Abstract

Sarcasm employs ambivalence, where one says something positive but actually means negative, and vice versa. Due to the sophisticated and obscure sentiment, sarcasm brings in great challenges to sentiment analysis. In this paper, we show up the essence of sarcastic text is that the literal sentiment (expressed by the surface form of the text) is opposite to the deep sentiment (expressed by the actual meaning of the text). To this end, we propose a Dual-Channel Framework by modeling both literal and deep sentiments to recognize the sentiment conflict. Specifically, the proposed framework is capable of detecting the sentiment conflict between the literal and deep meanings of the input text. Experiments on the political debates and the Twitter datasets show that our framework achieves the best performance on sarcasm recognition.

1 Introduction

Sarcasm is a complicated linguistic phenomenon. It means that when one says something positive on surface form, he/she actually expresses negative, and vice versa (Liu, 2012; Merrison, 2008). Take the sentence “Final exam is the best gift on my birthday” as an example shown in Figure 1, the literal sentiment on surface (e.g., “best gift”) is positive, while the deep sentiment corresponding to the actual meaning (e.g., “final exam happens on birthday”) is negative. The example shows it is the sentiment conflict that causes sarcasm phenomenon. To this end, detecting the conflict between the literal meaning and the deep meaning is the key to recognize sarcasm. To the best of our knowledge, it is the first attempt to recognize sarcasm by detecting sentiment conflict.

So far as we know, rare research work explores the conflict between the literal and deep sentiment. Existing methods for sarcasm recognition focus on the sentiment contradiction reflected in word pairs or phrase pairs that appear in the sentence explicitly. Riloff et al. (2013) propose a feature-based machine learning method to classify sarcastic texts by different situational disparity. The disparity comes from the co-occurrence of positive sentiment phrases and negative situational phrases. Phrase pairs with opposite sentiments are used as features for SVM or other classifiers. Whether word pairs or phrase pairs express opposite sentiment, they appear in the sentence explicitly. The pairs depicted implicit sentiment are not required to contain sentiment words. Along with Riloff’s study, Tay et al. (2018) follow that word pairs in a sarcastic sentence tend to be contradictory. To utilize this, they adopt attention mechanism to model sentiment conflict of word pairs.

However, the presence of words or phrases with opposite polarity does not truly reflect the essential characteristics of sarcasm. Besides, texts containing sentiment words is not necessarily ironic. For example, “Although prepared well, I’m still worried about the exam”. This sentence contains phrases with two contrast sentiment “well” and “worried”, but the sentiment is not sarcastic. Hence, a framework able to detect the sentiment conflict between the literal meaning and the deep meaning is the key to recognize sarcastic texts.

Dual-Channel Framework. In this paper, we propose a dual-channel framework to exploit the conflict between the literal sentiment and the deep

Figure 1: The Dual-Channel Framework for sarcasm recognition.

∗Indicates equal contribution
sentiment of given text. For non-sarcastic texts, the literal and deep sentiments are the same, but for sarcastic texts, they are opposite. To emphasize, the key point of sarcastic recognition is detecting the sentiment conflict between the literal and the deep meanings linguistically.

Figure 1 shows the architecture of the proposed framework. Given an input instance, decomposer splits the text into the two channels. As both channels are not specific to particular encoders, the Dual-Channel Framework is able to adapt to encoders. After getting the literal sentiment and the deep sentiment of the text from the two channels, we use analyzer to detect the conflict and distinguish the sarcasm or not. Experiments on three datasets show the proposed Dual-Channel Framework achieves state-of-the-art performance on sarcasm recognition. Especially, the datasets range from short to long text, nonstandard text to normative text, social media text to online forum text.

Recall that the essence of sarcasm is the contraction between literal and deep meanings linguistically. The sentiment contradiction of word/phrase pairs is a pattern of expressing sarcasm. Not all sarcastic texts contain words or phrases that express opposite sentiment. In fact, there are other sarcasm patterns. Fortunately, all of the patterns follow the essence. More importantly, the proposed framework could be further developed to detect more sentiment conflict patterns.

The main contributions of this paper are summarized as follows:

- To the best of our knowledge, Dual-Channel Framework is the first attempt to model the conflict between literal and deep sentiments. More, the framework with good explanations contributes to a further step towards understanding the linguistic essence of sarcasm phenomenon.

- The experiments conducted on three benchmark datasets show that the proposed model outperforms several baselines, without using any external information.

2 Related Work

2.1 Sarcasm Recognition

Sarcasm recognition is to detect whether a text is sarcastic or not, which is typically formalized as a text classification problem. Traditional approaches to solving this problem mainly rely on rules or manually crafted features. Based on the survey (Joshi et al., 2016), the important features contain: (i) unigram (Joshi et al., 2015), (ii) sentiment lexicons (González-Ibáñez et al., 2011), (iii) pragmatic features, such as emoticons (González-Ibáñez et al., 2011), capitalization, and punctuation (Joshi et al., 2015), (iv) pattern-based features, and (v) behavioral-based features. Riloff et al. (2013) find that sarcasm texts have contrast patterns, then design a boosting method to detect positive phrases and negative phrases in the same sentence. Rajadesingan et al. (2015) add personality features based on the behavioral theory of sociology and psychology. Accordingly, the accuracy for sarcasm recognition highly depends on the quality of features.

An interesting work proposed by Ghosh et al. (2015) shows that sarcasm involves a figurative meaning which is usually the opposite of the original literal meaning. This work re-frames the sarcasm recognition task as a type of word sense disambiguation problem, which is called Literal/Sarcastic Sense Disambiguation (LSSD). To tackle LSSD, they firstly paraphrase sarcastic texts manually to obtain target words that cause sarcastic disambiguation. Then a Twitter dataset for each target word is collected and labeled. The label is either Literal Sense or Sarcastic Sense. Finally, machine learning approaches are applied to classify Literal Sense and Sarcastic Sense. This work is novel but highly relies on manually paraphrasing and labeling datasets to find target words.

We recommend the readers to refer to (Joshi et al., 2016) for a more comprehensive survey. Moreover, there has been many systems developed for a shared task (Ghosh et al., 2020).

2.2 Neural Networks Based Models

Neural network-based models have achieved great success in a variety of natural language processing tasks, including sentiment analysis (Wang et al., 2018), named entity recognition (Liu et al., 2019), etc. Ghosh and Veale (2016) propose a model composed of CNN, LSTM, and DNN for sarcasm detection. As attention mechanism has led to improvements in various NLP tasks, Tay et al. (2018) uses attention to model the importance of different word pairs along with an LSTM to model the whole sentence. This model achieves state-of-the-art performance. To summary, those studies focus
3 The Dual-Channel Network (DC-Net)

3.1 The Structure of DC-Net

We develop the Dual-Channel Network (DC-Net) based on the proposed dual-channel framework. Figure 2 depicts the architecture of the DC-Net. It consists of five modules: the decomposer, the literal channel, the deep channel, the encoder, and the analyzer.

Decomposer. Sentiment words in the text directly reflect the literal sentiment. Considering this, we design the decomposer module to assign the input text to literal and deep channels. Given a text with $N$ words, $W_T = \{w_1, w_2, ..., w_N\}$, we pick up sentiment words with a sentiment lexicon (Wilson et al., 2005), and decompose the original text into two pieces of text: text with sentiment words $W_L$, and text with non-sentiment words $W_D$. $W_L$ is fed to the literal channel, while $W_D$ to the deep channel. If no sentiment words are matched from the given text, the original text is used as the literal channel’s input.

Notably, sarcasm as a complex linguistic phenomenon has many patterns. After traversing a large amount of sarcastic corpus, we observe that sarcastic texts containing evident sentiment words denote a common pattern. Hence, using sentiment words as decomposer is well-suited for this pattern.

Literal Channel. The literal Channel includes an encoder and a linear. First, we use Encoder$_L$ to encode the text with sentiment words $W_L$. It outputs the representation $v_L$ of the literal text, formulated as:

$$v_L = \text{Encoder}_L(W_L).$$

(1)

Then, we use the literal representations $v_L$ as the input of a softmax classifier for sentiment prediction.

$$P_l = \text{softmax}(W_r v_L + b_r),$$

(2)

where $W_r$ and $b_r$ are the parameters for predicting the literal sentiment distribution of the literal text.

Considering the semantic complexity of sarcasm text, single representations of sentiment words may lose the context information. So we adopt another Encoder to encode the original text $W_T$ and obtain the representations of the entire text $v_T$. Then we concatenate the literal hidden output $v_L$ and the entire text’s hidden output $v_T$, followed by a linear layer and ReLU activation function to reduce dimension. The final representations $v'_L$ of the literal channel is formulated as:

$$v_T = \text{Encoder}_T(W_T)$$

(3)

$$v'_L = \text{ReLU}(W_l[v_L; v_T] + b_l),$$

(4)

where $W_l$ and $b_l$ are the parameters of the linear layer.

Deep Channel. In the deep channel, we also adopt an Encoder with same structure but different parameters to encode the deep input text $W_D$, and the representations of the deep channel is formulated as:

$$v_D = \text{Encoder}_D(W_D)$$

(5)

Similarly, we use the deep hidden output $v_D$ to predict the deep sentiment of a text.

$$P_d = \text{softmax}(W_z v_D + b_z),$$

(6)

where $W_z$ and $b_z$ are the parameters for the deep sentiment distribution of the current text.

Again, we concatenate the deep hidden output $v_D$ with the entire text’s hidden output $v_T$, followed...
The final representations $v'_D$ of the deep channel is formulated as:

$$v'_D = \text{ReLU}(W_d[v_D; v_T] + b_d).$$

(7)

Here, $W_d$ and $b_d$ are the parameters of the linear layer.

Note that the structures of the two channels are symmetrical, as both channels use Encoder models. However, the two encoders in the two channels do not share parameters, and their inputs are different.

**Encoder.** The Dual-Channel Framework is generic and can be realized by plugging in existing sarcasm recognition or classification models such as LSTM (Hochreiter and Schmidhuber, 1997), CNN (Kim, 2014), Recursive Neural Network (Socher et al., 2011), BERT (Devlin et al., 2018) \textit{et al.}. In DC-Net, we adopt Multi-dimensional Intra-Attention Recurrent Network (MIARN) (Tay et al., 2018) as encoders for both channels.

The key design of MIARN is to learn two representations. One reflects the intra-sentence relationships of word pairs captured by attention mechanism. The other represents sequential relationships in a text exploited by LSTM. Then the two representations are used to learn the final representation of the given text. Last, MIARN uses a multi-dimensional linear transformation to project the concatenation of each word embedding pair into a scalar score. Hence, the multi-dimensional transformation provides multiple views between two words. More details about MIARN are given in (Tay et al., 2018).

**Analyzer.** The analyzer is designed to measure the conflict between the literal and the deep channels. We use a subtraction layer and pass the difference vector to a softmax layer.

$$P_s = \text{softmax}(W_p(v'_L - v'_D) + b_p),$$

(8)

where $W_p$ and $b_p$ are the parameters for the softmax layer.

Although sarcasm has a strong correlation with literal sentiment and deep sentiment, we do not have gold labels for both sentiments. Due to the limitation of lacking labels, directly and rigidly requiring the model to output sentiments on both channels is easy to confuse the model. For this reason, we develop the objective function of sarcasm classification by adding objectives the literal and deep channels.

### 3.2 Training Objective

The proposed DC-Net model has three learning objectives. One is to minimize the cross-entropy loss of the sarcasm probability distribution. The next is to minimize the cross-entropy loss of the literal sentiment probability distribution, and the last is to minimize the cross-entropy loss of the deep sentiment probability distribution.
Sarcasm Objective. The sarcasm objective is to ensure the basic ability of classification. Hence, we use the cross-entropy loss of sarcasm classification. The objective $J_s$ is formulated as:

$$J_s(\theta) = \sum_i \text{cross-entropy}(y^i_s, P^i_s),$$

where $P^i_s$ denotes the sarcasm probability distribution of text $i$. The label generating by Algorithm 1, the ground truth of the sarcasm label is $y^i_s$.

Literal Sentiment Objective. In our implementation, we determine the literal sentiment label based on the number of words with positive sentiment and words with negative sentiment in the text. The labeling processing is detailed in Algorithm 1.

**Algorithm 1: Sentiment labeling processing**

**Input:** The number of positive words, $n_{pos}$; The number of negative words, $n_{neg}$; The sarcasm label, $l_{sarc}$

**Output:** The literal sentiment label, $l_{literal}$; The deep sentiment label, $l_{deep}$

if $l_{sarc} = \text{True and } n_{pos} \geq n_{neg}$ then
  $l_{literal} = \text{Positive}$;
  $l_{deep} = \text{Negative}$;
else if $l_{sarc} = \text{True and } n_{pos} < n_{neg}$ then
  $l_{literal} = \text{Negative}$;
  $l_{deep} = \text{Positive}$;
else if $l_{sarc} = \text{False and } n_{pos} \geq n_{neg}$ then
  $l_{literal} = \text{Positive}$;
  $l_{deep} = \text{Positive}$;
else
  $l_{literal} = \text{Negative}$;
  $l_{deep} = \text{Negative}$;
end

The literal sentiment classification objective is then formulated as:

$$J_l(\theta) = \sum_j \text{cross-entropy}(y^j_l, P^j_l),$$

where $P^j_l$ is the literal sentiment probability distribution of text $j$. The label generated by Algorithm 1 of the literal sentiment is $y^j_l$.

Deep Sentiment Objective. We observe that the literal sentiment and deep sentiment of the sarcasm text are often opposite. Using the labels based on Algorithm 1, we calculate the deep sentiment classification objective by

$$J_d(\theta) = \sum_k \text{cross-entropy}(y^k_d, P^k_d),$$

where $P^k_d$ denotes the deep sentiment probability distribution of text $k$. The label generated by Algorithm 1 of the deep sentiment is $y^k_d$.

Considering the three objectives, we obtain the final objective function $L$ by adding them together:

$$L(\theta) = \lambda_1 J_s(\theta) + \lambda_2 J_l(\theta) + \lambda_3 J_d(\theta),$$

where $\theta$ is the parameter set of the model. $\lambda_1$, $\lambda_2$ and $\lambda_3$ are the hyperparameters for leveraging the weight of difference loss.

4 Experiment

4.1 Datasets

We experiment on three benchmark datasets obtained from online forums and Twitter respectively.

- **IAC-V1.** IAC-V1 collected from the online political debates forum is the subset of the Internet Argument Corpus (Lukin and Walker, 2017). This dataset contains long text and the text is more normative compared to tweets.

- **IAC-V2.** IAC-V2 (Oraby et al., 2017) is an updated version of IAC-V1. It contains much more data representing three categories of sarcasm. We use the largest dataset, known as general sarcasm subset in our experiments.

- **Tweets.** The dataset collected from the Twitter website is proposed in SemEval 2018 Task 3 (Van Hee et al., 2018). There are three variations of the text in this dataset: (i) original texts, (ii) texts with hashtags removed, and (iii) texts with hashtags and emoji expressions removed. Hashtags like "#not", "#sarcasm", and "#irony", are originally obtained from users. The hashtags are also used as prior knowledge for collecting sarcastic posts. In our experiments, we used the version with hashtags removed.

There is no user and context information in all datasets. Each document is labeled sarcastic or non-sarcasm. The statistics are reported in Table 1.

1http://www.4forums.com/political/
Table 1: Statistics of datasets. Avg $\ell$ denotes the average length of texts in the number of tokens. $s$ ratio is the proportion of texts that contain sentiment words.

<table>
<thead>
<tr>
<th>Dataset</th>
<th>Train</th>
<th>Dev</th>
<th>Test</th>
<th>Avg $\ell$</th>
<th>$s$ ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>IAC-V1(^2)</td>
<td>1596</td>
<td>80</td>
<td>320</td>
<td>68</td>
<td>91%</td>
</tr>
<tr>
<td>IAC-V2(^3)</td>
<td>5216</td>
<td>262</td>
<td>1042</td>
<td>43</td>
<td>96%</td>
</tr>
<tr>
<td>Tweets(^4)</td>
<td>3634</td>
<td>200</td>
<td>784</td>
<td>14</td>
<td>88%</td>
</tr>
</tbody>
</table>

Observe that over 88% of the texts in the datasets contain sentiment words. Therefore, it is reasonable to decompose the original text into sentiment words and non-sentiment words, as the input to the literal channel and the deep channel respectively.

There are another two Tweets datasets proposed by Riloff et al. (2013) and Ptáček et al. (2014), respectively. Different from Tweets and IAC dataset, these datasets only provide tweet IDs but not tweet texts. Due to modified authorization status, lots of tweets are unavailable or deleted. To this reason, we could not experiment on the two datasets. Khodak et al. (2017) builds a large self-annotated dataset from the Reddit forum platform. This dataset contains author and context information. Since our work focuses on text-only sarcasm recognition, we do not consider datasets with context.

4.2 Compared Methods

We evaluate our model against baselines including UCDCC, THU-NGN, Bi-LSTM, AT-LSTM, CNN-LSTM-DNN, and MIARN.

- **UCDCC** (Ghosh and Veale, 2018) is a Siamese LSTM model exploiting Glove word embedding features. It achieves the best performance on SemEval 2018 Task 3 Subtask A. The method has designed a lot of rules in preprocessing Twitter data.

- **THU-NGN** (Wu et al., 2018) ranks second on SemEval 2018 Task 3 Subtask A. The model consists of densely connected LSTMs based on word embeddings, sentiment features, and syntactic features.

- **Bi-LSTM** (Hochreiter and Schmidhuber, 1997) is a variant of RNN, which could learning long-term dependencies and bidirectional information.

- **AT-LSTM** (Wang et al., 2016) is an LSTM model followed by a neural attention mechanism. It uses weight scores to attend the important part of the input.

- **CNN-LSTM-DNN** (Ghosh and Veale, 2016) is a combination of CNN, LSTM, and Deep Neural Network (DNN) via stacking. It stacks two layers of convolution and two LSTM layers. The output then passes through a DNN for prediction.

- **MIARN** (Tay et al., 2018) could learn two representations. One reflects the intra-sentence relationships of word pairs. The other represents sequential relationships of a text.

4.3 Implementation Details and Metrics

We use Glove (Pennington et al., 2014) embeddings to initialize word vectors. The dimension of the vector is 300. There is a checkpoint every 16 mini-batch, and the batch size is 32. The dropout on embeddings is set to 0.5. Adam (Kingma and Ba, 2014) is used to optimize our model. In Adam, the two parameters $\beta_1$ and $\beta_2$ are 0.9 and 0.999 respectively. The learning rates for model parameters except word vectors are 1e-3, and 1e-4 for word vectors. Our model is implemented with Pytorch\(^5\) (version 1.4.0).

We re-implement all baseline models. The hyperparameter of MIARN is set to 20. On Tweets dataset, the hyperparameters of our DC-Net model are set to $\lambda_1 = \lambda_2 = \lambda_3 = 1$. On IAC-V2, they are set to 1, 1e-4 and 1e-1. On IAC-V1, they are set to 1, 1e-4 and 1e-4. The hyperparameters are searched over the development set.

Although the text is not normative as expected after decomposing, we do not fill in the full text with placeholders like “<MASK>”. Because sentiment words are mostly adjectives or adverbs, deleting them from sentences has not much influence on semantics. Experiment results also show that inputs without placeholder lead to better performance.

4.4 Experiment Results

Precision, recall, and macro $F_1$ are used to evaluate the performance of models. Table 2 reports the performance comparison of all benchmark models on Tweets and IAC datasets respectively.

\[^2\]https://nlds.soe.ucsc.edu/sarcasm1
\[^3\]https://nlds.soe.ucsc.edu/sarcasm2

</tr>
<tr>
<td><strong>DC-Net</strong></td>
<td>\textbf{66.4}</td>
<td>\textbf{66.1}</td>
<td>\textbf{66.0}</td>
</tr>
</tbody>
</table>

We observe that our DC-Net achieves the best macro \( F_1 \) results across all datasets. The relative improvements differ across domains and datasets. On Tweets dataset, DC-Net achieves about 1.2% improvement in \( F_1 \) score than the best baseline. On IAC-V2 dataset, our model outperforms the second-best baseline by 1.6% in \( F_1 \).

Surprisingly, compared with model MIARN, our DC-Net boosts the performance up to 5% and 3% respectively on Tweets and Debates V2. This result is a strong indication that our dual-channel design is effective. The average length of Tweets text is 14 words, which leads to a lack of information for sarcasm recognition. Despite this, the literal and deep channels are able to provide sufficient sentiment conflict information for effective detection of sarcasm. On the IAC datasets, texts are longer compared with Tweets. Therefore, more information are supported for all models to do complex analysis in this complicated sarcasm detection task. The dual-channel sentiment contrast has a relatively weaker enhancement on the IAC datasets. The experimental results are in line with our expectations.

Specifically, the UCDCC model achieves the second-best on Tweets dataset but performs the worst on the two IAC datasets. This is because UCDCC designs a lot of complicated preprocessing rules specifically for Tweets, and such rules are not robust enough on other datasets. We also analyze the confusion matrix of UCDCC. It shows that the high accuracy of UCDCC mainly contributes to a large number of True Negative (True label is sarcastic while predict label is not sarcastic). This category denotes non-sarcastic which is not much concerned. On the contrary, our model works better in predicting the category of sarcasm (True label and predict label are sarcastic), which is more important. Our model only performs basic preprocessing such as word segmentation, removal of URL, \textit{et al.}, and achieves the best performance, which shows the stability of our model. THU-NGN, Bi-LSTM, and AT-LSTM methods are all based on LSTM without significant differences in model structure. Thus the performance of these models on Tweets and IAC-V1 is very close. The CNN-LSTM-DNN model performs well on Tweets dataset, while the performance drops a lot on the IAC-V1 dataset. It is because the CNN-LSTM-DNN model is more suitable for dealing with short texts. In contrast, our DC-Net ranks first on both long text (IAC) and short text (Tweets), indicating its robustness. Our experiments also show that the basic MIARN model’s performance is not as good as expected. This shows the basic utilization of word correlation is not enough to improve the performance of sarcasm detection.

### 4.5 Comparisons with BERT

Transformers (Vaswani et al., 2017) and pre-trained models like BERT (Devlin et al., 2018) are empirically powerful on NLP tasks. We implement the BERT model on Tweets dataset. As mentioned before, our proposed Dual-Channel Framework can adapt to the existing models. To do a comprehensive comparison, we also apply the Dual-Channel Framework to the BERT model by using BERT as
Table 4: The F1 change from original models to models with Dual-Channel Framework.

encoder. The new model with BERT as building blocks is named DC-Net (w/ BERT). Table 3 gives the experimental results.

As expected, the DC-Net (w/ BERT) model performs much better than the basic BERT model, which proves that our Dual-Channel Framework is adaptable and effective. We observe that DC-Net (w/ MIARN), which is not BERT-based, outperforms DC-Net (w/ BERT) and BERT with a large improvement. It is not surprising because the BERT model without adding any extra design does not perform well on sarcasm recognition. This can be attributed to the fact that the corpus of pre-trained BERT is quite different from Tweets in both the length and the data source. Moreover, the amount of training data is relatively small for fine-tuning the BERT model. The poor performance of BERT further reinforces that sarcasm recognition is a difficult task. It motivates us that applying well-designed and well-performed text classification methods to this task directly does not lead to good performance. That is why considering the characteristic of sarcasm itself by detecting the sentiment conflict is the essence.

### 4.6 Flexibility of Dual-Channel Framework

To show our Dual-Channel Framework is flexible and generic, we implement several models as the encoder. The F1 change from original baseline models to Dual-Channel models is shown in Table 4. As expected, the performance of baseline models has different degrees of improvement on all datasets after applying Dual-Channel Framework.

### 4.7 Ablation Study on Loss Function

Recall that the model training objective (see Section 3) contains three (sub-)objectives: sarcasm recognition, literal sentiment classification, and deep sentiment classification. To study the effect of the three objectives, we conduct ablation experiments on the Tweets dataset.

Table 5 reports the detail of ablation study on Tweets dataset. \(J_s\) denotes using sarcasm loss only. \(J_s+J_d\) means using sarcasm and deep loss. \(J_s+J_l\) means using sarcasm and literal loss. \(J_s+J_l+J_d\) denotes using sarcasm, literal, and deep loss. The hyperparameters of all variations are set to 1.

Table 5: Ablation study on Tweets dataset. \(J_s\) denotes using sarcasm loss only. \(J_s+J_d\) means using sarcasm and deep loss. \(J_s+J_l\) means using sarcasm and literal loss. \(J_s+J_l+J_d\) denotes using sarcasm, literal, and deep loss.

### 4.8 Comparisons of Different Analyzers

The analyzer module is used to measure the difference between the literal channel and the deep channel. To analyze the effect of the analyzer module, we compare the effect of different analyzers, including concatenation and subtraction methods. Table 6 shows that using subtraction as the analyzer is better than using concatenation.

### 5 Conclusion and Future Work

In this study, we consider that the essential characteristic of sarcastic text is that its literal sentiment is opposite to the deep. To this end, we develop a Dual-Channel Framework to exploit the sentiment conflict between the literal meaning and the deep meaning of the sarcastic text. Based on the Dual-Channel Framework, we propose DC-Net to recognize sarcasm. The DC-Net is capable of exploiting the literal sentiment by encoding sentiment
words only, and exploiting the deep sentiment by encoding non-sentiment words in the input. Experiments show that the proposed DC-Net achieves superior performance than baseline models.

The Dual-Channel Framework reveals the essence of sarcasm phenomenon and has shown potentials for recognizing sarcasm. Further, the sentiment conflict could be approached in a more explainable way in our view. Recall that sarcasm phenomenon has many patterns. Using sentiment words as decomposer is trivial but could cover general patterns. In the future, we will explore more decomposing ways for more complicated sarcasm patterns. Moreover, we adopt an indirect way by combining loss to detect literal sentiment and deep sentiment. As part of our future work, we expect that the output of the two channels can directly achieve the opposite sentiment and reveal the essence of sarcasm.
