#### Abstract

This paper introduces the notion of Rota-Baxter $C^{*}$-algebras. Here a RotaBaxter $C^{*}$-algebra is a $C^{*}$-algebra with a Rota-Baxter operator. Symmetric Rota-Baxter operators, as special cases of Rota-Baxter operators on $C^{*}$-algebra, are defined and studied. A theorem of Rota-Baxter operators on concrete $C^{*}$ algebras is given, deriving the relationship between two kinds of Rota-Baxter algebras. As a corollary, some connection between *-representations and RotaBaxter operators is given. The notion of representations of Rota-Baxter $C^{*}$ algebras are constructed, and a theorem of representations of direct sums of Rota-Baxter representations is derived. Finally using Rota-Baxter operators, the notion of quasidiagonal operators on $C^{*}$-algebra is reconstructed.

Keywords Rota-Baxter operators, $C^{*}$-algebras, Rota-Baxter $C^{*}$-algebras.

## 1 Introduction

Let $\mathcal{A}$ be an associative algebra over a given field $F$. A linear operator $P$ on $\mathcal{A}$ is called a Rota-Baxter operator of weight $\lambda \in F$ if it satisfies

$$
\begin{equation*}
P(a) P(b)=P(a P(b))+P(P(a) b)+\lambda P(a b), \quad \forall a, b \in \mathcal{A} . \tag{1.1}
\end{equation*}
$$

An associative algebra with a Rota-Baxter operator is called a Rota-Baxter algebra, which can be regarded as an analogue of a differential algebra. In fact, when taking $\lambda=0$, Eq. (1.1) is an algebraic abstraction of the formula of integration by parts.

The study of Rota-Baxter algebras originated from probability theory [2] and has found applications in many areas of mathematics and physics. In the late 1990s, RotaBaxter algebras were found their applications in the work of Connes and Kremier [4] regarding the renormalization of perturbative quantum field theory. Since 2000, the connection between the classical Yang-Baxter equation in mathematical physics and Rota-Baxter operators has been found in [1].

[^0]The representations of Rota-Baxter algebras were studied in [12], where some basic concepts and properties were established. However, it is still in the early stages of development. In [12], Lin and Qiao studied the representations and regular-singular decomposition of Laurent series Rota-Baxter algebras. In [9], regular-singular decomposition of Rota-Baxter modules were obtained under the condition of quasi-idempotency. And in [15], representations of the polynomial Rota-Baxter algebras were studied.

The theory of operator algebras in Hilbert spaces was initiated by von Neumann [20] in 1929. In [13], Murray and von Neumann laid the foundation of the theory of $W^{*}$ algebras. The notion of $C^{*}$-algebras was introduced by Gelfand and Naimark [6] in 1943. Basic theory of representations of $C^{*}$-algebras was established in [7, 10, 14, 19]. Derivations on $C^{*}$-algebras and $W^{*}$-algebras were studied deeply in the 1960s and 1970s in $[10,11,16,17]$. Especially, in [17], it was shown that all derivations on $W^{*}$ algebras are inner derivations. While Rota-Baxter operators on $C^{*}$-algebras have not been studied.

In this note, we establish basic concepts of Rota-Baxter $C^{*}$-algebras. Some special Rota-Baxter operators in $C^{*}$-algebras, which are called symmetric Rota-Baxter operators and Rota-Baxter operators matching projections are studied. And representations of Rota-Baxter $C^{*}$-algebras are also established, which are special cases of traditional Rota-Baxter representations.

A $C^{*}$-algebra $\mathcal{A}$ is a special algebra in the complex field. Combined with a RotaBaxter operator on $\mathcal{A}$, the basic concepts of Rota-Baxter $C^{*}$-algebras were established in Subsection 2.2. A Rota-Baxter operator $P$ on the $C^{*}$-algebra $\mathcal{A}$ is symmetric if $P\left(a^{*}\right)=P(a)^{*}$ for any $a \in \mathcal{A}$. In Subsection 2.3, We show that a $C^{*}$-algebra $\mathcal{A}$ can be decomposed into a direct sum of two $C^{*}$-subalgebras if and only if there is a bounded idempotent symmetric Rota-Baxter operator of weight -1 on $\mathcal{A}$.

In Section 3, we study Rota-Baxter operators on the $C^{*}$-algebra $B(\mathcal{H})$, where $\mathcal{H}$ is a Hilbert space. In Subsection 3.2, the notion of Rota Baxter operators that match projections are introduced. We find that the Rota-Baxter operators matching projections on Hilbert spaces have many good properties. In fact, we can construct Rota-Baxter operators of this kind from Rota-Baxter operators on $C^{*}$-subalgebras of $B(\mathcal{H})$. As a corollary, we study the relationship between the Rota-Baxter operators matching projections and $*$-representations of $C^{*}$-algebras on a Hilbert space. In Subsection 3.3, we construct representations of Rota-Baxter $C^{*}$-algebras.

At last in Section 4, we reconstruct the notion of quasidiagonal operators of $C^{*}$ algebras with the help of Rota-Baxter operators.

## 2 Rota-Baxter $C^{*}$-algebras

## $2.1 C^{*}$-algebras

We first recall some basic concepts of $C^{*}$-algebras from [18]. Let $F$ be the complex field $\mathbb{C}$ or the real number field $\mathbb{R}$.

Let $\mathcal{A}$ be an associative algebra over $F$. The algebra $\mathcal{A}$ is called a normed algebra if associated to each element $a$ in $\mathcal{A}$ there is a real number $\|a\|$, called the norm of $a$, with the properties:
$\|a\| \geq 0$ for any $a \in \mathcal{A}$, and $\|a\|=0$ if and only if $a=0 ;$
(ii) $\|a+b\| \leq\|a\|+\|b\|$ for any $a, b \in \mathcal{A}$;
(iii) $\|\lambda a\|=|\lambda|\|a\|$ for any $a \in \mathcal{A}$ and $\lambda \in F$;
(iv) $\|a b\| \leq\|a\|\|b\|$ for any $a, b \in \mathcal{A}$.

The topology defined by the norm $\|\cdot\|$ on $\mathcal{A}$ is called the uniform topology. If $\mathcal{A}$ is complete with respect to the norm, then $\mathcal{A}$ is called a Banach algebra. A map $\mathcal{A} \rightarrow \mathcal{A} ; a \mapsto a^{*}$ is called an involution if it satisfies the following conditions:
(i) $\left(a^{*}\right)^{*}=a$ for any $a \in \mathcal{A}$;
(ii) $(a+b)^{*}=a^{*}+b^{*}$ for any $a, b \in \mathcal{A}$;
(iii) $(\lambda a)^{*}=\bar{\lambda} a^{*}$ for any $a \in \mathcal{A}$ and $\lambda \in F$;
(iv) $(a b)^{*}=b^{*} a^{*}$ for any $a, b \in \mathcal{A}$.

An algebra with an involution $*$ is called a $*$-algebra. Finally, a Banach $*$-algebra $\mathcal{A}$ is called a ( $F$-linear) $C^{*}$-algebra if it satisfies

$$
\left\|a^{*} a\right\|=\|a\|^{2}
$$

for any $a \in \mathcal{A}$. Note that a $\mathbb{C}$-linear $C^{*}$-algebra is natural a $\mathbb{R}$-linear $C^{*}$-algebra.
A subset $S$ of a $C^{*}$-algebra $\mathcal{A}$ is called self-adjoint if $a^{*} \in S$ for any $a \in S$. In particular, an element $a \in \mathcal{A}$ is called self-adjoint if $a^{*}=a$. A self-adjoint, uniformly closed subalgebra of $\mathcal{A}$ is called a $C^{*}$-subalgebra of $\mathcal{A}$, which is also a $C^{*}$-algebra.

As there is a new structure $*$ on a $C^{*}$-algebra, it is natural to consider the ${ }^{*}$ homomorphisms between two $C^{*}$-algebras. Let $\mathcal{A}$ and $\mathcal{B}$ be two $C^{*}$-algebras. A map $\phi: \mathcal{A} \rightarrow \mathcal{B}$ is called a $*$-homomorphism if it satisfies
(i) $\phi(a+b)=\phi(a)+\phi(b)$ for any $a, b \in \mathcal{A}$;
(ii) $\phi(\lambda a)=\lambda \phi(a)$ for any $a \in \mathcal{A}$ and $\lambda \in F$;
(iii) $\phi(a b)=\phi(a) \phi(b)$ for any $a, b \in \mathcal{A}$;
(iv) $\phi\left(a^{*}\right)=\phi(a)^{*}$ for any $a \in \mathcal{A}$.

We recall the definition of the direct sum of $C^{*}$-algebras. Let $\left\{\mathcal{A}_{k}\right\}_{k \in \Lambda}$ be a family of $C^{*}$-algebras. We define the direct sum

$$
\bigoplus_{k \in \Lambda} \mathcal{A}_{k}=\left\{\left(a_{k}\right)_{k \in \Lambda} \mid a_{k} \in \mathcal{A}_{k} \text { for any } k \in \Lambda, \sup _{k \in \Lambda}\left\|a_{k}\right\|<\infty\right\}
$$

Then $\bigoplus_{k \in \Lambda} \mathcal{A}_{k}$ is a $C^{*}$-algebra under the following operators:
(i) $\left(a_{k}\right)+\left(b_{k}\right)=\left(a_{k}+b_{k}\right)$;
(ii) $\lambda\left(a_{k}\right)=\left(\lambda a_{k}\right), \quad(\lambda \in F)$;
(iii) $\left(a_{k}\right)\left(b_{k}\right)=\left(a_{k} b_{k}\right)$;
(iv) $\left\|\left(a_{k}\right)\right\|=\sup _{k}\left\|a_{k}\right\| ;$
(v) $\left(a_{k}\right)^{*}=\left(a_{k}^{*}\right)$.

For any $k \in \Lambda$, it is natural to regard $\mathcal{A}_{k}$ as a $C^{*}$-subalgebra of $\bigoplus_{k \in \Lambda} \mathcal{A}_{k}$.

### 2.2 Rota-Baxter $C^{*}$-algebras

Now we introduce the concept of Rota-Baxter $C^{*}$-algebras.
Definition 2.1. Let $\mathcal{A}$ be a $C^{*}$-algebra. A linear operator $P: \mathcal{A} \rightarrow \mathcal{A}$ is called $a$ Rota-Baxter operator of weight $\lambda \in F$ on $\mathcal{A}$ if it satisfies:

$$
P(a) P(b)=P(a P(b))+P(P(a) b)+\lambda P(a b), \quad \forall a, b \in \mathcal{A} .
$$

If $P$ is a Rota-Baxter operator of weight $\lambda$, then it is easy to verify that

$$
\widetilde{P}=-\lambda \operatorname{id}_{\mathcal{A}}-P
$$

is also a Rota-Baxter operator of weight $\lambda$.
Definition 2.2. A Rota-Baxter $C^{*}$-algebra of weight $\lambda$ is a pair $(\mathcal{A}, P)$ consisting of a $C^{*}$-algebra $\mathcal{A}$, and a Rota-Baxter operator $P: \mathcal{A} \rightarrow \mathcal{A}$ of weight $\lambda$ on $\mathcal{A}$.

We give an example of Rota-Baxter $C^{*}$-algebras.
Example 2.3. Let $C([0,1])$ be the set of all complex valued, continuous functions on the closed interval $[0,1]$. Then $C([0,1])$ becomes a commutative algebra over $\mathbb{C}$ under pointwise addition and multiplication. It was showed in [18] that $C([0,1])$ is a commutative $C^{*}$-algebra, where for any $f \in C([0,1])$, the norm of $f$ is defined by

$$
\|f\|=\sup _{x \in[0,1]}|f(x)|,
$$

and the involution $f^{*}$ of $f$ is given by

$$
f^{*}(x)=\overline{f(x)}, \quad \forall x \in[0,1] .
$$

The linear operator $T$ on $C([0,1])$ defined by

$$
T(f)(x)=\int_{0}^{x} f(s) d s, \quad \forall f \in C([0,1]), \forall x \in[0,1]
$$

is called the Volterra operator. It is easy to verify that $T$ is a Rota-Baxter operator of weight 0 on $C([0,1])$. Then $(C([0,1]), T)$ is a Rota-Baxter $C^{*}$-algebra.

As in [18], basic concepts on $C^{*}$-algebras can be similarly defined for Rota-Baxter $C^{*}$-algebras. Particularly, a Rota-Baxter $C^{*}$-subalgebra of a Rota-Baxter $C^{*}$-algebra $\mathcal{A}$ is a $C^{*}$-subalgebra $I$ of $\mathcal{A}$ such that $P(I) \subseteq I$. A Rota-Baxter $C^{*}$-algebra homomorphism $\phi:\left(\mathcal{A}_{1}, P_{1}\right) \rightarrow\left(\mathcal{A}_{2}, P_{2}\right)$ between two Rota-Baxter $C^{*}$-algebras of the same weight $\lambda$ is a $*$-homomorphism such that $\phi \circ P_{1}=P_{2} \circ \phi$.

In below, we always take $F=\mathbb{C}$. Hence all the Hilbert spaces and algebras are assumed to be over the complex field $\mathbb{C}$.

We recall the definition of derivations of $C^{*}$-algebras from [18]. Let $\mathcal{A}$ be a $C^{*}$ algebra. A linear map $\delta: \mathcal{A} \rightarrow \mathcal{A}$ is called a derivation if

$$
\delta(a b)=\delta(a) b+a \delta(b), \quad \forall a, b \in \mathcal{A}
$$

It is easy to see that if $P$ is an invertible Rota-Baxter operator of weight 0 on $\mathcal{A}$, then the inverse operator of $P$ is a derivation of $\mathcal{A}$. As an application, we have the following proposition.

Proposition 2.4. If $\mathcal{A}$ is a commutative $C^{*}$-algebra, then there is no invertible RotaBaxter operator of weight 0 on $\mathcal{A}$.

Proof. From [18], we know that if $\delta$ is a derivation on $\mathcal{A}$, then $\delta=0$. While if there is an invertible Rota-Baxter operator $P$ of weight 0 on $\mathcal{A}$, then the inverse of $P$ is an invertible derivation on $\mathcal{A}$, which is a contradiction.

### 2.3 Symmetric Rota-Baxter operators

In this subsection, we introduce the notion of symmetric Rota-Baxter operators.
Definition 2.5. Let $\mathcal{A}$ be a $C^{*}$-algebra and let $\mathcal{A}_{1}$ be a $C^{*}$-subalgebra of $\mathcal{A}$. A RotaBaxter operator $P$ on $\mathcal{A}$ is called symmetric on $\mathcal{A}_{1}$ if

$$
P\left(a^{*}\right)=P(a)^{*}
$$

for any $a \in \mathcal{A}_{1}$. If $P$ is symmetric on $\mathcal{A}$, we just call that $P$ is symmetric.
Example 2.6. The Volterra operator $T$ on $C([0,1])$ in Example 2.3 is symmetric.
Let $\mathcal{A}$ be a commutative $C^{*}$-algebra. Let $\mathcal{A}^{s}$ be the set of all self-adjoint elements in $\mathcal{A}$. It is easy to verify that $\mathcal{A}^{s}$ is a $\mathbb{R}$-linear subalgebra of $\mathcal{A}$. We have the following result.

Proposition 2.7. Let $\mathcal{A}$ be a commutative $C^{*}$-algebra and $\lambda \in \mathbb{R}$. Then there is a 1-1 correspondence between the following two sets:
(1) the set of symmetric Rota-Baxter operators of weight $\lambda$ on $\mathcal{A}$;
(2) the set of $\mathbb{R}$-linear Rota-Baxter operators of weight $\lambda$ on $\mathcal{A}^{s}$.

Proof. Denote by $\Gamma$ the set of symmetric Rota-Baxter operators of weight $\lambda$ on $\mathcal{A}$, and by $\Gamma_{1}$ the set of $\mathbb{R}$-linear Rota-Baxter operators of weight $\lambda$ on $\mathcal{A}^{s}$.

Let $P \in \Gamma$. Then for any $a \in \mathcal{A}^{s}$, we have

$$
P(a)=P\left(a^{*}\right)=P(a)^{*} .
$$

Hence we get a restriction $\left.P\right|_{\mathcal{A}^{s}}: \mathcal{A}^{s} \rightarrow \mathcal{A}^{s}$, which is an element of $\Gamma_{1}$. Therefore we have a map $\Phi: \Gamma \rightarrow \Gamma_{1}$, such that $\Phi(P)=\left.P\right|_{\mathcal{A}^{s}}$.

Conversely, let $P_{1} \in \Gamma_{1}$. For any $a \in \mathcal{A}$, we have $a=a_{1}+i a_{2}$, where $i=\sqrt{-1}$ and

$$
a_{1}=\frac{1}{2}\left(a+a^{*}\right) \in \mathcal{A}^{s}, \quad a_{2}=\frac{1}{2 i}\left(a-a^{*}\right) \in \mathcal{A}^{s} .
$$

Then we get a map $P: \mathcal{A} \rightarrow \mathcal{A}$ by setting $P(a)=P_{1}\left(a_{1}\right)+i P_{1}\left(a_{2}\right)$. It is obvious that $P$ is linear.

We show that $P$ satisfies the Rota-Baxter relation. Let $b=b_{1}+i b_{2}$ be another element of $\mathcal{A}$ with $b_{1}, b_{2} \in \mathcal{A}^{s}$ defined similarly as above. We have

$$
\begin{aligned}
P(a) P(b) & =\left(P_{1}\left(a_{1}\right)+i P_{1}\left(a_{2}\right)\right)\left(P_{1}\left(b_{1}\right)+i P_{1}\left(b_{2}\right)\right) \\
& =P_{1}\left(a_{1}\right) P_{1}\left(b_{1}\right)-P_{1}\left(a_{2}\right) P_{1}\left(b_{2}\right)+i\left(P_{1}\left(a_{2}\right) P_{1}\left(b_{1}\right)+P_{1}\left(a_{1}\right) P_{1}\left(b_{2}\right)\right) .
\end{aligned}
$$

Since $P_{1}$ is a Rota-Baxter operator on $\mathcal{A}^{s}$, we find

$$
\begin{aligned}
P(a) P(b)= & P_{1}\left(a_{1} P_{1}\left(b_{1}\right)+P_{1}\left(a_{1}\right) b_{1}+\lambda a_{1} b_{1}\right)-P_{1}\left(a_{2} P_{1}\left(b_{2}\right)+P_{1}\left(a_{2}\right) b_{2}+\lambda a_{2} b_{2}\right) \\
& +i P_{1}\left(a_{2} P_{1}\left(b_{1}\right)+P_{1}\left(a_{2}\right) b_{1}+\lambda a_{2} b_{1}\right)+i P_{1}\left(a_{1} P_{1}\left(b_{2}\right)+P_{1}\left(a_{1}\right) b_{2}+\lambda a_{1} b_{2}\right) \\
= & P_{1}\left(a_{1} P_{1}\left(b_{1}\right)\right)-P_{1}\left(a_{2} P_{1}\left(b_{2}\right)\right)+i P_{1}\left(a_{2} P_{1}\left(b_{1}\right)\right)+i P_{1}\left(a_{1} P_{1}\left(b_{2}\right)\right) \\
& +P_{1}\left(P_{1}\left(a_{1}\right) b_{1}\right)-P_{1}\left(P_{1}\left(a_{2}\right) b_{2}\right)+i P_{1}\left(P_{1}\left(a_{2}\right) b_{1}\right)+i P_{1}\left(P_{1}\left(a_{1}\right) b_{2}\right) \\
& +\lambda P_{1}\left(a_{1} b_{1}-a_{2} b_{2}\right)+i \lambda P_{1}\left(a_{2} b_{1}+a_{1} b_{2}\right) .
\end{aligned}
$$

According to the following decompositions

$$
\begin{aligned}
& a b=\left(a_{1} b_{1}-a_{2} b_{2}\right)+i\left(a_{2} b_{1}+a_{1} b_{2}\right), \\
& a P(b)=\left(a_{1} P_{1}\left(b_{1}\right)-a_{2} P_{1}\left(b_{2}\right)\right)+i\left(a_{2} P_{1}\left(b_{1}\right)+a_{1} P_{1}\left(b_{2}\right)\right), \\
& P(a) b=\left(P_{1}\left(a_{1}\right) b_{1}-P_{1}\left(a_{2}\right) b_{2}\right)+i\left(P_{1}\left(a_{2}\right) b_{1}+P_{1}\left(a_{1}\right) b_{2}\right),
\end{aligned}
$$

we finally get

$$
P(a) P(b)=P(a P(b))+P(P(a) b)+\lambda P(a b),
$$

which means that $P$ is a Rota-Baxter operator of weight $\lambda$ on $\mathcal{A}$.
Now we show that $P$ is symmetric. Since we have the decomposition $a^{*}=a_{1}-i a_{2}$, we get

$$
P\left(a^{*}\right)=P_{1}\left(a_{1}\right)-i P_{1}\left(a_{2}\right) .
$$

On the other hand, we have

$$
P(a)^{*}=\left(P_{1}\left(a_{1}\right)+i P_{1}\left(a_{2}\right)\right)^{*}=P_{1}\left(a_{1}\right)^{*}-i P_{1}\left(a_{2}\right)^{*}=P_{1}\left(a_{1}\right)-i P_{1}\left(a_{2}\right) .
$$

Hence $P\left(a^{*}\right)=P(a)^{*}$ and then $P$ is symmetric.
Therefore we get a map $\Psi: \Gamma_{1} \rightarrow \Gamma$, such that $\Psi\left(P_{1}\right)=P$.
Finally, it is easy to verify that $\Phi \circ \Psi$ and $\Psi \circ \Phi$ are identity maps. And the proposition is proved.

The following result gives an equivalent condition for the idempotent and symmetric Rota-Baxter operators of weight -1 on $C^{*}$-algebras.

Theorem 2.8. Let $\mathcal{A}$ be a $C^{*}$-algebra and let $P$ be a bounded linear operator on $\mathcal{A}$. Then the following two statements are equivalent:
(1) $P$ is an idempotent and symmetric Rota-Baxter operator of weight -1 on $\mathcal{A}$;
(2) There is a direct sum decomposition $\mathcal{A}=\mathcal{A}_{1} \oplus \mathcal{A}_{2}$, such that $\mathcal{A}_{1}$ and $\mathcal{A}_{2}$ are $C^{*}$-subalgebras of $\mathcal{A}$ and $P$ is the projection of $\mathcal{A}$ onto $\mathcal{A}_{1}$.

Proof. Assume that $P$ is an idempotent and symmetric Rota-Baxter operator of weight -1 on $\mathcal{A}$. Let $\mathcal{A}_{1}=P(\mathcal{A})$ and $\mathcal{A}_{2}=\widetilde{P}(\mathcal{A})$, where $\widetilde{P}=\operatorname{id}_{\mathcal{A}}-P$. Then from [8, Theorem 1.1.13], we know that $\mathcal{A}_{1}$ and $\mathcal{A}_{2}$ are subalgebras of $\mathcal{A}, \mathcal{A}=\mathcal{A}_{1} \oplus \mathcal{A}_{2}$ is a direct sum decomposition, and $P$ is the projection of $\mathcal{A}$ onto $\mathcal{A}_{1}$. For any $a=P(b) \in \mathcal{A}_{1}$ with $b \in \mathcal{A}$, we have

$$
a^{*}=P(b)^{*}=P\left(b^{*}\right) \in \mathcal{A}_{1} .
$$

Hence $\mathcal{A}_{1}$ is closed under the involution $*$ and then self-adjoint. Now let $\left\{P\left(b_{n}\right)\right\}$ be a sequence in $\mathcal{A}_{1}$ that uniformly converges to $a \in \mathcal{A}$. Then since $P$ is bounded and
idempotent, we get $\left\{P\left(b_{n}\right)\right\}$ uniformly converges to $P(a) \in \mathcal{A}_{1}$. Therefore $\mathcal{A}_{1}$ is a $C^{*}$-subalgebra of $\mathcal{A}$. It is similar to show that $\mathcal{A}_{2}$ is a $C^{*}$-subalgebra of $\mathcal{A}$.

Conversely, assume that we have a direct sum decomposition $\mathcal{A}=\mathcal{A}_{1} \oplus \mathcal{A}_{2}$, such that $\mathcal{A}_{1}$ and $\mathcal{A}_{2}$ are $C^{*}$-subalgebras of $\mathcal{A}$, and $P$ is the projection of $\mathcal{A}$ onto $\mathcal{A}_{1}$. From [8, Theorem 1.1.13], we have $P$ is an idempotent Rota-Baxter operator of weight -1 on $\mathcal{A}$. For any $a \in \mathcal{A}$, assume that $a=a_{1}+a_{2}$ with $a_{1} \in \mathcal{A}_{1}$ and $a_{2} \in \mathcal{A}_{2}$, then we have $a^{*}=a_{1}^{*}+a_{2}^{*}$. Since $\mathcal{A}_{i}$ is a $C^{*}$-subalgebra of $\mathcal{A}$, we get $a_{i}^{*} \in \mathcal{A}_{i}$. Hence

$$
P\left(a^{*}\right)=a_{1}^{*}=P(a)^{*},
$$

which means that $P$ is symmetric. Finally, from [18, Corollary 1.2.6] and the definition of the direct sum of $C^{*}$-algebras in Subsection 2.1, we know that

$$
\|a\|=\max \left(\left\|a_{1}\right\|,\left\|a_{2}\right\|\right) \geq\left\|a_{1}\right\|=\|P(a)\| .
$$

Hence we have

$$
\|P\|=\sup _{a \in \mathcal{A}, a \neq 0} \frac{\|P(a)\|}{\|a\|} \leq 1
$$

which means that $P$ is bounded.

## 3 Rota-Baxter operators matching projections on Hilbert spaces

### 3.1 The $C^{*}$-algebra $B(\mathcal{H})$

We recall the notion of Hilbert spaces. A complex linear space $\mathcal{H}$ is an inner product space if associated to any $x, y \in \mathcal{H}$ there is a product $\langle x, y\rangle$ which satisfies the following properties:
(i) $\langle x, y\rangle=\overline{\langle y, x\rangle}$ for any $x, y \in \mathcal{H}$;
(ii) $\left\langle\lambda_{1} x_{1}+\lambda_{2} x_{2}, y\right\rangle=\lambda_{1}\left\langle x_{1}, y\right\rangle+\lambda_{2}\left\langle x_{2}, y\right\rangle$ for any $\lambda_{1}, \lambda_{2} \in \mathbb{C}$ and $x_{1}, x_{2}, y \in \mathcal{H}$;
(iii) $\langle x, x\rangle=0$ for $x=0$ and $\langle x, x\rangle>0$ for any nonzero $x$ in $\mathcal{H}$.

Then the norm of $\mathcal{H}$ induced from the inner product is defined by $\|x\|=\sqrt{\langle x, x\rangle}$ for any $x \in \mathcal{H}$. We call $\mathcal{H}$ a Hilbert space if it is complete with respect to the norm.

Let $B(\mathcal{H})$ be the set of all bounded linear operators on the Hilbert space $\mathcal{H}$. For any $f \in B(\mathcal{H})$ and any $x \in \mathcal{H}$, we sometimes denote $f(x)$ by $f . x$. From [18], we know that $B(\mathcal{H})$ is a $C^{*}$-algebra. In fact, the algebra $B(\mathcal{H})$ is a Banach algebra with the norm given by

$$
\|f\|=\sup _{\|x\| \leq 1, x \in \mathcal{H}}\|f(x)\|, \quad \forall f \in B(\mathcal{H}) .
$$

And then $B(\mathcal{H})$ is a $C^{*}$-algebra with the involution $*$ determined by

$$
\langle f(x), y\rangle=\left\langle x, f^{*}(y)\right\rangle, \quad \forall f \in B(\mathcal{H}), \quad \forall x, y \in \mathcal{H}
$$

For a projection $p$ on the Hilbert space $\mathcal{H}$, we mean that $p$ is a linear operator on $\mathcal{H}$ satisfying $p^{2}=p$ and $p^{*}=p$. We set $p^{\perp}=\operatorname{id}_{H}-p$. Then we have $\mathcal{H}=\mathcal{H}_{1} \oplus \mathcal{H}_{2}$,
where $\mathcal{H}_{1}=p \mathcal{H}$ and $\mathcal{H}_{2}=p^{\perp} \mathcal{H}$ are orthogonal closed subspaces of $\mathcal{H}$. We call the projection $p$ on $\mathcal{H}$ nontrivial if $p$ is not equal to 0 and $\operatorname{id}_{\mathcal{H}}$.

Using the projections on $\mathcal{H}$, we can construct Rota-Baxter operators on the $C^{*}$ algebra $B(\mathcal{H})$.

Example 3.1. Let p be a projection on $\mathcal{H}$. We define a linear operator $L_{p}$ on $B(\mathcal{H})$ by

$$
L_{p}(a)=p a
$$

for any $a \in B(\mathcal{H})$. It is easy to verify that $L_{p}$ is a Rota-Baxter operator of weight -1 on $B(\mathcal{H})$. Then $\left(B(\mathcal{H}), L_{p}\right)$ is a Rota-Baxter $C^{*}$-algebra.

### 3.2 Rota-Baxter operators on $B(\mathcal{H})$

From here to the end of this subsection, without further mention, we will always assume that $\mathcal{H}$ is a Hilbert space, $p$ is a projection on $\mathcal{H}$ with $\mathcal{H}_{1}=p \mathcal{H}$ and $\mathcal{H}_{2}=p^{\perp} \mathcal{H}, \mathcal{A}$ is a $C^{*}$-subalgebra of $B(\mathcal{H})$ and $\mathcal{A}_{1}$ is a $C^{*}$-subalgebra of $\mathcal{A}$. Note that we have $\mathcal{H}=\mathcal{H}_{1} \oplus \mathcal{H}_{2}$.

Definition 3.2. Let $f$ be a linear operator on $\mathcal{H}$ and let $P$ be a Rota-Baxter operator of weight $\lambda \in \mathbb{C}$ on $\mathcal{A}$. The operator $P$ is called a Rota-Baxter operator matching $f$ on $\mathcal{A}_{1}$ if

$$
P(a) \cdot f(x)=f(P(a) \cdot x)+f(a \cdot f(x))+\lambda f(a \cdot x), \quad \forall a \in \mathcal{A}_{1}, \forall x \in \mathcal{H} .
$$

As a special case of the above definition, Rota-Baxter operators matching projections on the Hilbert space $\mathcal{H}$ are the central notion of the article. We first give an equivalent condition for a Rota-Baxter operator of weight -1 which matching projections. Recall that for a Rota-Baxter operator $P$ of weight $\lambda$ on $\mathcal{A}$, we set $\widetilde{P}=-\lambda \operatorname{id}_{\mathcal{A}}-P$.

Lemma 3.3. Let $P$ be a Rota-Baxter operator of weight -1 on $\mathcal{A}$. Then $P$ is a RotaBaxter operator matching $\underset{\sim}{p}$ on $\mathcal{A}_{1}$ if and only if for any $a \in \mathcal{A}_{1}$ and any $x \in \mathcal{H}$, we have $P(a) \cdot p(x) \in \mathcal{H}_{1}$ and $\widetilde{P}(a) . p^{\perp}(x) \in \mathcal{H}_{2}$.

Proof. Assume that $P$ matches $p$ on $\mathcal{A}_{1}$. For any $x \in \mathcal{H}$ and any $a \in \mathcal{A}_{1}$, we have

$$
P(a) \cdot p^{2}(x)=p(P(a) \cdot p(x))+p\left(a \cdot p^{2}(x)\right)-p(a \cdot p(x)) .
$$

As $p^{2}=p$, we have

$$
P(a) \cdot p(x)=p(P(a) \cdot p(x)) \in \mathcal{H}_{1}
$$

Similarly, one can show that $\widetilde{P}(a) \cdot p^{\perp}(x) \in \mathcal{H}_{2}$.
Conversely, assume that for any $a \in \mathcal{A}_{1}$ and any $x \in \mathcal{H}$, we have $P(a) \cdot p(x) \in \mathcal{H}_{1}$ and $\widetilde{P}(a) \cdot p^{\perp}(x) \in \mathcal{H}_{2}$. We write $x=x_{1}+x_{2}$ with $x_{1}=p(x) \in \mathcal{H}_{1}$ and $x_{2}=p^{\perp}(x) \in \mathcal{H}_{2}$. Then we have

$$
\begin{aligned}
& p(P(a) \cdot x)+p(a \cdot p(x))-p(a \cdot x) \\
= & p\left(P(a) \cdot\left(x_{1}+x_{2}\right)\right)+p\left(a \cdot x_{1}\right)-p\left(a \cdot\left(x_{1}+x_{2}\right)\right) \\
= & p\left(P(a) \cdot x_{1}\right)+p\left(P(a) \cdot x_{2}\right)-p\left(a \cdot x_{2}\right) \\
= & p\left(P(a) \cdot x_{1}\right)-p\left(\widetilde{P}(a) \cdot x_{2}\right) .
\end{aligned}
$$

Since $P(a) . x_{1} \in \mathcal{H}_{1}$ and $\widetilde{P}(a) . x_{2} \in \mathcal{H}_{2}$, we have

$$
p(P(a) \cdot x)+p(a \cdot p(x))-p(a \cdot x)=P(a) \cdot x_{1}=P(a) \cdot p(x)
$$

which shows that $P$ matches $p$ on $\mathcal{A}_{1}$.
As $p^{\perp}$ is also a projection, the above lemma has an immediate corollary.
Corollary 3.4. Let $P$ be a Rota-Baxter operator of weight -1 on $\mathcal{A}$. Then $P$ matches $p$ on $\mathcal{A}_{1}$ if and only if $\widetilde{P}$ matches $p^{\perp}$ on $\mathcal{A}_{1}$.

Now we write an element $x=x_{1}+x_{2} \in \mathcal{H}$ with $x_{1}=p(x) \in \mathcal{H}_{1}$ and $x_{2}=p^{\perp}(x) \in \mathcal{H}_{2}$ as a vector $x=\left[\begin{array}{l}x_{1} \\ x_{2}\end{array}\right]$. As shown in [3, Theorem 2.10], for any $a \in B(\mathcal{H})$, since

$$
\begin{aligned}
& a . x=a(p(x))+a\left(p^{\perp}(x)\right) \\
& \quad=p(a(p(x)))+p^{\perp}(a(p(x)))+p\left(a\left(p^{\perp}(x)\right)\right)+p^{\perp}\left(a\left(p^{\perp}(x)\right)\right) \\
& =(p a p)\left(x_{1}\right)+\left(p a p^{\perp}\right)\left(x_{2}\right)+\left(p^{\perp} a p\right)\left(x_{1}\right)+\left(p^{\perp} a p^{\perp}\right)\left(x_{2}\right),
\end{aligned}
$$

we may write $a$ as a matrix

$$
a=\left[\begin{array}{ll}
a_{11} & a_{12} \\
a_{21} & a_{22}
\end{array}\right],
$$

with

$$
\begin{array}{ll}
a_{11}=p a p: \mathcal{H}_{1} \rightarrow \mathcal{H}_{1}, & a_{12}=p a p^{\perp}: \mathcal{H}_{2} \rightarrow \mathcal{H}_{1} \\
a_{21}=p^{\perp} a p: \mathcal{H}_{1} \rightarrow \mathcal{H}_{2}, & a_{22}=p^{\perp} a p^{\perp}: \mathcal{H}_{2} \rightarrow \mathcal{H}_{2}
\end{array}
$$

It is easy to show that the operations in $B(\mathcal{H})$ coincides with the corresponding matrix operations. For example, we have

$$
a^{*}=\left[\begin{array}{ll}
a_{11}^{*} & a_{21}^{*} \\
a_{12}^{*} & a_{22}^{*}
\end{array}\right],
$$

which comes from

$$
\begin{aligned}
\left(a^{*}\right)_{11} & =p a^{*} p=(p a p)^{*}=a_{11}^{*} \\
\left(a^{*}\right)_{12} & =p a^{*} p^{\perp}=\left(p^{\perp} a p\right)^{*}=a_{21}^{*} \\
\left(a^{*}\right)_{21} & =p^{\perp} a^{*} p=\left(p a p^{\perp}\right)^{*}=a_{12}^{*} \\
\left(a^{*}\right)_{22} & =p^{\perp} a^{*} p^{\perp}=\left(p^{\perp} a p^{\perp}\right)^{*}=a_{22}^{*}
\end{aligned}
$$

And if $b=\left[\begin{array}{ll}b_{11} & b_{12} \\ b_{21} & b_{22}\end{array}\right] \in B(\mathcal{H})$, then

$$
a b=\left[\begin{array}{ll}
a_{11} b_{11}+a_{12} b_{21} & a_{11} b_{12}+a_{12} b_{22} \\
a_{21} b_{11}+a_{22} b_{21} & a_{21} b_{12}+a_{22} b_{22}
\end{array}\right] .
$$

In fact, we have

$$
a b=\left(p a p+p a p^{\perp}+p^{\perp} a p+p^{\perp} a p^{\perp}\right)\left(p b p+p b p^{\perp}+p^{\perp} b p+p^{\perp} b p^{\perp}\right)
$$

$$
\begin{aligned}
= & p a p p b p+p a p^{\perp} p^{\perp} b p+p a p p b p^{\perp}+p a p^{\perp} p^{\perp} b p^{\perp}+p^{\perp} a p p b p \\
& +p^{\perp} a p^{\perp} p^{\perp} b p+p^{\perp} a p p b p^{\perp}+p^{\perp} a p^{\perp} p^{\perp} b p^{\perp} \\
= & p\left(a_{11} b_{11}+a_{12} b_{21}\right) p+p\left(a_{11} b_{12}+a_{12} b_{22}\right) p^{\perp}+p^{\perp}\left(a_{21} b_{11}+a_{22} b_{21}\right) p \\
& +p^{\perp}\left(a_{21} b_{12}+a_{22} b_{22}\right) p^{\perp} .
\end{aligned}
$$

Using the above matrix notation, we may restate Lemma 3.3 as in the following proposition.

Proposition 3.5. Let $P$ be a Rota-Baxter operator of weight -1 on $\mathcal{A}$. Then $P$ matches $p$ on $\mathcal{A}_{1}$ if and only if for any $a \in \mathcal{A}_{1}$, we have $P(a)_{21}=0$ and $P(a)_{12}=a_{12}$.

Proof. Assume that $P$ matches $p$ on $\mathcal{A}_{1}$. For any $x_{1} \in \mathcal{H}_{1}$, we have

$$
P(a)_{21}\left(x_{1}\right)=\left(p^{\perp} P(a) p\right)(p(x))=p^{\perp}(P(a) \cdot p(x)) .
$$

By Lemma 3.3, $P(a) \cdot p(x) \in \mathcal{H}_{1}$. Hence $P(a)_{21}\left(x_{1}\right)=0$ and then $P(a)_{21}=0$. Similarly, for any $x_{2} \in \mathcal{H}_{2}$, we have

$$
P(a)_{12}\left(x_{2}\right)=\left(p P(a) p^{\perp}\right)\left(p^{\perp}(x)\right)=p\left(P(a) \cdot p^{\perp}(x)\right) .
$$

Since $\widetilde{P}=\mathrm{id}-P$, we have

$$
P(a)_{12}\left(x_{2}\right)=p\left(a \cdot p^{\perp}(x)\right)-p\left(\widetilde{P}(a) \cdot p^{\perp}(x)\right)=a_{12}\left(x_{2}\right)-p\left(\widetilde{P}(a) \cdot p^{\perp}(x)\right)
$$

By Lemma 3.3, $\widetilde{P}(a) \cdot p^{\perp}(x) \in \mathcal{H}_{2}$. Therefore $P(a)_{12}\left(x_{2}\right)=a_{12}\left(x_{2}\right)$ and then $P(a)_{12}=$ $a_{12}$.

Conversely, assume that for any $a \in \mathcal{A}_{1}$, we have $P(a)_{21}=0$ and $P(a)_{12}=a_{12}$. For any $x \in \mathcal{H}$, we have

$$
\begin{aligned}
P(a) \cdot p(x) & =p P(a) p\left(x_{1}\right)+p^{\perp} P(a) p\left(x_{1}\right) \\
& =p P(a) p\left(x_{1}\right)+P(a)_{21}\left(x_{1}\right)=p P(a) p\left(x_{1}\right) \in \mathcal{H}_{1},
\end{aligned}
$$

and

$$
\begin{aligned}
\widetilde{P}(a) \cdot p^{\perp}(x) & =p \widetilde{P}(a) p^{\perp}\left(x_{2}\right)+p^{\perp} \widetilde{P}(a) p^{\perp}\left(x_{2}\right) \\
& =\operatorname{pap}^{\perp}\left(x_{2}\right)-p P(a) p^{\perp}\left(x_{2}\right)+p^{\perp} \widetilde{P}(a) p^{\perp}\left(x_{2}\right) \\
& =\left(a_{12}-P(a)_{12}\right)\left(x_{2}\right)+p^{\perp} \widetilde{P}(a) p^{\perp}\left(x_{2}\right)=p^{\perp} \widetilde{P}(a) p^{\perp}\left(x_{2}\right) \in \mathcal{H}_{2} .
\end{aligned}
$$

Hence by Lemma 3.3, the Rota-Baxter operator $P$ matches $p$ on $\mathcal{A}_{1}$.
Note that the direct sum $B\left(\mathcal{H}_{1}\right) \oplus B\left(\mathcal{H}_{2}\right)$ can be regarded as a $C^{*}$-subalgebra of $B(\mathcal{H})$ by the following embedding

$$
\iota: B\left(\mathcal{H}_{1}\right) \oplus B\left(\mathcal{H}_{2}\right) \rightarrow B(\mathcal{H}) ;\left(a_{1}, a_{2}\right) \mapsto\left[\begin{array}{cc}
a_{1} & 0 \\
0 & a_{2}
\end{array}\right] .
$$

The following is the main result of this note.
Theorem 3.6. Let $\mathcal{H}$ be a Hilbert space and let $p$ be a projection on $\mathcal{H}$. Set $\mathcal{H}_{1}=p \mathcal{H}$ and $\mathcal{H}_{2}=p^{\perp} \mathcal{H}$. Then there is a 1-1 correspondence between the following two sets:
(1) the set of Rota-Baxter operators of weight -1 on $B(\mathcal{H})$ matching $p$ on $B(\mathcal{H})$;
(2) the set of Rota-Baxter operators of weight -1 on $B\left(\mathcal{H}_{1}\right) \oplus B\left(\mathcal{H}_{2}\right)$.

Proof. Denote by $\Gamma$ the set of Rota-Baxter operators of weight -1 on $B(\mathcal{H})$ matching $p$ on $B(\mathcal{H})$, and by $\Lambda$ the set of Rota-Baxter operators of weight -1 on $B\left(\mathcal{H}_{1}\right) \oplus B\left(\mathcal{H}_{2}\right)$.

Assume that $P \in \Gamma$. For any $a_{1} \in B\left(\mathcal{H}_{1}\right)$ and $a_{2} \in B\left(\mathcal{H}_{2}\right)$, we have $a=\left[\begin{array}{cc}a_{1} & 0 \\ 0 & a_{2}\end{array}\right] \in$ $B(\mathcal{H})$ and

$$
P(a)=\left[\begin{array}{cc}
P(a)_{11} & 0 \\
0 & P(a)_{22}
\end{array}\right] \in B\left(\mathcal{H}_{1}\right) \oplus B\left(\mathcal{H}_{2}\right)
$$

by Proposition 3.5. Hence we get a linear operator $P^{\prime}$ on $B\left(\mathcal{H}_{1}\right) \oplus B\left(\mathcal{H}_{2}\right)$ defined by $P^{\prime}=\left.P\right|_{B\left(\mathcal{H}_{1}\right) \oplus B\left(\mathcal{H}_{2}\right)}$. It is obvious that $P^{\prime}$ is a Rota-Baxter operator of weight -1 on $B\left(\mathcal{H}_{1}\right) \oplus B\left(\mathcal{H}_{2}\right)$. Hence we have a map $\Phi: \Gamma \rightarrow \Lambda$ defined by $\Phi(P)=P^{\prime}$.

Conversely, assume that $P^{\prime} \in \Lambda$. For any $a=\left[\begin{array}{ll}a_{11} & a_{12} \\ a_{21} & a_{22}\end{array}\right] \in B(\mathcal{H})$, we have $\left[\begin{array}{cc}a_{11} & 0 \\ 0 & a_{22}\end{array}\right] \in B\left(\mathcal{H}_{1}\right) \oplus B\left(\mathcal{H}_{2}\right)$. We then define an operator $P$ on $B(\mathcal{H})$ by

$$
P(a)=P^{\prime}\left(\left[\begin{array}{cc}
a_{11} & 0 \\
0 & a_{22}
\end{array}\right]\right)+\left[\begin{array}{cc}
0 & a_{12} \\
0 & 0
\end{array}\right] .
$$

It is obvious that $P$ is linear.
We show that $P$ is a Rota-Baxter operator of weight -1 on $B(\mathcal{H})$. Assume that $P^{\prime}\left(\left[\begin{array}{cc}a_{11} & 0 \\ 0 & a_{22}\end{array}\right]\right)=\left[\begin{array}{cc}a_{11}^{\prime} & 0 \\ 0 & a_{22}^{\prime}\end{array}\right]$, then we have

$$
P(a)=\left[\begin{array}{cc}
a_{11}^{\prime} & 0 \\
0 & a_{22}^{\prime}
\end{array}\right]+\left[\begin{array}{cc}
0 & a_{12} \\
0 & 0
\end{array}\right] .
$$

For another element $b=\left[\begin{array}{ll}b_{11} & b_{12} \\ b_{21} & b_{22}\end{array}\right] \in B(\mathcal{H})$, we set $P^{\prime}\left(\left[\begin{array}{cc}b_{11} & 0 \\ 0 & b_{22}\end{array}\right]\right)=\left[\begin{array}{cc}b_{11}^{\prime} & 0 \\ 0 & b_{22}^{\prime}\end{array}\right]$. Hence we have

$$
P(a) P(b)=\left[\begin{array}{cc}
a_{11}^{\prime} & a_{12} \\
0 & a_{22}^{\prime}
\end{array}\right]\left[\begin{array}{cc}
b_{11}^{\prime} & b_{12} \\
0 & b_{22}^{\prime}
\end{array}\right]=\left[\begin{array}{cc}
a_{11}^{\prime} b_{11}^{\prime} & a_{11}^{\prime} b_{12}+a_{12} b_{22}^{\prime} \\
0 & a_{22}^{\prime} b_{22}^{\prime}
\end{array}\right] .
$$

Since

$$
a P(b)=\left[\begin{array}{ll}
a_{11} & a_{12} \\
a_{21} & a_{22}
\end{array}\right]\left[\begin{array}{cc}
b_{11}^{\prime} & b_{12} \\
0 & b_{22}^{\prime}
\end{array}\right]=\left[\begin{array}{ll}
a_{11} b_{11}^{\prime} & a_{11} b_{12}+a_{12} b_{22}^{\prime} \\
a_{21} b_{11}^{\prime} & a_{21} b_{12}+a_{22} b_{22}^{\prime}
\end{array}\right],
$$

we get

$$
P(a P(b))=P^{\prime}\left(\left[\begin{array}{cc}
a_{11} b_{11}^{\prime} & 0 \\
0 & a_{21} b_{12}+a_{22} b_{22}^{\prime}
\end{array}\right]\right)+\left[\begin{array}{cc}
0 & a_{11} b_{12}+a_{12} b_{22}^{\prime} \\
0 & 0
\end{array}\right] .
$$

Similarly, we have

$$
P(P(a) b)=P^{\prime}\left(\left[\begin{array}{cc}
a_{11}^{\prime} b_{11}+a_{12} b_{21} & 0 \\
0 & a_{22}^{\prime} b_{22}
\end{array}\right]\right)+\left[\begin{array}{cc}
0 & a_{11}^{\prime} b_{12}+a_{12} b_{22} \\
0 & 0
\end{array}\right]
$$

and

$$
P(a b)=P^{\prime}\left(\left[\begin{array}{cc}
a_{11} b_{11}+a_{12} b_{21} & 0 \\
0 & a_{21} b_{12}+a_{22} b_{22}
\end{array}\right]\right)+\left[\begin{array}{cc}
0 & a_{11} b_{12}+a_{12} b_{22} \\
0 & 0
\end{array}\right] .
$$

Therefore we find

$$
\begin{aligned}
& P(a P(b))+P(P(a) b)-P(a b) \\
= & P^{\prime}\left(\left[\begin{array}{cc}
a_{11} b_{11}^{\prime}+a_{11}^{\prime} b_{11}-a_{11} b_{11} & 0 \\
0 & a_{22} b_{22}^{\prime}+a_{22}^{\prime} b_{22}-a_{22} b_{22}
\end{array}\right]\right)+\left[\begin{array}{cc}
0 & a_{12} b_{22}^{\prime}+a_{11}^{\prime} b_{12} \\
0 & 0
\end{array}\right] .
\end{aligned}
$$

On the other hand, since $P^{\prime} \in \Lambda$, we have

$$
\begin{aligned}
& {\left[\begin{array}{cc}
a_{11}^{\prime} & 0 \\
0 & a_{22}^{\prime}
\end{array}\right]\left[\begin{array}{cc}
b_{11}^{\prime} & 0 \\
0 & b_{22}^{\prime}
\end{array}\right] } \\
= & P^{\prime}\left(\left[\begin{array}{cc}
a_{11} & 0 \\
0 & a_{22}
\end{array}\right]\left[\begin{array}{cc}
b_{11}^{\prime} & 0 \\
0 & b_{22}^{\prime}
\end{array}\right]+\left[\begin{array}{cc}
a_{11}^{\prime} & 0 \\
0 & a_{22}^{\prime}
\end{array}\right]\left[\begin{array}{cc}
b_{11} & 0 \\
0 & b_{22}
\end{array}\right]-\left[\begin{array}{cc}
a_{11} b_{11} & 0 \\
0 & a_{22} b_{22}
\end{array}\right]\right) .
\end{aligned}
$$

Then we get

$$
P(a P(b))+P(P(a) b)-P(a b)=\left[\begin{array}{cc}
a_{11}^{\prime} b_{11}^{\prime} & 0 \\
0 & a_{22}^{\prime} b_{22}^{\prime}
\end{array}\right]+\left[\begin{array}{cc}
0 & a_{12} b_{22}^{\prime}+a_{11}^{\prime} b_{12} \\
0 & 0
\end{array}\right],
$$

which implies that

$$
P(a) P(b)=P(a P(b))+P(P(a) b)-P(a b) .
$$

So $P$ is a Rota-Baxter operator of weight -1 on $B(\mathcal{H})$. And from Proposition 3.5, we see that $P$ matches $p$ on $B(\mathcal{H})$. Then we have a map $\Psi: \Lambda \rightarrow \Gamma$ defined by $\Psi\left(P^{\prime}\right)=P$.

It is easy to verify that $\Psi \circ \Phi$ and $\Phi \circ \Psi$ are identity maps. And so there is a 1-1 correspondence between $\Lambda$ and $\Gamma$.

Remark 3.7. We can't extend the above theorem to the $C^{*}$-subalgebra $\mathcal{A}$ of $B(\mathcal{H})$. For a Rota-Baxter operator $P^{\prime}$ of weight -1 on $p \mathcal{A} p \oplus p^{\perp} \mathcal{A} p^{\perp}$, as $p$ and $p^{\perp}$ may not be in $\mathcal{A}$, we can't construct a Rota-Baxter operator $P$ of weight -1 matching $p$ on $\mathcal{A}$ as above.

From Theorem 3.6, we can construct Rota-Baxter operators of weight -1 on $B(\mathcal{H})$ matching $p$ on $B(\mathcal{H})$ from the Rota-Baxter operators of weight -1 on $B\left(\mathcal{H}_{1}\right) \oplus B\left(\mathcal{H}_{2}\right)$. The following lemma gives a method to construct Rota-Baxter operators on $B\left(\mathcal{H}_{1}\right) \oplus$ $B\left(\mathcal{H}_{2}\right)$.

Lemma 3.8. Let $\mathcal{A}_{1}$ and $\mathcal{A}_{2}$ be two $C^{*}$-algebras. If $P_{1}$ and $P_{2}$ are Rota-Baxter operators of weight $\lambda \in \mathbb{C}$ on $\mathcal{A}_{1}$ and $\mathcal{A}_{2}$, respectively, then the operator

$$
P=P_{1} \oplus P_{2}: \mathcal{A}_{1} \oplus \mathcal{A}_{2} \rightarrow \mathcal{A}_{1} \oplus \mathcal{A}_{2} ;\left(a_{1}, a_{2}\right) \mapsto\left(P_{1}\left(a_{1}\right), P_{2}\left(a_{2}\right)\right)
$$

is a Rota-Baxter operator of weight $\lambda$ on $\mathcal{A}_{1} \oplus \mathcal{A}_{2}$.
Proof. Is is trivial to check.
Then using Lemma 3.8 and Theorem 3.6, we get

Corollary 3.9. Let $P_{1}$ be a Rota-Baxter operator of weight -1 on $B\left(\mathcal{H}_{1}\right)$ and let $P_{2}$ be a Rota-Baxter operator of weight -1 on $B\left(\mathcal{H}_{2}\right)$. Then the operator

$$
P=\left[\begin{array}{cc}
P_{1} & \text { id } \\
0 & P_{2}
\end{array}\right]: B(\mathcal{H}) \rightarrow B(\mathcal{H}) ;\left[\begin{array}{ll}
a_{11} & a_{12} \\
a_{21} & a_{22}
\end{array}\right] \mapsto\left[\begin{array}{cc}
P_{1}\left(a_{11}\right) & a_{12} \\
0 & P_{2}\left(a_{22}\right)
\end{array}\right]
$$

is a Rota-Baxter operator of weight -1 matching $p$ on $B(\mathcal{H})$.
Recall that a Rota-Baxter operator $P$ of weight $\lambda$ on $\mathcal{A}$ is called symmetric on $\mathcal{A}_{1}$ provided that

$$
P\left(a^{*}\right)=P(a)^{*}, \quad \forall a \in \mathcal{A}_{1}
$$

Proposition 3.10. If there is a Rota-Baxter operator $P$ of weight -1 on $\mathcal{A}$ which is symmetric and matches $p$ on $\mathcal{A}_{1}$, then we have $\mathcal{A}_{1} \subseteq B\left(\mathcal{H}_{1}\right) \oplus B\left(\mathcal{H}_{2}\right)$.
Proof. For any $a=\left[\begin{array}{ll}a_{11} & a_{12} \\ a_{21} & a_{22}\end{array}\right] \in \mathcal{A}_{1}$, from Proposition 3.5, we have

$$
P(a)=\left[\begin{array}{cc}
P(a)_{11} & a_{12} \\
0 & P(a)_{22}
\end{array}\right] .
$$

On the other hand, since $P$ is symmetric on $\mathcal{A}_{1}$, we have

$$
P(a)=P\left(a^{*}\right)^{*}=\left[\begin{array}{cc}
\left(P\left(a^{*}\right)_{11}\right)^{*} & 0 \\
a_{21} & \left(P\left(a^{*}\right)_{22}\right)^{*}
\end{array}\right]
$$

Then we get $a_{12}=0$ and $a_{21}=0$. So $\mathcal{A}_{1} \subseteq B\left(\mathcal{H}_{1}\right) \oplus B\left(\mathcal{H}_{2}\right)$.
To state the last result of this subsection, we recall the definition of $*$-representation from [18]. A $*$-representation $\pi$ of the $C^{*}$-algebra $\mathcal{A}$ is a $*$-homomorphism $\pi: \mathcal{A} \rightarrow$ $B(\mathcal{H})$ with $\mathcal{H}$ a Hilbert space. We denote this $*$-representation of $\mathcal{A}$ by $\{\pi, \mathcal{H}\}$. We say $\{\pi, \mathcal{H}\}$ is topologically irreducible if $\pi(\mathcal{A})$ has no proper invariant subspaces. It is called algebraically irreducible if it has no proper invariant manifolds(subspaces of $\mathcal{H}$ that are not necessarily closed). These two notions coincide for $C^{*}$-algebras from [5]. Hence we call $\{\pi, \mathcal{H}\}$ irreducible when either of the two conditions holds.
Corollary 3.11. Let $\{\pi, \mathcal{H}\}$ be $a *$-representation of a $C^{*}$-algebra $\mathcal{A}$. Then the representation $\{\pi, \mathcal{H}\}$ is irreducible if and only if there is no Rota-Baxter operator of weight -1 on $B(\mathcal{H})$ which is symmetric and matches $p$ on $\pi(\mathcal{A})$ for some nontrivial projection p on $\mathcal{H}$.

Proof. If there is such a Rota-Baxter operator on $\pi(\mathcal{A})$, then from Proposition 3.10, we have $\pi(\mathcal{A}) \subseteq B(p \mathcal{H}) \oplus B\left(p^{\perp} \mathcal{H}\right)$. Hence $\pi(\mathcal{A})$ has a proper invariant closed subspace $p \mathcal{H}$ of $\mathcal{H}$. Therefore $\{\pi, \mathcal{H}\}$ is not irreducible.

Conversely, if the representation $\{\pi, \mathcal{H}\}$ is not irreducible, then $\pi(\mathcal{A})$ has a proper invariant closed subspace $\mathcal{H}_{1}$. There exists a projection $p$ on $\mathcal{H}$ such that $\mathcal{H}_{1}=p \mathcal{H}$. Therefore $\pi(\mathcal{A}) \cdot p \mathcal{H} \subseteq p \mathcal{H}$. Define a linear operator $P$ on $B(\mathcal{H})$ by

$$
P(a)=p a p+p^{\perp} a p^{\perp}+p a p^{\perp}
$$

for any $a \in B(\mathcal{H})$. Then by the proof of Theorem 3.6, $P$ is a Rota-Baxter operator of weight -1 matching $p$ on $B(\mathcal{H})$. For any $b \in \pi(\mathcal{A})$, we have $b=P(b)$ and $b^{*}=P\left(b^{*}\right)$ from Proposition 3.5. Hence we find

$$
P(b)=b=\left(b^{*}\right)^{*}=P\left(b^{*}\right)^{*}
$$

which means that $P$ is symmetric on $\pi(\mathcal{A})$.
At the end of this subsection, we see an example.
Example 3.12. Let $f: \mathcal{A} \rightarrow \mathbb{C}$ be a linear function, where $\mathcal{A}$ is a $C^{*}$-algebra. The function $f$ is called a positive linear functional if $f(a) \geq 0$ for any $a \geq 0$ in $\mathcal{A}$ (the notion of $a \geq 0$ can be found in Section 4). The norm of $f$ is defined by

$$
\|f\|=\sup _{a \in \mathcal{A}, a \neq 0} \frac{|f(a)|}{\|a\|} .
$$

As in [5], the function $f$ is called a state on $\mathcal{A}$ if $f$ is a positive linear functional and $\|f\|=1$. The state $f$ is called a pure state if there is not $a \lambda \in(0,1)$ and two states $f_{1}$ and $f_{2}$ on $\mathcal{A}$, such that $f=\lambda f_{1}+(1-\lambda) f_{2}$.

From [5, Theorem I.9.6], for any state $f$ on $\mathcal{A}$, we can construct a Hilbert space $\mathcal{H}_{f}$ and $a$ *-representation $\left\{\pi_{f}, \mathcal{H}_{f}\right\}$ of $\mathcal{A}$. This method of building representations from states is called GNS-constructions. From [5, Theorem I.9.8], we know that the representation $\left\{\pi_{f}, \mathcal{H}_{f}\right\}$ is an irreducible representation of $\mathcal{A}$ if and only if $f$ is a pure state. Hence if $f$ is not a pure state, then from Corollary 3.11, there is at least one Rota-Baxter operator of weight -1 which is symmetric and matches $p$ on $\pi_{f}(\mathcal{A})$ for some nontrivial projection $p$ on $\mathcal{H}_{f}$.

### 3.3 Representations of Rota-Baxter $C^{*}$-algebras

We introduce the notion of representations of Rota-Baxter $C^{*}$-algebras.
Definition 3.13. Let $\mathcal{A}$ be a $C^{*}$-algebra and let $P$ be a Rota-Baxter operator of weight $\lambda$ on $\mathcal{A}$. Let $\mathcal{H}$ be a Hilbert space and let $P^{\prime}$ be a Rota-Baxter operator of weight $\lambda$ on $B(\mathcal{H})$. Let $\pi:(\mathcal{A}, P) \rightarrow\left(B(\mathcal{H}), P^{\prime}\right)$ be a Rota-Baxter $C^{*}$-algebra homomorphism and let $f$ be a linear operator on $\mathcal{H}$. Then $\{\pi, \mathcal{H}, f\}$ is a Rota-Baxter $*$-representation of $(\mathcal{A}, P)$ into $\left(B(\mathcal{H}), P^{\prime}\right)$ if $P^{\prime}$ matches $f$ on $\pi(\mathcal{A})$.

Hence $\{\pi, \mathcal{H}, f\}$ is a Rota-Baxter $*$-representation of $(\mathcal{A}, P)$ into $\left(B(\mathcal{H}), P^{\prime}\right)$ if for any $h \in \mathcal{H}$ and any $a \in \mathcal{A}$ we have

$$
\pi(P(a))(f(h))=f(\pi(P(a))(h))+f(\pi(a)(f(h)))+\lambda f(\pi(a)(h))
$$

We first prepare two lemmas.
Lemma 3.14. Let $\mathcal{H}$ be a Hilbert space and let $p$ be a projection on $\mathcal{H}$. Let $P^{\prime}$ be a Rota-Baxter operator of weight -1 on $B(p \mathcal{H}) \oplus B\left(p^{\perp} \mathcal{H}\right)$ and let $P$ be the Rota-Baxter operator of weight -1 on $B(\mathcal{H})$ matching $p$ that corresponding to $P^{\prime}$ (See Theorem 3.6.). Then the embedding $\iota: B(p \mathcal{H}) \oplus B\left(p^{\perp} \mathcal{H}\right) \rightarrow B(\mathcal{H})$ is a Rota-Baxter $C^{*}$-algebra homomorphism.

Proof. It needs to show that $\iota \circ P^{\prime}=P \circ \iota$, which is obvious.
Lemma 3.15. Let $\pi_{1}:\left(\mathcal{A}_{1}, P_{1}\right) \rightarrow\left(\mathcal{A}_{2}, P_{2}\right)$ and $\pi_{2}:\left(\mathcal{A}_{1}^{\prime}, P_{1}^{\prime}\right) \rightarrow\left(\mathcal{A}_{2}^{\prime}, P_{2}^{\prime}\right)$ be two Rota-Baxter $C^{*}$-algebra homomorphisms. Then the map

$$
\pi=\pi_{1} \oplus \pi_{2}: \mathcal{A}_{1} \oplus \mathcal{A}_{1}^{\prime} \rightarrow \mathcal{A}_{2} \oplus \mathcal{A}_{2}^{\prime} ;\left(a_{1}, b_{1}\right) \mapsto\left(\pi_{1}\left(a_{1}\right), \pi_{2}\left(b_{1}\right)\right)
$$

is a Rota-Baxter C*-algebra homomorphism.

Proof. It is easy to verify that $\pi$ is a Rota-Baxter $C^{*}$-algebra homomorphism.
Then we state the main theorem of this subsection.
Theorem 3.16. Let $\mathcal{H}_{1}$ and $\mathcal{H}_{2}$ be two Hilbert spaces. For $i=1,2$, let $P_{i}^{\prime}$ be a RotaBaxter operator of weight -1 on $B\left(\mathcal{H}_{i}\right), \mathcal{A}_{i}$ be a $C^{*}$-subalgebra of $B\left(\mathcal{H}_{i}\right)$, and let $P_{i}$ be a Rota-Baxter operator of weight -1 on $\mathcal{A}_{i}$. Set $\mathcal{H}=\mathcal{H}_{1} \oplus \mathcal{H}_{2}$. Let $P^{\prime}$ be the unique Rota-Baxter operator of weight -1 on $B(\mathcal{H})$ corresponding to $P_{1}^{\prime} \oplus P_{2}^{\prime}$ on $B\left(\mathcal{H}_{1}\right) \oplus B\left(\mathcal{H}_{2}\right)$ (See Theorem 3.6 and Lemma 3.8.). Let $p$ be the projection from $\mathcal{H}$ onto $\mathcal{H}_{1}$. Then the following two statements are equivalent:
(a) There are Rota-Baxter $*$-representations $\left\{\pi_{i}, \mathcal{H}_{i}, \operatorname{id}_{\mathcal{H}_{i}}\right\}$ from $\left(\mathcal{A}_{i}, P_{i}\right)$ into $\left(B\left(\mathcal{H}_{i}\right), P_{i}^{\prime}\right)$ with $i=1,2$;
(b) There is a Rota-Baxter *-representation $\{\pi, \mathcal{H}, p\}$ from $\left(\mathcal{A}_{1} \oplus \mathcal{A}_{2}, P_{1} \oplus P_{2}\right)$ into $\left(B(\mathcal{H}), P^{\prime}\right)$ such that $\pi\left(\mathcal{A}_{i}\right) \subseteq B\left(\mathcal{H}_{i}\right)$ for $i=1,2$.

Proof. Set $\mathcal{A}=\mathcal{A}_{1} \oplus \mathcal{A}_{2}$ and $P=P_{1} \oplus P_{2}$.
(a) $\Rightarrow$ (b) Assume that (a) holds. Using Lemmas 3.14 and 3.15, we have a RotaBaxter $C^{*}$-algebra homomorphism

$$
\pi:\left(\mathcal{A}_{1} \oplus \mathcal{A}_{2}, P_{1} \oplus P_{2}\right) \xrightarrow{\pi_{1} \oplus \pi_{2}}\left(B\left(\mathcal{H}_{1}\right) \oplus B\left(\mathcal{H}_{2}\right), P_{1}^{\prime} \oplus P_{2}^{\prime}\right) \xrightarrow{\iota}\left(B(\mathcal{H}), P^{\prime}\right) .
$$

It is obvious that $\pi\left(\mathcal{A}_{i}\right) \subseteq B\left(\mathcal{H}_{i}\right)$ for $i=1,2$.
We check that $P^{\prime}$ matches $p$ on $\pi(\mathcal{A})$. For any $a=\left(a_{1}, a_{2}\right) \in \mathcal{A}$ with $a_{i} \in \mathcal{A}_{i}$ and any $h=\left(h_{1}, h_{2}\right) \in \mathcal{H}$ with $h_{i} \in \mathcal{H}_{i}$, we have

$$
\begin{aligned}
& p(\pi(P(a))(h))+p(\pi(a)(p(h)))-p(\pi(a)(h)) \\
= & p\left(\pi_{1}\left(P_{1}\left(a_{1}\right)\right)\left(h_{1}\right), \pi_{2}\left(P_{2}\left(a_{2}\right)\right)\left(h_{2}\right)\right)+p\left(\pi_{1}\left(a_{1}\right)\left(h_{1}\right), 0\right)-p\left(\pi_{1}\left(a_{1}\right)\left(h_{1}\right), \pi_{2}\left(a_{2}\right)\left(h_{2}\right)\right) \\
= & \pi_{1}\left(P_{1}\left(a_{1}\right)\right)\left(h_{1}\right),
\end{aligned}
$$

and

$$
\pi(P(a))(p(h))=\left(\pi_{1}\left(P_{1}\left(a_{1}\right)\right), \pi_{2}\left(P_{2}\left(a_{2}\right)\right)\right)\left(h_{1}, 0\right)=\pi_{1}\left(P_{1}\left(a_{1}\right)\right)\left(h_{1}\right)
$$

Hence $P^{\prime}$ matches $p$ on $\pi(\mathcal{A})$.
$(\mathrm{a}) \Leftarrow(\mathrm{b})$ Assume that (b) holds. As $\pi$ is a Rota-Baxter $C^{*}$-algebra homomorphism, for any $a_{1} \in \mathcal{A}_{1}$ and $a_{2} \in \mathcal{A}_{2}$, we have

$$
\pi \circ P\left(a_{1}, a_{2}\right)=P^{\prime} \circ \pi\left(a_{1}, a_{2}\right)
$$

Taking $a_{2}=0$, we get $\pi \circ P_{1}\left(a_{1}\right)=P^{\prime} \circ \pi\left(a_{1}\right)$. Since $P_{1}\left(a_{1}\right) \in \mathcal{A}_{1}$ and $\pi\left(a_{1}\right) \in B\left(\mathcal{H}_{1}\right)$, we have

$$
\pi \circ P_{1}\left(a_{1}\right)=P_{1}^{\prime} \circ \pi\left(a_{1}\right)
$$

Hence we get a Rota-Baxter $C^{*}$-algebra homomorphism

$$
\pi_{1}=\left.\pi\right|_{\mathcal{A}_{1}}:\left(\mathcal{A}_{1}, P_{1}\right) \rightarrow\left(B\left(\mathcal{H}_{1}\right), P_{1}^{\prime}\right) .
$$

Similarly, we have a Rota-Baxter $C^{*}$-algebra homomorphism

$$
\pi_{2}=\left.\pi\right|_{\mathcal{A}_{2}}:\left(\mathcal{A}_{2}, P_{2}\right) \rightarrow\left(B\left(\mathcal{H}_{2}\right), P_{2}^{\prime}\right) .
$$

Finally, since $P^{\prime}$ matches $p$ on $\pi(\mathcal{A})$, one can show that $P_{i}^{\prime}$ matches $\operatorname{id}_{\mathcal{H}_{i}}$ on $\pi_{i}\left(\mathcal{A}_{i}\right)$ for $i=1,2$.

## 4 Quasidiagonal operators and Rota-Baxter operators

In this section, all Hilbert spaces and $C^{*}$-algebras are assumed to be separable. Here a topology space $X$ is separable if it contains a countable dense subset.

We recall some basic definitions of quasidiagonal linear operators from [3]. Let $\mathcal{A}$ be a $C^{*}$-algebra and let $a$ be a self-adjoint element of $\mathcal{A}$. If $\mathcal{A}$ is unital, the spectrum of $a$ is defined by

$$
\operatorname{Spec}(a)=\left\{\lambda \in \mathbb{C} \mid a-\lambda 1_{\mathcal{A}} \text { is not invertible }\right\}
$$

where $1_{\mathcal{A}}$ is the identity element of $\mathcal{A}$. If $\mathcal{A}$ is nonunital, then from [18, Proposition 1.1.7], there is a unital $C^{*}$-algebra $\mathcal{A}_{1}$ such that $\mathcal{A}_{1} \simeq \mathcal{A} \bigoplus \mathbb{C}$. Then for any $a \in \mathcal{A}$, the spectrum of $a$ is the spectrum of $a$ as an element of $\mathcal{A}_{1}$. The element $a$ is called positive if $\operatorname{Spec}(a)$ is contained in the non-negative reals. For any $a, b \in \mathcal{A}$, we say that $a$ is not bigger than $b$ if $b-a$ is positive, and we denote this by $a \leq b$. We also denote $a b-b a$ by the Lie bracket $[a, b]$.

Let $\mathcal{H}$ be a Hilbert space. A projection $p$ on $\mathcal{H}$ is of finite rank if $p \mathcal{H}$ is of finite dimension. For any sequence $a_{n} \in B(\mathcal{H})$ and $a \in B(\mathcal{H})$, we say that $a_{n} \rightarrow a$ as $n \rightarrow \infty$ in the strong operator topology if $\left\|a_{n} . h-a . h\right\| \rightarrow 0$ as $n \rightarrow \infty$ for any $h \in \mathcal{H}$.

We first give the definition of block diagonal linear operators.
Definition 4.1. A bounded linear operator d on a Hilbert space $\mathcal{H}$ is called block diagonal if there exists an increasing sequence of finite rank projections $p_{1} \leq p_{2} \leq p_{3} \leq$ $\cdots$ on $\mathcal{H}$, such that $\left\|\left[d, p_{n}\right]\right\|=0$ and $p_{n} \rightarrow \operatorname{id}_{\mathcal{H}}$ as $n \rightarrow \infty$ in the strong operator topology.

We can construct an equivalent condition of block diagonal operators with the help of Rota-Baxter operators. Let $\mathcal{A}$ be a $C^{*}$-algebra. For any $a \in \mathcal{A}$, there is a $C^{*}$ subalgebra of $\mathcal{A}$ generated by $a$, which is denoted by $C^{*}(a)$. In fact, $C^{*}(a)$ is the intersection of all $C^{*}$-subalgebras of $\mathcal{A}$ containing $a$, and $C^{*}(a)$ is the closure of the algebra generated by $a$ and $a^{*}$.

Proposition 4.2. Let $\mathcal{H}$ be a Hilbert space and $d \in B(\mathcal{H})$. Then the following statements are equivalent:
(a) The operator d is block diagonal;
(b) There exists an increasing sequence of finite rank projections $p_{1} \leq p_{2} \leq p_{3} \leq \cdots$ on $\mathcal{H}$ and a sequence of Rota-Baxter operators $\left\{P_{n}\right\}$ of weight -1 on $B(\mathcal{H})$, such that $p_{n} \rightarrow \mathrm{id}_{\mathcal{H}}$ as $n \rightarrow \infty$ in the strong operator topology, and $P_{n}$ are symmetric on $C^{*}(d)$ and matches $p_{n}$ on $B(\mathcal{H})$ for any $n \geq 1$.

Proof. For any $x \in \mathcal{H}, n \in \mathbb{N}$ and $b \in B(\mathcal{H})$, we have $p_{n}^{\perp} b p_{n}(x) \in p_{n}^{\perp} \mathcal{H}$ and $p_{n} b p_{n}^{\perp}(x) \in$ $p_{n} \mathcal{H}$. Therefore we find

$$
\left\|\left[b, p_{n}\right]\right\|=\left\|p_{n}^{\perp} b p_{n}-p_{n} b p_{n}^{\perp}\right\| \geq\left\|p_{n}^{\perp} b p_{n}\right\| .
$$

And similarly we have

$$
\left\|\left[b, p_{n}\right]\right\| \geq\left\|p_{n} b p_{n}^{\perp}\right\| .
$$

On the other hand, it holds

$$
\left\|\left[b, p_{n}\right]\right\|=\left\|p_{n}^{\perp} b p_{n}-p_{n} b p_{n}^{\perp}\right\| \leq\left\|p_{n}^{\perp} b p_{n}\right\|+\left\|p_{n} b p_{n}^{\perp}\right\| .
$$

Therefore $\left\|\left[b, p_{n}\right]\right\|=0$ if and only if $\left\|p_{n}^{\perp} b p_{n}\right\|=0$ and $\left\|p_{n} b p_{n}^{\perp}\right\|=0$.
$(\mathrm{a}) \Rightarrow(\mathrm{b})$ Assume that $d$ is block diagonal. Then there exists an increasing sequence of finite rank projections $p_{1} \leq p_{2} \leq p_{3} \leq \cdots$ on $\mathcal{H}$, such that $\left\|\left[d, p_{n}\right]\right\|=0$ for any $n \in \mathbb{N}$.

Let $A$ be the set of elements which are finite products of $d$ and $d^{*}$ in $C^{*}(d)$. For any $b \in A$, if $b=b_{1} b_{2} \cdots b_{n}$ with $b_{k}=d$ or $d^{*}$ for $1 \leq k \leq n$, we set $|b|=n$. We first prove that for any $b \in A,\left\|\left[b, p_{n}\right]\right\|=0$ by induction on $|b|$. The case of $|b|=1$ is trivial. For $|b| \geq 2$, we can assume that there is a $b_{1} \in A$ such that $\left|b_{1}\right|=|b|-1$, and $b=b_{1} d$ without loss of generality. We have

$$
\begin{aligned}
\left\|p_{n}^{\perp} b p_{n}\right\| & =\left\|p_{n}^{\perp} b_{1} p_{n} d+p_{n}^{\perp} b_{1}\left[d, p_{n}\right]\right\| \\
& \leq\left\|p_{n}^{\perp} b_{1} p_{n} d\right\|+\left\|p_{n}^{\perp} b_{1}\left[d, p_{n}\right]\right\| \\
& \leq\left\|p_{n}^{\perp} b_{1} p_{n}\right\|\|d\|+\left\|p_{n}^{\perp}\right\|\left\|b_{1}\right\|\left\|\left[d, p_{n}\right]\right\| .
\end{aligned}
$$

Hence using the inductive assumption $\left\|p_{n}^{\perp} b_{1} p_{n}\right\|=0$ and the fact $\left\|\left[d, p_{n}\right]\right\|=0$, we find $\left\|p_{n}^{\perp} b p_{n}\right\|=0$. Similarly we get $\left\|p_{n} b p_{n}^{\perp}\right\|=0$. Therefore we have $\left\|\left[b, p_{n}\right]\right\|=0$.

Using the above result, it is easy to know that for any $b \in C^{*}(d)$, we have $\left\|\left[b, p_{n}\right]\right\|=$ 0 . Define a linear operator $P_{n}$ on $B(\mathcal{H})$ such that for any $a \in B(\mathcal{H})$ we have

$$
P_{n}(a)=p_{n} a p_{n}+p_{n}^{\perp} a p_{n}^{\perp}+p_{n} a p_{n}^{\perp} .
$$

Then $P_{n}$ is a Rota-Baxter operator of weight -1 matching $p_{n}$ on $B(\mathcal{H})$ by Corollary 3.9. Finally, for any $b \in C^{*}(d)$, as

$$
\begin{aligned}
& \left\|P_{n}(b)-P_{n}\left(b^{*}\right)^{*}\right\| \\
& =\left\|p_{n} b p_{n}+p_{n}^{\perp} b p_{n}^{\perp}+p_{n} b p_{n}^{\perp}-p_{n} b p_{n}-p_{n}^{\perp} b p_{n}^{\perp}-p_{n}^{\perp} b p_{n}\right\| \\
& =\left\|p_{n} b p_{n}^{\perp}-p_{n}^{\perp} b p_{n}\right\| \\
& \leq\left\|p_{n} b p_{n}^{\perp}\right\|+\left\|p_{n}^{\perp} b p_{n}\right\|=0,
\end{aligned}
$$

we have $P_{n}(b)=P_{n}\left(b^{*}\right)^{*}$.
(b) $\Rightarrow$ (a) Assume that (b) holds. Then using Proposition 3.10, we know that $C^{*}(d) \subseteq B\left(p_{n} \mathcal{H}\right) \bigoplus B\left(p_{n}^{\perp} \mathcal{H}\right)$ for any $n \in \mathbb{N}$. Hence $\left\|p_{n} d p_{n}^{\perp}\right\|=\left\|p_{n}^{\perp} d p_{n}\right\|=0$. Therefore $\left\|\left[d, p_{n}\right]\right\|=0$, and (a) holds.

Now we give the definition of quasidiagonal linear operators.
Definition 4.3. A bounded linear operator d on a Hilbert space $\mathcal{H}$ is called quasidiagonal if there exists an increasing sequence of finite rank projections $p_{1} \leq p_{2} \leq p_{3} \leq \cdots$ on $\mathcal{H}$, such that $\left\|\left[d, p_{n}\right]\right\| \rightarrow 0$ as $n \rightarrow \infty$ and $p_{n} \rightarrow \operatorname{id}_{\mathcal{H}}$ as $n \rightarrow \infty$ in the strong operator topology.

As above, we have an equivalent condition of quasidiagonal operators in terms of Rota-Baxter operators.

Proposition 4.4. Let $\mathcal{H}$ be a Hilbert space and $d \in B(\mathcal{H})$. Then the following statements are equivalent:
(a) The operator d is quasidiagonal;
(b) There exists an increasing sequence of finite rank projections $p_{1} \leq p_{2} \leq p_{3} \leq \cdots$ on $\mathcal{H}$ and a sequence of Rota-Baxter operators $\left\{P_{n}\right\}$ of weight -1 on $B(\mathcal{H})$, such that $P_{n}$ matches $p_{n}$ on $B(\mathcal{H})$ for any $n \geq 1, p_{n} \rightarrow \operatorname{id}_{\mathcal{H}}$ and $\left\|P_{n}(b)-P_{n}\left(b^{*}\right)^{*}\right\| \rightarrow 0$ for any $b \in C^{*}(d)$ as $n \rightarrow \infty$.
Proof. For any $x \in \mathcal{H}$ and $b \in B(\mathcal{H})$, similarly as in the proof of Proposition 4.2, we have

$$
\left\|\left[b, p_{n}\right]\right\| \geq\left\|p_{n}^{\perp} b p_{n}\right\|, \quad\left\|\left[b, p_{n}\right]\right\| \geq\left\|p_{n} b p_{n}^{\perp}\right\|,
$$

and

$$
\left\|\left[b, p_{n}\right]\right\| \leq\left\|p_{n}^{\perp} b p_{n}\right\|+\left\|p_{n} b p_{n}^{\perp}\right\| .
$$

Therefore $\left\|\left[b, p_{n}\right]\right\| \rightarrow 0$ as $n \rightarrow \infty$ if and only if $\left\|p_{n}^{\perp} b p_{n}\right\| \rightarrow 0$ and $\left\|p_{n} b p_{n}^{\perp}\right\| \rightarrow 0$ as $n \rightarrow \infty$.
(a) $\Rightarrow(\mathrm{b})$ Assume that $d$ is quasidiagonal. Then there exists an increasing sequence of finite rank projections $p_{1} \leq p_{2} \leq p_{3} \leq \cdots$ on $\mathcal{H}$, such that $\left\|\left[d, p_{n}\right]\right\| \rightarrow 0$ and $p_{n} \rightarrow \operatorname{id}_{\mathcal{H}}$ as $n \rightarrow \infty$.

Let $A$ be the set of elements which are finite products of $d$ and $d^{*}$ in $C^{*}(d)$. We first prove that for any $b \in A,\left\|\left[b, p_{n}\right]\right\| \rightarrow 0$ as $n \rightarrow \infty$ by induction on $|b|$. The case of $|b|=1$ is trivial. For $|b| \geq 2$, we can assume that there is a $b_{1} \in A$ such that $\left|b_{1}\right|=|b|-1$, and $b=b_{1} d$ without loss of generality. We have

$$
\left\|p_{n}^{\perp} b p_{n}\right\| \leq\left\|p_{n}^{\perp} b_{1} p_{n}\right\|\|d\|+\left\|p_{n}^{\perp}\right\|\left\|b_{1}\right\|\left\|\left[d, p_{n}\right]\right\| .
$$

Hence using the inductive assumption, we find $\left\|p_{n}^{\perp} b p_{n}\right\| \rightarrow 0$ as $n \rightarrow \infty$. Similarly we get $\left\|p_{n} b p_{n}^{\perp}\right\| \rightarrow 0$ as $n \rightarrow \infty$. Therefore we have $\left\|\left[b, p_{n}\right]\right\| \rightarrow 0$ as $n \rightarrow \infty$.

Using the above result, it is easy to know that for any $b \in C^{*}(d)$, we have $\left\|\left[b, p_{n}\right]\right\| \rightarrow$ 0 as $n \rightarrow \infty$.

Define a linear operator $P_{n}$ on $B(\mathcal{H})$ such that for any $a \in B(\mathcal{H})$ we have

$$
P_{n}(a)=p_{n} a p_{n}+p_{n}^{\perp} a p_{n}^{\perp}+p_{n} a p_{n}^{\perp} .
$$

Then $P_{n}$ is a Rota-Baxter operator of weight -1 matching $p_{n}$ on $B(\mathcal{H})$ by Corollary 3.9. Finally, for any $b \in C^{*}(d)$, as

$$
\left\|P_{n}(b)-P_{n}\left(b^{*}\right)^{*}\right\| \leq\left\|p_{n} b p_{n}^{\perp}\right\|+\left\|p_{n}^{\perp} b p_{n}\right\|,
$$

we have $\left\|P_{n}(b)-P_{n}\left(b^{*}\right)^{*}\right\| \rightarrow 0$ as $n \rightarrow \infty$.
$(\mathrm{a}) \Leftarrow(\mathrm{b})$ Assume that (b) holds. For any $\epsilon>0$, there is a $N$ such that for any $n>N$ we have

$$
\left\|P_{n}(d)-P_{n}\left(d^{*}\right)^{*}\right\|<\epsilon .
$$

Then we find

$$
\begin{aligned}
\left\|p_{n}^{\perp} d p_{n}\right\| & =\left\|\left[\begin{array}{cc}
0 & 0 \\
-d_{21} & 0
\end{array}\right]\right\| \leq\left\|\left[\begin{array}{cc}
0 & d_{12} \\
-d_{21} & 0
\end{array}\right]\right\| \\
& =\left\|P_{n}(d)-P_{n}\left(d^{*}\right)^{*}\right\| \leq \epsilon .
\end{aligned}
$$

Hence $\left\|p_{n}^{\perp} d p_{n}\right\| \rightarrow 0$ as $n \rightarrow \infty$. We can prove that $\left\|p_{n} d p_{n}^{\perp}\right\| \rightarrow 0$ similarly. Finally we have $\left\|\left[d, p_{n}\right]\right\| \rightarrow 0$ as $n \rightarrow \infty$.

Such a sequence $\left\{P_{n}\right\}$ of Rota-Baxter operators of weight -1 on $B(\mathcal{H})$ in (b) of the above proposition is called a quasi symmetric Rota-Baxter operator sequence on $B(\mathcal{H})$.
