FUNCTION RECOVERY ON MANIFOLDS USING SCATTERED DATA

DAVID KRIEG AND MATHIAS SONNLEITNER

Institut für Analysis, Johannes Kepler Universität Linz, Austria

Abstract. We consider the task of recovering a Sobolev function on a connected compact Riemannian manifold $M$ when given a sample on a finite point set. We prove that the quality of the sample is given by the $L_\gamma(M)$-average of the geodesic distance to the point set and determine the value of $\gamma \in (0, \infty]$. This extends our findings on bounded convex domains [arXiv:2009.11275, 2020]. Further, a limit theorem for moments of the average distance to a set consisting of i.i.d. uniform points is proven. This yields that a random sample is asymptotically as good as an optimal sample in precisely those cases with $\gamma < \infty$. In particular, we obtain that cubature formulas with random nodes are asymptotically as good as optimal cubature formulas if the weights are chosen correctly. This closes a logarithmic gap left open by Ehler, Gräf and Oates [Stat. Comput., 29:1203-1214, 2019].

Disclaimer. This paper relies on our previous work [15] which is still in the revision process. The reader may therefore not yet find a complete proof of all the results that are presented in this paper. However, this only concerns the lower bound of Theorem 2 for smoothness $s \notin \mathbb{N}$ and the lower bound of Corollary 1 in the case that the dimension $d$ is even. See Remark 2 below.

We are interested in the problem of recovering a real-valued function on a connected compact Riemannian manifold which is only known through a finite number of function values, obtained on a finite set of sampling points. We study this problem
in the worst case setting, where the function is assumed to have some Sobolev regularity and the recovery error is measured in the $L_q$-norm.

If the sampling points can be chosen freely, this setting is classical and many results are known on the error that can be achieved with optimally chosen sampling points. For Sobolev spaces on domains, Novak and Triebel [19] show that the optimal rate of convergence can be achieved with evenly spaced quasi-uniform points using a polynomial reproducing map due to Wendland [30, 31], which is based on moving least squares. On the sphere, a special case of the manifolds we consider, Mhaskar [17] derives an asymptotically optimal upper bound in terms of zonal function networks. Wang and Sloan [29] use filtered polynomial approximation and Lu and Wang [16] rely on weighted least squares in the Hilbert space case to achieve optimal rates, improving upon Gröchenig [11]. On general manifolds, some results are obtained in Mhaskar [18, Theorem 3.3], which relies on approximation by eigenfunctions of the Laplace-Beltrami operator on the manifold. In the general case, more is known about recovering only an integral instead of the function itself, see Brandolini et al. [2]. The proofs behind many of these results rely on Marcinkiewicz-Zygmund inequalities and exact integration of such eigenfunctions by quadrature rules, again using evenly spaced quasi-uniform points, see for example Filbir and Mhaskar [10].

In all these papers, the recovery method is based on function values at very specific point sets. Here, we ask for the minimal worst case error that can be achieved with a given (arbitrary) set of sampling points that cannot be chosen by us. How can we assess the quality of the given set of sampling points? This question has been studied lately for Sobolev spaces on bounded convex domains by the present authors in [15]. A characterization of the quality of sampling points has been obtained which is based on the radius of the point set’s largest hole (in the case of large $q$) or the radius of an average hole (in the case of small $q$). The question arises whether the same can be done for Sobolev spaces defined on connected compact Riemannian manifolds, which we answer in the affirmative.

Before we state the result, let us shortly introduce the necessary notation. We recall basic facts on Riemannian geometry in Section 1. Let $M$ be a connected compact Riemannian manifold and let $\text{vol}_M$ be the Riemannian volume measure on $M$ and $\text{dist}_M(x, y)$ be the Riemannian distance between points $x$ and $y$. Let
$\Delta_M$ be the Laplace-Beltrami operator on $M$. Then for $1 < p < \infty$ and $s \in \mathbb{R}$ the Bessel potential (Sobolev) space is given by
\[
H^s_p(M) := \{ f \in L^p(M) : (I - \Delta_M)^{s/2} f \in L^p(M) \},
\]
where $I$ is the identity on $L^p(M) = L^p(M, \text{vol}_M)$. The norm of $f \in H^s_p(M)$ is
\[
\|f\|_{H^s_p(M)} := \| (I - \Delta_M)^{s/2} f \|_{L^p(M)}.
\]
We assume that $s > d/p$ such that the functions in $H^s_p(M)$ are continuous and function values are well-defined.

**Remark 1.** There are various ways to define Sobolev spaces, also in the case $p = 1$ and $p = \infty$. We demonstrate our result in the case $1 < p < \infty$, where many of the standard definitions coincide, see Section 1.4.

We consider the recovery problem in $L^q(M)$ for $1 \leq q \leq \infty$. For an operator $A : H^s_p(M) \to L^q(M)$ the worst case error is defined by
\[
e(A, H^s_p(M), L^q(M)) := \sup_{\|f\|_{H^s_p(M)} \leq 1} \| f - A(f) \|_{L^q(M)}.
\]
We consider recovery operators of the form $A = \varphi \circ N_P$, where $P \subset M$ is a given (finite) set of sampling points, $N_P : H^s_p(M) \to \mathbb{R}^P$ is the information mapping of the form $N_P(f) = (f(x))_{x \in P}$ and $\varphi : \mathbb{R}^P \to L^q(M)$ is any reconstruction map. The minimal worst case error that can be achieved with a sampling operator of this form is denoted by
\[
e(P, H^s_p(M), L^q(M)) := \inf_{A = \varphi \circ N_P} e(A, H^s_p(M), L^q(M)).
\]
It is a measure for the quality of the sampling point set $P$. If we only allow linear reconstruction maps $\varphi$, which might be beneficial for practical purposes, the infimum is denoted by $e^{\text{lin}}(P, H^s_p(M), L^q(M))$.

We have the following theorem. Here, the notation $A(P) \asymp B(P)$ means that there exist implied constants $c, C > 0$ such that $cA(P) \leq B(P) \leq CA(P)$ for all nonempty finite point sets $P \subset M$. Below, the notation is also used for a positive integer $n$ instead of $P$. Further, the distance function of a nonempty subset $P$ of a metric space $(M, \text{dist}_M)$ is defined by
\[
\text{dist}_M(\cdot, P) : M \to [0, \infty), \quad \text{dist}_M(x, P) := \inf_{y \in P} \text{dist}_M(x, y).
\]
Theorem 1. Let $M$ be a connected compact Riemannian manifold of dimension $d \in \mathbb{N}$ and let $1 < p < \infty$, $1 \leq q \leq \infty$ and $s > d/p$. Then we have for any nonempty and finite point set $P \subset M$ that

$$
e(P, H^s_p(M), L_q(M)) \asymp e^{\text{lin}}(P, H^s_p(M), L_q(M)) \asymp \|\text{dist}_M(\cdot, P)\|_{L_\gamma(M)},$$

where the implied constants are independent of $P$ and

$$
\gamma = \begin{cases} 
  s(1/q - 1/p)^{-1}, & q < p, \\
  \infty, & q \geq p,
\end{cases} \quad \alpha = \begin{cases} 
  s, & q < p, \\
  s - d(1/p - 1/q), & q \geq p.
\end{cases}
$$

Thus, we can characterize the quality of an arbitrary set of sampling points $P$ by the $L_\gamma(M)$-norm (or quasi-norm) of the distance function. In the case $\gamma = \infty$, this is nothing but the covering radius of $P$ in $M$, which is the radius of the largest hole in the data set. In the case $\gamma < \infty$, this is the radius of an average-sized hole in the data set and sometimes called the distortion of $P$ in $M$, see, e.g., Zador [32].

The upper bound of Theorem 1 is achieved by a linear algorithm which is constructed from the algorithm in [15], which in turn is based on moving least squares, applied locally to sets where the point set is “dense enough”. In the case $p > q$, this yields the improvement $\gamma < \infty$ compared to previous works supposing a small covering radius. This enables us to show optimality of other point sets, possibly with rather large holes in them.

In particular, we are interested in the quality of i.i.d. sampling points which are distributed according to the normalized Riemannian volume measure. We think this is a good and common model for sampling points that cannot be chosen freely. By Theorem 1, it only remains to examine the covering radius and the distortion of random points. We refer to Cohort [7] as well as Reznikov and Saff [22] where this has been done in similar settings. We obtain the following.

Proposition 1. Let $X_1, X_2, \ldots$ be i.i.d. with respect to the normalized Riemannian volume on $M$ and let $\alpha > 0$. Then

$$
\mathbb{E} \|\text{dist}_M(\cdot, \{X_1, \ldots, X_n\})\|_{L_\gamma(M)}^\alpha \asymp \begin{cases} 
  n^{-\alpha/d}, & 0 < \gamma < \infty, \\
  (n/\log n)^{-\alpha/d}, & \gamma = \infty,
\end{cases}
$$

where the implied constants are independent of $n$. 
This should be compared with the quality of optimal sampling points, for which it follows from elementary volume comparison arguments, see also Lemma 4, that, for all $0 < \gamma \leq \infty$ and $\alpha > 0$,

$$(1) \quad \inf_{P \subset M: |P| \leq n} \|\text{dist}_M(\cdot, P)\|_{L_\gamma(M)}^\alpha \asymp n^{-\alpha/d},$$

where the infimum is over all point sets of cardinality at most $n$. We refer to Iacobelli [12] and Kloeckner [14], where exact asymptotics for this so-called minimal quantization error are obtained. Thus, the distortion of random points is asymptotically optimal, while the covering radius of random points exceeds the covering radius of optimal points by a logarithmic factor. We therefore obtain that i.i.d. uniform sampling points are, on average, asymptotically optimal for $L_q(M)$-approximation on $H^s_p(M)$ if and only if $q < p$. In the case $q \geq p$, there is a loss of a logarithmic factor compared to optimally chosen sampling points.

We also consider the problem of integration with respect to the Riemannian volume $\text{vol}_M$. The worst case error of an operator $A: H^s_p(M) \to \mathbb{R}$ for the integration problem on $H^s_p(M)$ is defined by

$$e(A, H^s_p(M), \text{INT}) := \sup_{\|f\|_{H^s_p(M)} \leq 1} \left| \int f \, d\text{vol}_M - A(f) \right|.$$ 

The minimal worst case error that can be achieved with a given set of sampling points $P \subset M$ is denoted by

$$e(P, H^s_p(M), \text{INT}) := \inf_{A = \varphi \circ N_P} e(A, H^s_p(M), \text{INT}),$$

where the infimum ranges over all mappings $\varphi: \mathbb{R}^P \to \mathbb{R}$. Note that, in this case, the infimum will not change if we only minimize over all linear mappings $\varphi$. This is a classical result due to Smolyak and Bakhvalov, see, e.g., Theorem 4.7 in the book by Novak and Woźniakowski [20]. Thus, it is no restriction to assume that $A$ is of the form

$$A(f) = \sum_{x \in P} w_x f(x), \quad w_x \in \mathbb{R}.$$ 

The results that we obtain for the integration problem are the same as for the $L_1(M)$-approximation problem.
Theorem 2. Let $M$ be a connected compact Riemannian manifold and let $1 < p < \infty$ and $s > d/p$. Then we have the equivalence

$$e(P, H^s_p(M), \text{INT}) \asymp \| \text{dist}_M(\cdot, P) \|^s_{L^{p^*}(M)},$$

where $p^*$ is the Hölder conjugate of $p$ and the implied constants are independent of the point set $P \subset M$.

This improves upon Theorem 1 in Ehler, Gräf and Oates [9] by replacing the covering radius of a point set with its distortion. In particular, we obtain via Proposition 1 that independent and uniformly distributed points are, on average, asymptotically optimal for numerical integration on $H^s_p(M)$ for all $1 < p < \infty$ and close a logarithmic gap in Corollary 1 of [9].

As a geometric application of our results, we deduce an asymptotic equivalence for the minimal weighted spherical $L_2$-discrepancy. To this end, consider the $d$-dimensional sphere $S^d = \{ x \in \mathbb{R}^{d+1} : \|x\| = 1 \}$ equipped with a Riemannian metric inducing the usual geodesic distance $\text{dist}_{S^d}$. Then the balls with respect to this metric are the spherical caps

$$C(x, t) := \{ y \in S^d : x \cdot y \geq t \} \quad \text{with center } x \in S^d \text{ and height } t \in [-1, 1].$$

Given points $x_1, \ldots, x_n \in S^d$ and weights $w_1, \ldots, w_n \in \mathbb{R}$ attached to them, their weighted spherical $L_2$-discrepancy is given by

$$D_2(\{(x_j, w_j)\}_{j=1}^n) := \left( \int_{[-1, 1]} \int_{S^d} \left| \sum_{j=1}^n w_j 1_{C(x,t)}(x_j) - \sigma_d(C(x,t)) \right|^2 d\sigma_d(x)dt \right)^{1/2},$$

where $\sigma_d$ is the normalized uniform measure on $S^d$ and $1_A$ denotes the characteristic function of a set $A$. It is a measure of equidistribution of the weighted point set and returns the average approximation error when one uses the measure $\sum_{j=1}^n w_j \delta_{x_j}$ to measure the volume of spherical caps. For equal weights $w_j = 1/n$ it reduces to the spherical $L_2$-discrepancy, see, e.g., Drmota and Tichy [8, Chapter 2.1.3].

If we are interested in recovering the integral of a function $f$ in the Sobolev space $H = H^{(d+1)/2}_{2}(S^d)$ with respect to $\sigma_d$ by means of evaluating $f$ at the points $P = \{ x_1, \ldots, x_n \}$, the best we can do is to consider a linear algorithm $f \mapsto Q_{P,w}(f) := \sum_{j=1}^n w_j f(x_j)$, where $w = (w_1, \ldots, w_n) \in \mathbb{R}^n$ are suitable weights. The representation of the reproducing kernel of $H$, obtained by Brauchart and Dick [3],
together with the formula on the worst-case integration error for functions in a reproducing kernel Hilbert space, give the identity

\[(2) \quad e(Q_{P,w}, H^{(d+1)/2}_2(\mathbb{S}^d), \text{INT}) = D_2\{(x_j, w_j)\}_{j=1}^n,\]

if the Sobolev space is normed as in [3], see Section 1.5 for details. Thus, Theorem 2 has the following consequence for the minimal weighted spherical \(L_2\)-discrepancy.

**Corollary 1.** For all \(d \in \mathbb{N}\), we have the equivalence

\[
\inf_{w_1, \ldots, w_n} D_2(\{(x_j, w_j)\}_{j=1}^n) \asymp \|\text{dist}_{\mathbb{S}^d} (\cdot, P)\|^{(d+1)/2}_{L^{d+1}(\mathbb{S}^d)},
\]

where the implied constants are independent of the point set \(P \subset \mathbb{S}^d\).

From this and the lower bound (1) for the minimal distortion one can deduce in particular the known lower bound on spherical \(L_2\)-discrepancy of any \(n\)-point set which is of order \(n^{-1/2-1/2d}\).

**Remark 2.** Let us now elaborate on the details regarding the disclaimer. The lower bound in Theorem 2 for smoothness \(s \notin \mathbb{N}\) and consequently the lower bound in Corollary 1 for even \(d\) rely on the validity of Proposition 3 below in the case of non-integral \(s\). However, it cannot be concluded from [15] that the function in (1) is non-negative, see [15, Remark 7]. This may be resolved using atomic decompositions. An updated proof will be published in an upcoming version of [15].

We give a brief overview of the remainder of this article. In Section 1 we introduce notation and concepts underlying our results and their proofs. Section 2 contains the proofs of Theorems 1 and 2 and in Section 3 we analyze the distortion of random points. In particular, we prove a limit theorem which is stronger and more general than needed and might be of independent interest.

### 1. Preliminaries

Let \(d \in \mathbb{N}\) and \(M = (M, g)\) be a connected compact Riemannian manifold of dimension \(d\), which is equipped with a smooth Riemannian metric \(g\). Note that \(M\) is smooth, without boundary and closed. In the following we present useful information needed later on which we derive from Chavel [5], Jost [13] and Triebel [27, Chapter 7.2].
If $U \subset M$ is open and $x : U \to \mathbb{R}^d$ is any smooth chart, we can identify the tangent space $T_p M$ at $p \in M$ with $\mathbb{R}^d$ by taking the basis $\{ \frac{\partial}{\partial x_i} : i = 1, \ldots, d \}$ and any tangent vector in $T_p M$ may be written as $\xi = \sum_{i=1}^d \xi_i \frac{\partial}{\partial x_i}$, $\xi_i \in \mathbb{R}$. In the coordinates given by $x$ the metric tensor $g$ at $p \in U$ can be written as a positive definite matrix, whose entries are given by the inner product of the tangent vectors $\frac{\partial}{\partial x_i}$ and any tangent vector in $T_p M$, where $i, j = 1, \ldots, d$. We denote these entries by $g_{i j}(z)$, where $z = x(p)$. Then $g_{i j} : x(U) \to \mathbb{R}$ is a smooth function.

1.1. The exponential map. Choosing a basis $\{ e_1, \ldots, e_d \}$ of the tangent space $T_p M$ at $p \in M$ which is orthonormal with respect to $g$ we can identify $T_p M$ with $\mathbb{R}^d$ and, abusing notation, we write $\exp_p$ for the exponential map taking $y \in \mathbb{R}^d$ to $c_v(1) \in M$, where $v = \sum_{i=1}^d y_i e_i$ and $c_v$ is the unique geodesic with $c_v(0) = p$ and tangent vector $v$. This map is a diffeomorphism defined on a neighbourhood around $0 \in \mathbb{R}^d$ and the supremum of all $\rho > 0$ such that it is a diffeomorphism on the Euclidean ball $B(0, \rho) := \{ x \in \mathbb{R}^d : \| x \|_2 < \rho \}$ is called the local injectivity radius $r_p$. The (global) injectivity radius is $\text{inj}(M) = \inf_{p \in M} r_p$, which is positive as $M$ is compact. For $0 < \rho < \text{inj}(M)$ the set $B_M(p, \rho) := \exp_p(B(0, \rho))$ is a geodesic ball with center $p$ and radius $\rho$. Then $\exp_p^{-1} : B_M(p, \rho) \to B(0, \rho)$ is a chart and the corresponding coordinates are called normal coordinates with center $p$.

The Riemannian metric $g$ induces a metric $\text{dist}_M$ on $M$, which then becomes a complete metric space. We want to record the following basic result, which allows us to locally compare the Riemannian distance with the Euclidean distance. It is well known and can be deduced for example from the proof of [13, Corollary 1.4.1].

**Lemma 1.** Let $p \in M$ and $0 < \rho < \text{inj}(M)$. The map $\exp_p : B(0, \rho) \to B_M(p, \rho)$ is bi-Lipschitz. That is, there are constants $0 < c < C$ such that

$$c \| z_1 - z_2 \|_2 \leq \text{dist}_M(\exp_p(z_1), \exp_p(z_2)) \leq C \| z_1 - z_2 \|_2 \quad \text{for all } z_1, z_2 \in B(0, \rho).$$

1.2. Integration. Let $U \subset M$ be open and let $x : U \to \mathbb{R}^d$ be a chart of $M$. If $z \in x(U)$, we let $g^x(z)$ be the determinant of $(g_{i j}^x(z))_{i,j=1}^d$. If $f : M \to \mathbb{R}$ is supported in $U$ and measurable with respect to the Borel $\sigma$-algebra we define the integral of $f$ by

$$\int_M f \, d\text{vol}_M := \int_{x(U)} f(x^{-1}(z)) \sqrt{g^x(z)} \, dz,$$

where $x(U)$ is the image of $U$ under $x$.
if this quantity exists and is finite. It is independent of the choice of the coordinates \( x \). We can extend the integral to global functions using a partition of unity, which we now describe. Since \( M \) is compact, there is a finite atlas \( \{(U_j, x_j)\}_{j \leq J} \) of \( M \). For every such atlas, there exists a subordinate partition of unity \( \{(U_j, \psi_j)\}_{j \leq J} \) satisfying

\[
\psi_j \in C^\infty(M), \quad \text{supp} \, \psi_j \subset U_j, \quad 0 \leq \psi_j(x) \leq 1, \quad \sum_{j=1}^J \psi_j(x) = 1
\]

for all \( j \leq J \) and \( x \in M \), see, e.g., Tu [28, Proposition 13.6]. Here supp denotes the support of a function. We define the integral of a measurable function \( f : M \to \mathbb{R} \) by setting

\[
\int f \, d\text{vol}_M := \sum_{j=1}^J \int_{U_j} f \psi_j \, d\text{vol}_M
\]

if this quantity exists and is finite. This definition of the integral is independent of the atlas and the partition of unity. In particular, (3) and (5) yield the same result if \( f \) is supported in \( U \). As usual, the integral over a Borel measurable set \( E \subset M \) is defined by

\[
\int_E f \, d\text{vol}_M := \int_M f 1_E \, d\text{vol}_M
\]

and the Riemannian volume of \( E \) is defined by \( \text{vol}_M(E) = \int_M 1_E \, d\text{vol}_M \). Note that the volume is well-defined and finite for all Borel sets \( E \subset M \).

1.3. **Bounded Geometry.** Being compact, \( M \) is of bounded geometry in the sense of Triebel [26, 27] (see also Cheeger, Gromov and Taylor [6] and Shubin [23]). This means that for every \( 0 < \rho < \text{inj}(M) \) and every multiindex \( \alpha \in \mathbb{N}_0^d \), there exist constants \( c > 0 \) and \( c_\alpha > 0 \) such that

\[
\sqrt{g(z)} \geq c \quad \text{and} \quad |D^\alpha g_{ij}(z)| \leq c_\alpha \quad \text{for every multiindex } \alpha
\]

in the normal coordinates of every local chart \( (B_M(p, \rho), \exp_p^{-1}) \), where \( z \in B(0, \rho) \) is arbitrary. From now on, we shall work in normal coordinates only, which justifies the abuse of notation. In particular, we find constants \( c, C > 0 \) such that \( c \leq \sqrt{g(z)} \leq C \) for all \( z \in B(0, \rho) \) in coordinates of the chart \( (B_M(p, \rho), \exp_p^{-1}) \). This follows from (6) via \( |g_{ij}(z)| \leq c_0 \) and a determinant bound in terms of entries. From this one can obtain a useful integral estimate, which we now state.
Lemma 2. There exist constants $c, C > 0$ such that for every non-negative function $f$ and every $p \in M$ and $0 < \delta < \text{inj}(M)/2$ it holds that

$$c \int_{B(0, \delta)} f(\exp_p(z)) \, dz \leq \int_{B_M(p, \delta)} f(x) \, d\text{vol}_M(x) \leq C \int_{B(0, \delta)} f(\exp_p(z)) \, dz.$$ 

Proof. We use the chart $\exp_p^{-1} : B_M(p, 2\delta) \to B(0, 2\delta)$ and the definition (3) of the integral to compute

$$\int_{B_M(z, \delta)} f(x) \, d\text{vol}_M(x) = \int_M (f 1_{B_M(p, \delta)})(x) \, d\text{vol}_M(x) = \int_{B(0, 2\delta)} (f 1_{B_M(p, \delta)})(\exp_p(z)) \sqrt{g(z)} \, dz = \int_{B(0, \delta)} f(\exp_p(z)) \sqrt{g(z)} \, dz.$$ 

Using the estimates $c \leq \sqrt{g(z)} \leq C$ completes the proof. $\square$

1.4. Sobolev Spaces. In this subsection we collect useful information about the Bessel potential (Sobolev) spaces $H^s_p(M)$, where $s > 0$ and $1 < p < \infty$. First we give some details regarding their definition and then present an equivalent definition by means of a partition of unity. This will be important for the proof of Theorem 1. Recall that

$$H^s_p(M) = \{ f \in L_p(M) : (I - \Delta_M)^{s/2} f \in L_p(M) \},$$

where $I$ is the identity on $L_p(M)$ and $\Delta_M$ is the Laplace-Beltrami operator on $M$. The norm of $f \in H^s_p(M)$ is

$$\|f\|_{H^s_p(M)} = \| (I - \Delta_M)^{s/2} f \|_{L_p(M)}.$$ 

In addition to [27] see also Strichartz [24] for details. Alternatively, the spaces can be defined using a partition of unity and the corresponding spaces on $\mathbb{R}^d$.

Let $\Delta$ be the usual Laplace operator on $\mathbb{R}^d$. Then the Bessel potential space on $\mathbb{R}^d$ is given by

$$H^s_p(\mathbb{R}^d) := \{ f \in L_p(\mathbb{R}^d) : (I - \Delta)^{s/2} f \in L_p(\mathbb{R}^d) \} = \{ f \in L_p(\mathbb{R}^d) : \mathfrak{F}^{-1}((1 + \|\xi\|_2^2)^{s/2} \mathfrak{F} f) \in L_p(\mathbb{R}^d) \},$$

where $I$ is the identity on $L_p(\mathbb{R}^d)$, with $\|f\|_{H^s_p(\mathbb{R}^d)} = \| \mathfrak{F}^{-1}((1 + \|\xi\|_2^2)^{s/2} \mathfrak{F} f) \|_{L_p}$ for $f \in H^s_p(\mathbb{R}^d)$. Here $\mathfrak{F}$ ($\mathfrak{F}^{-1}$) denotes the (inverse) Fourier transform.
In order to give the equivalent definition, we follow Triebel [27, Section 7], who considers the more general scale of $F$-spaces, also known as Triebel-Lizorkin spaces. Let $0 < \delta < \text{inj}(M)/8$ be small enough and consider a finite covering of $M$ by the geodesic balls $B_j := B_M(p_j, \delta), j \leq J$, as well as a subordinate partition of unity $\Psi = \{(B_j, \psi_j) : j \leq J\}$ satisfying (4) with $U_j$ replaced by $B_j$.

We can now state the equivalent definition.

**Proposition 2.** Let $M$ and $\Psi = \{(B_j, \psi_j) : j \leq J\}$ be as above. Further, let $s > 0$ and $1 < p < \infty$. Then the space of all functions $f \in L^p(M)$, for which

$$\|f\|_{H^s_p(M)}^\Psi := \left( \sum_{j=1}^J \| (f \psi_j) \circ \exp_{p_j} \|_{H^s_p(\mathbb{R}^d)}^p \right)^{1/p}$$

is finite, coincides with $H^s_p(M)$ and $\| \cdot \|_{H^s_p(M)}^\Psi$ defines an equivalent norm on it. Moreover, if $\Phi$ is another partition of unity as above, the norms $\| \cdot \|_{W^s_p(M)}^\Phi$ and $\| \cdot \|_{W^s_p(M)}^\Psi$ are equivalent.

**Proof.** This follows from [27, Theorem 7.2.3] and the fact that the spaces $H^s_p(M)$ are contained in the scale of $F$-spaces, see [25, Theorem 2.5.6] and [27, Theorem 7.4.5] for this on $\mathbb{R}^d$ and $M$, respectively. \hfill $\square$

**Remark 3.** Actually, one can define the more general scales of Triebel-Lizorkin and Besov spaces on $M$ completely analogously as in Proposition 2, and as in [15], our results may be obtained for the Triebel-Lizorkin spaces $F^s_{\tau p}(M)$, where $1 < p < \infty$ and $0 < \tau \leq \infty$.

It follows from Proposition 2 and the corresponding embedding on $\mathbb{R}^d$ that $H^s_p(M)$ is continuously embedded into $C(M)$, the space of continuous functions on $M$ whenever $s > d/p$. If $s \in \mathbb{N}$, then $H^s_p(\mathbb{R}^d)$ coincides with the Sobolev space $W^s_p(\mathbb{R}^d)$ of functions with finite norm

$$\|f\|_{W^s_p(\mathbb{R}^d)} := \left( \sum_{|\alpha| \leq s} \| D^\alpha f \|_{L^p(\mathbb{R}^d)}^p \right)^{1/p},$$

where $\alpha \in \mathbb{N}_0^d$ is a multiindex, $|\alpha| = \alpha_1 + \cdots + \alpha_d$ and $D^\alpha = \frac{\partial^{|\alpha|}}{\partial x_1^{\alpha_1} \cdots \partial x_d^{\alpha_d}} f$ denotes a weak partial derivative of order $|\alpha|$. For this fact note that norms on finite-dimensional spaces are equivalent and see, e.g., [25, Theorem 2.5.6]. Analogously, one can use covariant derivatives to define a Sobolev space of integer smoothness $s \in \mathbb{N}$ on a manifold and these coincide again with $H^s_p(M)$, see Theorem 7.4.5.
in [27]. More about the spaces $H^p_0(M)$ may be found in the paper [2] by Brandolini et al., where the eigensystem of $\Delta_M$ is employed and also $p = 1, \infty$ is allowed. We exclude these boundary values of $p$ because of Proposition 2.

1.5. Spherical cap discrepancy. As mentioned in the introduction, see (2), the minimal worst case error of a point set for the integration problem on $H := H^{(d+1)/2}(\mathbb{S}^d)$ equals the minimal weighted spherical cap discrepancy of the point set. For completeness, we give some details on this relation while relying on standard techniques, see, e.g., Novak and Woźniakowski [21, Section 9].

According to [3, Theorem 1], an equivalent norm on the Hilbert space $H$ is given via the reproducing kernel

$$K : \mathbb{S}^d \times \mathbb{S}^d \to \mathbb{R}, \quad K(x, y) = \int_{[-1,1]} \int_{\mathbb{S}^d} 1_{C(z,t)}(x) 1_{C(z,t)}(y) \, d\sigma_d(z) \, dt.$$ 

The representer $h \in H$ of the integral on $H$ is given by

$$h(x) = \langle h, K(x, \cdot) \rangle = \int_{\mathbb{S}^d} K(x, y) \, d\sigma_d(y).$$

Thus the worst case error of the cubature rule $f \mapsto Q(f) := \sum_{j=1}^n w_j f(x_j)$ can be computed as

$$e(Q, H, \text{INT})^2 = \sup_{\|f\|_H \leq 1} \left| \int_{\mathbb{S}^d} f(x) \, d\sigma_d(x) - \sum_{j=1}^n w_j f(x_j) \right|^2 = \left\| h - \sum_{j=1}^n w_j K(x_j, \cdot) \right\|^2$$

$$= \int_{\mathbb{S}^d} \int_{\mathbb{S}^d} K(x, y) \, d\sigma_d(y) \, d\sigma_d(x) - 2 \int_{\mathbb{S}^d} \sum_{j=1}^n w_j K(x_j, y) \, d\sigma_d(y) + \sum_{i,j=1}^n w_i w_j K(x_i, x_j).$$

Inserting the definition of the kernel $K$ and interchanging integrals, we arrive at

$$= \int_{[-1,1]} \int_{\mathbb{S}^d} \left[ \sigma_d(C(z,t))^2 - 2 \sum_{j=1}^n w_j 1_{C(z,t)}(x_j) \sigma_d(C(z,t)) \right.$$ 

$$\left. + \sum_{i,j=1}^n w_i w_j 1_{C(z,t)}(x_i) 1_{C(z,t)}(x_j) \right] \, d\sigma_d(z) \, dt = D_2(\{(x_j, w_j)\}_{j=1}^n).$$

2. The proof of Theorems 1 and 2

Thanks to our preparations, we are able to lift Theorem 1 from Euclidean balls to Riemannian manifolds. More precisely, we use the following proposition from [15]. All parameters are given as in Theorem 1.
Proposition 3 ([15]). Let $\delta > 0$ and set $B = B(0, \delta) \subset \mathbb{R}^d$. Then there are positive constants $C$ and $c$ such that the following holds for all finite and nonempty point sets $P \subset B$.

(1) There is a non-negative function $f \in H^s_p(\mathbb{R}^d)$ with support in $B$ and $f|_P = 0$ such that $\|f\|_{H^s_p(\mathbb{R}^d)} \leq 1$ and

$$\|f\|_{L_q(B)} \geq c \|\text{dist}(\cdot, P)\|_{L^a(B)}^a.$$

(2) There are bounded functions $u_x : B \to \mathbb{R}$ for $x \in P$ such that for all $f \in H^s_p(\mathbb{R}^d)$ with support in $B$ and $\|f\|_{H^s_p(\mathbb{R}^d)} \leq 1$ we have

$$\left\| f - \sum_{x \in P} f(x)u_x \right\|_{L_q(B)} \leq C \|\text{dist}(\cdot, P \cup \partial B)\|_{L^a(B)}^a.$$

Proof. The first property is proven precisely this way in [15] and thus we turn to the second property. Let $Q \subset \partial B$ be finite. By Theorems 1 and 2 in [15] there are bounded functions $u_x : B \to \mathbb{R}$ for $x \in P \cup Q$ such that we have for all $f \in H^s_p(B)$ with $\|f\|_{H^s_p(B)} \leq 1$ that

$$\left\| f - \sum_{x \in P \cup Q} f(x)u_x \right\|_{L_q(B)} \leq C \|\text{dist}(\cdot, P \cup Q)\|_{L^a(B)}^a$$

with a constant $C$ independent of $P$ and $Q$ (and $f$). See also [15, Remark 8]. If $f$ is supported in $B$, this turns into

$$\left\| f - \sum_{x \in P} f(x)u_x \right\|_{L_q(B)} \leq C \|\text{dist}(\cdot, P \cup Q)\|_{L^a(B)}^a.$$

Taking the infimum over all finite point sets $Q \subset \partial B$, we get the statement. More precisely, we find a sequence of finite point sets $Q_k \subset \partial B$ such that the $1/k$-balls centered at $Q_k$ cover $\partial B$. Then $\text{dist}(\cdot, P \cup Q_k)$ converges uniformly to $\text{dist}(\cdot, P \cup \partial B)$ on $B$ and thus $\|\text{dist}(\cdot, P \cup Q_k)\|_{L^a(B)}^a$ converges to $\|\text{dist}(\cdot, P \cup \partial B)\|_{L^a(B)}^a$. □

In the following, fix a partition of unity $\Psi = \{(B_j, \psi_j) : j \leq J\}$ as in Proposition 2, where $B_j = B_M(p_j, \delta)$ with $0 < \delta < \text{inj}(M)/24$ small enough to accommodate for a factor of three, see the proof of the lower bound below for a justification. We use the shorthand $B = B(0, \delta)$ and $\exp_j = \exp_{p_j}$. 
2.1. The upper bound. We construct our algorithm as follows. Let \( f \in H^p_w(M) \) with \( \|f\|_{H^p_w(M)} \leq 1 \) and \( j \leq J \) be arbitrary but fixed for now. We write

\[ f_j := (\psi_j f) \circ \exp_j \]

which is supported in \( B \) and belongs to \( H^p_w(\mathbb{R}^d) \) with

\[ \|f_j\|_{H^p_w(\mathbb{R}^d)} \leq \|f\|_{H^p_w(M)} \leq C_{\psi}, \]

where \( C_{\psi} \) is independent of \( f \). This follows from Proposition 2. We take the point set \( P_j := \exp^{-1}_j(P \cap B_j) \subset B \). Applying Proposition 3 to the rescaled functions \( C_{\psi}^{-1} f_j \) we get bounded functions \( u_x: B \to \mathbb{R}, x \in P_j \), such that we have for all \( f \in H^p_w(M) \) that

\[ \|f_j - \sum_{x \in P_j} f_j(x)u_x^j\|_{L_q(B)} \leq C_{\psi} C \|\text{dist}(\cdot, P_j \cup \partial B)\|_{L_\infty(B)}^{\alpha}. \]

Define a function \( A_j(f) \) on \( B_j \) by

\[ A_j(f) := \left( \sum_{x \in P_j} f_j(x)u_x^j \right) \circ \exp_j^{-1} = \sum_{p \in P \cap B_j} (\psi_j f)(p) u_p^j \]

and extend the function to \( M \) by zero. Here we carried out the substitution \( p = \exp_j(x) \) and denote \( u_p^j = u_x^j \circ \exp_j^{-1} \). Rewriting (7) gives

\[ \|(\psi_j f - A_j(f)) \circ \exp_j\|_{L_q(B)} \leq \|\text{dist}(\cdot, P_j \cup \partial B)\|_{L_\infty(B)}^{\alpha}. \]

We proceed like this for every \( j \leq J \). Note that the constant \( C \) is independent of \( f \), \( P \) and \( j \). We set

\[ A(f) := \sum_{j=1}^J A_j(f). \]

The recovery operator \( A: H^p_w(M) \to L_\infty(M) \) is linear and uses only function values at \( P \). It remains to exhibit an appropriate upper bound. This is now straightforward. The triangle inequality and \( \sum_{j=1}^J \psi_j \equiv 1 \) imply

\[ \|f - A(f)\|_{L_q(M)} \leq \sum_{j=1}^J \|\psi_j f - A_j(f)\|_{L_q(M)} \].
We apply the upper estimate of Lemma 2 for every $j$ to the non-negative functions $|\psi_j f - A_j(f)|^q$, supported in $B_j = B_M(z_j, \delta)$, and arrive at

$$\|f - A(f)\|_{L_q(M)} \leq C^{1/q} \sum_{j=1}^J \| (\psi_j f - A_j(f)) \circ \exp_j \|_{L_q(B_j)}.$$  

Applying the local estimate (8) to each term in the sum yields

$$\|f - A(f)\|_{L_q(M)} \lesssim \sum_{j=1}^J \| \text{dist}(\cdot, P_j \cup \partial B_j) \|_{L_\gamma(B_j)}^\alpha.$$  

Let us note that the constants of Lemma 1 and Lemma 2 are independent of $p$, but we do not need this fact here and in the following, since we use the lemmas only for a constant number of points $p_j$. Here and in the following, the notation $A \lesssim B$ means that there exists an implicit constant $C > 0$, which does not depend on $f$ or $P$, such that $A \leq CB$ everywhere. We interpret $A \gtrsim B$ as $B \lesssim A$.

Using the lower estimate of Lemma 2 for $\text{dist}(\exp_j^{-1}(\cdot), P_j \cup \partial B_j)^\gamma$ for every $j$ gives

$$\|f - A(f)\|_{L_q(M)} \lesssim \sum_{j=1}^J \| \text{dist}(\exp_j^{-1}(\cdot), P_j \cup \partial B_j) \|_{L_\gamma(B_j)}^\alpha.$$  

Note that $\exp_j(P_j \cup \partial B_j) = (P \cap B_j) \cup \partial B_j$ and Lemma 1 implies that

$$\text{dist}(\exp_j^{-1}(x), P_j \cup \partial B_j) \leq c^{-1} \text{dist}_M(x, (P \cap B_j) \cup \partial B_j) \leq c^{-1} \text{dist}_M(x, P)$$

for some $c > 0$ and all $x \in B_j$. Combining these inequalities and taking the $L_\gamma(B_j)$-norm we derive from (9) that

$$\|f - A(f)\|_{L_q(M)} \lesssim \sum_{j=1}^J \| \text{dist}(\cdot, P_j) \|_{L_\gamma(B_j)}^\alpha \leq J \| \text{dist}(\cdot, P) \|_{L_\gamma(M)}^\alpha.$$  

This proves the upper bound for Theorem 1, where we allow the implicit constants to depend on the chosen partition, and in particular on $J$. The upper bound in Theorem 2 is achieved by the cubature rule $Q(f) := \int_M A(f) \, d\text{vol}_M$ which follows from

$$\left| \int_M f \, d\text{vol}_M - \int_M A(f) \, d\text{vol}_M \right| \leq \|f - A(f)\|_{L_1(M)}.$$

2.2. The lower bound. As in [15], the proof of the lower bound relies on the well-known technique of fooling functions. Namely, we provide a non-negative function $f_*$ which belongs to the unit ball of $H^s_p(M)$ that vanishes on the point set $P$. Then any algorithm based on $P$ cannot distinguish $f_*$ from its negative
and for one of the two functions, the algorithm makes an error at least $\|f_*\|_{L_q(M)}$, respectively $\int_M f_* \, \text{dvol}_M = \|f_*\|_{L_1(M)}$ for the integration problem. It thus suffices to find $f_*$ with

$$\|f_*\|_{L_q(M)} \gtrsim \|\text{dist}_M(\cdot, P)\|_{L_\gamma(M)}.$$

In order to prepare the proof, we introduce a set of nice partitions of unity, which are well adapted for constructing our fooling function. Namely, for each $k \leq J$ we choose a partition of unity $\Psi_k$ by removing all elements of the partition $\Psi$ which intersect the ball $B_k$ and adjoin the larger ball $3B_k$ together with the sum of the deleted functions. In this way, we obtain a partition with only one element not equal to the zero function on $B_k$. More precisely, let $J_k := \{j \leq J : B_j \cap B_k = \emptyset\}$ and

$$\Psi_k := \{(3B_j, \psi_j) : j \in J_k\} \cup \{(3B_k, \tilde{\psi}_k)\} \quad \text{with} \quad \tilde{\psi}_k = \sum_{j \in J_k} \psi_j,$$

where $J_k^C = \{j \leq J : B_j \cap B_k \neq \emptyset\}$. It is readily checked that we have a partition of unity as before: Any point which belonged to some $B_j, j \in J_k^C$, is included in $3B_j$ and $\tilde{\psi}_k$ is supported in $3B_k$. Moreover, we gain the property $\tilde{\psi}_k(x) = 1$ for $x \in B_k$. The enlargement of the balls $B_j, j \in J_k$, to $3B_j$ is due to technical reasons since only equally sized balls are used in [27]. As the Sobolev norms $\|\cdot\|_{H^s_p(M)}$ and $\|\cdot\|_{H^s_p(M)}$ are equivalent for all $k_1, k_2 \leq J$, we can take suitable constants $c_\Psi, C_\Psi > 0$ such that for all $f \in H^s_p(M)$ and all $k_1, k_2 \leq J$, we have

$$c_\Psi \|f\|_{H^{k_1}_p(M)} \leq \|f\|_{H^{k_2}_p(M)} \leq C_\Psi \|f\|_{H^{k_1}_p(M)}.$$

We begin to construct our fooling function. If $\gamma < \infty$, then because of

$$\|\text{dist}_M(\cdot, P)\|_{L_\gamma(M)} = \sum_{j=1}^J \int_M \psi_j(x) \text{dist}_M(x, P)^\gamma \, \text{dvol}_M(x) \leq \sum_{j=1}^J \int_{B_j} \text{dist}_M(x, P)^\gamma \, \text{dvol}_M(x),$$

there must exist $i_0 \leq J$ such that

$$\int_{B_{i_0}} \text{dist}_M(x, P)^\gamma \, \text{dvol}_M(x) \geq \frac{1}{J} \|\text{dist}_M(\cdot, P)\|_{L_\gamma(M)}.$$

If $\gamma = \infty$, we replace formula (11) by

$$\|\text{dist}_M(\cdot, P)\|_{L_\infty(B_{i_0})} = \|\text{dist}_M(\cdot, P)\|_{L_\infty(M)}.$$
We consider now the partition of unity $\Psi_{i_0}$. Recall that $3B_{i_0}$ belongs to it and $\tilde{\psi}_{i_0} = 1$ on $B_{i_0}$. The exponential maps $\exp_j$ are now considered as mappings from $3B$ to $3B_j$ for $j \in J_k$.

We construct a fooling function on $B$ on which we consider the point set $P_{i_0} = \exp_{i_0}^{-1}(P \cap B_{i_0})$. By Proposition 3 we get a non-negative function $f \in H_p^s(\mathbb{R}^d)$ with support in $B$,

$$\|f\|_{H_p^s(\mathbb{R}^d)} \leq 1, \quad f|_{P_{i_0}} = 0 \quad \text{and} \quad \|f\|_{L_q(B)} \gtrsim \|\operatorname{dist}(\cdot, P_{i_0})\|_{L_q(B)}^{\alpha}.$$ 

We define the function $f_*$ by $f_*(x) = f(\exp^{-1}_{i_0}(x))$ if $x \in B_{i_0}$ and zero else.

We compute that $\psi_j f_* \circ \exp_j = 0$ if $j \in J_{i_0}$, since $\psi_j \equiv 0$ on $B_{i_0}$ for those $j$, and $\psi_{i_0} f_* \circ \exp_{i_0} = f$. By definition

$$\|f_*\|^q_{H_p^s(M)} = \left( \sum_{j \in J_{i_0}} \|\psi_j f_* \circ \exp_j\|^p_{H_p^s(\mathbb{R}^d)} + \|\psi_{i_0} f_* \circ \exp_{i_0}\|^p_{H_p^s(\mathbb{R}^d)} \right)^{1/p}$$

and thus, by Proposition 2,

$$\|f_*\|_{H_p^s(M)} \asymp \|f_*\|^q_{H_p^s(M)} = \|\psi_{i_0} f_* \circ \exp_{i_0}\|_{H_p^s(\mathbb{R}^d)} = \|f\|_{H_p^s(\mathbb{R}^d)} \leq 1.$$ 

Therefore, we can replace $f_*$ by a rescaled version such that $\|f_*\|_{H_p^s(M)} \leq 1$. Additionally, we have $f_*|_P = 0$. In the case $q < \infty$, we apply Lemma 2 to the support $B_{i_0}$ to get

$$\|f_*\|_{L_q(M)} \gtrsim \|f\|_{L_q(B)} \gtrsim \|\operatorname{dist}(\cdot, P_{i_0})\|_{L_q(B)}.$$ 

It is straightforward that this relation also holds for $q = \infty$. It remains to to prove a lower estimate of the form

$$(12) \quad \|\operatorname{dist}(\cdot, P_{i_0})\|_{L_q(B)} \gtrsim \|\operatorname{dist}_M(\cdot, P)\|_{L_q(B_{i_0})},$$

which by means of (11) yields that the function $f_*$ satisfies (10) and concludes the proof of the lower bounds of Theorems 1 and 2.

We start with the right-hand side of (12). By Lemma 2 we have for $\gamma < \infty$

$$\|\operatorname{dist}_M(\cdot, P)\|_{L_q(B_{i_0})} \lesssim \|\operatorname{dist}(\exp_{i_0}(\cdot), P)\|_{L_q(B_{i_0})}.$$ 

For $\gamma = \infty$, we even have equality. We estimate for $z \in B$ using Lemma 1

$$\operatorname{dist}_M(\exp_{i_0}(z), P) \leq \min_{x \in P \cap B_{i_0}} \operatorname{dist}_M(\exp_{i_0}(z), x) \lesssim \min_{y \in P_{i_0}} \|z - y\|_2 = \operatorname{dist}(z, P_{i_0}).$$
Applying the $L_\gamma(B)$-norm gives

$$\left\| \text{dist}_M(\exp_{i_0}(\cdot), P) \right\|_{L_\gamma(B)} \lesssim \left\| \text{dist}(\cdot, P_{i_0}) \right\|_{L_\gamma(B)},$$

and we arrive at (12).

### 3. Random points

In this section, we will essentially prove Proposition 1.

For $\gamma = \infty$ the upper and lower bound from Proposition 1 follow from Theorems 2.1 and 2.2 in Reznikov and Saff [22] and the Ahlfors-regularity of $M$, see Lemma 4 below. For $0 < \gamma < \infty$ the lower bound follows from relation (1) since random points can be no better than optimal points. We now proceed with the upper bound in the case $0 < \gamma < \infty$. In fact, we prove the following more general and more precise statement. This is a simple modification of Cohort [7, Theorem 2].

**Theorem 3.** Let $M$ be a compact Riemannian manifold of dimension $d \in \mathbb{N}$ and $\gamma \in (0, \infty)$. Let $\nu$ be a Borel probability measure on $M$ which is absolutely continuous with respect to $\text{vol}_M$ with density $h_\nu : M \to [c, \infty)$ for some $c > 0$. Let $X_1, X_2, \ldots$ be i.i.d. with law $\nu$. Then the distortion of the random point set $P_n = \{X_1, \ldots, X_n\}$ satisfies

$$n^{\gamma/d} \int_M \text{dist}_M(x, P_n)\gamma \text{dvol}_M(x) \longrightarrow \omega_d^{-\gamma/d} \Gamma\left(1 + \frac{\gamma}{d}\right) \int_M h_\nu(x)^{-\gamma/d} \text{dvol}_M(x),$$

as $n \to \infty$ in $L_p$ for all $p \in (0, \infty)$.

The proof of Proposition 1 is complete if we apply Theorem 3 for $p = \alpha/\gamma$. Thus, it remains to prove Theorem 3. The only essential thing we shall use is the following lemma, a proof of which can be found for example in Blümlinger [1, Lemma 2].

**Lemma 3.** Let $M$ be a compact $d$-dimensional Riemannian manifold. Then

$$\lim_{r \to 0} \frac{\text{vol}_M(B_M(p, r))}{\text{vol}(B(0, r))} = 1$$

uniformly in $p \in M$, where $\text{vol}$ denotes the $d$-dimensional Lebesgue measure.

In other words, letting $\omega_d$ be the $d$-dimensional volume of the unit ball of $\mathbb{R}^d$ we have $\lim_{r \to 0} \text{vol}_M(B_M(p, r))r^{-d} = \omega_d$ uniformly in $p \in M$. As a consequence of Lemma 3, one can obtain the well-known fact that the volume and the metric on $M$ satisfy a compatibility condition which is also known as Ahlfors-regularity.
Lemma 4. Let $M$ be a compact $d$-dimensional Riemannian manifold. Then there are constants $c, C > 0$ such that

$$c r^d \leq \text{vol}_M(B_M(p, r)) \leq C r^d \quad \text{for all } 0 < r < \text{diam}(M) \text{ and all } p \in M.$$ 

We are now ready to prove the limit theorem for the distortion of i.i.d. random points on a manifold.

Proof of Theorem 3. To ease the notation in this proof, we denote the geodesic distance by dist and the volume integral on $M$ by $\text{d}x$. We set

$$Z_n := n^{\gamma/d} \int_M \text{dist}(x, P_n)^\gamma \text{d}x,$$

$$z := \omega_d^{-\gamma/d} \Gamma\left(1 + \frac{\gamma}{d}\right) \int_M h_v(x)^{-\gamma/d} \text{d}x.$$ 

We show that

$$E Z_n^p \to z^p \quad \text{for all } p \in \mathbb{N}. \quad (13)$$

From this it follows that, for any even integer $p$,

$$E |Z_n - z|^p = \sum_{k=0}^{p} \binom{p}{k} (-z)^{p-k} E Z_n^k \xrightarrow{n \to \infty} \sum_{k=0}^{p} \binom{p}{k} (-z)^{p-k} z^k = 0,$$

i.e., that $Z_n$ converges to $z$ in $L_p$ for all even integers $p$. By Jensen’s inequality, the convergence holds for all $p \in (0, \infty)$, which completes the proof.

We show (13). We have

$$E Z_n^p = E \int_{(M)^p} \prod_{j=1}^{p} n^{\gamma/d} \text{dist}(x_j, P_n)^\gamma \text{d}x_1 \cdots \text{d}x_p.$$ 

Interchanging the integrals yields

$$E Z_n^p = \int_{(M)^p} E \prod_{j=1}^{p} n^{\gamma/d} \text{dist}(x_j, P_n)^\gamma \text{d}x_1 \cdots \text{d}x_p.$$ 

We use $a_j = \int_{\mathbb{R}_+} 1_{[v_j, \infty)}(a_j) \text{d}v_j$ for $a_j = n^{\gamma/d} \text{dist}(x_j, P_n)^\gamma$ and put

$$I_n(v_1, \ldots, v_p, x_1, \ldots, x_p) := E \prod_{j=1}^{p} 1_{[v_j, \infty)}(n^{\gamma/d} \text{dist}(x_j, P_n)^\gamma)$$

to see after an interchange of integrals that

$$E Z_n^p = \int_{(M)^p} \int_{(\mathbb{R}_+)^p} I_n(v_1, \ldots, v_p, x_1, \ldots, x_p) \text{d}v_1 \cdots \text{d}v_p \text{d}x_1 \cdots \text{d}x_p.$$
Since
\[ \int_{(\mathbb{R}^+)^p} \int_{(\mathbb{R}^+)^p} \exp \left( - \omega_d \sum_{j=1}^p v_j^{d/\gamma} h_{\nu}(x_j) \right) \, dv_1 \cdots dv_p \, dx_1 \cdots dx_p = z^p, \]
the desired statement (13) follows from the dominated convergence theorem once we show that
\[ I_n(v_1, \ldots, v_p, x_1, \ldots, x_p) \xrightarrow{n \to \infty} \exp \left( - \omega_d \sum_{j=1}^p v_j^{d/\gamma} h_{\nu}(x_j) \right) \]
for almost all \( v_1, \ldots, v_p, x_1, \ldots, x_p \) and find an integrable majorant of \( I_n \). For the latter we observe that
\[ I_n(v_1, \ldots, v_p, x_1, \ldots, x_p) = \mathbb{P} \left[ n^{\gamma/d} \text{dist}_M(x_j, P_n)^\gamma \geq v_j \text{ for all } j \right] \]
\[ = \mathbb{P} \left[ X_i \notin B_M(x_j, v_1^{1/\gamma} n^{-1/d}) \text{ for all } i, j \right] \left( 1 - \nu \left( \bigcup_{j=1}^p B_M(x_j, v_1^{1/\gamma} n^{-1/d}) \right) \right)^n. \]
Clearly, it holds that \( I_n = 0 \) whenever there is some \( j \leq p \) with \( v_1^{1/\gamma} n^{-1/d} \geq \text{diam}(M) \). In the other case, we use Lemma 4 and the lower bound on the density of \( \nu \) to find a constant \( c_1 > 0 \) such that \( \nu(B_M(x, r)) \geq c_1 r^d \) for all \( x \in M \) and \( 0 < r < \text{diam}(M) \). Therefore,
\[ I_n(v_1, \ldots, v_p, x_1, \ldots, x_p) \leq \left( 1 - \max_{j \leq p} \nu(B_M(x_j, v_1^{1/\gamma} n^{-1/d})) \right)^n \]
\[ \leq \left( 1 - \frac{c_1 \max_{j \leq p} v_j^{d/\gamma}}{n} \right)^n \leq \exp \left( -c_1 \max_{j \leq p} v_j^{d/\gamma} \right) \leq \exp \left( - \frac{c_1}{p} \sum_{j=1}^p v_j^{d/\gamma} \right), \]
which gives an integrable majorant of \( I_n \).

For the almost sure convergence, we use that for almost every choice of the \( x_j \) and \( v_j \) we have for \( n \) large enough that the balls \( B_M(x_j, v_j^{1/\gamma} n^{-1/d}) \) are disjoint and thus
\[ I_n(v_1, \ldots, v_p, x_1, \ldots, x_p) = \left( 1 - \sum_{j=1}^p \nu(B_M(x_j, v_j^{1/\gamma} n^{-1/d})) \right)^n. \]
Define \( a_n := \sum_{j=1}^p \nu(B_M(x_j, v_j^{1/\gamma} n^{-1/d})) \). We will establish the almost sure convergence of \( n a_n \to a := \omega_d \sum_{j=1}^p v_j^{d/\gamma} h_{\nu}(x_j) \), from which it follows that \((1-a_n)^n \to e^{-a}. \)
This implies the almost sure convergence (14) and completes the proof.
To this end, write, for $1 \leq j \leq p$,

$$n\nu(B_M(x_j, v_j^{1/\gamma} n^{-1/d})) = \frac{n \text{vol}_M(B_M(x_j, v_j^{1/\gamma} n^{-1/d}))}{\text{vol}_M(B_M(x_j, v_j^{1/\gamma} n^{-1/d})))} \int_{B_M(x_j, v_j^{1/\gamma} n^{-1/d})} h_\nu(x) \, dx,$$

where $h_\nu \in L_1(M)$ is the density of $\nu$. By Lemma 3 the numerator satisfies

$$n \text{vol}_M(B_M(x_j, v_j^{1/\gamma} n^{-1/d}))) \rightarrow \omega_d v_j^{d/\gamma} \text{ as } n \rightarrow \infty,$$

and by the differentiation theorem of Lebesgue we have

$$\frac{1}{\text{vol}_M(B_M(x_j, v_j^{1/\gamma} n^{-1/d})))} \int_{B_M(x_j, v_j^{1/\gamma} n^{-1/d})} h_\nu(x) \, dx \rightarrow h_\nu(x_j)$$

for almost all $x_j$ and $v_j$. Therefore,

$$n\nu(B_M(x_j, v_j^{1/\gamma} n^{-1/d})) \rightarrow \omega_d v_j^{d/\gamma} h_\nu(x_j)$$

and the desired convergence $na_n \rightarrow a$ follows. \hfill \Box

**Remark 4.** In the case of $\gamma < \infty$ and the sphere $S^d$ one can prove the upper bound of Proposition 1 with the help of a covering by holes in the random point set and Theorem 2.2 in [4] due to Brauchart et al. which states that the average hole size behaves well.
