Abstract

We study how to enhance language models (LMs) with textual commonsense knowledge. Previous work (e.g., KnowBERT) has focused on the integrating entity knowledge from knowledge graphs. In order to introduce the external entity embeddings, they learn to jointly represent the original sentences and external knowledge by pre-training on a large scale corpus. However, when switching to textual commonsense, unlike the “light” entity embeddings, the encoding of commonsense descriptions is “heavy”. Therefore, the pre-training for learning to jointly represent the target sentence and external commonsense descriptions is unaffordable. On the other hand, since pre-trained LMs for representing the target sentences alone are readily available, is it feasible to introduce commonsense knowledge in downstream tasks by fine-tuning them only?

In this paper, we propose a plug-and-play method for large-scale commonsense integration without pre-training. Our method is inspired by the observation that in the regular fine-tuning for downstream tasks where no external knowledge was introduced, the variation in the parameters of the language model was minor. Our method starts from a pre-trained LM that represents the target sentences only (e.g., BERT). We think that the pre-training for joint representation learning can be avoided, if the joint representation reduces the impact of parameters on the starting LM. Previous methods such as KnowBERT proposed complex modifications to the vanilla LM to introduce external knowledge. Our model (Cook-Transformer, commonsense knowledge-enhanced Transformer), on the other hand, hardly changes the vanilla LM except adding a knowledge token in each Transformer layer. In a variety of experiments, COOK-Transformer-based BERT/RoBERTa improve their effect without any pre-training.

1 Introduction

Although unsupervised language models have achieved big success on many tasks (Devlin et al. [2019]), they are incapable of learning low-frequency knowledge. In Fig. [1] we found that even if we replace “Kevin was” (left) with “Jim was” (right), BERT (Devlin et al. [2019]) still predicts the masked word as sick, crying, dying etc. This is because similar texts in its training corpus rarely describe the subject of “comforted”. To improve the model’s ability to generalize and understand low-frequency knowledge, we propose to incorporate commonsense into language models. In Fig. [1] to make correct predictions, we need to enhance the language model with the commonsense c₁. It can be seen that commonsense like c₁ is more suitable to be represented in textual form, instead of the structured knowledge graphs. In this paper, we focus on integrating commonsense in the text form as in Fig. [1].

We analogize introducing textual commonsense knowledge to the previous studies of introducing entity knowledge from knowledge graphs (Peters et al. [2019], Zhang et al. [2019]). They typically represent each entity via an embedding. They modify the structure of Transformer-based LMs to allow the interaction between the target sentence and the corresponding entities, instead of the original Transformer that only represents the target sentence. In order to “accustom” the joint representation, their models need to be pre-trained on large-scale corpora with objectives like masked language modeling.

However, following these methods to introduce commonsense knowledge will be unaffordable. Unlike discrete symbolic knowledge that can be represented by independent embeddings, textual knowledge uses more complicated encoders (e.g., BERT). The costs of both feedforward and backpropagation of text encoders are much higher than for standalone symbolic knowledge embeddings. This makes the pre-training on a large scale corpus unaffordable.

In this paper, we propose to introduce commonsense knowledge so that existing pre-trained LMs (e.g. BERT) can leverage the newly introduced commonsense knowledge without further pre-training. We denote this setting as integrating plug-and-play commonsense into LMs. We are inspired by an observation of fine-tuning LMs (Radiya-Dixit and Wang [2020]), i.e., the parameters after fine-tuning are very close to those before fine-tuning. This phenomenon is easy to explain because a pre-trained LM can be fine-tuned in much fewer steps to perform specific tasks than the number of steps required for pre-training.

Reviewing the previous LMs which introduce external entity knowledge, we find that all of them have made significant changes to the existing language models. For example, KnowBERT (Peters et al. [2019]), Ernie (Zhang et al. [2019]), and BERT-MK () are typical models based on BERT. In
order to introduce knowledge, they all propose additional knowledge fusion layers. In these knowledge fusion layers, the entity embeddings and the target sentence tokens are combined via self-attention. Undoubtedly, after these drastic model modifications, the parameters of the original pre-trained LM (i.e. BERT) are no longer applicable. Therefore it is necessary for them to learn to jointly represent the target sentences and entity embeddings through pre-training.

Based on the phenomenon of minor variations of parameters after fine-tuning, we propose to avoid the expensive pre-training. The new proposed commonsense-enhanced LM consists of an existing LM (i.e. BERT or RoBERTa in this paper) to represent the target sentence. We denote the LM for the target sentence as the meta language model (meta LM). We further propose that if we can introduce external commonsense while reducing the impact on the meta LM, the commonsense-enhanced LM can accustom to the external commonsense more easily without pre-training. Thus, we keep most of the structure of the meta LMs and only add a new knowledge token to represent the commonsense knowledge. The commonsense embeddings are introduced through residuals (·) to this token. In this way, the meta LM is minimally affected. In particular, if the external commonsense embedding is zero vectors, the commonsense-enhanced LM will be the same as the meta LM. Compared with other knowledge integration models, our model has two advantages. First, it only adds one knowledge token to the target sentence to retain the meta LM. Second, our model still allows multiple layers of attentions between the commonsense and the meta LM. We refer to this new model as the Cook-Transformer.

Some other ways of introducing textual knowledge include continuing pre-training on textual knowledge [Guururangan et al. 2020; Sun et al. 2019], and directly using common knowledge as additional textual input (e.g., ExpBERT (Murty, Koh, and Liang 2020)). Continue pre-training the LM on the corpus of the external knowledge requires external knowledge and downstream tasks to have similar domains (Gururangan et al. 2020). However, as can be seen in Fig. 1 the commonsense and the downstream task has obvious distribution discrepancy, which leads to a decrease in effectiveness. We will verify this empirically in Sec 6.3.

If we introduce commonsense knowledge by ExpBERT, we will meet the challenge of the scale of the commonsense. Because ExpBERT only captures small-scale commonsense with a fixed size. We will also verify this empirically in Sec 6.3.

2 Related work

In this section, we compare different ways to introduce knowledge into language models. We divide the knowledge introduction methods into (1) continuing pre-training method (Gururangan et al. 2020; Sun et al. 2019) and (2) explicit introduction in the downstream task (Guu et al. 2020; Murty, Koh, and Liang 2020).

Continuing pre-training the language model is effective when the external knowledge is similar to the downstream task (Gururangan et al. 2020; Sun et al. 2019). However, commonsense and downstream tasks are OOD, so continuing pre-training is unsuitable for commonsense introduction. We have empirically verified this in Sec 6.3.

Introducing explicit knowledge in downstream tasks

We classify the knowledge into structured knowledge, plain text, and semi-structured knowledge, depending on its form. The entries of structured knowledge are represented as individual embeddings (Peters et al. 2019; Zhang et al. 2019; Guan et al. 2020; Zhou et al. 2018), while commonsense descriptions in this paper can be represented more accurately by the contextual information of their word sequences.

Plain text knowledge A typical work of introducing plain text knowledge is REALM (Guu et al. 2020), which contains an expensive knowledge retriever. The knowledge retriever determines whether external knowledge can be introduced. However, the commonsense we use is not plain text. Each commonsense description is associated with a verb/verb phrase, therefore the retrieval is much easier. This motivates us to propose new models to represent the commonsense.

Semi-structured commonsense knowledge Note that the commonsense knowledge base used in this paper is semi-structured. That is, each commonsense description is associated with corresponding one verb or verb phrase. In Fig. 1 c1, c2, c3 are associated with comforted. With the association, we can find all candidate commonsense...
descriptions efficiently and precisely. Therefore, we focus on the knowledge integration for semi-structured knowledge, rather than the knowledge retrieval in REALM. ExpBERT (Murty, Koh, and Liang 2020) also integrates several candidate commonsense descriptions as inputs. However, ExpBERT directly concatenates the representations of these commonsense descriptions. Such knowledge integration cannot be scaled up to the large scale commonsense knowledge base in this paper. We verified this empirically in Sec 6.3. So we need to propose a new representation that makes full use of the contextual information for large-scale commonsense knowledge base.

3 Problem Setup: Integrate Plug-and-Play Commonsense into Language Models

We consider a text classification task where the text $x$ and its label $y$ are provided for training. Assuming that the commonsense descriptions come from a large-scale commonsense knowledge base (e.g. ATOMIC2020 in this paper), we retrieve all relevant commonsense for $x$, denoted as $cs(x) = \{c_1 \cdots c_n\}$, where each $c_i$ is a commonsense description. The retrieval process will be shown in Sec 6.

Our model is based on a meta LM $LM_0(x|\theta_0)$, where $\theta$ is its parameter. To avoid any other pre-training, the commonsense-enhanced model $LM_c$ consists of $LM_0$. As we stated in the introduction, we tried to minimize the variation of $LM_0$’s parameters after fine-tuning $LM_c$ for specific tasks. To this end, the commonsense-enhanced does not directly change the structure of the $LM_0$. Instead, it introduces commonsense through the transformation of $x$. Our new model $LM_c$ is defined as:

$$LM_c(x, cs(x)|\theta_0, \theta_c) = LM(t(x, cs(x)|\theta_c)|\theta_0)$$  \hspace{1cm} (1)

That is, the model introduces commonsense knowledge in the model by transforming $x$ to $t(x, cs(x)|\theta_c)$, rather than modify the language model as in KnowBERT. The goal of training is to find parameters $\theta_0, \theta_c$ which minimize the loss of training examples given the texts and candidate commonsense descriptions:

$$\arg \min_{\theta_0, \theta_c} \mathbb{E}_{(x,y) \in \text{train}} \mathcal{L}(f(x, cs(x)|\theta_0, \theta_c), y)$$  \hspace{1cm} (2)

where $\mathcal{L}$ is the loss function.

4 Cook-Transformer

In this section, we propose Cook-Transformer based on Transformer to introduce extra commonsense descriptions. We first show Cook-Transformer on an abstract level in Sec 4.1. Then we elaborate two modules within it, i.e. knowledge enhancement and knowledge integration, in Sec 4.2 and Sec 4.3 respectively.

4.1 Framework

In this subsection, we show how our Cook-Transformer works at an abstract level. For the target sentence $x$, Cook-Transformer takes both $x$ and $cs(x)$ as inputs. To incorporate all the information of $x$ and $cs(x)$, the Cook-Transformer contains three vanilla Transformers, denoted by $\text{Transformer}^{(1)}$, $\text{Transformer}^{(2)}$, and $\text{Transformer}^{(3)}$ as shown in Fig. 2. $\text{Transformer}^{(1)}$ encodes the commonsense knowledge base, $\text{Transformer}^{(2)}$ encodes the target sentence $x$, and $\text{Transformer}^{(3)}$ integrates all candidate commonsense descriptions and transfers knowledge to $\text{Transformer}^{(1)}$.

Transformer$^{(1)(2)(3)}$, Transformer$^{(1)}$ is the Transformer of the meta LM, which is used to model the target sentence $x$. To avoid changing the parameters of the meta LM, we only add an additional knowledge token to the target sentence to represent the commonsense knowledge, without modifying others structure of Transformer. We will describe how this knowledge token interacts with other tokens of $x$ and enhances knowledge in Sec 4.2. Each commonsense description will be represented as a knowledge encoding by Transformer$^{(2)}$ and then introduced into the knowledge token by Transformer$^{(3)}$. This knowledge integration model will be introduced in Sec 4.3. The framework is shown in Fig. 2.

4.2 Knowledge Enhancement Module

The knowledge enhancement module represents the target sentence while allowing commonsense to enhance its representation. Interaction between words and commonsense. We use Transformer$^{(1)}$ to represent the interaction between words of the target text $x$. In addition, we introduce a special token $[k]$ to represent the commonsense knowledge. We denote it as the knowledge token. Transformer$^{(1)}$ encodes
null Commonsense Some target texts may not have valid commonsense from the commonsense knowledge base to enhance their representations. Therefore, we refer to the settings of REALM (Guo et al. 2020) to add a null commonsense into the candidate commonsense of all target texts. We denote the null commonsense as \( c_0 \). Matching to the null commonsense indicates that the commonsense knowledge base cannot help enhance the target text.

5 Adaptation to Pre-trained Language Models

In this section, we take BERT as an example to illustrate how we adapt Cook-Transformer to existing pre-trained language models. In addition to using BERT as the meta language model, we also use Transformer layers in BERT as Transformer\(^{(2)}\) to represent common knowledge more accurately.

We denote the adapted model as Cook-BERT. An important manifestation of the effectiveness of the Transformer structure is its applications in large-scale pre-trained models (e.g., BERT, RoBERTa). In order to introduce external knowledge, many other studies conduct pre-training over large-scale unsupervised corpus (Peters et al. 2019; Xiong et al. 2019). However, Cook-Transformer is able to directly adapt to the existing pre-trained language models without the pre-training. In other words, when adapting Cook-Transformer to Cook-BERT, we directly use the parameters of each Transformer layer of BERT to initialize the Cook-Transformer layers of Cook-BERT. This property greatly improves the applicability of Cook-BERT. In the rest of this section, we will describe how Transformer\(^{(1)}\), Transformer\(^{(2)}\), and Transformer\(^{(3)}\) are adapted respectively in Sec 5.1 and how to fine-tune Cook-BERT in Sec 5.2.

5.1 Layer-by-Layer Connection and Adaptation

As we have described in Sec 4.1, Transformer\(^{(1)}\) will use the original pre-trained language model. In addition, in order to allow Transformer\(^{(2)}\) to provide more accurate commonsense encodings as well, we use a separate pre-trained language model to represent multiple Transformer\(^{(2)}\) layers. We denote the two pre-trained language model as BERT1 and BERT2. We connect the Transformer\(^{(1)}\) and Transformer\(^{(2)}\) in the corresponding layer of each BERT by Transformer\(^{(3)}\). Therefore, Cook-BERT makes full use of the multi-layer structure of BERT, while allowing commonsense in the knowledge token to fully interact with the target text in each layer. The architecture is shown in Fig 3.

Transformer\(^{(4)}\) We adapt the Transformer of BERT1 to Transformer\(^{(1)}\) in the knowledge enhancement module of Cook-Transformer. Note that the original BERT’s tokens are \([CLS] w_1 \cdots w_n \ [SEP]\) (for a single sentence) or \([CLS] w_1 \cdots w_m \ [SEP] w_{m+1} \cdots w_L \ [SEP]\) (for a sentence pair). We follow \(\text{Wang et al. 2020}\) and use a special token \([k]\) as the knowledge token. When tokenizing sentences, we insert the \([k]\) token after the \([CLS]\) token for each given text. In this way,
the input tokens become [CLS] [k] w₁ ⋯ wₗ [SEP] or [CLS] [k] w₁ ⋯ wₘ [SEP] wₘ₊₁ ⋯ wₗ [SEP], respectively. This simple modification allows us to use [k] as the knowledge token in the knowledge enhancement module.

In addition, Transformer₁ contains a knowledge update step so that we can add the csemb from the same layer of Transformer₃ to the knowledge token.

**Transformer**₂ We adapt each Transformer layer of BERT2 to the Transformer₂ layer. The adaptation is straightforward since Transformer₂ uses the vanilla Transformer structure. We use the encoding of the [CLS] token in each corresponding layer as the commonsense representation emb to enhance the representation of the corresponding layer in BERT₁.

**Transformer**₃ For each pair of corresponding Transformer₁ and Transformer₂ from the same layer, we use one Transformer₃ to connect them to transfer the information from BERT2 to BERT1.

In summary, when adapting to BERT-base with 12 Transformer layers, Cook-BERT contains 12 Transformer₁ layers for BERT1, 12 Transformer₂ layers for BERT2, and 12 Transformer₃ layers for layer-wise knowledge integration.

### 5.2 Parameter Initialization and Model Training

In our implementation, BERT1 and BERT2 have independent parameters. We use the parameters of BERT to initialize both BERT1 and BERT2. The parameters of Transformer₃ layers are randomly initialized. For downstream tasks, we then fine-tune all the parameters in the fashion of end2end.

### 6 Experiments

We evaluate the effectiveness of our proposed models in three scenarios: cloze-style commonsense reasoning, text classification, and low-resource commonsense settings. All the experiments run over a computer with 4 Nvidia Tesla V100 GPUs.

**Models** We consider adapting Cook-Transformer to BERT and RoBERTa, which are denoted as Cook-BERT and Cook-RoBERTa, respectively. We use the BERT-base and RoBERTa-large from the HuggingFace Transformer library (Wolf et al. 2020).

**Implementation details for candidate knowledge retrieval** For a given text x, we retrieve candidate commonsense from ATOMIC2020. We use the if-then descriptions in ATOMIC2020 (e.g. Fig. 1). Since these descriptions cover 173k different verb phrases – one of the fundamental elements of language – the retrieval is applicable to a broad range of downstream text understanding tasks.

We use a simple retrieval method. We simply consider word segments with window size 5 of the input text x. All the commonsense descriptions matching one of these text segments will be regarded as the candidate commonsense descriptions cs ∈ cs(x).

### 6.1 Natural Language Commonsense Reasoning

**Datasets** We consider the following commonsense reasoning benchmarks: WSC273 (Levesque, Davis, and Morgenstern 2012), PDP (Morgenstern, Davis, and Ortiz 2016), Winogender (Rudinger et al. 2018), WinoGrande (Sakaguchi et al. 2019).

**Model details** Due to the different implementations between (Kocijan et al. 2019b) and (Sakaguchi et al. 2019), in this paper we also follow their settings to compare with them, respectively. For (Kocijan et al. 2019b), we conduct disambiguation task directly through masked language modeling in Cook-BERT. For the latter one, we convert cloze-style problems to multiple-choice classification problems in Cook-RoBERTa. In particular, we replace the target pronoun of one query sentence with each candidate reference, then put the new sentences into the language model. We use a single linear layer and a softmax layer over the encoding of its [CLS] token to compute the probability of each new sentence, and select the one with highest probability as the pronoun disambiguation result.

**Hyperparameters of pre-training** We follow (Kocijan et al. 2019b) Sakaguchi et al. 2019) to first pre-train models for 30 and 3 epochs over WSCR (Kocijan et al. 2019b) or WinoGrande (Sakaguchi et al. 2019), respectively. Then we fine-tune models over specific tasks. We use AdamW as the optimizer with learning rate 5e-6, which is selected from {2e−5, 1e−5, 5e−6}. We set the batch size to 8.

**Results** We compare our models with state-of-the-art commonsense reasoning models in Table 1. It can be seen that our models outperform other models in most settings. This verifies the effectiveness of our proposed models for commonsense reasoning.

**Ablations** In Table 1, we also compare Cook-BERT with BERT. We found that Cook-BERT with Cook-Transformers effectively improved the accuracy of BERT with Transformers. Similar results can be found between Cook-RoBERTa and RoBERTa. This shows that the proposed Cook-Transformer improves pre-trained language models by adapting them for free, i.e. without retraining on large-scale unsupervised corpora.
6.3 Comparison of Different Commonsense Introduction Methods

Continue pre-train In the introduction section, we mentioned that a typical method of introducing textual knowledge is continuing pre-training (Gururangan et al. 2020; Sun et al. 2019). However, due to the OOD nature of commonsense, this method will cause catastrophic forgetting. To verify this intuition, in this subsection we compare with the continuing pre-trained model. We first continue pre-training the language model over ATOMIC2020, then fine-tune it over the target task.

ExpBERT (Murty, Koh, and Liang 2020) We also compare with ExpBERT, another model that is able to introduce textual knowledge. In Sec[1] we mentioned that ExpBERT is not applicable to large-scale commonsense knowledge bases for its disability to select related commonsense and ignore unrelated commonsense. To verify this, we use the retrieved candidate commonsense descriptions from ATOMIC2020 as the additional explanations for ExpBERT. ExpBERT concatenates all the embedding of fixed number of commonsense, which is inflexible for ATOMIC2020. For this reason, we fix the number of commonsense to 48. If there are more than 48 candidate commonsense descriptions for one sample, we will randomly select 48 of them. Otherwise we will pad null commonsense to it. In our experiments, we also apply ExpBERT to RoBERTa (Liu et al. 2019) (i.e. ExpRoBERTa).

We show the results in Table 4. We do not report the results of ExpBERT on WSC273, as ExpBERT cannot solve the cloze-style problems. It can be seen that the performance of language models was suffered when we simply continue pre-training the models on commonsense knowledge base. This verifies that the continuing pre-training on the OOD commonsense will cause catastrophic forgetting and injure the effectiveness. On the other hand, using Cook-Transformer to introduce OOD commonsense as the extra textual knowledge. In Sec 1, we mentioned that ExpBERT is not applicable to large-scale commonsense knowledge bases.

6.4 Effect in Low-Resource Commonsense Settings

Since there is a large number of commonsense descriptions in ATOMIC2020, a large portion of descriptions only occur a few times in the training set. In this subsection, we want to verify for these rare descriptions, can the model still benefit from it? If so, we think it means that the model uses the contextual information of the commonsense to improve the understanding of the commonsense.

To do this, we proposed a low-resource commonsense setting. We evaluate the effect of the model if the training dataset only contains \( k = 8/16/32/64 \) samples. Therefore the frequency of the appeared commonsense descriptions is low. In order to exclude the influence of other samples, we only use test samples whose candidate commonsense descriptions have already occurred in the \( k \) training samples. For example, when \( k = 8 \), we randomly select 8 samples from the training set for training, and use all samples in the
Table 4: Comparison of different commonsense introduction approaches. Continuing pre-training even injures the effectiveness. On the other hand, using Cook-Transformers to introduce external knowledge achieves better results than using Transformer.

Through the case studies of the samples in WSC273, we found that although commonsense with higher influence is somewhat interpretable for people, the interpretability is not significant. We show some examples in Table 5. We believe that this is because some commonsense for people has been learned in pre-training. Therefore, the OOD commonsense that these pre-trained language models need to incorporate for downstream tasks is inconsistent with human understanding.

7 Conclusion

In this paper, we study how to use commonsense to enhance the general text representation. We first analyzed the challenges brought by the OOD nature of commonsense. Then, we propose Cook-Transformer to allow commonsense integration and enhancement. In the experiments, we verified the effectiveness of our proposed models in a variety of scenarios, including commonsense reasoning, general text classification, and low-resource commonsense. Our models consistently outperform the baselines. We have also empirically analyzed other properties (e.g., interpretability) of the model.
