#### ABSTRACT

*Context.* Little is known about the chemistry of isocyanates (compounds with the functional group R-N=C=O) in the interstellar medium, as only four of them have been detected so far: isocyanate radical (NCO), isocyanic acid (HNCO), N-protonated isocyanic acid ( $H_2NCO^+$ ) and methyl isocyanate (CH<sub>3</sub>NCO). The molecular cloud G+0.693-0.027, located in the Galactic Centre, represents an excellent candidate to search for new isocyanates since it exhibits high abundances of the simplest ones, HNCO and CH<sub>3</sub>NCO. *Aims.* After CH<sub>3</sub>NCO, the next complex isocyanates are ethyl isocyanate ( $C_2H_3NCO$ ) and vinyl isocyanate ( $C_2H_3NCO$ ). Their detec-

tion in the ISM would enhance our understanding of the formation of these compounds in space.

*Methods.* We have searched for  $C_2H_3NCO$ ,  $H_2NCO^+$ ,  $C_2H_3NCO$  and cyanogen isocyanate (NCNCO) in a sensitive unbiased spectral survey carried out in the 2 mm and 7 mm radio windows using IRAM 30m and Yebes 40m radio telescopes, respectively.

*Results.* We have detected  $C_2H_5NCO$  and  $H_2NCO^+$  towards G+0.693-0.027 (the former for the first time in the interstellar medium) with molecular abundances of  $(4.7-7.3)\times10^{-11}$  and  $(1.0-1.5)\times10^{-11}$ , respectively. A ratio  $CH_3NCO / C_2H_5NCO = 8\pm1$  is obtained; therefore the relative abundance determined for  $HNCO:CH_3NCO:C_2H_5NCO$  is 1:1/55:1/447, which implies a decrease by more than one order of magnitude going progressively from HNCO to  $CH_3NCO$  and to  $C_2H_5NCO$ . This is similar to what has been found for e.g. alcohols and thiols and suggests that  $C_2H_5NCO$  is likely formed on the surface of dust grains. In addition, we have obtained column density ratios of HNCO / NCO > 269,  $HNCO / H_2NCO^+ \sim 2100$  and  $C_2H_3NCO / C_2H_5NCO < 4$ . A comparison of the Methyl / Ethyl ratios for isocyanates (-NCO), alcohols (-OH), formiates (HCOO-), nitriles (-CN) and thiols (-SH) is performed and shows that ethyl-derivatives may be formed more efficiently for the N-bearing molecules than for the O- and S-bearing molecules.

Key words. Astrochemistry - ISM: molecules - line: identification

## 1. Introduction

More than 240 molecules<sup>1</sup> have been detected in the interstellar medium (ISM). Among them, only four are carrying the isocyanate functional group (-N=C=O). Namely: isocyanic acid (HNCO), one of the first detected molecule in space (Snyder & Buhl 1972); isocyanic radical (NCO) and N-protonated isocyanic acid (H<sub>2</sub>NCO<sup>+</sup>), only reported in the L483 dense core (Marcelino et al. 2018); and methyl isocyanate (CH<sub>3</sub>NCO, hereafter MeNCO), reported in hot cores (e.g. Sgr B2N, Orion KL, G10.47+0.03; Halfen et al. 2015; Cernicharo et al. 2016; Gorai et al. 2020), hot corinos (e.g. IRAS 16293-2422, Serpens SMM1; Ligterink et al. 2017; Martín-Doménech et al. 2017; Ligterink et al. 2021) and in the G+0.693-0.027 molecular cloud (hereafter G+0.693; Zeng et al. 2018).

Isocyanates are molecules with prebiotic interest, since they play a role in the synthesis of amino acids, polymerisation of peptides (Pascal et al. 2005), and in the production of nucleotides (Choe 2021) and nucleosides (Schneider et al. 2018). Until now, MeNCO has been the most complex isocyanate detected in the ISM, while the search of more complex species, such as ethyl isocyanate ( $C_2H_5NCO$ , hereafter EtNCO), only yielded upper limits (Kolesniková et al. 2018; Colzi et al. 2021).

In this Letter we describe the detection of EtNCO towards G+0.693. This cloud, located in the Galactic Centre within the Sgr B2 molecular complex, It contains a very rich chemical inventory (Requena-Torres et al. 2008; Zeng et al. 2018; Rivilla et al. 2019, 2020; Jiménez-Serra et al. 2020; Rodríguez-Almeida et al. 2021; Rivilla et al. 2021b). G+0.693 is thought to be undergoing a cloud-cloud collision (Zeng et al. 2020), which produces large-scale shocks that sputter dust grains, enhancing the gasphase abundance of molecules by several orders of magnitude (Requena-Torres et al. 2006). Since the abundances of HNCO are MeNCO in this cloud are relatively high (>  $10^{-10}$ ; Zeng et al. 2018), together with several detections of other ethyl derivatives,

**Fig. 1.** Selected lines of EtNCO. The grey areas indicate the observed spectra smoothed up to 3 km s<sup>-1</sup> for optimal line visualisation; while the red and blue lines represent the best LTE fit for the single EtNCO and all the other detected species, respectively. Blue labels are indicating the detected species within each spectral range while the quantum numbers of each EtNCO line are indicated in red. See the text and Table 1 for more details.

such as ethanol ( $C_2H_5OH$ , hereafter EtOH; Requena-Torres et al. 2006), ethyl cyanide ( $C_2H_5CN$ , hereafter EtCN; Zeng et al. 2018), and recently ethyl mercaptan ( $C_2H_5SH$ , hereafter EtSH; Rodríguez-Almeida et al. 2021), G+0.693 represents an excellent candidate for the search of EtNCO and other isocyanates.

### 2. Observations

A high sensitivity spectral survey was carried out towards G+0.693. We used both IRAM 30m (Granada, Spain) and Yebes 40m telescopes (Guadalajara, Spain). The observations were centred at  $\alpha(J2000.0) = 17^{h}47^{m}22^{s}$ , and  $\delta$ (J2000.0) =  $-28^{\circ}21'27''$ . The position switching mode was used in all the observations with the off position located at an offset  $\Delta \alpha = -885$ ",  $\Delta \delta = 290$ ". For the IRAM 30m observations, the dual polarisation receiver EMIR was used connected to the fast Fourier transform spectrometers (FFTS), which provided a channel width of 200 kHz in the radio windows from 71.8 to 116.7 GHz and from 124.8 to 175.5 GHz. The observations with the Yebes 40m radiotelescope (project number 20A008, PI Jiménez-Serra) used the Nanocosmos Q-band (7 mm) HEMT receiver (Tercero et al. 2021). The receiver was connected to 16 FFTS providing a channel width of 38 kHz and a bandwidth of 18.5 GHz per lineal polarisation, covering the frequency range between 31.3 GHz and 50.6 GHz. See Zeng et al. (2020) and Rivilla et al. (2021b) for a more detailed description of the observations.

#### 3. Analysis and results

For the line identification of the molecular species, we have used the MADCUBA software<sup>2</sup>. This is supported by the Spectral Line Identification and Modelling (SLIM) tool, which generates a synthetic spectra under the assumption of Local Thermodynamic Equilibrium (LTE) conditions and also considering line opacity effects (Martín et al. 2019). The free parameters of the fits are: the column density (N), the excitation temperature ( $T_{ex}$ ), the full width at half maximum (*FWHM*) and the local standard of rest velocity ( $v_{LSR}$ ). For the LTE analysis of each molecular species, we have also considered the emission from other molecules previously identified in our spectral survey that could potentially produce line contamination (Requena-Torres et al. 2006, 2008; Zeng et al. 2018; Rivilla et al. 2019; Jiménez-Serra et al. 2020; Rivilla et al. 2020, 2021b,a; Rodríguez-Almeida et al. 2021).

For each molecule analysed in this work, we have listed the details of the spectroscopy in Appendix A.

#### 3.1. Detection of EtNCO

Figure 1 shows the brightest lines of EtNCO (details of the spectroscopy in Table A.1) detected at levels above  $5\sigma$  in integrated intensity towards G+0.693, which add up to a total of 8 transitions. Five of them appear unblended, while the other three are slightly blended with known (and identified) molecular species (see Table 1). The contamination from unidentified lines is negligible for these transitions, except for the line at 33.966 GHz which shows a small excess with respect to the LTE fit. The remaining lines of EtNCO with line intensities predicted by the LTE fit at levels above  $5\sigma$  are strongly blended with emission of other species. It is worth mentioning that all clear transitions have been detected in the 7 mm radio window, which is less affected by line overlaps. The LTE fit was carried out by fixing FWHM and  $v_{LSR}$  to 21 km s<sup>-1</sup> and 68 km s<sup>-1</sup>, respectively, giving a  $T_{\text{ex}} = 10 \pm 2$  K and  $N = (8.1 \pm 1.3) \times 10^{12}$  cm<sup>-2</sup>, To calculate the molecular abundance with respect to  $H_2$  (all the abundances through the text are given with respect to  $H_2$ , unless otherwise mentioned), we have used  $N_{\rm H_2} = 1.35 \times 10^{23} \text{ cm}^{-2}$  derived by Martín et al. (2008). To estimate the uncertainties of the molecular abundance we have considered the error in the column density obtained with MADCUBA with an additional 15% of uncertainty on account of calibration errors. We obtain a molecular abundance of  $(4.7-7.3) \times 10^{-11}$ . With the results obtained from EtNCO and the derived column density of MeNCO towards G+0.693 (Zeng et al. 2018), a ratio MeNCO / EtNCO =  $8 \pm 1$  is obtained.

<sup>&</sup>lt;sup>2</sup> MADCUBA is a software developed by the Centro de Astrobiología (CSIC-INTA) located in Madrid (Spain). https://cab.inta-csic.es/madcuba/index.html.

**Table 1.** Spectroscopic and information of the LTE fitting of the selected lines of EtNCO shown in Figure 1. The frequency, quantum numbers (QNs) the energy of the upper level ( $E_u$ ), logarithm of the Einstein coefficients (log  $A_{ul}$ ), root mean square (rms) of the analysed spectral region, integrated intensity ( $\int T_A^* d\nu$ ) and signal-to-noise ratio in integrated intensity (S/N) are given.

Frequency	QNs	Eu	$\log A_{ul}$	rms	$\int T_A^* d\nu$	S/N <sup>b</sup>	blending
(GHz)	$(J_{K_a'',K_c''}'^{-} J_{K_a',K_c'}')$	(K)	$(s^{-1})$	(mK)	$(\mathbf{m}\mathbf{K}\mathbf{k}\mathbf{m}\mathbf{s}^{-1})^a$		
32.537109	$6_{1,6} - 5_{1,5}$	6.0	-5.4198	1.5	61	7	blended with HC <sub>9</sub> N
33.545973	$6_{0,6} - 5_{0,5}$	5.7	-5.3818	1.2	67	10	clean

46.895390	$8_{1,8} - 7_{0,7}$	10.7	-5.3581	2.7	77	5	blended with unidentified species

**Notes.** <sup>(a)</sup> Integrated intensity derived from MADCUBA LTE fit, see Section 3 for details. <sup>(b)</sup>  $S/N = \left(\int T_A^* d\nu\right) / \left[rms\left(\frac{\Delta \nu}{FWHM}\right)^{\circ} FWHM\right]$ , where  $\Delta \nu$  represents the spectral resolution of the data in velocity units.

**Fig. 2.** Selected lines of  $H_2NCO^+$ . See Figure 1 for a description of the information given in the plot. In this case, the LTE fit was carried out separating ortho (o- $H_2NCO^+$ ) and para (p- $H_2NCO^+$ ) species (see the text for details) which are indicated above each panel. See Table B.1 for a complete description of the quantum numbers.

# 3.2. Detection of $H_2NCO^+$ and search for other isocyanates

 $H_2NCO^+$  (see Table A.1 for the spectroscopic references) has been already reported towards L483 (Marcelino et al. 2018) and tentatively detected towards Sgr B2 (Gupta et al. 2013). Since the  $T_{ex}$  towards G+0.693 is low, we have separated ortho and para states for the analysis (energy difference ~15 K; Gupta et al. 2013).

In Figure 2 and Table B.1 we show the H<sub>2</sub>NCO<sup>+</sup> transitions detected towards G+0.693: 6 transitions of the ortho state (K<sub>a</sub> odd, o-H<sub>2</sub>NCO<sup>+</sup>), 3 of which are unblended, and 3 transitions of the para state (K<sub>a</sub> even, p-H<sub>2</sub>NCO<sup>+</sup>) which appear blended with other species. The LTE fits of the ortho and para states have been obtained separately. For o-H<sub>2</sub>NCO<sup>+</sup>, we fixed  $v_{\rm LSR}$  and FWHM at 69 and 18 km s<sup>-1</sup>, respectively, obtaining  $N = (1.1 \pm 0.2) \times 10^{12}$  cm<sup>-2</sup> and  $T_{\rm ex} = 7 \pm 1$  K. For the para states, we have assumed the same  $T_{\rm ex}$  and obtained  $N = (6.3 \pm 1.7) \times 10^{11}$  cm<sup>-2</sup>. The total N (ortho + para) gives  $(1.7 \pm 0.2) \times 10^{12}$  cm<sup>-2</sup> and an abundance of  $(1.1-1.5) \times 10^{-11}$ (Figure 3).

We have also searched for other isocyanates, namely: isocyanate radical (NCO) – previously found towards L483

(Marcelino et al. 2018) – vinyl isocyanate (C<sub>2</sub>H<sub>3</sub>NCO), cyanogen isocyanate (NCNCO) and ethynyl isocyanate (HC-CNCO) with the references used to search for them listed in Table A.1. Since none of them were detected, a  $3\sigma$  upper limit to their column densities have been measured using in each case the cleanest and brightest transition in the dataset (presented in the Appendix C). The derived upper limits are  $< 1.4 \times 10^{13}$  cm<sup>-2</sup> for NCO,  $< 1.2 \times 10^{12}$  cm<sup>-2</sup> for NCNCO,  $< 2.5 \times 10^{12}$  cm<sup>-2</sup> for trans-C<sub>2</sub>H<sub>3</sub>NCO,  $< 9.3 \times 10^{12}$  cm<sup>-2</sup> for cis-C<sub>2</sub>H<sub>3</sub>NCO and  $< 8.9 \times 10^{12}$  cm<sup>-2</sup> for HCCNCO (see Table C.1).

#### 4. Discussion

#### 4.1. Isocyanate family in G+0.693

We have plotted in Figure 3 the abundances of the isocyanates already detected in G+0.693 (HNCO and MeNCO; Zeng et al. 2018) together with the ones reported in this work (detected: EtNCO and H<sub>2</sub>NCO<sup>+</sup>, and non-detected upper limits: NCO, cis/trans-C<sub>2</sub>H<sub>3</sub>NCO and NCNCO). Among the detected species, the molecular abundances decrease when increasing the chemical complexity (Figure 3): HNCO > MeNCO > EtNCO. Contrary, the simplest species, the radical NCO, is not detected, with

an upper limit that is a factor of 5 lower than the abundance of MeNCO. The high reactivity of this radical could explain its low gas-phase abundance.

Fig. 3. Molecular abundances with respect to  $H_2$  of the isocyanates targeted towards G+0.693.

The ratio ethyl/vinyl (i.e. EtNCO /  $C_2H_3NCO$ ) gives > 3.7 and > 1.5 for the cis and trans isomers of  $C_2H_3NCO$ , respectively. This is in contrast with the ethyl/vinyl ratio found towards G+0.693 in cyanides ( $C_2H_5CN/C_2H_3CN\sim0.5$ , Zeng et al. 2018) and amines ( $C_2H_5NH_2$  /  $C_2H_3NH_2 \sim 0.7$ , Zeng et al. submitted).

The ratio between HNCO and its protonated species is  $H_2NCO^+$  / HNCO is ~0.5×10<sup>-3</sup>, which is around five times lower than that found towards the cold core L483 of  $\sim 2.5 \times 10^{-3}$  (Marcelino et al. 2018). This might indicate that the  $H_2NCO^+$  / HNCO ratio decreases with the kinetic temperature of the source (~50-150 K in G+0.693 and ~10 K in L483; Zeng et al. 2018 and Agúndez et al. 2019, respectively). A similar behaviour has been recently observed for HCNH<sup>+</sup> / HCN towards a sample of massive star-forming regions, where the ratio varies from 0.1–0.05 in starless (i.e. cold) sources (in agreement with the value found in the low-mass cold core L1544 of ~0.05 to  $(1-5)\times10^{-3}$  in protostellar (i.e. hot) sources; Quénard et al. 2017; Fontani et al. 2021, respectively). These authors proposed that the distinct values are due to different formation routes of HCNH<sup>+</sup> at low and hot temperatures. Further observations of H<sub>2</sub>NCO<sup>+</sup> towards new sources, and dedicated chemical models (see also Section 4.3) are needed to understand how the  $H_2NCO^+$  / HNCO varies with the gas temperature.

#### 4.2. Methyl-to-ethyl ratios in the ISM

The detection of EtNCO in the ISM, and the recent confirmation of EtSH (Rodríguez-Almeida et al. 2021), led us to study the methyl / ethyl (Me / Et) ratios in different molecular families in G+0.693 and other interstellar regions. In Figure 4 we have compared the Me / Et ratio in G+0.693 with those found in the massive hot cores G31.41+0.31, Orion KL, and Sgr B2N, and the low-mass hot corino IRAS 16293-2422. We have considered different chemical families: alcohols (-OH), nitriles (-CN), formiates (-HCOO), thiols (-SH) and isocyanates (-NCO).

Figure 4 shows that in G+0.693 the observed ratio MeNCO / EtNCO~8 is 2-4 times lower than the ratios for the formiates, alcohols and thiols (32, 24 and 16, respectively) and ~4 times higher than the MeCN / EtCN ratio.

Within each source, the Me / Et ratio of formiates, alcohols and thiols fall within the same range considering the uncertainties. However, the Me / Et ratio is clearly lower in the N-bearing species: isocyanates (for which only the G+0.693 value is available) and nitriles. This suggests a more efficient production of EtNCO and EtCN, compared to their methyl-counterparts, than others ethyl-derivatives.

Article number, page 4 of 9

#### 4.3. Formation of $C_2H_5NCO$ and $H_2NCO^+$ and in the ISM

The interstellar formation of the simplest isocyanates, HNCO and CH<sub>3</sub>NCO, have been studied both theoretically (e.g. Quan et al. 2010; Cernicharo et al. 2016; Martín-Doménech et al. 2017; Quénard et al. 2018; Majumdar et al. 2018) and experimentally (Ligterink et al. 2017; Maté et al. 2018). However, little is known about EtNCO and  $H_2NCO^+$ .

Regarding EtNCO, there is no reaction proposed in UMIST (McElroy et al. 2013) or KIDA (KInetic Database for Astrochemistry; Wakelam et al. 2012) chemical databases. Sewiło et al. (2019) proposed the ion-molecule reaction in the gas phase  $C_2H_5OH_2^+$  + HNCO  $\rightarrow C_2H_5NCO$  + H<sub>2</sub>O. Despite the viability of the reaction, the abundance of a protonated species normally decreases by few orders of magnitude with respect to the nonprotonated one, as we have seen e.g. with H<sub>2</sub>NCO<sup>+</sup> and HNCO towards G+0.693 (H<sub>2</sub>NCO<sup>+</sup>/ HNCO~ $0.5 \times 10^{-3}$ ). Since the abundance of EtOH towards G+0.693 is ~ $5 \times 10^{-9}$  (Requena-Torres et al. 2006), the expected abundance of  $C_2H_5OH_2^+$  would be of the order of  $10^{-12}$ , below the derived abundance of EtNCO. Therefore, it seems unlikely that C<sub>2</sub>H<sub>5</sub>OH<sup>+</sup><sub>2</sub> would be a progenitor of EtNCO. Another possible formation pathway could involve analogous routes to that proposed for MeNCO. As discussed by Majumdar et al. (2018), MeNCO can be efficiently formed on the dust grains by the radical-radical reaction  $CH_3$  +  $NCO \rightarrow CH_3NCO$ , which has been also proven experimentally (Ligterink et al. 2017). Therefore, the analogous grain surface reaction  $C_2H_5 + NCO \rightarrow C_2H_5NCO$  might play an important role in the production of this species, although further experimental and/or theoretical work is needed to confirm this hypothesis.

Regarding H<sub>2</sub>NCO<sup>+</sup>, Marcelino et al. (2018) suggested the thermodynamically possible ion-molecule reaction NH<sub>3</sub> +  $HCO^+ \rightarrow H_2NCO^+ + H_2$ . This process is exothermic but clearly competes with the -probably- faster acid-base channel, i.e.,  $HCO^+ + NH_3 \rightarrow CO + NH_4^+$ . Another possible reaction, proposed in the UMIST database, involves the ion-molecule reaction HNCO<sup>+</sup> + H<sub>2</sub>  $\rightarrow$  H<sub>2</sub>NCO<sup>+</sup> + H. HNCO<sup>+</sup> could be obtained by photoionization (HNCO first ionization potential ~ 11.60 eV; Holzmeier et al. 2015) through secondary photons, since the cosmic-ray ionisation rate is high in the Galactic Centre (Goto 2013). A similar ion-molecule reaction was proposed by Iglesias (1977) with NCO<sup>+</sup> and H<sub>2</sub>. However, none of these ions are detected in the ISM up to date. Alternative routes involve the gas phase proton transfer with a more acidic compound: HNCO +  $HX^+ \rightarrow H_2NCO^+ + X$ . The best candidate is  $H_3^+$  due to its high abundance in the ISM (Oka 2006) and considering that its gas basicity is lower than HNCO (4.4 versus 7.8 eV, respectively; Hunter & Lias 1998). This reaction is also proposed in both KIDA and UMIST databases with a temperature-dependent reaction rate that decreases in a factor of  $\sim 3$  when the temperature goes from 10 K to 100 K; which could explain the differences seen in the  $H_2NCO^+$  / HNCO ratios towards L483 and G+0.693.

#### 5. Conclusions

In this Letter we report the detection of EtNCO (for the first time in the ISM) and H<sub>2</sub>NCO<sup>+</sup> towards the molecular cloud G+0.693-0.027. We derived molecular abundances of  $(6\pm 2)\times 10^{-11}$  and  $(1.3\pm 0.5)\times 10^{-11}$ , respectively. While the formation of EtNCO is more likely to proceed on the surface of dust grains, H<sub>2</sub>NCO<sup>+</sup> is possibly formed via the proton exchange of of H<sub>3</sub><sup>+</sup> with HNCO, as suggested by the change in the abundance ratio H<sub>2</sub>NCO<sup>+</sup> / HNCO with temperature.

We have also studied the full inventory of the isocyanate family towards G+0.693. The relative abundance of

Fig. 4. Comparison of MeX / EtX ratios among different regions of the ISM; where X = HCOO, OH, SH, NCO and CN (from right to left). The data has been taken from: Zeng et al. (2018), Rodríguez-Almeida et al. (2021) and this work for G+0.693-0.027; Kolesniková et al. (2014), López et al. (2014), Tercero et al. (2015) and Kolesniková et al. (2018) for Orion KL; Belloche et al. (2009) and Kolesniková et al. (2018) for Sgr B2N; Mininni et al. (2020), Colzi et al. (2021) and Mininni et al. (in prep) for G31.41+0.31; Drozdovskaya et al. (2019) for IRAS 16293-2422.

HNCO:MeNCO:EtNCO is 1:1/55:1/447, which implies a decrease by a factor of 10 progressively going from HNCO to MeNCO and to EtNCO.

We have compared the Me / Et ratios among functional groups derived towards G+0.693 and several Galactic hot cores / corinos. Within each source, the values of HCOOMe / HCOOEt and MeOH / EtOH are similar, which is also followed by the MeSH / EtSH ratio towards G+0.693. However, the Me / Et ratio for the N-bearing compounds (isocyanates and nitriles) are lower, which might indicate a more efficient production of their associated ethyl-derivatives.

IRAM is supported by the National Institute for Universe Sciences and Astronomy/National Center for Scientific Research (France), Max Planck Society for the Advancement of Science (Germany), and the National Geographic Institute (IGN) (Spain). The 40m radio telescope at Yebes Observatory is operated by the IGN, Ministerio de Transportes, Movilidad y Agenda Urbana. L.F.R.-A., V.M.R. and L.C. acknowledge support from the Comunidad de Madrid through the Atracción de Talento Investigador Modalidad 1 (Doctores con experiencia) Grant (COOL:Cosmic Origins of Life; 2019-T1/TIC-15379). I.J.-S. and J.M.-P. have received partial support from the Spanish State Research Agency (AEI) project number PID2019-105552RB-C41. We also acknowledge support from the Spanish National Research Council (CSIC) through the i-Link project number LINKA20353. PdV and BT thank the support from the European Research Council through Synergy Grant ERC-2013-SyG, G.A. 610256 (NANOCOSMOS) and from the Spanish Ministerio de Ciencia e Innovación (MICIU) through project PID2019-107115GB-C21. BT also thanks the Spanish MICIU for funding support from grant PID2019-106235GB-I00.

# Appendix A: Spectroscopic information of the isocyanates searched towards G+0.693

In Table A.1 we have introduced all the molecules searched in our spectral survey, each one with its pertinent references for the line list and dipole moments.

For EtNCO, the spectral predictions were done re-evaluating the ro-vibrational partition function in a similar way as with MeNCO by Cernicharo et al. (2016) accounting only for the vibrational states below 2.6 GHz. See the details in Colzi et al. 2021 (Appendix B.2).

# Appendix B: Observed transitions and line parameters derived from the LTE fit of H<sub>2</sub>NCO<sup>+</sup>

In Table B.1 we have listed the complete description of the lines of  $H_2NCO^+$  plotted in Figure 1. The transition of  $o-H_2NCO^+$  at 100.307 GHz ( $5_{1,5} - 4_{1,4}$ ,  $E_u = 13.5$  K) is not shown, and it has not been considered for the fit, because it is heavily blended with CH<sub>3</sub>OCHO (line at 100.308 GHz; intensity ~ 60 mK vs. ~ 7 mK for  $H_2NCO^+$ ).

Note that both ortho and para  $H_2NCO^+$  CDMS entries incorporate the <sup>14</sup>N nuclear spin hyper-fine splitting, but in our data these lines are unresolved. Hence, for simplicity, the F quantum numbers have been omitted from Figure 2 (see Table B.1 for a complete description of the lines and quantum numbers).

# Appendix C: Selected lines for computing the upper limits

In Table C.1 we have listed the brightest and cleanest lines for the column density upper limit determination for the non-detected isocyanates, namely: NCO, cis/trans- $C_2H_3NCO$  and NCNCO.

# Appendix D: Molecular abundances of the isocyanates searched towards G+0.693

In Table D.1 we list the values of the molecular abundances of the isocyanates studied in this work with respect to  $H_2$ , which are plotted in Figure 3. Additionally, we have also included the values of the column density together with the errors derived from the LTE fit with MADCUBA. The uncertainties of the molecular abundances are considering the errors derived from the column density and an additional 15% that consider the calibration errors.

 Table A.1. Spectroscopic information and references for the molecules studied in this work.

Molecule	Catalogue	Tag	Dipole moment	Line list
C <sub>2</sub> H <sub>5</sub> NCO	MADCUBA <sup>a</sup>		Sakaizumi et al. (1976)	Heineking et al. (1994); Kolesniková et al. (2018)
$H_2NCO^+$	CDMS	044516	Lattanzi et al. (2012)	Gupta et al. (2013)
NCO	CDMS	042503	Saito & Amano (1970)	Kawaguchi et al. (1985)
cis-C <sub>2</sub> H <sub>3</sub> NCO	MADCUBA <sup>a</sup>		Bouchy & Roussy (1977)	Kirby & Kroto (1978)
trans-C <sub>2</sub> H <sub>3</sub> NCO	MADCUBA <sup>a</sup>		Bouchy & Roussy (1977, 1979)	Kirby & Kroto (1978)
NCNCO	MADCUBA <sup>a</sup>		Hocking & Gerry (1976)	Hocking & Gerry (1976)
HCCNCO	MADCUBA <sup>a</sup>		Assumed <sup>b</sup>	Ross et al. (1992)

Notes.

<sup>(a)</sup> The entry was imported into MADCUBA using the spectroscopic works listed in the table. <sup>(b)</sup> Since there is no value reported in the literature, the \*.cat file was generated assuming  $\mu_a = 1.0 \text{ D}$ .

**Table B.1.** Spectroscopic and information of the LTE fitting of the selected lines of  $o-H_2NCO^+$  and  $p-H_2NCO^+$  shown in Figure 2. The frequency, the QNs, the energy of the upper level (E<sub>u</sub>), the logarithm of the intensity (at 300 K),  $\int T_A^* d\nu$  and S/N in integrated intensity of the lines are given.

Molecule	Frequency	QNs <sup>a</sup>	Eu	log Intensity	$\int T^*_{A} dv^b$	S/N <sup>b</sup>

	101.13223	$5_{0.5}$ - $4_{0.4}$ F = 5 - 5	14.6	-4.5138		

Notes.

<sup>(a)</sup> The CDMS entry accounts for the hyper-fine splitting because of the nuclear spin of <sup>14</sup>N. Hence the QNs are presented in this way:  $J''_{K'_{4},K''_{c}} \rightarrow J'_{K'_{4},K'_{c}}$   $F = F'' \rightarrow F'$ . <sup>(b)</sup> In our data, the hyper-fine splitting is unresolved. Thus, the S/N is calculated by the sum of the individual  $F'' \rightarrow F'$  components.
