# On the rank of Hankel matrices over finite fields 

Omesh Dhar Dwivedi, Darij Grinberg

September 11, 2021

Given three nonnegative integers $p, q, r$ and a finite field $F$, how many Hankel matrices $\left(x_{i+j}\right)_{0 \leqslant i \leqslant p, 0 \leqslant j \leqslant q}$ over $F$ have rank $\leqslant r$ ? This question is classical, and the answer ( $q^{2 r}$ when $r \leqslant \min \{p, q\}$ ) has been obtained independently by various authors using different tools ([Daykin60, Theorem 1 for $m=n$ ], [Elkies02, (26)], [GaGhRa11, Theorem 5.1]). In this note, we will study a refinement of this result: We will show that if we fix the first $k$ of the entries $x_{0}, x_{1}, \ldots, x_{k-1}$ for some $k \leqslant r \leqslant \min \{p, q\}$, then the number of ways to choose the remaining $p+q-k+1$ entries $x_{k}, x_{k+1}, \ldots, x_{p+q}$ such that the resulting Hankel matrix $\left(x_{i+j}\right)_{0 \leqslant i \leqslant p, 0 \leqslant j \leqslant q}$ has rank $\leqslant r$ is $q^{2 r-k}$. This is exactly the answer that one would expect if the first $k$ entries had no effect on the rank, but of course the situation is not this simple (and we had to combine some ideas from [Elkies02, (26)] and from [GaGhRa11, Theorem 5.1 for $r=n$ ] to obtain our proof). The refined result generalizes (and provides an alternative proof of) ACGKLP18, Corollary 6.4].

## Acknowledgments

This note owes much to a short conversation between Peter Scholze and the second author about a more conceptual reason for [ACGKLP18, Corollary 6.4] to be true. Peter, while having bigger fish to fry, quickly ventured a guess, predicting that the known enumerative results for Hankel matrices could be refined by fixing the first few entries. Despite his major contribution, Peter declined to be a coauthor.

The second author is also grateful to the Mathematisches Forschungsinstitut Oberwolfach, which hosted him as a Leibniz Fellow in 2020.

We also thank Jonah Blasiak for helpful and enlightening conversations.

## 1. Results

We let $\mathbb{N}$ denote the set $\{0,1,2, \ldots\}$.
Fix a field $F$. For any $n \in \mathbb{N}$, any $(n+1)$-tuple $x=\left(x_{0}, x_{1}, \ldots, x_{n}\right) \in F^{n+1}$, and any two integers $p, q \in\{-1,0,1, \ldots\}$ satisfying $p+q \leqslant n$, we define a $(p+1) \times(q+1)$-matrix $H_{p, q}(x)$ by

$$
H_{p, q}(x):=\left(x_{i+j}\right)_{0 \leqslant i \leqslant p, 0 \leqslant j \leqslant q}=\left(\begin{array}{cccc}
x_{0} & x_{1} & \cdots & x_{q} \\
x_{1} & x_{2} & \cdots & x_{q+1} \\
\vdots & \vdots & \ddots & \vdots \\
x_{p} & x_{p+1} & \cdots & x_{p+q}
\end{array}\right) \in F^{(p+1) \times(q+1)} .
$$

Such a matrix $H_{p, q}(x)$ is called a Hankel matrix. The study of Hankel matrices has a long history in linear algebra (see, e.g., [Iohvid82]) and relates to linearly recurrent sequences ([Elkies02], [LidNie97, §8.6]), coprime polynomials ([GaGhRa11]), determinants ([Muir60, Section XII.II]), orthogonal polynomials and continued fractions ([Kratte99, §2.7]), total positivity ([Khare21]), and various applications such as x-ray imaging ([Natter01, §V.5]). 1 Numerous results have been obtained about their ranks in particular ([Iohvid82, §11]). When the field $F$ is finite, a strikingly simple formula can be given for the number of Hankel matrices of a given rank (more precisely, of rank $\leqslant$ to a given number):

Theorem 1.1. Assume that $F$ is finite. Let $q=|F|$. Let $r, m, n \in \mathbb{N}$ satisfy $r \leqslant m$ and $r \leqslant n$. The number of $(m+n+1)$-tuples $x \in F^{m+n+1}$ satisfying $\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant r$ is $q^{2 r}$.

Example 1.2. For a simple example, let $r=1$ and $m=2$ and $n=3$. Thus, for every $x=\left(x_{0}, x_{1}, x_{2}, x_{3}, x_{4}, x_{5}\right) \in F^{6}$, we have

$$
H_{m, n}(x)=H_{2,3}(x)=\left(\begin{array}{llll}
x_{0} & x_{1} & x_{2} & x_{3} \\
x_{1} & x_{2} & x_{3} & x_{4} \\
x_{2} & x_{3} & x_{4} & x_{5}
\end{array}\right) .
$$

Theorem 1.1 yields that the number of 6-tuples $x \in F^{6}$ satisfying $\operatorname{rank}\left(H_{2,3}(x)\right) \leqslant 1$ is $q^{2 \cdot 1}=q^{2}$. These 6 -tuples can indeed be described explicitly:

- Any 6-tuple of the form $\left(u, u v, u v^{2}, u v^{3}, u v^{4}, u v^{5}\right)$ with $u \in F \backslash\{0\}$ and $v \in F$ is such a 6-tuple $x$. This gives a total of $|F \backslash\{0\}| \cdot|F|=(q-1) q$ many such 6-tuples.

[^0]- Any 6-tuple of the form $(0,0,0,0,0, w)$ with $w \in F$ is such a 6-tuple $x$. This gives a total of $|F|=q$ many such 6-tuples.

For higher values of $r$, it is harder to describe all the $q^{2 r}$ pertinent tuples.
To our knowledge, Theorem 1.1 has not appeared in this exact form in the literature; however, it is easily seen to be equivalent to the following variant, which has appeared in [Daykin60, Theorem 1]:

Corollary 1.3. Assume that $F$ is finite. Let $q=|F|$. Let $r, m, n \in \mathbb{N}$ satisfy $m \leqslant n$. The number of $(m+n+1)$-tuples $x \in F^{m+n+1}$ satisfying $\operatorname{rank}\left(H_{m, n}(x)\right)=r$ is

$$
\begin{cases}1, & \text { if } r=0 ; \\ q^{2 r-2}\left(q^{2}-1\right), & \text { if } 0<r \leqslant m ; \\ q^{2 r-2}\left(q^{n-m+1}-1\right), & \text { if } r=m+1 ; \\ 0, & \text { if } r>m+1\end{cases}
$$

The particular case of Corollary 1.3 for $m=n$ also appears in [GaGhRa11, Theorem 5.1]2 and [Elkies02, (26)]. The particular case when $r=m=n$ appears in [KalLob96, Corollary 3] as well.

Another setting in which Hankel matrices appear is the theory of symmetric functions, specifically Schur functions (see, e.g., [Stanle01, Chapter 7]). While we will not use this setting to prove our main results, it has provided the main inspiration for this note, so we shall briefly recall it now. The Jacobi-Trudi formula [Stanle01, Theorem 7.16.1] expresses a Schur function $s_{\lambda}$ as the determinant of a matrix, which is a Hankel matrix when the partition $\lambda$ is rectangleshaped. The recent result [ACGKLP18, Corollary 6.4] by Anzis, Chen, Gao, Kim, Li and Patrias can thus be framed as a formula for the probability of a certain $(n+1) \times(n+1)$ Hankel matrix over a finite field to have determinant 0 (that is, rank $\leqslant n$ ). This would be a particular case of Theorem 1.1]if not for the fact that the entries of the relevant Hankel matrix are not chosen uniformly at random; instead, the first few of them are fixed, while the rest are chosen uniformly at random 3 . This suggests a generalization of Theorem 1.1 in which the first few entries $4^{4}$ of the $(m+n+1)$-tuples $x \in F^{m+n+1}$ are fixed. The existence of such a generalization was suggested to us by Peter Scholze.

This generalization indeed exists, and will be the main result of this note. In stating it, we will use the following notation:

[^1]Definition 1.4. Let $n \in \mathbb{N}$. Let $x=\left(x_{0}, x_{1}, \ldots, x_{n}\right)$ be any $(n+1)$-tuple of any kinds of objects. Let $i \in\{0,1, \ldots, n+1\}$. Then, $x_{[0, i)}$ denotes the $i$-tuple $\left(x_{0}, x_{1}, \ldots, x_{i-1}\right)$.

For instance, $(a, b, c, d, e)_{[0,3)}=(a, b, c)$.
We can now state our generalization of Theorem 1.1.
Theorem 1.5. Assume that $F$ is finite. Let $q=|F|$. Let $k, r, m, n \in \mathbb{N}$ satisfy $k \leqslant r \leqslant m$ and $r \leqslant n$. Fix any $k$-tuple $a=\left(a_{0}, a_{1}, \ldots, a_{k-1}\right) \in F^{k}$. The number of $(m+n+1)$-tuples $x \in F^{m+n+1}$ satisfying $x_{[0, k)}=a$ and $\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant r$ is $q^{2 r-k}$.

Example 1.6. For an example, let $k=2, r=2, m=3$ and $n=3$. Let $a=\left(a_{0}, a_{1}\right) \in F^{2}$. Then, Theorem 1.5 yields that the number of 7 -tuples $x \in F^{7}$ satisfying $x_{[0,2)}=a$ and $\operatorname{rank}\left(H_{3,3}(x)\right) \leqslant 2$ is $q^{2 \cdot 2-2}=q^{2}$. Note that a 7-tuple $x \in F^{7}$ satisfying $x_{[0,2)}=a$ is nothing but a 7-tuple $x \in F^{7}$ that begins with the entries $a_{0}$ and $a_{1}$; thus, we could just as well be counting the 5 -tuples $\left(x_{2}, x_{3}, x_{4}, x_{5}, x_{6}\right) \in F^{5}$ satisfying rank $\left(H_{3,3}\left(a_{0}, a_{1}, x_{2}, x_{3}, x_{4}, x_{5}, x_{6}\right)\right) \leqslant 2$.

Clearly, Theorem 1.1 is the particular case of Theorem 1.5 for $k=0$, since the 0 -tuple $a=() \in F^{0}$ automatically satisfies $x_{[0,0)}=a$ for every $x \in F^{m+n+1}$.

By specializing Theorem 1.1 to the case $r=m=n$ (and recalling that a square matrix has determinant 0 if and only if it has less-than-full rank), we can easily obtain the following:

Corollary 1.7. Assume that $F$ is finite. Let $q=|F|$. Let $k, n \in \mathbb{N}$ satisfy $k \leqslant n$. Fix any $k$-tuple $a=\left(a_{0}, a_{1}, \ldots, a_{k-1}\right) \in F^{k}$. The number of $(2 n+1)$-tuples $x \in F^{2 n+1}$ satisfying $x_{[0, k)}=a$ and $\operatorname{det}\left(H_{n, n}(x)\right)=0$ is $q^{2 n-k}$.

We shall prove Theorem 1.5 in Section 4, we will then derive Theorem 1.1 , Corollary 1.3 and Corollary 1.7 from it. Finally, in Section 5, we will explain how Corollary 1.7 generalizes [ACGKLP18, Corollary 6.4].

Remark 1.8. Theorem 1.5 also holds if we replace the assumptions " $k \leqslant$ $r \leqslant m$ and $r \leqslant n$ " by " $k \leqslant r \leqslant m \leqslant n+1$ ". In fact, the only case covered by the latter assumptions but not by the former is the case when $k \leqslant r=m=n+1$; however, Theorem 1.5 is easy to prove directly in this case. (To wit, if $k \leqslant r=m=n+1$, then every $(m+n+1)$-tuple $x \in F^{m+n+1}$ satisfies rank $\left(H_{m, n}(x)\right) \leqslant r$, since the matrix $H_{m, n}(x)$ has $n+1$ columns and therefore has rank $\leqslant n+1=r$. Hence, the number of $(m+n+1)$ tuples $x \in F^{m+n+1}$ satisfying $x_{[0, k)}=a$ and $\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant r$ equals the number of all $(m+n+1)$-tuples $x \in F^{m+n+1}$ satisfying $x_{[0, k)}=a$ in this case. But this number is easily seen to be $q^{m+n+1-k}=q^{2 r-k}$ (since
$\underbrace{m}_{=r}+\underbrace{n+1}_{=r}=r+r=2 r$ ). Thus, Theorem 1.5 is proved in the case when $k \leqslant r=m=n+1$.)

As a consequence, Theorem 1.1 also holds if we replace the assumptions " $r \leqslant m$ and $r \leqslant n$ " by " $r \leqslant m \leqslant n+1$ ". Hence, Corollary 1.3 still holds if we replace the assumption " $m \leqslant n$ " by " $m \leqslant n+1$ ". However, we gain nothing significantly new in this way, since the newly covered cases can also be easily obtained from the old ones.

## 2. Rank lemmas

Before we come to the proof of Theorem 1.5, we are going to build a toolbox of general lemmas about ranks of the Hankel matrices $H_{p, q}(x)$. We note that none of these lemmas requires $F$ to be finite; they can equally well be applied to fields like $\mathbb{R}$ and $\mathbb{C}$.

Lemma 2.1. Let $n \in \mathbb{N}$. Let $p, q \in \mathbb{N}$ be such that $p+q \leqslant n+1$. If $x \in F^{n+1}$ satisfies rank $\left(H_{p, q-1}(x)\right) \leqslant p$, then

$$
\operatorname{rank}\left(H_{p, q-1}(x)\right) \leqslant \operatorname{rank}\left(H_{p-1, q}(x)\right)
$$

Proof of Lemma 2.1. We proceed by induction on $p$ (without fixing $x$ ):
Induction base: Proving Lemma 2.1 in the case when $p=0$ is easy: In this case, the assumption $\operatorname{rank}\left(H_{p, q-1}(x)\right) \leqslant p$ rewrites as $\operatorname{rank}\left(H_{p, q-1}(x)\right) \leqslant 0$, which immediately yields the claim.

Induction step: Let $p$ be a positive integer. Assume (as the induction hypothesis) that Lemma 2.1 holds for $p-1$ instead of $p$. Our goal is now to prove Lemma 2.1 for $p$.

Let $q \in \mathbb{N}$ be such that $p+q \leqslant n+1$. Let $x \in F^{n+1}$ satisfy $\operatorname{rank}\left(H_{p, q-1}(x)\right) \leqslant$ $p$. We must thus prove that

$$
\operatorname{rank}\left(H_{p, q-1}(x)\right) \leqslant \operatorname{rank}\left(H_{p-1, q}(x)\right) .
$$

Write the $(n+1)$-tuple $x \in F^{n+1}$ as $x=\left(x_{0}, x_{1}, \ldots, x_{n}\right)$. Then,

$$
\begin{aligned}
H_{p, q-1}(x) & =\left(\begin{array}{cccc}
x_{0} & x_{1} & \cdots & x_{q-1} \\
x_{1} & x_{2} & \cdots & x_{q} \\
\vdots & \vdots & \ddots & \vdots \\
x_{p} & x_{p+1} & \cdots & x_{p+q-1}
\end{array}\right) \quad \text { and } \\
H_{p-1, q}(x) & =\left(\begin{array}{cccc}
x_{0} & x_{1} & \cdots & x_{q} \\
x_{1} & x_{2} & \cdots & x_{q+1} \\
\vdots & \vdots & \ddots & \vdots \\
x_{p-1} & x_{p} & \cdots & x_{p+q-1}
\end{array}\right) \quad \text { and } \\
H_{p-1, q-1}(x) & =\left(\begin{array}{cccc}
x_{0} & x_{1} & \cdots & x_{q-1} \\
x_{1} & x_{2} & \cdots & x_{q} \\
\vdots & \vdots & \ddots & \vdots \\
x_{p-1} & x_{p} & \cdots & x_{p+q-2}
\end{array}\right) .
\end{aligned}
$$

Hence, the matrix $H_{p, q-1}(x)$ is $H_{p-1, q-1}(x)$ with one extra row inserted at the bottom, whereas the matrix $H_{p-1, q}(x)$ is $H_{p-1, q-1}(x)$ with one extra column inserted at the right end.

For any matrix $A$ that has at least one row, we let $\bar{A}$ denote the matrix $A$ with its first row removed. The following properties of $\bar{A}$ are well-known:

- If the first row of $A$ is a linear combination of the remaining rows, then

$$
\begin{equation*}
\operatorname{rank} A=\operatorname{rank} \bar{A} \tag{1}
\end{equation*}
$$

- If the first row of $A$ is not a linear combination of the remaining rows, then

$$
\begin{equation*}
\operatorname{rank} A=\operatorname{rank} \bar{A}+1 \tag{2}
\end{equation*}
$$

It is furthermore well-known that if $A$ is any matrix, and if $B$ is any submatrix of $A$, then $\operatorname{rank} B \leqslant \operatorname{rank} A$. However, the matrix $\overline{H_{p, q-1}(x)}$ is a submatrix of $H_{p-1, q}(x)$ (indeed, it can be obtained from $H_{p-1, q}(x)$ by removing the first column). Hence,

$$
\operatorname{rank}\left(\overline{H_{p, q-1}(x)}\right) \leqslant \operatorname{rank}\left(H_{p-1, q}(x)\right) .
$$

Let $\bar{x}$ denote the $n$-tuple $\left(x_{1}, x_{2}, \ldots, x_{n}\right) \in F^{n}$. It is easy to see that

$$
\begin{equation*}
\overline{H_{u, v}(x)}=H_{u-1, v}(\bar{x}) \tag{3}
\end{equation*}
$$

for all $u \in \mathbb{N}$ and $v \in\{-1,0,1, \ldots\}$ satisfying $u+v \leqslant n$. Thus, in particular,

$$
\begin{equation*}
\overline{H_{p, q-1}(x)}=H_{p-1, q-1}(\bar{x}) \tag{4}
\end{equation*}
$$

and

$$
\begin{equation*}
\overline{H_{p-1, q}(x)}=H_{p-2, q}(\bar{x}) . \tag{5}
\end{equation*}
$$

If the first row of the matrix $H_{p, q-1}(x)$ is a linear combination of the remaining rows, then (1) yields

$$
\operatorname{rank}\left(H_{p, q-1}(x)\right)=\operatorname{rank}\left(\overline{H_{p, q-1}(x)}\right) \leqslant \operatorname{rank}\left(H_{p-1, q}(x)\right),
$$

which is precisely what we wanted to show. Hence, for the rest of this proof, we WLOG assume that the first row of the matrix $H_{p, q-1}(x)$ is not a linear combination of the remaining rows. Thus, (2) yields

$$
\operatorname{rank}\left(H_{p, q-1}(x)\right)=\operatorname{rank}\left(\overline{H_{p, q-1}(x)}\right)+1
$$

In view of (4), this rewrites as

$$
\begin{equation*}
\operatorname{rank}\left(H_{p, q-1}(x)\right)=\operatorname{rank}\left(H_{p-1, q-1}(\bar{x})\right)+1 \tag{6}
\end{equation*}
$$

Hence,

$$
\operatorname{rank}\left(H_{p-1, q-1}(\bar{x})\right)=\underbrace{\operatorname{rank}\left(H_{p, q-1}(x)\right)}_{\leqslant p}-1 \leqslant p-1 .
$$

Recall that the first row of the matrix $H_{p, q-1}(x)$ is not a linear combination of the remaining rows. This entails that the first row of the matrix $H_{p-1, q-1}(x)$ is not a linear combination of the remaining rows (since the matrix $H_{p-1, q-1}(x)$ is the same as $H_{p, q-1}(x)$ without the last row). Therefore, the first row of the matrix $H_{p-1, q}(x)$ is not a linear combination of the remaining rows (since the matrix $H_{p-1, q}(x)$ is just $H_{p-1, q-1}(x)$ with an extra column). Thus, (2) yields

$$
\operatorname{rank}\left(H_{p-1, q}(x)\right)=\operatorname{rank}\left(\overline{H_{p-1, q}(x)}\right)+1
$$

In view of (5), this rewrites as

$$
\begin{equation*}
\operatorname{rank}\left(H_{p-1, q}(x)\right)=\operatorname{rank}\left(H_{p-2, q}(\bar{x})\right)+1 . \tag{7}
\end{equation*}
$$

However, our induction hypothesis shows that we can apply Lemma 2.1 to $n-1, p-1$ and $\bar{x}$ instead of $n, p$ and $x\left(\right.$ since $\left.\operatorname{rank}\left(H_{p-1, q-1}(\bar{x})\right) \leqslant p-1\right)$. We thus obtain

$$
\operatorname{rank}\left(H_{p-1, q-1}(\bar{x})\right) \leqslant \operatorname{rank}\left(H_{p-2, q}(\bar{x})\right) .
$$

Adding 1 to both sides of this inequality, we find

$$
\operatorname{rank}\left(H_{p-1, q-1}(\bar{x})\right)+1 \leqslant \operatorname{rank}\left(H_{p-2, q}(\bar{x})\right)+1 .
$$

In view of (6) and (7), this rewrites as rank $\left(H_{p, q-1}(x)\right) \leqslant \operatorname{rank}\left(H_{p-1, q}(x)\right)$. This completes the induction step. Thus, Lemma 2.1 is proved.

Lemma 2.2. Let $n \in \mathbb{N}$. Let $p, q \in \mathbb{N}$ be such that $p+q \leqslant n+1$. If $x \in F^{n+1}$ satisfies rank $\left(H_{p-1, q}(x)\right) \leqslant q$, then

$$
\operatorname{rank}\left(H_{p-1, q}(x)\right) \leqslant \operatorname{rank}\left(H_{p, q-1}(x)\right)
$$

Proof of Lemma 2.2. This is just a restatement of Lemma 2.1 (applied to $p$ and $q$ instead of $q$ and $p$ ), since the matrices $H_{p-1, q}(x)$ and $H_{p, q-1}(x)$ are the transposes of the matrices $H_{q, p-1}(x)$ and $H_{q-1, p}(x)$. (Alternatively, you can prove it by the same argument as we used to prove Lemma 2.1. except that rows and columns switch roles.)

Lemma 2.3. Let $n \in \mathbb{N}$. Let $p, q \in \mathbb{N}$ be such that $p+q \leqslant n+1$. If $x \in F^{n+1}$ satisfies $\operatorname{rank}\left(H_{p, q-1}(x)\right) \leqslant p$ and $\operatorname{rank}\left(H_{p-1, q}(x)\right) \leqslant q$, then

$$
\operatorname{rank}\left(H_{p, q-1}(x)\right)=\operatorname{rank}\left(H_{p-1, q}(x)\right)
$$

Proof of Lemma 2.3. This follows by combining Lemma 2.1 with Lemma 2.2,
Our next lemma is a simple corollary of Lemma 2.3:
Lemma 2.4. Let $n \in \mathbb{N}$. Let $p, q \in \mathbb{N}$ be such that $p+q \leqslant n+1$. Let $r \in \mathbb{N}$ satisfy $r+1 \leqslant p$ and $r+1 \leqslant q$. Let $x \in F^{n+1}$. Then, we have the logical equivalence

$$
\left(\operatorname{rank}\left(H_{p, q-1}(x)\right) \leqslant r\right) \Longleftrightarrow\left(\operatorname{rank}\left(H_{p-1, q}(x)\right) \leqslant r\right) .
$$

Proof of Lemma 2.4. We must prove the two implications

$$
\begin{equation*}
\left(\operatorname{rank}\left(H_{p, q-1}(x)\right) \leqslant r\right) \Longrightarrow\left(\operatorname{rank}\left(H_{p-1, q}(x)\right) \leqslant r\right) \tag{8}
\end{equation*}
$$

and

$$
\begin{equation*}
\left(\operatorname{rank}\left(H_{p-1, q}(x)\right) \leqslant r\right) \Longrightarrow\left(\operatorname{rank}\left(H_{p, q-1}(x)\right) \leqslant r\right) . \tag{9}
\end{equation*}
$$

We shall only prove (8), since (9) is entirely analogous.
So let us prove (8). We assume that rank $\left(H_{p, q-1}(x)\right) \leqslant r$; we then must show that rank $\left(H_{p-1, q}(x)\right) \leqslant r$.

The matrix $H_{p-1, q-1}(x)$ is a submatrix of $H_{p, q-1}(x)$, and thus its rank cannot surpass the rank of $H_{p, q-1}(x)$. In other words, we have $\operatorname{rank}\left(H_{p-1, q-1}(x)\right) \leqslant$ $\operatorname{rank}\left(H_{p, q-1}(x)\right)$.

However, the matrix $H_{p-1, q}(x)$ can be viewed as being the matrix $H_{p-1, q-1}(x)$ with one extra column attached to it (at its right end). Thus,

$$
\operatorname{rank}\left(H_{p-1, q}(x)\right) \leqslant \operatorname{rank}\left(H_{p-1, q-1}(x)\right)+1
$$

(since attaching one column cannot increase the rank of a matrix by more than 1). Hence,

$$
\operatorname{rank}\left(H_{p-1, q}(x)\right) \leqslant \underbrace{\operatorname{rank}\left(H_{p-1, q-1}(x)\right)}_{\leqslant \operatorname{rank}\left(H_{p, q-1}(x)\right) \leqslant r}+1 \leqslant r+1 \leqslant q .
$$

Moreover, $\operatorname{rank}\left(H_{p, q-1}(x)\right) \leqslant r \leqslant r+1 \leqslant p$. Hence, we can apply Lemma 2.3, and conclude that $\operatorname{rank}\left(H_{p, q-1}(x)\right)=\operatorname{rank}\left(H_{p-1, q}(x)\right)$. Thus, of course, $\operatorname{rank}\left(H_{p-1, q}(x)\right) \leqslant r$ follows immediately from our assumption rank $\left(H_{p, q-1}(x)\right) \leqslant$ $r$. Hence, (8) is proved.

As we said, the proof of (9) is analogous. Thus, the proof of Lemma 2.4 is complete.

The following lemma is a (much simpler) counterpart to Lemma 2.1 that replaces the assumption $\operatorname{rank}\left(H_{p, q-1}(x)\right) \leqslant p$ by the reverse inequality:

Lemma 2.5. Let $n \in \mathbb{N}$. Let $p, q \in \mathbb{N}$ be such that $p+q \leqslant n+1$. If $x \in F^{n+1}$ satisfies rank $\left(H_{p, q-1}(x)\right)>p$, then

$$
\operatorname{rank}\left(H_{p-1, q}(x)\right)=p
$$

Proof of Lemma 2.5, Let $x \in F^{n+1}$ satisfy rank $\left(H_{p, q-1}(x)\right)>p$. The assumption rank $\left(H_{p, q-1}(x)\right)>p$ shows that the $p+1$ rows of the matrix $H_{p, q-1}(x)$ are linearly independent. Hence, in particular, the $p$ rows of the matrix $H_{p-1, q-1}(x)$ are linearly independent (since these $p$ rows are simply the first $p$ rows of the matrix $H_{p, q-1}(x)$ ). Therefore, the $p$ rows of the matrix $H_{p-1, q}(x)$ are linearly independent as well (since the matrix $H_{p-1, q}(x)$ is just $H_{p-1, q-1}(x)$ with an extra column, and therefore the rows of the former contain the rows of the latter as subsequences). In other words, $\operatorname{rank}\left(H_{p-1, q}(x)\right)=p$. This proves Lemma 2.5 .

Our above lemmas have related ranks of the "adjacent" Hankel matrices $\operatorname{rank}\left(H_{p, q-1}(x)\right)$ and $\operatorname{rank}\left(H_{p-1, q}(x)\right)$. By induction, we shall now extend these to further-apart Hankel matrices:

Lemma 2.6. Let $u \in \mathbb{N}$. Let $m, n, r \in \mathbb{N}$ be such that $m+n \leqslant u$ and $r \leqslant m$ and $r \leqslant n$. Let $s=m+n-r$. Let $x \in F^{u+1}$ be arbitrary. Then, we have the logical equivalence

$$
\left(\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant r\right) \Longleftrightarrow\left(\operatorname{rank}\left(H_{r, s}(x)\right) \leqslant r\right)
$$

Before we prove this lemma, let us comment on its significance (even though we will use it rather directly): If one wants to determine the rank of a $(m+1) \times$
$(n+1)$-matrix $A$, it suffices to probe for each $r \in\{0,1, \ldots, \min \{m, n\}\}$ whether $\operatorname{rank} A \leqslant r$ is true (since $0 \leqslant \operatorname{rank} A \leqslant \min \{m, n\}+1$ ). Thus, Lemma 2.6 allows us to determine the ranks of the various matrices $H_{m, n}(x)$ for a given $x \in F^{u+1}$ if we know which pairs $(r, s)$ satisfy $\operatorname{rank}\left(H_{r, s}(x)\right) \leqslant r$.

Proof of Lemma 2.6. From $s=m+n-r=(m-r)+n$, we obtain $s-(m-r)=$ $n$. Furthermore, $s=m+n-\underbrace{r}_{\leqslant m} \geqslant m+n-m=n$ and similarly $s \geqslant m$. Hence, $m \leqslant s$.

We now claim that the equivalence

$$
\begin{equation*}
\left(\operatorname{rank}\left(H_{r+i, s-i}(x)\right) \leqslant r\right) \Longleftrightarrow\left(\operatorname{rank}\left(H_{r, s}(x)\right) \leqslant r\right) \tag{10}
\end{equation*}
$$

holds for each $i \in\{0,1, \ldots, s-r\}$.
[Proof of (10): We proceed by induction on $i$ :
Induction base: Clearly, (10) holds for $i=0$, since we have $H_{r+i, s-i}(x)=$ $H_{r+0, s-0}(x)=H_{r, s}(x)$ in this case.

Induction step: Let $j \in\{1,2, \ldots, s-r\}$. Assume (as the induction hypothesis) that (10) holds for $i=j-1$. We must prove that (10) holds for $i=j$. In other words, we must prove the equivalence

$$
\begin{equation*}
\left(\operatorname{rank}\left(H_{r+j, s-j}(x)\right) \leqslant r\right) \Longleftrightarrow\left(\operatorname{rank}\left(H_{r, s}(x)\right) \leqslant r\right) \tag{11}
\end{equation*}
$$

However, our induction hypothesis tells us that the equivalence

$$
\begin{equation*}
\left(\operatorname{rank}\left(H_{r+(j-1), s-(j-1)}(x)\right) \leqslant r\right) \Longleftrightarrow\left(\operatorname{rank}\left(H_{r, s}(x)\right) \leqslant r\right) \tag{12}
\end{equation*}
$$

holds.
We have

$$
(r+j)+(s-j+1)=r+\underbrace{s}_{=m+n-r}+1=r+(m+n-r)+1=\underbrace{m+n}_{\leqslant u}+1 \leqslant u+1 .
$$

Furthermore, we have $j \in\{1,2, \ldots, s-r\}$, so that $1 \leqslant j \leqslant s-r$. From $j \leqslant s-r$, we obtain $r \leqslant s-j$, so that $r+1 \leqslant s-j+1$. This entails $s-j+1 \in \mathbb{N}$ (since $r+1 \in \mathbb{N}$ ). Also, $r+1 \leqslant r+j$ (since $j \geqslant 1$ ). Hence, Lemma 2.4 (applied to $p=r+j$ and $n=s-j+1$ ) yields that we have the logical equivalence

$$
\left(\operatorname{rank}\left(H_{r+j, s-j+1-1}(x)\right) \leqslant r\right) \Longleftrightarrow\left(\operatorname{rank}\left(H_{r+j-1, s-j+1}(x)\right) \leqslant r\right)
$$

In other words, we have the equivalence

$$
\left(\operatorname{rank}\left(H_{r+j, s-j}(x)\right) \leqslant r\right) \Longleftrightarrow\left(\operatorname{rank}\left(H_{r+(j-1), s-(j-1)}(x)\right) \leqslant r\right)
$$

(since $s-j+1-1=s-j$ and $r+j-1=r+(j-1)$ and $s-j+1=s-(j-1)$ ). Combining this equivalence with (12), we obtain precisely the equivalence (11) that we were meaning to prove.

Thus, we have shown that (10) holds for $i=j$. This completes the induction step, so that (10) is proven.]

Now, $m \in\{r, r+1, \ldots, s\}$ (since $r \leqslant m \leqslant s$ ), so that $m-r \in\{0,1, \ldots, s-r\}$. Hence, we can apply (10) to $i=m-r$. As a result, we obtain that the equivalence

$$
\left(\operatorname{rank}\left(H_{r+m-r, s-(m-r)}(x)\right) \leqslant r\right) \Longleftrightarrow\left(\operatorname{rank}\left(H_{r, s}(x)\right) \leqslant r\right)
$$

holds. In other words, the equivalence

$$
\left(\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant r\right) \Longleftrightarrow\left(\operatorname{rank}\left(H_{r, s}(x)\right) \leqslant r\right)
$$

holds (since $r+m-r=m$ and $s-(m-r)=n$ ). This proves Lemma 2.6.

## 3. Auxiliary enumerative results

### 3.1. Assumptions and notations

From now on, we assume that the field $F$ is finite. We set $q=|F|$.
We shall use the so-called Iverson bracket notation:
Definition 3.1. If $\mathcal{A}$ is any logical statement, then we define an integer $[\mathcal{A}] \in$ $\{0,1\}$ by

$$
[\mathcal{A}]= \begin{cases}1, & \text { if } \mathcal{A} \text { is true } \\ 0, & \text { if } \mathcal{A} \text { is false }\end{cases}
$$

For example, $[2+2=4]=1$ but $[2+2=5]=0$.
If $\mathcal{A}$ is any logical statement, then $[\mathcal{A}]$ is known as the truth value of $\mathcal{A}$.
The following fact ("counting by roll-call") makes truth values useful to us:
Proposition 3.2. Let $S$ be a finite set. Let $\mathcal{A}(s)$ be a logical statement for each $s \in S$. Then, $\sum_{s \in S}[\mathcal{A}(s)]$ equals the number of elements $s \in S$ satisfying $\mathcal{A}(s)$.

### 3.2. Sums over $v$ for fixed $x$

The following proposition is a restatement of [Elkies02, Proposition 2] (but we shall prove it nevertheless to keep this note self-contained):

Proposition 3.3. Let $m, n \in \mathbb{N}$ satisfy $m \leqslant n+1$. Let $x \in F^{m+n+1}$ be a $(m+n+1)$-tuple. Then,

$$
\begin{aligned}
& (q-1) \cdot\left[\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant m\right] \\
& =\sum_{\substack{v \in F^{1 \times(m+1)} ; \\
v \neq 0}}\left[v H_{m, n}(x)=0\right]-q \sum_{\substack{v \in F^{1 \times m} ; \\
v \neq 0}}\left[v H_{m-1, n+1}(x)=0\right] .
\end{aligned}
$$

Before we prove this proposition, a few words about its significance are worth saying. Assume that, as a first step towards proving Theorem 1.5, we want to count the $(m+n+1)$-tuples $x \in F^{m+n+1}$ satisfying $\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant$ $m$. (This is just an interim goal; we will later generalize this inequality to rank $\left(H_{m, n}(x)\right) \leqslant r$ and impose the additional condition $x_{[0, k)}=a$.) In view of Proposition 3.2, this boils down to computing $\sum_{x \in F^{m+n+1}}\left[\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant m\right]$. Using Proposition 3.3, we can rewrite the addends $\left[\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant m\right.$ ] in this sum in terms of other truth values, which are more "local" (one can think of "rank $\left(H_{m, n}(x)\right) \leqslant m$ " as a "global" statement about the matrix $H_{m, n}(x)$, whereas the statements " $v H_{m, n}(x)=0$ " and " $v H_{m-1, n+1}(x)=0$ " are local in the sense that they only "sample" the matrix at a single vector each) and thus (as we will soon see) are easier to sum.

Proof of Proposition 3.3. We are in one of the following two cases:
Case 1: We have rank $\left(H_{m, n}(x)\right)>m$.
Case 2: We have rank $\left(H_{m, n}(x)\right) \leqslant m$.
Let us first consider Case 1. In this case, we have $\operatorname{rank}\left(H_{m, n}(x)\right)>m$. Thus, $\operatorname{rank}\left(H_{m, n}(x)\right)=m+1$ (since $H_{m, n}(x)$ is an $(m+1) \times(n+1)$-matrix). Therefore, the rows of the matrix $H_{m, n}(x)$ are linearly independent. Hence, there exists no nonzero $v \in F^{1 \times(m+1)}$ satisfying $v H_{m, n}(x)=0$. Therefore,

$$
\begin{equation*}
\sum_{\substack{v \in F^{1 \times(m+1)} \\ v \neq 0}}\left[v H_{m, n}(x)=0\right]=0 . \tag{13}
\end{equation*}
$$

Moreover, Lemma 2.5 (applied to $m+n, m$ and $n+1$ instead of $n, p$ and $q$ ) yields that $\operatorname{rank}\left(H_{m-1, n+1}(x)\right)=m$ (since $\left.\operatorname{rank}\left(H_{m, n}(x)\right)>m\right)$. In other words, the $m \times(n+2)$-matrix $H_{m-1, n+1}(x)$ has rank $m$. Hence, there exists no nonzero $v \in F^{1 \times m}$ satisfying $v H_{m-1, n+1}(x)=0$. Therefore,

$$
\begin{equation*}
\sum_{\substack{v \in F^{1 \times m} ; \\ v \neq 0}}\left[v H_{m-1, n+1}(x)=0\right]=0 . \tag{14}
\end{equation*}
$$

Finally, $\left[\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant m\right]=0$ (since $\left.\operatorname{rank}\left(H_{m, n}(x)\right)>m\right)$. In view of this equality, as well as (13) and (14), the equality that we are trying to prove rewrites as $(q-1) \cdot 0=0-q \cdot 0$, which is clearly true. Thus, Proposition 3.3 is proved in Case 1.

Let us now consider Case 2. In this case, we have $\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant m$. Also, the matrix $H_{m-1, n+1}(x)$ has $m$ rows; thus, $\operatorname{rank}\left(H_{m-1, n+1}(x)\right) \leqslant m \leqslant n+1$. Therefore, Lemma 2.3 (applied to $m+n, m$ and $n+1$ instead of $n, p$ and $q$ ) yields

$$
\begin{equation*}
\operatorname{rank}\left(H_{m, n}(x)\right)=\operatorname{rank}\left(H_{m-1, n+1}(x)\right) \tag{15}
\end{equation*}
$$

Now, Proposition 3.2 shows that $\sum_{v \in F^{1 \times(m+1)}}\left[v H_{m, n}(x)=0\right]$ is the number of all $v \in F^{1 \times(m+1)}$ satisfying $v H_{m, n}(x)=0$. In other words, $\sum_{v \in F^{1 \times(m+1)}}\left[v H_{m, n}(x)=0\right]$
is the size of the left kerne $5^{5}$ of the matrix $H_{m, n}(x)$. But the dimension of this left kernel is $(m+1)-\operatorname{rank}\left(H_{m, n}(x)\right)$ (by the rank-nullity theorem ${ }^{6}$ ); hence, the size of this left kernel is $q^{(m+1)-\operatorname{rank}\left(H_{m, n}(x)\right)}$. Thus,

$$
\begin{equation*}
\sum_{v \in F^{1 \times(m+1)}}\left[v H_{m, n}(x)=0\right]=q^{(m+1)-\operatorname{rank}\left(H_{m, n}(x)\right)} . \tag{16}
\end{equation*}
$$

The same reasoning shows that

$$
\begin{equation*}
\sum_{v \in F^{1 \times m}}\left[v H_{m-1, n+1}(x)=0\right]=q^{m-\operatorname{rank}\left(H_{m-1, n+1}(x)\right)} . \tag{17}
\end{equation*}
$$

Now, (15) yields

$$
q^{(m+1)-\operatorname{rank}\left(H_{m, n}(x)\right)}=q^{(m+1)-\operatorname{rank}\left(H_{m-1, n+1}(x)\right)}=q \cdot q^{m-\operatorname{rank}\left(H_{m-1, n+1}(x)\right)} .
$$

In view of

$$
\begin{aligned}
& q^{(m+1)-\operatorname{rank}\left(H_{m, n}(x)\right)} \\
& =\sum_{\substack{v \in F^{1 \times(m+1)}}}\left[v H_{m, n}(x)=0\right] \quad(\text { by (16)) } \\
& =1+\sum_{\substack{v \in F^{1 \times(m+1)} \\
v \neq 0}}\left[v H_{m, n}(x)=0\right]
\end{aligned} \quad\left(\text { since } 0 H_{m, n}(x)=0\right), ~ \$
$$

and

$$
\begin{aligned}
& q^{m-\operatorname{rank}\left(H_{m-1, n+1}(x)\right)} \\
& =\sum_{\substack{v \in F^{1 \times m}}}\left[v H_{m-1, n+1}(x)=0\right] \quad(\text { by (17)) } \\
& =1+\sum_{\substack{v \in F^{1 \times m} ; \\
v \neq 0}}\left[v H_{m-1, n+1}(x)=0\right] \quad\left(\text { since } 0 H_{m-1, n+1}(x)=0\right),
\end{aligned}
$$

we can rewrite this as

$$
1+\sum_{\substack{v \in F^{1 \times(m+1)} ; \\ v \neq 0}}\left[v H_{m, n}(x)=0\right]=q \cdot\left(1+\sum_{\substack{v \in F^{1 \times m} ; \\ v \neq 0}}\left[v H_{m-1, n+1}(x)=0\right]\right) .
$$

In other words,

$$
\sum_{\substack{v \in F^{1 \times(m+1) ;} \\ v \neq 0}}\left[v H_{m, n}(x)=0\right]-q \sum_{\substack{v \in F^{1 \times m} ; \\ v \neq 0}}\left[v H_{m-1, n+1}(x)=0\right]=q-1 .
$$

[^2]Comparing this with

$$
(q-1) \cdot \underbrace{\left[\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant m\right]}_{\left(\operatorname{since} \operatorname{rank}\left(H_{m, n}(x)\right) \leqslant m\right)}=q-1,
$$

we obtain precisely the claim of Proposition 3.3. Thus, Proposition 3.3 is proved in Case 2.

We have now proved Proposition 3.3 in both Cases 1 and 2. Thus, Proposition 3.3 always holds.

### 3.3. Sums over $x$ for fixed $v$

We need another definition. Namely, if $m \in \mathbb{N}$, and if $v=\left(v_{0}, v_{1}, \ldots, v_{m}\right) \in$ $F^{1 \times(m+1)}$ is a row vector of size $m+1$, then last $v$ will denote $v_{m}$ (that is, the last entry of $v$ ). There is a bijection

$$
\begin{aligned}
R:\left\{v \in F^{1 \times(m+1)} \mid \text { last } v=0\right\} & \rightarrow F^{1 \times m} \\
\left(v_{0}, v_{1}, \ldots, v_{m}\right) & \mapsto\left(v_{0}, v_{1}, \ldots, v_{m-1}\right) .
\end{aligned}
$$

Its inverse map $R^{-1}$ sends each row vector $\left(v_{0}, v_{1}, \ldots, v_{m-1}\right) \in F^{1 \times m}$ to the row vector $\left(v_{0}, v_{1}, \ldots, v_{m-1}, 0\right)$.

Lemma 3.4. Let $k, m, n \in \mathbb{N}$ satisfy $k \leqslant m$. Let $v \in F^{1 \times(m+1)}$ be a row vector of size $m+1$ such that last $v \neq 0$. Fix any $k$-tuple $a \in F^{k}$. Then,

$$
\sum_{\substack{x \in F^{m+n+1} ; \\ x_{[0, k)}=a}}\left[v H_{m, n}(x)=0\right]=q^{m-k}
$$

Proof of Lemma 3.4. Proposition 3.2 shows that $\sum_{\substack{x \in F^{m+n+1 ;} \\ x_{[0, k}=a}}\left[v H_{m, n}(x)=0\right]$ is the
number of all $x \in F^{m+n+1}$ satisfying $x_{[0, k)}=a$ and $v H_{m, n}(x)=0$. Thus, we must prove that this number is $q^{m-k}$.

Write $v$ and $a$ as $v=\left(v_{0}, v_{1}, \ldots, v_{m}\right)$ and $a=\left(a_{0}, a_{1}, \ldots, a_{k-1}\right)$, respectively. Thus, last $v=v_{m}$, so that $v_{m}=$ last $v \neq 0$.

Now, we are looking for an $x=\left(x_{0}, x_{1}, \ldots, x_{m+n}\right) \in F^{m+n+1}$ satisfying $x_{[0, k)}=$ $a$ and $v H_{m, n}(x)=0$. The condition $x_{[0, k)}=a$ says that the first $k$ entries of $x$ equal the respective entries of $a$; that is, $x_{i}=a_{i}$ for each $i \in\{0,1, \ldots, k-1\}$. Thus, $x_{0}, x_{1}, \ldots, x_{k-1}$ are uniquely determined. The condition $v H_{m, n}(x)=0$ is
equivalent to $x$ satisfying the following system of linear equations:

$$
\left\{\begin{array}{c}
v_{0} x_{0}+v_{1} x_{1}+\cdots+v_{m} x_{m}=0 ;  \tag{18}\\
v_{0} x_{1}+v_{1} x_{2}+\cdots+v_{m} x_{m+1}=0 ; \\
v_{0} x_{2}+v_{1} x_{3}+\cdots+v_{m} x_{m+2}=0 ; \\
\cdots ; \\
v_{0} x_{n}+v_{1} x_{n+1}+\cdots+v_{m} x_{m+n}=0
\end{array}\right.
$$

Since $v_{m} \neq 0$, this latter system of equations can be uniquely solved for the unknowns $x_{m}, x_{m+1}, \ldots, x_{m+n}$ (by recursive substitution) when the $m$ entries $x_{0}, x_{1}, \ldots, x_{m-1}$ are given. Hence, each $(m+n+1)$-tuple $x=\left(x_{0}, x_{1}, \ldots, x_{m+n}\right) \in$ $F^{m+n+1}$ satisfying $x_{[0, k)}=a$ and $v H_{m, n}(x)=0$ can be constructed as follows:

- First, we set $x_{i}=a_{i}$ for each $i \in\{0,1, \ldots, k-1\}$. This determines the first $k$ entries $x_{0}, x_{1}, \ldots, x_{k-1}$ of $x$.
- Then, we choose arbitrary values for the next $m-k$ entries $x_{k}, x_{k+1}, \ldots, x_{m-1}$.
- Finally, we uniquely determine the remaining entries $x_{m}, x_{m+1}, \ldots, x_{m+n}$ by solving the system (18).

Clearly, the number of ways to perform this construction is $q^{m-k}$ (since there are $|F|=q$ many options for each of the $m-k$ entries $\left.x_{k}, x_{k+1}, \ldots, x_{m-1}\right)$. Thus, the number of all $x \in F^{m+n+1}$ satisfying $x_{[0, k)}=a$ and $v H_{m, n}(x)=0$ is $q^{m-k}$. This proves Lemma 3.4.

Lemma 3.5. Let $k, m, n \in \mathbb{N}$ satisfy $k \leqslant n+1$. Let $v \in F^{1 \times(m+1)}$ be a nonzero row vector of size $m+1$ such that last $v=0$. Fix any $k$-tuple $a \in F^{k}$. Then,

$$
\begin{align*}
& \sum_{\substack{x \in F^{m+n+1 ;} \\
x_{[0, k)}=a}}\left[v H_{m, n}(x)=0\right] \\
& =q \sum_{\substack{x \in F^{m+n+1} ; \\
x_{[0, k]}=a}}\left[R(v) H_{m-1, n+1}(x)=0\right] . \tag{19}
\end{align*}
$$

Proof of Lemma 3.5. The sum on the left hand side of (19) is the number of all $(m+n+1)$-tuples $x \in F^{m+n+1}$ satisfying $x_{[0, k)}=a$ and $v H_{m, n}(x)=0$ (because of Proposition (3.2). Let us refer to such $(m+n+1)$-tuples $x$ as weakly nice tuples.

The sum on the right hand side of (19) is the number of all $(m+n+1)$ tuples $x \in F^{m+n+1}$ satisfying $x_{[0, k)}=a$ and $R(v) H_{m-1, n+1}(x)=0$ (because of Proposition 3.2). Let us refer to such $(m+n+1)$-tuples $x$ as strongly nice tuples.

We thus need to prove that the number of weakly nice tuples equals $q$ times the number of strongly nice tuples.

We shall achieve this by constructing a bijection

$$
\{\text { weakly nice tuples }\} \rightarrow F \times\{\text { strongly nice tuples }\} .
$$

Indeed, let us unravel the definitions of weakly and strongly nice tuples.
Write $v$ and $a$ as $v=\left(v_{0}, v_{1}, \ldots, v_{m}\right)$ and $a=\left(a_{0}, a_{1}, \ldots, a_{k-1}\right)$, respectively. Thus, last $v=v_{m}$, so that $v_{m}=$ last $v=0$. Consider the largest $j \in\{0,1, \ldots, m\}$ satisfying $v_{j} \neq 0$. (This exists, since $v$ is nonzero.) Thus, $v_{j} \neq 0$ but $v_{j+1}=$ $v_{j+2}=\cdots=v_{m}=0$. Also, the definition of $R$ yields $R(v)=\left(v_{0}, v_{1}, \ldots, v_{m-1}\right)$.

We have $j \neq m$ (since $v_{j} \neq 0$ but $v_{m}=0$ ). Thus, $j \leqslant m-1$. Furthermore,

$$
\underbrace{j}_{\geqslant 0}+n+1 \geqslant n+1>n \geqslant k-1 \quad(\text { since } k \leqslant n+1) \text {. }
$$

The weakly nice tuples are the $(m+n+1)$-tuples $x=\left(x_{0}, x_{1}, \ldots, x_{m+n}\right) \in$ $F^{m+n+1}$ satisfying

$$
\begin{equation*}
x_{i}=a_{i} \quad \text { for each } i \in\{0,1, \ldots, k-1\} \tag{20}
\end{equation*}
$$

as well as

$$
\left\{\begin{array}{c}
v_{0} x_{0}+v_{1} x_{1}+\cdots+v_{m} x_{m}=0 ;  \tag{21}\\
v_{0} x_{1}+v_{1} x_{2}+\cdots+v_{m} x_{m+1}=0 ; \\
v_{0} x_{2}+v_{1} x_{3}+\cdots+v_{m} x_{m+2}=0 ; \\
\cdots ; \\
v_{0} x_{n}+v_{1} x_{n+1}+\cdots+v_{m} x_{m+n}=0
\end{array}\right.
$$

(because the condition " $x_{[0, k)}=a$ " is equivalent to (20), whereas the condition "v $H_{m, n}(x)=0$ " is equivalent to (21)). In view of $v_{j+1}=v_{j+2}=\cdots=v_{m}=0$, we can rewrite this as follows: The weakly nice tuples are the $(m+n+1)$ tuples $x=\left(x_{0}, x_{1}, \ldots, x_{m+n}\right) \in F^{m+n+1}$ satisfying

$$
x_{i}=a_{i} \quad \text { for each } i \in\{0,1, \ldots, k-1\}
$$

as well as

$$
\left\{\begin{array}{c}
v_{0} x_{0}+v_{1} x_{1}+\cdots+v_{j} x_{j}=0  \tag{22}\\
v_{0} x_{1}+v_{1} x_{2}+\cdots+v_{j} x_{j+1}=0 \\
v_{0} x_{2}+v_{1} x_{3}+\cdots+v_{j} x_{j+2}=0 \\
\cdots ; \\
v_{0} x_{n}+v_{1} x_{n+1}+\cdots+v_{j} x_{j+n}=0
\end{array}\right.
$$

A similar argument (using $R(v)=\left(v_{0}, v_{1}, \ldots, v_{m-1}\right)$ ) shows that the strongly nice tuples are the $(m+n+1)$-tuples $x=\left(x_{0}, x_{1}, \ldots, x_{m+n}\right) \in F^{m+n+1}$ satisfying

$$
x_{i}=a_{i} \quad \text { for each } i \in\{0,1, \ldots, k-1\}
$$

as well as

$$
\left\{\begin{array}{c}
v_{0} x_{0}+v_{1} x_{1}+\cdots+v_{j} x_{j}=0 ;  \tag{23}\\
v_{0} x_{1}+v_{1} x_{2}+\cdots+v_{j} x_{j+1}=0 ; \\
v_{0} x_{2}+v_{1} x_{3}+\cdots+v_{j} x_{j+2}=0 ; \\
\cdots ; \\
v_{0} x_{n}+v_{1} x_{n+1}+\cdots+v_{j} x_{j+n}=0 ; \\
v_{0} x_{n+1}+v_{1} x_{n+2}+\cdots+v_{j} x_{j+n+1}=0 .
\end{array}\right.
$$

These characterizations of weakly and strongly nice tuples are very similar: The system (23) consists of all the equations of (22) as well as one extra equation

$$
\begin{equation*}
v_{0} x_{n+1}+v_{1} x_{n+2}+\cdots+v_{j} x_{j+n+1}=0 \tag{24}
\end{equation*}
$$

This latter equation (24) uniquely determines the entry $x_{j+n+1}$ in terms of the other entries of $x$ (since $v_{j} \neq 0$ ), whereas $x_{j+n+1}$ is entirely unconstrained by the system (22). Thus, the entry $x_{j+n+1}$ is uniquely determined (in terms of the other entries of $x$ ) in a strongly nice tuple $x$, while being entirely unconstrained in a weakly nice tuple ${ }^{7}$. Informally speaking, this shows that a weakly nice tuple has "one more degree of freedom" than a strongly nice tuple (and this degree of freedom is the entry $x_{j+n+1}$, which can take $q$ possible values in a weakly nice tuple). This easily entails that the number of weakly nice tuples equals $q$ times the number of strongly nice tuples 8 . This proves Lemma 3.5,

Lemma 3.5 and Lemma 3.4 combined lead to the following:

```
\({ }^{7}\) Here we are using the fact that the " \(x_{i}=a_{i}\) for each \(i \in\{0,1, \ldots, k-1\}\) " conditions don't
    constrain \(x_{j+n+1}\) either (since \(j+n+1>k-1\) ).
\({ }^{8}\) Here is a rigorous way to show this: Consider the map
```

```
\(\alpha: F \times\{\) strongly nice tuples \(\} \rightarrow\{\) weakly nice tuples \(\}\),
    \(\left(y,\left(x_{0}, x_{1}, \ldots, x_{m+n}\right)\right) \mapsto\left(x_{0}, x_{1}, \ldots, x_{j+n}, y_{1}, x_{j+n+2}, x_{j+n+3}, \ldots, x_{m+n}\right)\),
```

which simply replaces the entry $x_{j+n+1}$ of the strongly nice tuple $\left(x_{0}, x_{1}, \ldots, x_{m+n}\right)$ by the element $y$. Consider the map

$$
\begin{aligned}
\beta:\{\text { weakly nice tuples }\} & \rightarrow F \times\{\text { strongly nice tuples }\}, \\
\left(x_{0}, x_{1}, \ldots, x_{m+n}\right) & \mapsto\left(x_{j+n+1},\left(x_{0}, x_{1}, \ldots, x_{j+n}, z, x_{j+n+2}, x_{j+n+3}, \ldots, x_{m+n}\right)\right),
\end{aligned}
$$

where $z$ is the unique element of $F$ that would make the equation (24) valid when it is substituted for $x_{j+n+1}$ (that is, explicitly, $z$ is given by the formula $z=$ $\left.-\left(v_{0} x_{n+1}+v_{1} x_{n+2}+\cdots+v_{j-1} x_{j+n}\right) / v_{j}\right)$. Our above characterizations of weakly nice and strongly nice tuples show that these two maps $\alpha$ and $\beta$ are mutually inverse. Hence, $\alpha$ and $\beta$ are bijections. Thus,

$$
\begin{aligned}
\mid\{\text { weakly nice tuples }\} \mid & =\mid F \times\{\text { strongly nice tuples }\} \mid \\
& =q \cdot \mid\{\text { strongly nice tuples }\} \mid .
\end{aligned}
$$

In other words, the number of weakly nice tuples equals $q$ times the number of strongly nice tuples.

Lemma 3.6. Let $k, m, n \in \mathbb{N}$ satisfy $k \leqslant m$ and $k \leqslant n+1$. Fix any $k$-tuple $a \in F^{k}$. Then,

$$
\begin{aligned}
& \sum_{\substack{x \in F^{m+n+1} ; \\
x_{[0, k}=a}} \sum_{\substack{v \in F^{1 \times(m+1)} ; \\
v \neq 0}}\left[v H_{m, n}(x)=0\right]-q \sum_{\substack{x \in F^{m+n+1} ; \\
x_{[0, k)}=a}} \sum_{\substack{v \in F^{1 \times m ;} \\
v \neq 0}}\left[v H_{m-1, n+1}(x)=0\right] \\
& =(q-1) q^{2 m-k} .
\end{aligned}
$$

Proof of Lemma 3.6. We first observe that

$$
\begin{align*}
& \left(\text { the number of all vectors } v \in F^{1 \times(m+1)} \text { satisfying last } v \neq 0\right) \\
& =(q-1) q^{m} \tag{25}
\end{align*}
$$

(since a vector $v \in F^{1 \times(m+1)}$ satisfying last $v \neq 0$ can be constructed by choosing its last entry from the $(q-1)$-element set $F \backslash\{0\}$ and then choosing its remaining $m$ entries from the $q$-element set $F$ ).

For any row vector $v \in F^{1 \times(m+1)}$, we define a number

$$
\begin{equation*}
\chi_{v}:=\sum_{\substack{x \in F^{m+n+1 ;} \\ x_{[0, k)}=a}}\left[v H_{m, n}(x)=0\right] . \tag{26}
\end{equation*}
$$

Thus, if $v \in F^{1 \times(m+1)}$ is a row vector satisfying last $v \neq 0$, then

$$
\begin{equation*}
\chi_{v}=\sum_{\substack{x \in F^{m+n+1} ; \\ x_{[0, k)}=a}}\left[v H_{m, n}(x)=0\right]=q^{m-k} \tag{27}
\end{equation*}
$$

(by Lemma 3.4).
Recall that $R:\left\{v \in F^{1 \times(m+1)} \mid\right.$ last $\left.v=0\right\} \rightarrow F^{1 \times m}$ is a bijection. This bijection sends 0 to 0 , and therefore restricts to a bijection

$$
\begin{aligned}
\left\{v \in F^{1 \times(m+1)} \mid \text { last } v=0 \text { and } v \neq 0\right\} & \rightarrow\left\{v \in F^{1 \times m} \mid v \neq 0\right\}, \\
v & \mapsto R(v) .
\end{aligned}
$$

Hence, given any $x \in F^{m+n+1}$, we can substitute $R(v)$ for $v$ in the sum $\sum_{\substack{v \in F^{1 \times m} \\ v \neq 0}}\left[v H_{m-1, n+1}(x)=0\right]$, and thus obtain

$$
\sum_{\substack{v \in F^{1 \times m} ; \\ v \neq 0}}\left[v H_{m-1, n+1}(x)=0\right]=\sum_{\substack{v \in F^{1 \times(m+1) ;} \\ \text { lasv=0; } \\ v \neq 0}}\left[R(v) H_{m-1, n+1}(x)=0\right] .
$$

Thus,

$$
\begin{align*}
& q \sum_{\substack{x \in F^{m+n+1} ; \\
x_{[0, k)}=a}} \sum_{\substack{v \in F^{1 \times m} ; \\
v \neq 0}}\left[v H_{m-1, n+1}(x)=0\right] \\
& =q \sum_{\substack{x \in F^{m+n+1} ; \\
x_{[0, k)}=a}} \sum_{\substack{v \in F^{1 \times(m+1)} \\
\text { lastv=0; } \\
v \neq 0}}\left[R(v) H_{m-1, n+1}(x)=0\right] \\
& =\sum_{\begin{array}{c}
v \in F^{1 \times(m+1)} \\
\text { last } v=0 ; \\
v \neq 0
\end{array}} ; \underbrace{}_{\begin{array}{c}
\sum_{\substack{m+n+1 \\
x_{[0, k)}=a}}\left[v H_{m, n}(x)=0\right]
\end{array} \sum_{\substack{x \in F^{m+n+1} \\
x_{[0, k)}=a}}\left[R(v) H_{m-1, n+1}(x)=0\right]} \\
& \text { (by Lemma } 3.5 \\
& =\sum_{\begin{array}{c}
v \in F^{1 \times(m+1)} \\
\text { last } v=0 ; \\
v \neq 0
\end{array}} ; \underbrace{\sum_{\substack{x \in F^{m+n+1} ; \\
x_{[0, k)}=a}}\left[v H_{m, n}(x)=0\right]}_{\begin{array}{c}
=\mathcal{X}_{v} \\
\text { (by (26)) }
\end{array}} \\
& =\sum_{\substack{v \in F^{1 \times(m+1) ;} \\
\text { last } v=0 ; \\
v \neq 0}} \chi_{v}=\sum_{\substack{v \in F^{1 \times(m+1) ;} \\
v \neq 0 ; \\
\text { last } v=0}} \chi_{v} . \tag{28}
\end{align*}
$$

On the other hand,

$$
\begin{align*}
& \left.\sum_{\substack{x \in F^{m+n+1} ; \\
x_{[0, k)}=a}} \sum_{v \in F^{1 \times(m+1) ;}}^{v \neq 0} 0<v H_{m, n}(x)=0\right] \\
& =\sum_{\substack{v \in F^{1 \times(m+1)} \\
v \neq 0}} ; \underbrace{\sum_{\substack{x \in F^{m+n+1 ;} \\
x_{[0, k)}=a}}\left[v H_{m, n}(x)=0\right]}_{=\chi_{v}} \\
& =\sum_{\substack{v \in F^{1 \times(m+1)} ; \\
v \neq 0}} \chi_{v} . \tag{29}
\end{align*}
$$

Subtracting the equality (28) from the equality (29), we obtain
$\left(\begin{array}{c}\text { here, we have removed the condition " } v \neq 0 \text { " from under } \\ \text { the summation sign, since any vector } v \in F^{1 \times(m+1)} \\ \text { satisfying last } v \neq 0 \text { automatically satisfies } v \neq 0\end{array}\right)$
$=\underbrace{\left(\text { the number of all vectors } v \in F^{1 \times(m+1)} \text { satisfying last } v \neq 0\right)}_{\substack{=(q-1) q^{m} \\(\text { by }(25))}} \cdot q^{m-k}$

$$
=(q-1) \underbrace{q^{m} \cdot q^{m-k}}_{=q^{2 m-k}}=(q-1) q^{2 m-k}
$$

This proves Lemma 3.6.

### 3.4. Theorem 1.5 for $r=m$

Before we prove Theorem 1.5 in full generality, let us first show it in the particular case when $r=m$ :

Lemma 3.7. Let $k, m, n \in \mathbb{N}$ satisfy $k \leqslant m \leqslant n+1$. Fix any $k$-tuple $a \in$ $F^{k}$. The number of $(m+n+1)$-tuples $x \in F^{m+n+1}$ satisfying $x_{[0, k)}=a$ and $\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant m$ is $q^{2 m-k}$.

Proof of Lemma 3.7. Write the $k$-tuple $a$ in the form $a=\left(a_{0}, a_{1}, \ldots, a_{k-1}\right)$.

$$
\begin{aligned}
& \sum_{\substack{x \in F^{m+n+1} ; \\
x_{[0, k)}=a}} \sum_{\substack{v \in F^{1 \times(m+1)} ; \\
v \neq 0}}\left[v H_{m, n}(x)=0\right]-q \sum_{\substack{x \in F^{m+n+1} ; \\
x_{[0, k)}=a}} \sum_{\substack{v \in F^{1 \times m} ; \\
v \neq 0}}\left[v H_{m-1, n+1}(x)=0\right] \\
& =\sum_{\substack{v \in F^{1 \times(m+1)} ; \\
v \neq 0}} \chi_{v}-\sum_{\begin{array}{c}
v \in F^{1 \times(m+1) ;} \\
v \neq 0 ; \\
\text { last } v=0
\end{array}} \chi_{v}=\sum_{\begin{array}{c}
v \in F^{v \times(m+1)} ; \\
\text { last } v \neq 0
\end{array}} \underbrace{\chi_{v}}_{\begin{array}{c}
=q^{m-k} \\
(\text { by } \\
(27)
\end{array}} \\
& \binom{\text { since } \sum_{\substack{v \in F^{1 \times(m+1) ;} \\
v \neq 0}} \rho_{v}-\sum_{\substack{v \in F^{1 \times(m+1) ;} \\
v \neq 0 ; \\
\text { last } v=0}} \rho_{v}=\sum_{\substack{v \in F^{1 \times(m+1) ;} \\
v \neq 0 ; \\
\text { last } v \neq 0}} \rho_{v}}{\text { for any numbers } \rho_{v}} \\
& =\sum_{\substack{v \in F^{v \times(m+1)} \\
v \neq 0 ; \\
\text { last } v \neq 0}} q^{m-k}=\sum_{\substack{v \in F^{1 \times(m+1) ;} \\
\text { last } v \neq 0}} q^{m-k}
\end{aligned}
$$

We have

$$
\begin{aligned}
& (q-1) \cdot \sum_{\substack{x \in F^{m+n+1} ; \\
x_{[0, k)}=a}}\left[\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant m\right] \\
& =\sum_{\substack{x \in F^{m+n+1} ; \\
x_{[0, k}=a}}=\underbrace{}_{\substack{v \in F^{1 \times(m+1) ;} \\
v \neq 0}} \underbrace{(q-1) \cdot\left[v H_{m, n}(x)=0\right]-q}{\underset{\substack{v \in F^{1 \times m} \\
v \neq 0}}{ }\left[v H_{m-1, n+1}(x)=0\right]}^{\left(\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant m\right]} \\
& \text { (by Proposition 3.3) } \\
& =\sum_{\substack{x \in F^{m+n+1} ; \\
x_{[0, k)}=a}}\left(\sum_{\substack{v \in F^{1 \times(m+1)} ; \\
v \neq 0}}\left[v H_{m, n}(x)=0\right]-q \sum_{\substack{v \in F^{1 \times m} ; \\
v \neq 0}}\left[v H_{m-1, n+1}(x)=0\right]\right) \\
& =\sum_{\substack{x \in F^{m+n+1}, x_{[0, k}=a}} \sum_{\substack{v \in F^{1 \times(m+1)}, v \neq 0}}\left[v H_{m, n}(x)=0\right]-q \sum_{\substack{x \in F^{m+n+1} ; \\
x_{[0, k)}=a}} \sum_{\substack{v \in F^{1 \times m ;} \\
v \neq 0}}\left[v H_{m-1, n+1}(x)=0\right] \\
& =(q-1) q^{2 m-k} \quad(\text { by Lemma 3.6) } .
\end{aligned}
$$

Cancelling $q-1$ from this equality (since $q-1 \neq 0$ ), we obtain

$$
\sum_{\substack{x \in F^{m+n+1 ;} \\ x_{[0, k)}=a}}\left[\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant m\right]=q^{2 m-k} .
$$

But the left hand side of this equality is the number of $(m+n+1)$-tuples $x \in$ $F^{m+n+1}$ satisfying $x_{[0, k)}=a$ and $\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant m$ (because of Proposition 3.2). Thus, this number is $q^{2 m-k}$. This proves Lemma 3.7.

## 4. Proofs of the main results

We can now prove the results from Section 1 in their full generality.
Proof of Theorem 1.5 Let $s=m+n-r$. Then, $r+s=m+n$. Also, $r \leqslant s$ (since $\underbrace{s}_{=m+n-r}-r=m+n-\underbrace{r}_{\leqslant m}-\underbrace{r}_{\leqslant n} \geqslant m+n-m-n=0$ ), so that $r \leqslant s \leqslant s+1$ and thus $k \leqslant r \leqslant s+1$.

Lemma 2.6 (applied to $u=m+n$ ) yields the logical equivalence

$$
\left(\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant r\right) \Longleftrightarrow\left(\operatorname{rank}\left(H_{r, s}(x)\right) \leqslant r\right)
$$

for any $(m+n+1)$-tuple $x \in F^{m+n+1}$. Thus, 9

$$
\begin{aligned}
& \left(\# \text { of all }(m+n+1) \text {-tuples } x \in F^{m+n+1} \text { satisfying } x_{[0, k)}=a\right. \\
& \left.\quad \text { and } \operatorname{rank}\left(H_{m, n}(x)\right) \leqslant r\right) \\
& =\left(\# \text { of all }(m+n+1) \text {-tuples } x \in F^{m+n+1} \text { satisfying } x_{[0, k)}=a\right. \\
& \left.\quad \text { and } \operatorname{rank}\left(H_{r, s}(x)\right) \leqslant r\right) \\
& =\left(\# \text { of all }(r+s+1) \text {-tuples } x \in F^{r+s+1} \text { satisfying } x_{[0, k)}=a\right. \\
& \left.\left.\quad \text { and } \operatorname{rank}\left(H_{r, s}(x)\right) \leqslant r\right) \quad \quad \text { (since } m+n=r+s\right)
\end{aligned}
$$

$=q^{2 r-k} \quad($ by Lemma 3.7 applied to $r$ and $s$ instead of $m$ and $n)$.
This proves Theorem 1.5 ,
Proof of Theorem 1.1 Let $a$ be the 0 -tuple () $\in F^{0}$. Thus, Theorem 1.5 (applied to $k=0$ ) yields that the number of ( $m+n+1$ )-tuples $x \in F^{m+n+1}$ satisfying $x_{[0,0)}=a$ and $\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant r$ is $q^{2 r-0}$. We can remove the " $x_{[0,0)}=a$ " condition from the previous sentence (since every $(m+n+1)$ tuple $x \in F^{m+n+1}$ satisfies $\left.x_{[0,0)}=()=a\right)$, and thus obtain the following: The number of $(m+n+1)$-tuples $x \in F^{m+n+1}$ satisfying $\operatorname{rank}\left(H_{m, n}(x)\right) \leqslant r$ is $q^{2 r-0}$. But this is precisely the claim of Theorem 1.1 (since $2 r-0=2 r$ ). Thus, Theorem 1.1 is proved.

Proof of Corollary 1.3. We need to prove the following four claims: 10
Claim 1: If $r=0$, then the \# of $(m+n+1)$-tuples $x \in F^{m+n+1}$ satisfying $\operatorname{rank}\left(H_{m, n}(x)\right)=r$ is 1 .

Claim 2: If $0<r \leqslant m$, then the \# of $(m+n+1)$-tuples $x \in F^{m+n+1}$ satisfying $\operatorname{rank}\left(H_{m, n}(x)\right)=r$ is $q^{2 r-2}\left(q^{2}-1\right)$.

Claim 3: If $r=m+1$, then the \# of $(m+n+1)$-tuples $x \in F^{m+n+1}$ satisfying $\operatorname{rank}\left(H_{m, n}(x)\right)=r$ is $q^{2 r-2}\left(q^{n-m+1}-1\right)$.

Claim 4: If $r>m+1$, then the \# of $(m+n+1)$-tuples $x \in F^{m+n+1}$ satisfying $\operatorname{rank}\left(H_{m, n}(x)\right)=r$ is 0 .
[Proof of Claim 1: We need to show that the \# of $(m+n+1)$-tuples $x \in F^{m+n+1}$ satisfying $\operatorname{rank}\left(H_{m, n}(x)\right)=0$ is 1 . In other words, we need to show that there is exactly one $(m+n+1)$-tuple $x \in F^{m+n+1}$ satisfying $\operatorname{rank}\left(H_{m, n}(x)\right)=0$. But

[^3]this is rather simple: The $(m+n+1)$-tuple $(0,0, \ldots, 0) \in F^{m+n+1}$ does satisfy $\operatorname{rank}\left(H_{m, n}(x)\right)=0$ (since $H_{m, n}(x)$ is the zero matrix when $x$ is this $(m+n+1)$ tuple), and no other $(m+n+1)$-tuple does this (because if $x \in F^{m+n+1}$ is not $(0,0, \ldots, 0)$, then the matrix $H_{m, n}(x)$ has at least one nonzero entry, and therefore its rank cannot be 0 ). Thus, Claim 1 is proved.]
[Proof of Claim 2: Assume that $0<r \leqslant m$. Thus, $r$ and $r-1$ are elements of $\mathbb{N}$ and satisfy $r \leqslant m \leqslant n$ and $r-1 \leqslant r \leqslant m \leqslant n$. Hence:

- Theorem 1.1 yields that

$$
\begin{aligned}
& \left(\# \text { of }(m+n+1) \text {-tuples } x \in F^{m+n+1} \text { satisfying } \operatorname{rank}\left(H_{m, n}(x)\right) \leqslant r\right) \\
& =q^{2 r} .
\end{aligned}
$$

- Theorem 1.1 (applied to $r-1$ instead of $r$ ) yields that

$$
\begin{aligned}
& \left(\# \text { of }(m+n+1) \text {-tuples } x \in F^{m+n+1} \text { satisfying } \operatorname{rank}\left(H_{m, n}(x)\right) \leqslant r-1\right) \\
& =q^{2(r-1)} .
\end{aligned}
$$

However, a matrix $A$ satisfies rank $A=r$ if and only if it satisfies rank $A \leqslant r$ but not rank $A \leqslant r-1$. Hence,

$$
\begin{aligned}
& \left(\# \text { of }(m+n+1) \text {-tuples } x \in F^{m+n+1} \text { satisfying } \operatorname{rank}\left(H_{m, n}(x)\right)=r\right) \\
& =\underbrace{\left(\# \text { of }(m+n+1) \text {-tuples } x \in F^{m+n+1} \text { satisfying } \operatorname{rank}\left(H_{m, n}(x)\right) \leqslant r\right)}_{=q^{2 r}} \\
& \quad-\underbrace{\left(\# \text { of }(m+n+1) \text {-tuples } x \in F^{m+n+1} \text { satisfying } \operatorname{rank}\left(H_{m, n}(x)\right) \leqslant r-1\right)}_{=q^{2(r-1)}} \\
& =q^{2 r}-q^{2(r-1)}=q^{2 r-2}\left(q^{2}-1\right) .
\end{aligned}
$$

This proves Claim 2.]
[Proof of Claim 3: Assume that $r=m+1$. Thus, $2 r=2(m+1)=2 m+2$, so that $2 m=2 r-2$. The matrix $H_{m, n}(x)$ (for any given $x$ ) is an $(m+1) \times(n+1)-$ matrix; thus, its rank is always $\leqslant m+1$. Hence, it has rank $m+1$ if and only if
it does not have rank $\leqslant m$. Thus,

$$
\begin{aligned}
& \left(\# \text { of }(m+n+1) \text {-tuples } x \in F^{m+n+1} \text { satisfying } \operatorname{rank}\left(H_{m, n}(x)\right)=m+1\right) \\
& =\underbrace{\left(\# \text { of all }(m+n+1) \text {-tuples } x \in F^{m+n+1}\right)}_{\begin{array}{c}
\text { (since }|F|=q)
\end{array}} \\
& \quad-\underbrace{\left(\# \text { of }(m+n+1) \text {-tuples } x \in F^{m+n+1} \text { satisfying } \operatorname{rank}\left(H_{m, n}(x)\right) \leqslant m\right)}_{\begin{array}{c}
=q^{2 m} \\
\text { (by Theorem 1.1 applied to } m \text { instead of } r \text { ) }
\end{array}} \\
& =q^{m+n+1}-q^{2 m}=q^{2 m}\left(q^{n-m+1}-1\right)=q^{2 r-2}\left(q^{n-m+1}-1\right)
\end{aligned}
$$

(since $2 m=2 r-2$ ). But this is precisely the claim of Claim 3 (since $r=m+1$ ). Thus, Claim 3 is proven.]
[Proof of Claim 4: Assume that $r>m+1$. The matrix $H_{m, n}(x)$ (for any given $x)$ is an $(m+1) \times(n+1)$-matrix; thus, its rank is always $\leqslant m+1$. Hence, its rank is never $r$ (because $r>m+1$ ). Thus,

$$
\left(\# \text { of }(m+n+1) \text {-tuples } x \in F^{m+n+1} \text { satisfying } \operatorname{rank}\left(H_{m, n}(x)\right)=r\right)=0 \text {. }
$$

This proves Claim 4.]
Having proved all four claims, we thus have completed the proof of Corollary 1.3

Proof of Corollary 1.7 If $x \in F^{2 n+1}$ is any $(2 n+1)$-tuple, then the condition " $\operatorname{det}\left(H_{n, n}(x)\right)=0$ " is equivalent to " $\operatorname{rank}\left(H_{n, n}(x)\right) \leqslant n$ " (since $H_{n, n}(x)$ is an $(n+1) \times(n+1)$-matrix, and thus its determinant vanishes if and only if its rank is $\leqslant n)$. Hence, the number of $(2 n+1)$-tuples $x \in F^{2 n+1}$ satisfying $x_{[0, k)}=a$ and $\operatorname{det}\left(H_{n, n}(x)\right)=0$ is precisely the number of $(2 n+1)$-tuples $x \in F^{2 n+1}$ satisfying $x_{[0, k)}=a$ and $\operatorname{rank}\left(H_{n, n}(x)\right) \leqslant n$. But Theorem 1.5 (applied to $m=n$ and $r=n$ ) shows that the latter number is $q^{2 n-k}$. This proves Corollary 1.7

## 5. Application to Jacobi-Trudi matrices

Let us now discuss how ACGKLP18, Corollary 6.4] follows from Corollary 1.7. For the sake of simplicity, we shall first restate [ACGKLP18, Corollary 6.4] in a self-contained form that does not rely on the concepts of symmetric functions:

Corollary 5.1. Assume that $F$ is finite. Let $q=|F|$. Let $u, v \in \mathbb{N}$. For each $(u+v-1)$-tuple $y=\left(y_{1}, y_{2}, \ldots, y_{u+v-1}\right) \in F^{u+v-1}$, we define the matrix

$$
J_{u, v}(y):=\left(y_{u-i+j}\right)_{1 \leqslant i \leqslant v, 1 \leqslant j \leqslant v} \in F^{v \times v,}
$$

where we set $y_{0}:=1$ and $y_{k}:=0$ for all $k<0$.
Then, the number of all $(u+v-1)$-tuples $y \in F^{u+v-1}$ satisfying $\operatorname{det}\left(J_{u, v}(y)\right)=0$ is $q^{u+v-2}$.

Example 5.2. (a) If $u=1$ and $v=3$, then each 3-tuple $y=\left(y_{1}, y_{2}, y_{3}\right) \in F^{3}$ satisfies

$$
\begin{aligned}
J_{u, v}(y) & =J_{1,3}(y)=\left(y_{1-i+j}\right)_{1 \leqslant i \leqslant 3,1 \leqslant j \leqslant 3}=\left(\begin{array}{ccc}
y_{1} & y_{2} & y_{3} \\
y_{0} & y_{1} & y_{2} \\
y_{-1} & y_{0} & y_{1}
\end{array}\right) \\
& \left.=\left(\begin{array}{ccc}
y_{1} & y_{2} & y_{3} \\
1 & y_{1} & y_{2} \\
0 & 1 & y_{1}
\end{array}\right) \quad \text { (since } y_{0}=1 \text { and } y_{-1}=0\right)
\end{aligned}
$$

and thus $\operatorname{det}\left(J_{u, v}(y)\right)=y_{3}+y_{1}^{3}-2 y_{1} y_{2}$.
(b) If $u=4$ and $v=3$, then each 6-tuple $y=\left(y_{1}, y_{2}, \ldots, y_{6}\right) \in F^{6}$ satisfies

$$
J_{u, v}(y)=J_{4,3}(y)=\left(y_{4-i+j}\right)_{1 \leqslant i \leqslant 3,1 \leqslant j \leqslant 3}=\left(\begin{array}{lll}
y_{4} & y_{5} & y_{6} \\
y_{3} & y_{4} & y_{5} \\
y_{2} & y_{3} & y_{4}
\end{array}\right)
$$

and thus $\operatorname{det}\left(J_{u, v}(y)\right)=y_{6} y_{3}^{2}-2 y_{3} y_{4} y_{5}+y_{4}^{3}-y_{2} y_{6} y_{4}+y_{2} y_{5}^{2}$.
Why is Corollary 5.1 equivalent to [ACGKLP18, Corollary 6.4]? In fact, Corollary 5.1 can be restated in probabilistic terms; then it says that a uniformly random $(u+v-1)$-tuple $y \in F^{u+v-1}$ satisfies $\operatorname{det}\left(J_{u, v}(y)\right)=0$ with a probability of $\frac{q^{u+v-2}}{q^{u+v-1}}=\frac{1}{q}$. However, the matrix $J_{u, v}(y)$ in Corollary 5.1 is precisely the Jacobi-Trudi matrix $\sqrt{11}$ corresponding to the rectangle-shaped partition $\left(u^{v}\right)$, except that the entries of $y$ have been substituted for the complete homogeneous symmetric functions $h_{1}, h_{2}, \ldots, h_{u+v-1}$. The determinant $\operatorname{det}\left(J_{u, v}(y)\right)$ therefore is the image of the Schur function $s_{\left(u^{v}\right)}$ under this substitution. Thus, Corollary 5.1 says that when a uniformly random $(u+v-1)$-tuple of elements of $F$ is substituted for $\left(h_{1}, h_{2}, \ldots, h_{u+v-1}\right)$, the Schur function $s_{\left(u^{v}\right)}$ becomes 0 with a probability of $\frac{1}{q}$. This is precisely the claim of [ACGKLP18, Corollary 6.4].

We shall now sketch (on an example) how Corollary 5.1 can be derived from our Corollary 1.7,

Proof of Corollary 5.1 (sketched). For a sufficiently representative example, we pick the case when $u=2$ and $v=5$; the reader will not find any difficulty in generalizing our reasoning to the general case.

[^4]Thus, we must show that the number of all 6-tuples $y \in F^{6}$ satisfying $\operatorname{det}\left(J_{2,5}(y)\right)=$ 0 is $q^{5}$. Let $y=\left(y_{1}, y_{2}, \ldots, y_{6}\right) \in F^{6}$ be any 6-tuple. Then,

$$
J_{2,5}(y)=\left(\begin{array}{ccccc}
y_{2} & y_{3} & y_{4} & y_{5} & y_{6} \\
y_{1} & y_{2} & y_{3} & y_{4} & y_{5} \\
y_{0} & y_{1} & y_{2} & y_{3} & y_{4} \\
y_{-1} & y_{0} & y_{1} & y_{2} & y_{3} \\
y_{-2} & y_{-1} & y_{0} & y_{1} & y_{2}
\end{array}\right)=\left(\begin{array}{ccccc}
y_{2} & y_{3} & y_{4} & y_{5} & y_{6} \\
y_{1} & y_{2} & y_{3} & y_{4} & y_{5} \\
1 & y_{1} & y_{2} & y_{3} & y_{4} \\
0 & 1 & y_{1} & y_{2} & y_{3} \\
0 & 0 & 1 & y_{1} & y_{2}
\end{array}\right)
$$

(since $y_{0}=1$ and $y_{-1}=0$ and $y_{-2}=0$ ). If we turn the matrix $J_{2,5}(y)$ upside down (i.e., we reverse the order of its rows), then we obtain the matrix

$$
\left(\begin{array}{ccccc}
0 & 0 & 1 & y_{1} & y_{2} \\
0 & 1 & y_{1} & y_{2} & y_{3} \\
1 & y_{1} & y_{2} & y_{3} & y_{4} \\
y_{1} & y_{2} & y_{3} & y_{4} & y_{5} \\
y_{2} & y_{3} & y_{4} & y_{5} & y_{6}
\end{array}\right)
$$

which is precisely the Hankel matrix $H_{4,4}(x)$ for the 9-tuple

$$
x=\left(0,0,1, y_{1}, y_{2}, y_{3}, y_{4}, y_{5}, y_{6}\right) .
$$

Hence, this 9-tuple $x$ satisfies $\operatorname{det}\left(H_{4,4}(x)\right)= \pm \operatorname{det}\left(J_{2,5}(y)\right)$ (since the determinant of a matrix is multiplied by $\pm 1$ when the rows of the matrix are permuted). Therefore, the condition " $\operatorname{det}\left(J_{2,5}(y)\right)=0$ " is equivalent to the condition " $\operatorname{det}\left(H_{4,4}(x)\right)=0$ " for this 9 -tuple $x$. Hence, the number of all 6tuples $y \in F^{6}$ satisfying $\operatorname{det}\left(J_{2,5}(y)\right)=0$ is precisely the number of all 9-tuples $x \in F^{9}$ that start with the entries $0,0,1$ and satisfy $\operatorname{det}\left(H_{4,4}(x)\right)=0$. In other words, it is precisely the number of all 9-tuples $x \in F^{9}$ satisfying $x_{[0,3)}=(0,0,1)$ and $\operatorname{det}\left(H_{4,4}(x)\right)=0$. However, Corollary 1.7 (applied to $k=3$ and $n=4$ and $a=(0,0,1))$ shows that the latter number is $q^{2 \cdot 4-3}=q^{5}$. This is precisely what we wanted to show. Thus, Corollary 5.1 is proved.

[^0]:    ${ }^{1}$ Some of these references are studying Toeplitz matrices instead of Hankel matrices. However, this is equivalent, since a Toeplitz matrix is just a Hankel matrix turned upside down (i.e., the result of reversing the order of the rows in a Hankel matrix).

[^1]:    ${ }^{2}$ Note that [GaGhRa11, Theorem 5.1] works with Toeplitz matrices instead of Hankel matrices, but this makes no real difference, since a Toeplitz matrix is just a Hankel matrix turned upside down (and this operation clearly does not change the rank of the matrix).
    ${ }^{3}$ See Section 5 for concrete examples of such matrices.
    ${ }^{4}$ Specifically, "first few" means "at most $m$ ".

[^2]:    ${ }^{5}$ The left kernel of an $s \times t$-matrix $A \in F^{s \times t}$ is defined to be the set of all row vectors $v \in F^{1 \times s}$ satisfying $v A=0$. This is a vector subspace of $F^{1 \times s}$.
    ${ }^{6}$ The rank-nullity theorem (in the form we are using it here) says that the dimension of the left kernel of a matrix $A \in F^{s \times t}$ equals $s-\operatorname{rank} A$.

[^3]:    ${ }^{9}$ The symbol "\#" means "number".
    ${ }^{10}$ The symbol "\#" means "number".

[^4]:    ${ }^{11}$ We are using the terminology of [ACGKLP18] here.
