7.2.

NDV induces a counterpart relation that identifies people born at the same time in different futures. To see this, consider two futures, $w = ((u_1, p_1), (u_2, p_2), \dots)$ and $w' = ((u'_1, p'_1), (u'_2, p'_2), \dots)$. If there was no non-identity effect, then p_t and p'_t would be the same individual. By NDV, we can therefore reason as if p_t and p'_t are

¹¹Note also that the plausibility of NDV is strongly dependent on the forward-looking nature of examples like Depletion, as the backward-looking implications of the non-identity effect are not as easily dismissed. We may, for example, find it difficult to formulate sincere apologies for the wrongdoings of our ancestors (Thompson, 2000). Likewise, if we choose to deplete natural resources, then our decedants will not be able to blame us for failing to provide them with better living conditions.

¹²Here is a more compact alternative: If we would have faced a same-people choice had it not been for the non-identity effect, then we can reason as if we have a same-people choice.

¹³Arrhenius et al. (2017) describe NDV as what would strike most people as 'the most plausible response' to Parfit's (1984: 358) case of the '14-year-old girl'.

the same individual. I will refer to the counterpart relation that identifies p_t and p'_t as *Relation N*.

Note that the meaning of a counterpart in the present discussion is somewhat different compared with David Lewis's counterpart theory (CT), where counterpart relations are similarity relations.¹⁴ For example, in CT, the statement 'Jane could have been a historian' means that there exists a possible world where some person that is very similar to Jane (her counterpart) is a historian.¹⁵ In the present discussion, that p and p' are counterparts means that it is not morally relevant to distinguish p and p' . This is not a claim to the effect that p and p' are in anyway similar to each other.

Similarity relations are typically intransitive relations—that a is similar to b and b is similar to c does not mean that a is similar to c . In CT, counterpart relations are therefore not transitive, in general. On the other hand, a relation of being 'morally equivalent to', defined on a set of value bearers, should be symmetric, reflexive and transitive (i.e., an equivalence relation). Let us call such a relation a *moral equivalence relation*.

5. PEOPLE AT TIMES

If we have a moral equivalence relation on a set of locations, then it is not morally relevant to make distinctions between locations in the same equivalence class. It is therefore natural to take the equivalence classes as the ultimate locations. This is the basic idea of my proposal.¹⁶

Let us see how to turn this idea into a concrete proposal in the setting of the previous section. To this end, let P be a set of potential people, and let \mathcal{W} be the set of possible futures. Thus, $w \in \mathcal{W}$ means that $w = ((u_1, p_1), (u_2, p_2), \dots)$, where u_i is the utility of $p_i \in P$. Relation N defines a moral equivalence relation \sim_N on P , where $p \sim_N p'$ if p and p' live at the same time in different futures. Formally,

$p \sim_N p'$ if and only if there exist $w = ((u_1, p_1), (u_2, p_2), (u_3, p_3), \dots) \in \mathcal{W}$ and $w' = ((u'_1, p'_1), (u'_2, p'_2), (u'_3, p'_3), \dots) \in \mathcal{W}$ such that for some positive integer t , $p = p_t$ and $p' = p'_t$.

The equivalence classes of \sim_N consist of people born at the same time in different futures. They provide a formal definition of the concept of people at times.

Some comments are in order. First, the arguments that I have given generalize trivially to a setting where single people come into existence at arbitrary times $t_1 < t_2 < t_3, \dots$ and the person born at time t_i lives for $l_i > 0$ units of time. In this more general setting, a future can be defined as a sequence $w = ((u_1, p_1), (u_2, p_2), \dots)$, where u_i is the lifetime utility of p_i , the person born at time t_i .¹⁷ This definition reflects a choice to focus on lifetime utility rather than utilities in arbitrary time periods. This is not the only way in which my proposal places significance on people. I have also elected to consider counterpart relations defined on sets of people rather than on sets of times, preferences, or subjective experiences.

¹⁴It is also different compared with Vallentyne and Kagan (1997: 19), whose counterpart functions are defined by a topological condition.

¹⁵See Lewis (1968).

¹⁶This idea is in part inspired by Meacham (2012), who uses counterpart relations to deal with some of the questions that I address.

¹⁷This includes the setting of Ordeal (see §2.1), where $t_i = i$ and $l_i = 2$.

Second, the specification of a future as a list of pairs $((u_1, p_1), (u_2, p_2), \dots)$ can be simplified if people at times are the ultimate locations. Since $((u_1, p_1), (u_2, p_2), \dots)$ and $((u_1, p'_1), (u_2, p'_2), \dots)$ are indistinguishable if we identify people born at the same time, it becomes convenient to associate a future with a sequence u_1, u_2, u_3, \dots of utilities. We then interpret u_i not as the lifetime utility of a particular person, but as the lifetime utility the person born at time t_i , whoever he or she will be.

Third, the difference between the *de re* and *de dicto* interpretations of ‘the person born at time t ’ seems to bear on the question of whether people come in a natural order. (I return to this question several times below.) As an illustration, consider the statement

‘The person born at time t could have been born at time $t - 1$.’

Interpreted *de re*, this statement makes perfect sense (although the correctness of the claim depends, among other things, on our conception of personal identity). On the *de dicto* interpretation, the statement does not make sense. Relatedly, while it is difficult to see how a set of specific people can have a natural order, the claim that people at times come in a natural order is not as easily dismissed.

It is also worth noting that the *de dicto* interpretation of ‘the person born at time t ’ accords with how many of us think about people whose identities we do not yet know, but whose appearance we expect at some particular point in time. We think of ‘Monday’s client’ and ‘the class of 2030’ abstractly, knowing that our choices may very well affect who these individuals will be. That we find it natural to do so can perhaps in part be explained by the fact that during any given time period, we have a certain amount of attention and energy that can only be used during that time. If a clinic is equipped to operate on one person per day, then the person whose life it has the best chance of improving on a particular day is the person that it admits *on that day*. It seems its primary obligation on that day is therefore not to any particular person, but to the person that it admits on that particular day, whoever he or she will be.

Finally, it should be noted that there is a close resemblance between the concept of people at times and the concept of a generation that is used in the social choice literature.¹⁸ The framework with time-indexed utilities that this literature employs appears in several works from the pre-Cain (1995) era in infinite ethics.¹⁹ Subsequently, the question of whether time should be allowed to play a role received considerable attention. On the one hand, one might expect time dependence as an artefact of the separation of people in time. On the other hand, as Bostrom (2011: 19) points out, that people are separated in time does not *per se* provide a reason for allowing time dependence in an ethical theory. Considering this, the interesting question seems to be whether time dependence can in some way be justified on philosophical grounds. Here we have seen that a certain degree of time dependence is inevitable if we accept the No-Difference View.

¹⁸An often used assumption in this literature is that there is a constant (finite) number of people in each time period (see, e.g., Fleurbaey and Michel, 2003: 799). In the special case when there is one person per period, the definition of a generation coincides with my informal definition of a person at a time.

¹⁹E.g., Vallentyne (1993) and van Liedekerke (1995)

6. OUTLINE

The rest of the paper explores the implications of taking people at times as the ultimate locations. I first illustrate the difference between the time-centered view and the people at times-centered view by revisiting Ordeal (§7.1). We will see that the people-at-times-centered approach avoids the standard criticism of time-centeredness. I then illustrate the difference between person-centeredness and people-at-times-centeredness. There are two differences to look out for. Firstly, if we take individuals as the locations, then we cannot plausibly assume that different futures have the same locations. By contrast, if people at times are the locations, then the locations are the same. Secondly, while people at times are defined in terms of times, which arguably have a natural order, there appears to be no reason to think that a set of specific individuals come in a morally significant order. For utilitarians, neither difference is decisive if the worlds that we compare are finite in duration. On the other hand, without sameness or a natural order, it becomes virtually impossible to discriminate between infinite worlds. In §8 I discuss a class of problem cases where incomparability can be avoided by taking people at times as the locations.

7. ORDEAL AND DEPLETION

This section revisits the two problem cases discussed in §2.

7.1. Ordeal: times vs people at times. Recall from §2.1 that one version of the standard objection to time-centeredness is that it leads us to conclude that Ordeal is worse than a world where everyone has utility 0. From the people-centered viewpoint, each person in Ordeal has a life fully worth living, and Ordeal is therefore better than a world where everyone has utility 0. The same is true for people at times. Hence, the people at times-centered approach is not subject to the criticism that is often leveled at time-centeredness.

Ordeal illustrates the difference between the time-centered approach and the people at times-centered approach. The difference between person-centeredness and people at times-centeredness is here more subtle. To illustrate, consider the choice between bringing about (i) Ordeal, or (ii) a world where people are born at $t = 1, 2, 3, \dots$ and live for two units of time, and everyone has utility 0. If the choice is not identity-affecting, then it is better to bring about Ordeal by Pareto over persons. In terms of people at times we can argue that it is better to bring about Ordeal if the choice between (i) and (ii) is identity-affecting.

7.2. Depletion: people vs people at times. Let us now return to Eternal Depletion (i.e., the twist to the Depletion case that we obtain by replacing ‘for many centuries’ with ‘for eternity’; see §2.2). Assume, for simplicity, that there is one person per period (say eighty years), and that everyone in the conservation world, w_c , has utility 2. In the depletion world, w_d , the people that live in the first two periods have utility 2.1 and the rest have utility 1. In other words, the utility sequences that go with w_c and w_d are as follows.

$$w_c : (2, 2, 2, 2, 2, 2, 2, \dots)$$

$$w_d : (2.1, 2.1, 1, 1, 1, 1, \dots).$$

Due to the non-identity effect, the two worlds have at most a small number of individuals in common.

In the original version of Depletion, utilitarianism prefers conservation since conservation produces more utility. But since utilitarianism leads Parfit to unwanted implications in different number cases, he resorts to intuition.²⁰ He suggests that, all else being equal,

it is better that those who live are better off than those who would have lived. (Parfit, 1984: 360)

Does this intuition become any less appealing in the Depletion case if the future is infinite? Would depletion be permissible if it increased the quality of life for a few centuries, but then reduced the quality of life for all eternity? I have found no good reason to think that this is so.

The Depletion case is a key reason why Parfit adopts NDV.²¹ As indicated in §3, Eternal Depletion provides stronger reasons for accepting NDV. Those reasons stem from the fact that it is difficult to give a principled defence of conservation when the future is infinite, without appealing to NDV. To be sure, principles that rank w_c above w_d are easily constructed. For example, the following seemingly plausible principle ranks w_c above w_d .

(†) If there are cofinite subsets L and L' of the location sets of worlds w and w' , respectively, such that the utility of every location in L is greater than c and the utility of every location in L' is smaller than c' , where c' is less than c , then w is better than w' .

In the context of worlds that have the same locations, † is fairly uncontroversial. In this context, † reduces to Vallentyne and Kagan's (1997: 11) first strengthening of their Basic Idea. The problem is that principles like † have implausible implications when we consider infinite worlds whose locations are not the same. (As mentioned in §3, this observation goes back at least to Vallentyne (1995).) We might restrict their range of application in such a way that they apply in Eternal Depletion with people as locations, but are silent in other cases where locations are not the same. However, in doing so we will need to explain what distinguishes Depletion from other cases where the locations are not the same. It seems that such explanations will ultimately have to appeal to the fact that Depletion is about *future* people. We then end up with the conclusion that cases involving different future people can be dealt with as if they involved the same people, which is precisely what NDV suggests.

Note that the person-centered principles that the literature provides typically do *not* rank w_c and w_d . This is the case, for instance, for Arntzenius' (2014: 55) Weak People Criterion.²² and the principles developed by Vallentyne and Kagan (1997).

²⁰Parfit's intuition in the Depletion case is shared by many, but it is by no means unchallenged (cf. Boonin, 2008: 145–150). For discussion, see Roberts (2019: §3.1).

²¹He rhetorically asks if the non-identity effect made us any less concerned about policies such as depletion, after we became aware of it (see Parfit, 1984: 367).

²²Askell (2018: 160) formalizes Arntzenius' criterion using the following notation: Given worlds w and w' , let P be the set of all people that are in either w or w' . If $p \in P$ exists in w , let $u_w(p)$ denote p 's utility in w ; if p does not exist in w , then $u_w(p) = 0$. The Weak People Criterion says that w is better than w' if and only if $\sum_{i=1}^n (u_w(p_i) - u_{w'}(p_i))$ tends to a positive real number or plus infinity for every enumeration p_1, p_2, p_3, \dots of P . To see that this criterion does not rank w_c above w_d , note that if we enumerate P in such a way that p_i exists in w_c if and only if i is an integer multiple of (say) 10, then $\sum_{i=1}^n (u_{w_c}(p_i) - u_{w_d}(p_i)) < 0$ for every $n \geq 1$.

That these principles do not rank w_c above w_d (with people as the locations) should not be held against them. It might very well be the case that silence is often the most appropriate response if no counterpart relation has been specified.²³

If the locations are people at times, then w_c and w_d have the same locations. The betterness of w_c is then entailed by principles that enjoy relatively wide support. For instance, with people at times as the locations, w_c is better than w_d by the aforementioned extension of Vallentyne and Kagan's Basic Idea.

8. PERSON-CENTEREDNESS AND INCOMPARABILITY

As we have just seen, person-centeredness does not seem to allow us to determine whether it is better to conserve natural resources than to deplete them. In this section, I consider another case where the person-centered approach does not deliver verdicts. The central question is whether or not the spatiotemporal density of value can be used to discriminate between alternatives. This question has been considered in virtually all works on infinite ethics.

The setting of the following case was described in §4,

The perpetual clinic I. We must choose between two treatments: T_1 and T_2 . On each day, T_i is successful with probability P_i , independently of what happens on other days, where $P_1 = 0.9$ and $P_2 = 0.1$. Patients have utility 0 before treatment and utility 1 after a successful treatment.

As consequentialists, we might ask which choice brings about the better outcome. The result of choosing T_i will be some future $w_i = ((u_1, p_1), (u_2, p_2), (u_3, p_3), \dots)$ where u_1, u_2, u_3, \dots is a sequence of 0s and 1s. By the law of large numbers, the fraction of 1s in this sequence equals P_i , with probability 1. So the utility sequences that go with w_1 and w_2 might be as follows.

$$\begin{aligned} w_1 &: (1, 1, 1, 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 0, 1, 1, 1, \dots) \\ w_2 &: (0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 1, 0, 0, 1, 0, 1, 0, 0, 0, \dots). \end{aligned}$$

Our first reaction is perhaps that w_1 is better than w_2 since the long-run fraction of 1s is higher in the first sequence. However, this notion of relative frequency is order-dependent. We therefore need to ask ourselves what the ultimate locations are and whether they come in a morally significant order.

The strongest principle developed by Vallentyne and Kagan (1997) entails that w_1 is better than w_2 if the locations have what they refer to as an *essential natural order*. In particular, they argue that worlds like w_1 are better than worlds like w_2 if the locations are points in time. But, like many others, they are unwilling to take points in time as the ultimate locations. For instance, Bostrom (2011: 19) points out that since people do not have a natural order, it is not clear that worlds like w_1 are morally better than worlds like w_2 . This standpoint is further developed by Askill (2018). She defends the view that people are ultimate locations and argues that worlds like w_1 and w_2 are incomparable—that is, that they cannot be strictly ranked, but are not equally good.

As an illustration of Askill's argument, let us consider a world, call it w'_2 , that has the same qualitative properties as w_2 . That w'_2 has the same qualitative properties as w_2 means that the utility sequence that goes with w'_2 looks exactly like the one that goes with w_2 . The people in w'_2 are precisely the same as the people in w_1 ,

²³This is precisely what Vallentyne and Kagan (1997: 20) contend.

but the order in which they appear in w'_2 is not the same as the order in which they appear in w_1 . Let the person that is admitted on day 4 in w_1 be admitted on day 5 in w'_2 ; this person is better off in w'_2 than in w_1 . Since the sequences that go with w_1 and w_2 each contain infinitely many 0s and infinitely many 1s, the remaining individuals in w_1 can be assigned to days in such a way that no one is worse off in w'_2 . By a similar argument, we can consider a duplicate of w_1 , call it w'_1 , that has the same qualitative properties as w_1 , contains the same individuals as w_2 , and is such that some are better off in w_2 than in w'_1 , and no one is worse off in w_2 .

Now, suppose we believe that the qualitative properties of w_1 and w_2 entail that w_1 is better than w_2 . Since the pair (w'_1, w'_2) is a qualitative duplicate of (w_1, w_2) , it seems we must then conclude that w'_1 is better than w'_2 . But the Pareto axiom (over persons) says that w'_2 is better than w_1 , and that w'_1 is worse than w_2 . From the person-centered viewpoint, we therefore have that w_2 is better than w'_1 , w'_1 is better than w'_2 , and w'_2 is better than w_1 . Assuming transitivity of ‘better than’, this contradicts that w_1 is better than w_2 .

There are two ways to avoid this contradiction without abandoning the person-centered view. The first is to appeal to Parfit’s Time-Dependence Claim (TDC), which says that a person cannot exist at radically different times in different futures.²⁴ If TDC is true and w_1 and w_2 are possible worlds, then w_1^* and w_2^* are impossible worlds. This is because there is no upper bound on the difference between the time at which a person exists in w'_2 (w'_1) and the time at which that person exists in w_1 (w_2). So, if we decide to refrain from comparing worlds whose existence is incompatible with TDC we may assert, without contradicting ourselves, that w_1 and w_2 can be strictly ranked, but w'_1 and w'_2 are incomparable.²⁵

The second way to avoid a contradiction is to conclude, as Askill (2018) does, that w_1 and w_2 are incomparable. This conclusion does not come without cost. Because the *act* of choosing T_1 must be better than that of choosing T_2 . (At least there is a strong intuition which suggests that this should be so, one that does not involve the qualitative properties of w_1 and w_2 or the notion of an essential natural order.) Hence, as Jonsson and Peterson (2020) observe, the incomparability of worlds like w_1 and w_2 implies that one act can be better than another even though the probability is 0 that it brings about a better outcome.

The preceding remarks were not meant to provide a definitive argument against person-centered accounts of consequentialism in infinite worlds. Yet one might see it as a problem for such accounts that choosing a treatment that cures sick people with probability 0.9 has no chance of bringing about a better outcome than choosing a treatment that cures them with probability 0.1. This problem is circumvented if people at times are ultimate locations. Indeed, since people at times are defined in terms of times, which arguably do come in a natural order, the main criticism of order-dependent principles does not apply when the locations are people at times.

²⁴More precisely, TDC asserts that if a person had not been conceived within a month of when he or she was in fact conceived, then he or she would never have existed (see Parfit, 1984: 351). Parfit argues that TDC is *in fact true* given the nature of human biology and natural reproduction. In §9.2 I consider a thought experiment where TDC is false.

²⁵Parfit contends that an ethical theory should be consistent with TDC. This proposal has not been left unquestioned. For instance, Mulgan (2002a) points out that TDC presumes the falsity of beliefs about reincarnation held by millions of people. I will not take a stance on whether ethical theories should be consistent with TDC. My aim here is simply to indicate how we may consistently maintain that w_1 and w_2 can be strictly ranked.

And as we have seen (in §7.1), the people at times-centered approach avoids the standard criticism of time-centeredness.

9. FURTHER PROBLEM CASES

I have used a framework where it is assumed that single individuals come into existence at successive points in time. This framework is flexible enough to handle many problem cases from the literature on infinite ethics, from Segerberg (1976) to Askill (2018). In this concluding section I discuss some problem cases where the assumptions that I have used do not hold.

9.1. Number-affecting choices. As indicated in §5, the framework that I have used can handle some cases where people live contemporaneously. In Ordeal, for instance, there is one person in the first period and two people in each one of the remaining periods. We get a similar case if we consider a school that each year admits a single student to a three-year program. In this case, the school accommodates one student during the first year, two students during the second year, and three students during each one of the remaining years.

However, further arguments are needed if our acts not only affect the identities of the people that are admitted, but also the number of people that are admitted. Consider the following twist to the case from the previous section.

The perpetual clinic II. We can either **(a)** treat one patient per day and use a treatment that on any given day is successful with probability 0.9, independently of what happens on other days, or **(b)** we can treat two patients per day and use a treatment that is successful with probability 0.1.

If we take groups of individuals admitted on the same day as the locations, then the utility sequences that go with **(a)** and **(b)** might be as follows.

$$\begin{aligned} \text{(a)} : & (1, 1, 1, 1, 1, 0, 1, 1, 1, 1, 0, 1, 1, 1, 1, 1, 0, 1, 1, 1, 1, \dots) \\ \text{(b)} : & (0, 0, 0, 0, 0, 2, 0, 0, 0, 0, 2, 0, 0, 0, 0, 0, 0, 0, 0, 2, \dots). \end{aligned}$$

We could also take single individuals as the locations. In this case, the utility sequence that goes with **(b)** is made up of 0s and 1s.

Expected utility theory suggests that choosing **(a)** is better than choosing **(b)**. But does the act of choosing **(a)** bring about a better outcome? If we take individuals as the locations (in the strict, person-affecting sense), then the locations are not the same, have no natural order, and incomparability entails by Askill's argument—see §8. The same is true (for the same reasons) if the locations are groups of individuals. Thus, whether we consider individuals or groups of individuals is not crucial for the questions that I have discussed.

The crucial distinction is that between particular individuals and people at times. I started out (in §4) in a setting where this difference is easy to flesh out. Matters become increasingly complicated when we consider acts which not only affect the number of people come into existence and their identities, but also the times at which they come into existence.²⁶ I will not try to defend the concept of people at times in the greatest generality possible. Besides reasons of space, the main reason for this is that I doubt that it would lead us to new insights about infinite ethics. A central question in infinite ethics concerns if and how generic incomparability

²⁶See Arntzenius (2014: 56) for discussion of such a case.

can be avoided. The arguments provided in this paper show that we can avoid incomparability in a class of problem cases that have been frequently discussed. Given this, it would be unsurprising to learn that incomparability can be avoided in other, more complicated cases. It would, for example, be unsurprising if the act of choosing **(a)** brings about a better outcome than that of choosing **(b)**. To defend such conclusions, further arguments are needed. They will not be presented here.

9.2. Beyond the Time Dependence Claim. During most of the discussion in this paper I have assumed that any two futures eventually have no individuals in common. This means, in particular, that the assertion in the Time Dependence Claim is true (i.e., that a person cannot exist at radically different times in different futures). I conclude by considering a case from Askill (2018) where the Time Dependence Claim is false. I will suggest that the people at times-centered view, perhaps surprisingly, does not yield implausible prescriptions in this case. I will also show that weakening the assumptions that I have used in fact leads to further problems for person-centered views.

Consider the following thought experiment from Askill (2018: 13).

Freezer A freezer contains infinitely many fertilized eggs, e_1, e_2, e_3, \dots , which can be defrosted at any point in time. The person that e_i will become, once defrosted, will live for eighty years on an island that only has room for one person at a time.

The person-centered approach has the peculiar implication that it matters in which order the embryos are defrosted. To see this, suppose that the living conditions on the island are such that people living in odd-numbered periods have utility 0 while people living in even-numbered periods have utility 1. Let p_i denote the person that e_i will be, and let w be the world that obtains by defrosting e_t at the beginning of period $t, t = 1, 2, 3, \dots$. By choosing an alternative order, we can create a world, call it w^* , such that one person (say p_1) is better off in w than in w^* , and no-one is worse off—see Table 2. Then w is better than w^* by Pareto over people.

period	1	2	3	4	5	6	7	8	...
utility	1	2	1	2	1	2	1	2	...
w :	e_1	e_2	e_3	e_4	e_5	e_6	e_7	e_8	...
w^* :	e_3	e_1	e_5	e_2	e_7	e_4	e_9	e_6	...

TABLE 2. Two worlds obtained by defrosting the embryos in two different orders.

From the people-at-times-centered viewpoint, w and w^* are indistinguishable, because the order in which the embryos are defrosted does not affect the utility of the person born at time t (*de dicto*). Thus, there is a conflict between the person-centered view and the people-at-times-centered view. From the person-centered viewpoint, this conflict might be interpreted as a problem for the concept of people at times. But the conflict can also be interpreted as a yet another problem for person-centeredness. On this interpretation, what matters is that the world is populated by people that have good lives; who these people are the order in which they appear is insignificant.
