Anomaly cascade in (2+1)D fermionic topological phases

Daniel Bulmash and Maissam Barkeshli
Condensed Matter Theory Center and Joint Quantum Institute,
Department of Physics, University of Maryland, College Park, Maryland 20742 USA

We develop a theory of anomalies of fermionic topological phases of matter in (2+1)D with a
general fermionic symmetry group \(G_f\). In general, \(G_f\) can be a non-trivial central extension of the
bosonic symmetry group \(G_b\) by fermion parity \((-1)^F\). We encounter four layers of obstructions to
gauging the \(G_f\) symmetry, which we dub the anomaly cascade: (i) An \(H^1(G_b, Z_T)\) obstruction to
extending the symmetry permutations on the anyons to the fermion parity gauged theory, (ii) An
\(H^2(G_b, \ker r)\) obstruction to extending the \(G_b\) group structure of the symmetry permutations to
the fermion parity gauged theory, where \(r\) is a map that restricts symmetries of the fermion parity
gauged theory to the anyon theory, (iii) An \(H^3(G_b, Z_2)\) obstruction to extending the symmetry
fractionalization class to the fermion parity gauged theory, and (iv) the well-known \(H^4(G_b, U(1))\)
obstruction to developing a consistent theory of \(G_b\) symmetry defects for the fermion parity gauged
theory. We describe how the \(H^2\) obstruction can be canceled by anomaly inflow from a bulk
(3+1)D symmetry-protected topological state (SPT) and also its relation to the Arf invariant of
spin structures on a torus. If any anomaly in the above sequence is non-trivial, the subsequent ones
become relative anomalies. A number of conjectures regarding symmetry actions on super-modular
categories, guided by general expectations of anomalies in physics, are also presented.

I. INTRODUCTION

Topological phases of matter in (2+1)D can exhibit the remarkable phenomenon of symmetry fractionalization: in the presence of a global symmetry group \( G \), topologically non-trivial quasi-particles can carry fractional quantum numbers under \( G \). Such phases are called symmetry-enriched topological phases (SETs) and are described in full generality using the mathematics of \( G \)-crossed modular tensor categories [1, 2]. Remarkably, some patterns of symmetry fractionalization yield SETs that, while they are mathematically consistent in the absence of a background \( G \) gauge field, cannot be consistently coupled to a \( G \) gauge field. The physical interpretation of this inconsistency is that such SETs cannot occur in a purely (2+1)D system with the symmetry generated on-site [1, 3–5]. In the language of quantum field theory, such SETs are said to have a ‘t Hooft anomaly.

Anomalies provide crucial information about a phase of matter; they are renormalization group invariants which connect microscopic and low-energy physics, leading, for example, to generalizations of the famed Lieb-Schulz-Mattis theorem [6]. Anomalies are subject to the bulk-boundary correspondence, in the sense that the classification of anomalies in \( d \) space-time dimensions is believed to be equivalent to the classification of invertible topological phases in \((d + 1)\) space-time dimensions [7]. In particular, anomalous \((2+1)\)D SETs can exist on the surface of \((3+1)\)D symmetry-protected topological phases (SPTs) [3, 4, 8–23]. This remarkable fact begs the question of understanding anomaly inflow - can we determine physical processes on the boundary which are sensitive to the anomaly and then see how the non-trivial bulk cancels that anomaly?

For bosonic SETs, the ‘t Hooft anomaly is relatively well-understood [1, 3–5, 22]. A bosonic \((3+1)\)D \(G\)-SPT is (partially) specified by an element of the cohomology group \( H^4(G, U(1)) \), and this element dictates the inconsistency of fusion and braiding of symmetry defects together with anyons in the \((2+1)\)D boundary SET. The data specifying a \((3+1)\)D fermionic SPT (FSPT) has much more structure; FSPT phases form [24] a torsor over the cohomology groups \( H^1(G_b, \mathbb{Z}_{2T}) \), \( H^2(G_b, \mathbb{Z}_2) \), and \( H^3(G_b, U(1)) \), where \( G_b \) is the “bosonic” symmetry group obtained by modding out fermion parity symmetry. The appearance of this data as an inconsistency of the \((2+1)\)D boundary SET is only partially understood [25, 26]. Ref. [23] recently showed how in general, given any \((2+1)\)D fermionic SET (FSET), one can identify the bulk SPT using a state sum construction. However the results of [23] do not directly explain the appearance of the above cohomology groups in terms of an inconsistency of the boundary \((2+1)\)D SET.

The main aim of this paper is to obtain a detailed and general understanding of the ‘t Hooft anomaly of any \((2+1)\)D FSET, and in particular the appearance of the above cohomology groups. The most general description of the anomaly is that it is an obstruction to gauging the full global symmetry group \( G_f \). Rather than gauging \( G_f \) all at once, our approach is to gauge fermion parity first, which is always possible [27]. If the \( G_b = G_f/\mathbb{Z}_2^f \) symmetry is to be preserved after gauging, the data specifying symmetry fractionalization must be lifted to the parity-gauged theory. We break the process of finding a consistent lift into a sequence of physically meaningful steps, each of which may be obstructed; the obstruction to each step is given by a piece of data used in specifying a \((3+1)\)D FSPT.
A. Summary of main results

Below we give a brief summary of our results, with additional technical details presented in the main part of the paper.

We start with a super-modular category \( \mathcal{C} \), which is a unitary braided fusion category (UBFC) that captures the braiding and fusion properties of the anyons. A super-modular category contains a single “invisible” particle \( \psi \), which braids trivially with all other particles and which physically corresponds to the local fermion of the system. We then consider the minimal modular extensions \( \tilde{\mathcal{C}}_\nu \) of the super-modular category. A minimal modular extension is a unitary modular tensor category (UMTC) that characterizes the phase obtained by gauging fermion parity. In particular \( \tilde{\mathcal{C}}_\nu \) characterizes properties of the anyons, the local fermion \( \psi \), and the fermion parity vortices. It was recently proved that every super-modular category admits a minimal modular extension \([27]\), and therefore, according to the “16-fold way” theorem \([28]\), admits exactly 16 distinct minimal modular extensions labeled by \( \nu = 0, \ldots, 15 \).

In the absence of symmetry, it is expected that a (2+1)D fermionic topological phase can be fully specified by either a choice of \( (\mathcal{C}, c_-) \) or \( (\tilde{\mathcal{C}}_\nu, c_-) \), where \( c_- \) is the chiral central charge of the theory which, physically, determines the system’s thermal Hall conductivity. \( \mathcal{C} \) determines the theory modulo a fermionic invertible phase (e.g. up to stacking with \( p + ip \) superconductors), and therefore determines \( c_- \mod 1/2 \). In contrast, \( \tilde{\mathcal{C}}_\nu \) determines the phase modulo a bosonic invertible phase, and therefore determines \( c_- \mod 8 \). Two different minimal modular extensions \( \tilde{\mathcal{C}}_\nu \) and \( \tilde{\mathcal{C}}_{\nu'} \) have central charges that differ by \( \nu - \nu' \)/2 mod 8.

Fermionic systems always have a \( \mathbb{Z}_2 \) fermion parity symmetry \((-1)^F\), which generates a symmetry group we call \( \mathbb{Z}_2^f \). The full symmetry group \( G_f \) of a fermionic system is in general a central extension of \( G_b = G_f/\mathbb{Z}_2^f \) by \( \mathbb{Z}_2^f \), characterized by a cocycle

\[
\omega_2 \in \mathbb{Z}^2(G_b, \mathbb{Z}_2). \tag{1}
\]

In this paper, we assume that we are given \( G_f \) symmetry fractionalization data on \( \mathcal{C} \); we review what this data entails in Sec. IV B. Given a minimal modular extension \( \tilde{\mathcal{C}}_\nu \), our aim is to lift the given symmetry fractionalization data from \( \mathcal{C} \) to \( \tilde{\mathcal{C}}_\nu \). That is, we wish to gauge fermion parity while preserving the \( G_b \) symmetry. We perform this procedure systematically and characterize the cascade of obstructions that appear along the way.

1. Anomaly cascade: first layer

The first step is to define a lifted “topological symmetry” of \( \tilde{\mathcal{C}} \), that is, a map

\[
[p] : G_b \rightarrow \text{Aut}_{LR}(\tilde{\mathcal{C}}_\nu). \tag{2}
\]

The group \( \text{Aut}_{LR}(\tilde{\mathcal{C}}_\nu) \), where the subscript refers to “locality-respecting,” was defined in \([29]\) and will be reviewed in Sec. IV B; while conceptually similar to the group \( \text{Aut}(\tilde{\mathcal{C}}_\nu) \) of braided autoequivalences of \( \mathcal{C} \) modulo certain gauge redundancies, it reflects the fact that symmetry gauge transformations are constrained in fermionic systems.

For a particular \( \nu \), generically not all elements of \( \text{Aut}_{LR}(\mathcal{C}) \) can be lifted to elements of \( \text{Aut}_{LR}(\tilde{\mathcal{C}}_\nu) \). Thus we encounter the first possible obstruction, which concerns whether there exists some \( \nu \) such that for every \( \mathbf{g} \in G_b \), the autoequivalence \([p_\mathbf{g}] \in \text{Aut}_{LR}(\mathcal{C}) \) can be lifted to an element \([\tilde{p}_\mathbf{g}] \in \text{Aut}_{LR}(\tilde{\mathcal{C}}_\nu) \).

In the case that there does not exist a \( \nu \) such that one can lift every element \([\rho_\mathbf{g}] \) to \([\tilde{\rho}_\mathbf{g}] \in \text{Aut}_{LR}(\tilde{\mathcal{C}}_\nu) \), a weaker lift may be possible. In particular, it may be possible that there exists at least one pair \( \nu_1 \) and \( \nu_2 \), such that a representative of each \([\rho_\mathbf{g}] \) lifts to a map

\[
\tilde{\rho}_\mathbf{g} : \tilde{\mathcal{C}}_{\nu_1} \rightarrow \tilde{\mathcal{C}}_{\nu_2}. \tag{3}
\]

By comparing with the classification of (3+1)D fermion SPTs, which defines the anomaly of (2+1)D fermionic topological phases, we conjecture that the existence of such a weak lift is unobstructed:

**Conjecture I.1.** Given a super-modular category \( \mathcal{C} \) with an action \([\rho_\mathbf{g}] : G_b \rightarrow \text{Aut}_{LR}(\mathcal{C}) \), there always exists at least one pair \( \nu_1 \) and \( \nu_2 \) such that there exists a map \( \tilde{\rho}_\mathbf{g} : \tilde{\mathcal{C}}_{\nu_1} \rightarrow \tilde{\mathcal{C}}_{\nu_2} \) and \( \tilde{\rho}_\mathbf{g} \) restricts to a representative \( \rho_\mathbf{g} \) on \( \mathcal{C} \).

Next, regarding lifts of the form Eq. 3, we prove the following:

**Theorem I.2.** Let \( \rho_\mathbf{g} : \mathcal{C} \rightarrow \mathcal{C} \) be a unitary map. Then any pair \( (\nu_1, \nu_2) \) satisfying Eq. 3 must have \( \nu_1 = \nu_2 \).
This follows from the fact that the number of anyons, quantum dimensions, and topological twists must be invariant under the map $\hat{\rho}_g$, which fixes $\nu_1 = \nu_2$ by the Gauss sum. Furthermore, we have

**Theorem I.3.** Let $\rho_g : \mathcal{C} \to \mathcal{C}$ be an anti-unitary map. Then the pair $(\nu_1, \nu_2)$ satisfying Eq. 3 must necessarily satisfy $e^{2\pi i c_{\nu_1}/8} = e^{-2\pi i c_{\nu_1}/8} = e^{2\pi i (c_{\nu_1} + o_1(g)/2)/8}$, for some integer $o_1(g)$. If there are multiple pairs $(\nu_{1,1}, \nu_{1,2})$ satisfying Eq. 3, then $e^{2\pi i c_{\nu_1}/4} = e^{-2\pi i c_{\nu_1}/4} = e^{2\pi i (c_{\nu_1} + o_1(g)/2)/8}$, where $o_1(g)$ is independent of $i$, modulo 2.

A corollary of the above is that:

**Corollary I.4.** A collection of maps $[\rho_g] \in \text{Aut}_{LR}(\mathcal{C})$ for each $g \in G_b$ defines an element $[o_1] \in H^1(G_b, \mathbb{Z}_T)$.

We conjecture that $[o_1]$ is really the obstruction to lifting the symmetry the action, in the following sense:

**Conjecture I.5.** Suppose that for each $g \in G_b$ we are given a lift $\tilde{\rho}_g^{(1)} : \tilde{\mathcal{C}}_{\nu_1} \to \tilde{\mathcal{C}}_{\nu_2}$ of $\rho_g : \mathcal{C} \to \mathcal{C}$. Then there exists a minimal modular extension $\tilde{\mathcal{C}}_{\nu_0}$ with lifts $\tilde{\rho}_g^{(0)} : \tilde{\mathcal{C}}_{\nu_0} \to \tilde{\mathcal{C}}_{\nu_0}$ for every $g \in G_b$ if and only if $[o_1] = 0$.

A well-known example of the above $H^1$ anomaly occurs for the SO(3)$_3$ supermodular category, which was studied in [13] as an example of a $(2+1)$D surface theory for an odd index topological superconductor in the class DIII. (Here SO(3)$_3$ consists of the integer spin representations of the SU(2)$_3$ affine Kac-Moody algebra, which arises in SO(3)$_3$ Chern-Simons theory.) All minimal modular extensions of this theory have central charge $c = 1/4 \mod 1/2$, and no minimal modular extension can be compatible with time-reversal symmetry. This is because a UMTC that is compatible with time-reversal symmetry must have central charge $c = 0 \mod 4$.

2. Anomaly cascade: second layer

Suppose that the $H^1$ anomaly vanishes. Then, according to the discussion above, for each $g \in G_b$, we assume we have an invertible map

$$\tilde{\rho}_g : \tilde{\mathcal{C}}_\nu \to \tilde{\mathcal{C}}_\nu,$$

for at least some subset of the possible values of $\nu$. Unless otherwise stated, we now fix a particular choice of $\nu$ and omit it from our notation.

Next, we need to require that $[\tilde{\rho}_g]$ is a group homomorphism $G_b \to \text{Aut}_{LR}(\tilde{\mathcal{C}})$. We show that there is an obstruction $[o_2] \in H^2(G_b, \ker r)$ to $[\tilde{\rho}_g]$ defining a group homomorphism. Here $r$ is the restriction map,

$$r : \text{Aut}_{LR}(\tilde{\mathcal{C}}) \to \text{Aut}_{LR}(\tilde{\mathcal{C}}|_C) = \text{Aut}_{LR}(\mathcal{C})$$

which has a non-trivial kernel. We characterize $\ker r$ in the following way. First, note that a fermion parity vortex $x$ is called $v$-type if $x \times \psi \neq x$.

**Theorem I.6.** Suppose that the modular S-matrix of $\tilde{\mathcal{C}}$, when restricted to its block involving only $v$-type vortices, is block diagonal with $k$ decoupled blocks. Then if $[\rho] \in \ker r$ and $x$ is a fermion parity vortex, $q(x) = x \times \psi^{q(x)}$, where $q(x) \in \{0,1\}$ is independent of $x$ within a block if $x$ is a $v$-type vortex.

The proof of Theorem I.6 is given in Section VIB.3. Theorem I.6 fully characterizes all possible ways that elements of $\ker r$ can permute the vortices. In Section VI.I, we fully characterize $r \subset \text{Aut}_{LR}(\tilde{\mathcal{C}})$ in cases where permutation actions of the anyons and vortices uniquely determine the Aut groups. In Section VI.E, we conjecture that in general $\ker r = \mathbb{Z}_2$ and we also provide an explicit example of a theory where $k = 2$.

In Section VIB, we will define a special element $[\alpha_\psi] \in \ker r$, such that $\alpha_\psi(\phi) = \phi \times \psi$ for all $v$-type fermion parity vortices $\phi$.

In cases where $\ker r = \mathbb{Z}_2 \cong \{[1], [\alpha_\psi]\}$, the anomaly $[o_2] \in H^2(G_b, \mathbb{Z}_2)$ can be directly related to the physical origin of $H^2(G_b, \mathbb{Z}_2)$ in the classification of $(3+1)$D FSPT phases. Non-trivial data $[n_2] \in H^2(G_b, \mathbb{Z}_2)$ specifying an FSPT can be understood as decorating each codimension-2 trijunction of $G_b$ domain walls with $g, h, gh$ in the $(3+1)$D bulk with a $(1+1)$D Kitaev chain if $n_2(g, h)$ is non-trivial. We show how the anomaly $[o_2]$ arising in the problem of extending the group homomorphism $\rho$ to $\tilde{\rho}$ is related to the presence of Kitaev chains on domain walls in the bulk $(3+1)$D SPT.

Recently, [26] has shown that in the case $G_b = \mathbb{Z}_2^T$, the $H^2(\mathbb{Z}_2^T, \mathbb{Z}_2)$ anomaly corresponds to an anomaly in the action of $T^2$ on the torus Hilbert space of the fermionic topological phase. We generalize their results and show how, for $\ker r = \mathbb{Z}_2$, the non-trivial $[o_2]$ that we find implies that the action of the symmetry operators $\tilde{\rho}_g$ for $g \in G_b$ get
extended on the torus. Letting $|\Psi\rangle_s$ be a state in the Hilbert space of the topological quantum field theory on the torus with a fixed spin structure $s$, we find
\[ \tilde{\rho}_g \tilde{\rho}_h |\Psi\rangle_s = \tilde{\rho}_{gh} (-1)^{\alpha_2(g,h)\text{Arf}(s)} |\Psi\rangle_s \] (6)
where $\alpha_2$ means we are interpreting $\alpha_2 \in \mathbb{Z}_2 \simeq \{0, 1\}$ instead of $\alpha_2 \in \mathbb{Z}_2 \simeq \ker r$. In fact, we show that the element $[\alpha_2] \in \ker r$ discussed above allows us to in general change the symmetry action $\tilde{\rho}_g \rightarrow \tilde{\rho}_g \circ \alpha_2$, which has the effect of changing the symmetry action on the torus Hilbert space by
\[ \tilde{\rho}_g |\Psi\rangle_s \rightarrow \tilde{\rho}_g (-1)^{\text{Arf}(s)} |\Psi\rangle_s \] (7)

As an example, we show that the semion-fermion theory, $U(1)_2 \times U(1)_{-1}$ which exists at the surface of a $\nu = 2$ fermionic topological superconductor in Class DIII, possesses the above $\mathcal{H}^2(G_b, \mathbb{Z}_2)$ obstruction.

We note that the $[\alpha_2]$ anomaly defined above can, a priori, depend on which particular modular extension $\nu$ we consider. We partially prove a conjecture that this does not occur (see Theorem VI.3 and Section VI F):

**Conjecture I.7.** $[\alpha_2] \in \mathcal{H}^2(G_b, \mathbb{Z}_2)$ is the same for every $\nu$ for which we have, for every $g \in G_b$, a consistent set of actions $\tilde{\rho}_g : \tilde{\mathcal{C}}_\nu \rightarrow \tilde{\mathcal{C}}_\nu$.

Finally, we note that there is still a remnant of the $\mathcal{H}^2$ anomaly if the $\mathcal{H}^1$ anomaly is non-trivial. Specifically, one can always define a relative $\mathcal{H}^2$ anomaly for two theories $\mathcal{C}_1$ and $\mathcal{C}_2$ that possess the same $\mathcal{H}^1$ anomaly. This can be done by considering the theory $\mathcal{C}_{12}$ obtained by stacking $\mathcal{C}_1$ and $\tilde{\mathcal{C}}_2$, so that the $\mathcal{H}^1$ anomaly of the stacked theory vanishes, and then computing the resulting $\mathcal{H}^2$ anomaly of $\mathcal{C}_{12}$. The $\mathcal{H}^2$ anomaly of $\mathcal{C}_{12}$ defines the relative $\mathcal{H}^2$ anomaly between $\mathcal{C}_1$ and $\mathcal{C}_2$. This agrees with the $(3+1)$D fermion SPT classification, where the $(3+1)$D fermion SPTs form a torsor over $\mathcal{H}^2$ if the $\mathcal{H}^1$ piece is non-trivial.

3. **Anomaly cascade: third layer**

Assume that the first and second layer obstructions vanish, so that the map $[\tilde{\rho}_g]$ defined in Eq. 4 defines a group homomorphism.

The next task is to determine if the symmetry fractionalization class for $\mathcal{C}$, defined by a set of $U(1)$ phases $\eta_a : G_b \times G_b \rightarrow U(1)$ for each anyon $a$, can be extended to the full modular extension $\tilde{\mathcal{C}}$. In [25], it was shown that there is an anomaly $[\alpha_3] \in \mathcal{H}^3(G_b, \mathbb{Z}_2)$ which quantifies the obstruction to such an extension. The analysis of [25] was restricted to the special case where $G_f = G_b \times \mathbb{Z}_4^f$, with some additional technical assumptions on the symmetry fractionalization on $\mathcal{C}$. Here we provide a completely general discussion which applies to arbitrary group extensions $G_f$ and symmetry fractionalization.

As an example, we compute the $\mathcal{H}^3(G_b, \mathbb{Z}_2)$ obstruction for the case of the doubled semion-fermion theory $\{U(1)_2 \times U(1)_{-1}\}^2$, which exists at the surface of a $\nu = 4$ topological superconductor in class DIII, where $\mathbb{T}^2 = (-1)^F$ so that $G_b = \mathbb{Z}_2^T$, $G_f = \mathbb{Z}_4^T$. We show that this $[\alpha_3]$ class is non-trivial, which matches the expectation from the bulk-boundary correspondence.

As in the $\mathcal{H}^2$ case, a priori there may be multiple different modular extensions $\tilde{\mathcal{C}}_\nu$ for which we have a valid group homomorphism $[\tilde{\rho}_g]$, which leads to a class $[\alpha_3]$ for each such $\nu$. This leads us to the next conjecture:

**Conjecture I.8.** The class $[\alpha_3] \in \mathcal{H}^3(G_b, \mathbb{Z}_2)$ is the same for all $\nu$ for which we have a valid group homomorphism $[\tilde{\rho}]

Just like the $\mathcal{H}^2$ anomaly, we can always define a relative $\mathcal{H}^3$ anomaly between two theories $\mathcal{C}_1$ and $\mathcal{C}_2$ with identical $\mathcal{H}^1$ and $\mathcal{H}^2$ anomalies. That is, we consider $\mathcal{C}_1$ and $\mathcal{C}_2$ to have identical $\mathcal{H}^1$ anomaly, and vanishing relative $\mathcal{H}^2$ anomaly. Then, we can consider the stacked theory $\mathcal{C}_{12}$, which has vanishing $\mathcal{H}^1$ and $\mathcal{H}^2$ anomaly, and for which we can define an $\mathcal{H}^3$ anomaly. The $\mathcal{H}^3$ anomaly of $\mathcal{C}_{12}$ defines the relative $\mathcal{H}^3$ anomaly between $\mathcal{C}_1$ and $\mathcal{C}_2$.

4. **Anomaly cascade: fourth layer**

If all the preceding obstructions vanish, we can define a fermion parity gauged theory described by the modular extension $\tilde{\mathcal{C}}$, and a notion of symmetry fractionalization on $\tilde{\mathcal{C}}$. Thus we can define a fully bosonic topological phase with a symmetry fractionalization class. We can then refer to the theory of $G_b$-crossed modular categories, for which there is an $\mathcal{H}^4(G_b, U(1))$ obstruction to gauging $G_b$, which is now known how to explicitly compute in general [5, 22].
One may think of the first three layers of anomalies as the mixed anomaly between fermion parity and $G_b$ - they are the obstructions to gauging fermion parity while preserving $G_b$ symmetry. If the mixed anomaly vanishes, then this fourth layer characterizes the remaining pure $G_b$ anomaly. In general, there may be multiple different $\nu$ for which we can define the above actions. This leads us to a final conjecture:

**Conjecture I.9.** For every $\nu$ for which we can define symmetry fractionalization on $\hat{C}$, the resulting $H^1(G_b, U(1))$ anomaly is independent of $\nu$.

Just as in the previous cases, even if a theory possess a non-trivial $H^i$ anomaly with $i < 4$, we can always define a relative $H^4$ anomaly between two theories $C_1$ and $C_2$ that have vanishing relative $H^1$, $H^2$, and $H^3$ anomalies.

The rest of this paper is structured as follows. In Sec. II, we review some basic facts about super-modular and spin modular categories and the Hilbert space of a spin modular theory on a torus. In Sec. III, we give a brief review of symmetry fractionalization in bosonic systems, and we summarize symmetries and symmetry fractionalization in fermionic systems in Sec. IV. We then consider each level of the anomaly cascade in order. We prove Theorem I.3 about the $H^1(G_b, \mathbb{Z}_T)$ obstruction in Sec. V. Sec. VI is devoted to a thorough discussion of the $H^2(G_b, \ker r)$ obstruction and its relation to the $H^2(G_b, \mathbb{Z}_2)$ part of the 't Hooft anomaly. In Sec. VII, we give a fully general discussion of the $H^3(G_b, \mathbb{Z}_2)$ obstruction. Sec. VIII contains additional interesting examples, and some summary and discussion appears in Sec. IX.

## II. SUPER-MODULAR AND SPIN MODULAR CATEGORIES AND FERMIONIC TOPOLOGICAL PHASES OF MATTER

There are two equivalent descriptions of a fermionic topological phase of matter. One description uses a super-modular tensor category, denoted $\hat{C}$, along with a chiral central charge $c_-$. In this description, the super-modular tensor category determines $c_- \mod 1/2$. A super-modular tensor category $[28, 30, 31]$ is a unitary braided fusion category with exactly one nontrivial invisible particle $\psi$, which is a fermion and satisfies $Z_2$ fusion rules. “Invisible” means that the double braid

$$M_{a,\psi} = +1$$

(8)

for all $a \in \hat{C}$, “fermion” means that the topological twist $\theta_\psi = -1$, and the $Z_2$ fusion rules means $\psi \times \psi = 1$. Physically, this description tracks the topologically non-trivial quasi-particle content of the phase. The presence of $\psi$ is used to track the presence of a fermion which is topologically trivial in the sense that the fermion can be created or annihilated by a local fermion operator. Different fermionic phases with the same quasi-particle content are distinguished by stacking with $p + ip$ superconductors, each of which changes $c_- \mod 1/2$.

The alternate description is via a spin modular category, denoted $\tilde{C}$, and a chiral central charge $c_-$ which is determined modulo 8 by $\tilde{C}$. A spin modular category is a UMTC together with a preferred choice of fermion $\psi$ which has $Z_2$ fusion rules. Physically, the spin modular category describes the phase after gauging fermion parity, that is, it describes the quasi-particle content of the phase along with the fermion parity vortices. More precisely, $\tilde{C}$ possesses a natural $Z_2$ grading determined by double braids with $\psi$:

$$\tilde{C} = \tilde{C}_0 \oplus \tilde{C}_1$$

(9)

and

$$\tilde{C}_0 \cong C$$

(10)

where $M_{a,\psi} = +1$ if $a \in \tilde{C}_0$ and $M_{a,\psi} = -1$ if $a \in \tilde{C}_1$. Fusion respects this grading. The objects in $\tilde{C}_1$ are physically interpreted as fermion parity vortices, or equivalently symmetry defects of fermion parity symmetry.

The sector $\tilde{C}_1$ can be further decomposed as follows:

$$\tilde{C}_1 = \tilde{C}_\nu \oplus \tilde{C}_\sigma$$

(11)

where

$$\tilde{C}_\nu = \{ a \in \tilde{C}_1 | a \times \psi \neq a \}$$

(12)

and

$$\tilde{C}_\sigma = \{ a \in \tilde{C}_1 | a \times \psi = a \}.$$  

(13)
The two descriptions are related as follows. Every super-modular category \( \mathcal{C} \) admits [27] a minimal modular extension \( \tilde{\mathcal{C}} \), which means that \( \tilde{\mathcal{C}} \) contains \( \mathcal{C} \) as a subcategory, the preferred fermion of \( \tilde{\mathcal{C}} \) is the invisible fermion of \( \mathcal{C} \), and \( \tilde{\mathcal{C}} \) has minimal possible total quantum dimension

\[
D^2 \tilde{\mathcal{C}} = 2D^2 \mathcal{C}.
\] (14)

Every super-modular category has precisely 16 distinct minimal modular extensions \( \tilde{\mathcal{C}}_\nu \), for \( \nu = 0, \ldots, 15 \), and whose chiral central charges modulo 8 differ by \( \nu/2 \). A fermionic topological phase is described either by \( (\mathcal{C}, c_-) \) or by \( (\tilde{\mathcal{C}}_\nu, c_-) \) where the chiral central charge of \( \tilde{\mathcal{C}}_\nu \) is equal to \( c_- \) modulo 8.

We will make use of the following fact [30] about the topological S-matrix of a minimal modular extension \( \tilde{\mathcal{C}} \):

\[
S_{x,y} = \begin{cases} 
S_{x\times \psi,y} & y \in \tilde{\mathcal{C}}_0 \\
-S_{x\times \psi,y} & y \in \tilde{\mathcal{C}}_1
\end{cases}
\] (15)

Note that the second line implies that \( S_{\sigma,y} = 0 \) for \( \sigma \in \tilde{\mathcal{C}}_\sigma \), \( y \in \tilde{\mathcal{C}}_1 \).

As we will see now, the full spin modular category, not just the super-modular tensor category, is required to describe the fermionic system on non-trivial surfaces and with arbitrary spin structures.

### A. Torus degeneracy and spin structure

The spin modular category determines the Hilbert space and the action of the mapping class group of the fermionic topological phase of matter on a topologically non-trivial surface.

Consider the (spatial) torus \( T^2 \) with nontrivial cycles \( \alpha \) and \( \beta \). Let us label the states of the spin modular category as \( |a\rangle_\alpha \), for \( a \in \tilde{\mathcal{C}} \) an anyon. This means that the topological charge as measured through the loop \( \alpha \) is \( a \). Below for ease of notation we drop the subscript \( \alpha \) and keep it implicit in the definition of the state \( |a\rangle \).

Now suppose we have a choice of spin structure \((\mu,\nu)\) where \( \mu = 0 \) corresponds to Neveu-Schwarz (anti-periodic) boundary conditions on the loop \( \alpha \) and \( \mu = 1 \) corresponds to Ramond (periodic) boundary conditions on \( \alpha \), with \( \nu_\beta \) similar for the \( \beta \) loop\(^1\). We drop the \( \alpha \) and \( \beta \) labels in what follows. Let \( \mathcal{H}_{\mu,\nu} \) denote the Hilbert space of the fermionic topological phase on the torus with the chosen spin structure, \( |\Psi\rangle_{\mu,\nu} \in \mathcal{H}_{\mu,\nu} \), and let \( W_x(\gamma) \) denote the Wilson loop of a particle \( x \) around the loop \( \gamma \).

The defining distinction between the different sectors \( (\mu,\nu) \) is in the fermion boundary conditions, which defines the eigenvalue of the fermion Wilson loop \( W_\psi \):

\[
W_\psi(\alpha)|\Psi\rangle_{\mu,\nu} = (-1)^\mu|\Psi\rangle_{\mu,\nu} \\
W_\psi(\beta)|\Psi\rangle_{\mu,\nu} = (-1)^\nu|\Psi\rangle_{\mu,\nu}.
\] (16)

Note that \( W_\psi(\alpha) \) has \(-1\) eigenvalue for the sector with periodic (\( \mu = 1 \)) boundary conditions along the \( \alpha \) cycle. This is because periodic boundary conditions occur when there is a fermion parity vortex threading the conjugate cycle, as can be derived by studying the modular matrices carefully. The \(-1\) then arises due to the mutual statistics between \( \psi \) and \( \nu \).

A basis of states for the fermionic topological phase on a torus is as follows (see e.g. [26] for a recent discussion):

\[
\mathcal{H}_{0,0}: |a\rangle_{00} = \frac{1}{\sqrt{2}}(|a\rangle + |a \times \psi\rangle) \\
\mathcal{H}_{1,0}: \begin{cases} 
|v\rangle_{10} = \frac{1}{\sqrt{2}}(|v\rangle + |v \times \psi\rangle) \\
|\sigma\rangle_{10} = |\sigma\rangle
\end{cases} \\
\mathcal{H}_{0,1}: |a\rangle_{01} = \frac{1}{\sqrt{2}}(|a\rangle - |a \times \psi\rangle) \\
\mathcal{H}_{1,1}: \begin{cases} 
|v\rangle_{11} = \frac{1}{\sqrt{2}}(|v\rangle - |v \times \psi\rangle) \\
|\sigma\rangle_{11} = |\sigma; \psi\rangle
\end{cases}
\] (17)

---

\(^1\) Our convention is slightly unusual because the modular \( T \) transformation does not act linearly on the \( \mu \) and \( \nu \) indices. However, the formulas relevant to us like Eq. 16 are more natural.
where \( a \in \tilde{C}_0, \psi \in \tilde{C}_c, \) and \( \sigma \in \tilde{C}_\sigma. \) Furthermore, \( |\sigma; \psi\rangle \) denotes the state on a torus with a puncture labeled \( \psi. \)

These states on the torus can be built by gluing together states on the 3-punctured sphere, i.e. splitting spaces \( V_{ac}^b \) and their duals \( V_{ab}^c. \) Eq. 17 can be re-expressed in this language as

\[
\mathcal{H}_0 = \left( \bigoplus_{a \in \tilde{C}_0} V_1^{a\langle \pi} \otimes V_{ab\rangle} \right)_{\text{symm}}
\]

\[
\mathcal{H}_1 = \left( \bigoplus_{a \in \tilde{C}_0} V_1^{a\langle \pi} \otimes V_{ab\rangle} \right)_{\text{anti-symm}}
\]

\[
\mathcal{H}_{1,0} = \left( \bigoplus_{b \in \tilde{C}_c} V_{bc\pi} \otimes V_{ab\rangle} \right)_{\text{symm}} \oplus \left( \bigoplus_{\sigma \in \tilde{C}_\sigma} (V_1^{\sigma\pi} \otimes V_{ab\rangle}^\sigma) \right)
\]

\[
\mathcal{H}_{1,1} = \left( \bigoplus_{b \in \tilde{C}_c} V_{bc\pi} \otimes V_{ab\rangle}^\sigma \right)_{\text{anti-symm}} \oplus \left( \bigoplus_{\sigma \in \tilde{C}_\sigma} (V_1^{\sigma\pi} \otimes V_{ab\rangle}^\sigma) \right)
\]

The “(anti)-symm” notation means we restrict to the subspace which consists of (anti)-symmetric sums of states in the \( a \) and \( a \times \psi \) sectors.

### III. REVIEW OF SYMMETRY FRACTIONALIZATION IN BOSONIC SYSTEMS

We briefly review the formalism for symmetry fractionalization in bosonic systems.

Consider a UMTC \( \mathcal{B} \) with global symmetry group \( G. \) The basic data required to define symmetry fractionalization is the following. First, we define a group homomorphism

\[
[\rho_g] : G \to \text{Aut}(\mathcal{B})
\]

where \( \text{Aut}(\mathcal{B}) \) is the group of braided autoequivalences of \( \mathcal{B}, \) modulo a set of gauge equivalences called natural isomorphisms. A braided autoequivalence, or autoequivalence for short, is a map from \( \mathcal{B} \) to itself which preserves the data of the theory up to a gauge transformation. We will also use the term “autoequivalence” to refer to braided anti-autoequivalences, which, up to a gauge transformation, complex conjugate the data of the theory. A natural isomorphism \( \Upsilon \) is an autoequivalence which acts on fusion vertices as

\[
\Upsilon (|a, b; c; \mu\rangle) = \frac{\gamma_a \gamma_b}{\gamma_c} |a, b; c; \mu\rangle
\]

where \( \gamma_a \in \text{U}(1). \) Natural isomorphisms have a redundancy

\[
\gamma_a \to \gamma_a \zeta_a
\]

where \( \zeta_a \in \text{U}(1) \) obeys the fusion rules in the sense that \( \zeta_a \zeta_b = \zeta_c \) whenever \( N_{ab}^c > 0. \) A representative \( \rho_g \) of the equivalence class \([\rho_g] \) determines a permutation of the anyons \( a \to \sigma a \) and a set of unitary matrices \( U_g(a, b; c) \) as follows:

\[
\rho_g (|a, b; c; \mu\rangle) = \sum_{\mu'} U_g(\sigma a, \sigma b; \sigma c |\sigma a, \sigma b; \sigma c; \nu\rangle).
\]

The statement that \( \rho_g \) is an autoequivalence means that the \( F \)- and \( R \)-symbols are preserved (up to complex conjugation) according to the following consistency conditions:

\[
(F^{abc}_{df}(e, \alpha, \beta, f, \mu, \nu))^{(g)} = \sum_{\alpha', \beta', \mu', \nu'} U_g(\sigma a, \sigma b; \sigma c)_{\alpha \alpha'} U_g(\sigma c, \sigma d; \sigma e)_{\beta \beta'} F^{e\sigma a \sigma b \sigma c}_{d\sigma e \alpha' \beta'} (\sigma f, \mu', \nu', \nu) \times
\]

\[
\times (U_g(\sigma b, \sigma c; \sigma f)^{-1}_{\mu' \nu} U_g(\sigma a, \sigma f; \sigma d)^{-1}_{\mu' \nu})
\]

\[
(R^{abc}_{\mu \nu})^{(g)} = U_g(\sigma b, \sigma a; \sigma c)_{\mu \nu'} (R^{\sigma b \sigma a \sigma c}_{\mu \nu'})_{\mu' \nu}
\]

2 We define natural isomorphisms using Eq. 20. There exists a more abstract mathematical definition, and it is unclear if this definition is equivalent to ours. In considering equivalence classes of braided autoequivalences, we will restrict our attention to natural isomorphisms in our definition, since this appears to naturally describe SETs [1].
Here
\[ \sigma(g) = \begin{cases} 
1 & g \text{ unitary} \\
\ast & g \text{ anti-unitary} 
\end{cases} \]  
(25)

The maps \( \rho_g \) define the natural isomorphisms
\[ \kappa_{g,h} = \rho_{gh}\rho_h^{-1}\rho_g^{-1} \]  
(26)

which have actions on fusion vertices given by
\[ \kappa_{g,h}|a,b;c;\mu\rangle = \kappa_{g,h}(a,b;c)\langle a,b;c;\mu|. \]  
(27)

Here
\[ \kappa_{g,h}(a,b;c) = \frac{\beta_a(g,h)\beta_b(g,h)}{\beta_{g,h}} = U_g^{-1}(a,b;c)U_h(\overline{g},\overline{h},\overline{c})^{-\sigma(g)}U_{gh}(a,b;c) \]  
(28)

and \( \beta_a(g,h) \) are phases defining \( \kappa_{g,h} \) as a natural isomorphism. The \( \beta_a \) define the phases
\[ \Omega_a(g,h,k) = \frac{\beta_{g,h}^{\sigma(g)}(h,k)\beta_a(g,hk)}{\beta_a(g,h)\beta_a(gh,k)} \]  
(29)

which can be shown to obey the fusion rules, in the sense
\[ \Omega_a\Omega_b = \Omega_c \text{ whenever } N_{ab} > 0. \]  
(30)

These phases define, for modular \( \mathcal{B} \), an obstruction \( [\mathcal{G}] \in H^3(G,A) \) to localizing \( G \) on the anyons, where \( A \subset \mathcal{B} \) is the group of Abelian anyons of the theory; see standard references, e.g. [1], for further details.

If said obstruction vanishes, then one can define symmetry fractionalization on \( \mathcal{B} \), which amounts to a choice of phases \( \eta_a(g,h) \in U(1) \) which satisfy the following consistency conditions:
\[ \eta_{\pi_a(h,k)}^{\sigma(g)}\eta_a(g,hk) = \eta_a(g,h)\eta_a(gh,k) \]  
(31)

\[ \frac{\eta_a(k,l)}{\eta_a(k,l)\eta_b(k,l)}U_{kl}(a,b;c)_{\mu\nu} = \sum_\lambda U_1(\overline{F}_a,\overline{F}_b,\overline{F}_c)_{\mu\lambda}U_k(a,b;c)_{\lambda\nu} \]  
(32)

Symmetry fractionalization can equivalently be specified by a set of phases \( \omega_a(g,h) \) which obey the fusion rules and satisfy
\[ \Omega_a(g,h,k) = \frac{\omega_{\pi_a(h,k)}^{\sigma(g)}\omega_a(g,hk)}{\omega_a(g,h)\omega_a(gh,k)} = (d\omega)_a(g,h,k). \]  
(33)

The relationship between the \( \eta_a \) and \( \omega_a \) descriptions is
\[ \eta_a(g,h) = \frac{\beta_a(g,h)}{\omega_a(g,h)}. \]  
(34)

In all of the above, we have taken a fixed representative \( \rho_g \) of the class \([\rho_g]\). If \( \rho_g \) is modified by a natural isomorphism given by the phases \( \gamma_a(g) \), then we obtain gauge-equivalent data
\[ U'_g(a,b;c)_{\mu\nu} = \frac{\gamma_a(g)\gamma_b(g)}{\gamma_c(g)}U_g(a,b;c)_{\mu\nu} \]  
(35)

\[ \eta'_a(g,h) = \frac{\gamma_a(gh)}{[\gamma_{\pi_a(h)}]^{\sigma(g)}\gamma_a(g)}\eta_a(g,h). \]  
(36)

Separately, there is gauge freedom
\[ \beta_a(g,h) \rightarrow \beta_a(g,h)\nu_a(g,h) \]
\[ \Omega_a(g,h,k) \rightarrow \Omega_a(g,h,k)(d\nu)_a(g,h,k) \]
\[ \omega_a(g,h) \rightarrow \omega_a(g,h)\nu_a(g,h) \]  
(37)
where $\nu_n(\mathbf{g}, \mathbf{h})$ is a phase obeying the fusion rules.

For a fixed map $[\rho_\mathbf{g}]$, the set of symmetry fractionalization patterns form a torsor over $\mathcal{H}^2(G, \mathcal{A})$. Specifically, given consistent symmetry fractionalization data $\eta_n(\mathbf{g}, \mathbf{h})$ and an element $t(\mathbf{g}, \mathbf{h}) \in Z^2(G, \mathcal{A})$, then one obtains a new symmetry fractionalization pattern

$$\tilde{\eta}_n(\mathbf{g}, \mathbf{h}) = M_{t(\mathbf{g}, \mathbf{h})}\eta_n(\mathbf{g}, \mathbf{h}).$$  \hspace{1cm} (38)

One can check that up to gauge transformations, $\tilde{\eta}$ depends only on the cohomology class $[t] \in \mathcal{H}^2(G, \mathcal{A})$ and that different cohomology classes produce gauge-inequivalent symmetry fractionalization patterns.

IV. SYMMETRIES IN FERMIONIC TOPOLOGICAL PHASES

In this section, we briefly review fermionic symmetries, the classification of (3+1)D fermionic SPTs, and the results of [29] on fermionic symmetry fractionalization in fermionic topological phases.\(^3\)

We assume that we are describing a system whose Hilbert space decomposes into a tensor product of local Hilbert spaces which include fermionic degrees of freedom. Further, we assume the dynamics of the system are given by a local Hamiltonian with an energy gap such that the system is in the fermionic topological phase associated to $\mathcal{C}$.

In order for the formalism to describe anomalous fermionic SETs, we use the term “symmetry fractionalization of a fermionic topological phase” to refer only to fractionalization data on the super-modular category $\mathcal{C}$.

A. Fermionic symmetries

Fermionic systems always have a special symmetry, fermion parity symmetry $(-1)^F$, which generates a central $\mathbb{Z}_2$ subgroup $\mathbb{Z}_2^f$ of the full symmetry group $G_f$. Define the “bosonic” symmetry group $G_b = G_f/\mathbb{Z}_2^f$; then the symmetry generators restricted to their action on bosonic operators form a representation of $G_b$. An alternate characterization of $G_f$ is as a $\mathbb{Z}_2^f$ central extension of $G_b$ via the short exact sequence

$$1 \to \mathbb{Z}_2^f \to G_f \to G_b \to 1$$  \hspace{1cm} (39)

and a cocycle $\omega_2 \in Z^2(G_b, \mathbb{Z}_2)$. Physically, we can write a set of operators $R_\mathbf{g}$ for $\mathbf{g} \in G_b$ which implement the action of $G_b$ on the microscopic Hilbert space. Since the symmetry group on the full fermionic Hilbert space is actually $G_f$, these operators multiply projectively,

$$R_\mathbf{g}R_\mathbf{h} = (\omega_2(\mathbf{g}, \mathbf{h}))^F R_{\mathbf{g}\mathbf{h}},$$  \hspace{1cm} (40)

where we are viewing $\omega_2 \in \{\pm 1\} \cong \mathbb{Z}_2$.

The cocycle $\omega_2 \in Z^2(G_b, \mathbb{Z}_2)$ determines a decomposition $G_f = G_b \times \mathbb{Z}_2^f$ as sets, but all choices of cocycle representative in the same cohomology class $[\omega_2]$ lead to isomorphic groups $G_f$. Physically, modifying $\omega_2 \to \omega_2 \times d\phi$ for $\phi \in C^1(G_b, \mathbb{Z}_2)$ changes

$$R_\mathbf{g} \to (\phi(\mathbf{g}))^F R_\mathbf{g},$$  \hspace{1cm} (41)

where we are taking $\phi \in \{\pm 1\}$. Such a transformation changes the physical meaning of $R_\mathbf{g}$; for example, if $G_b = \mathbb{Z}_2^2$, the time-reversal operator $\mathbf{T}$ is physically distinct from $(-1)^F \mathbf{T}$, and these operators should not be interchanged. Therefore, a microscopic realization of $G_f$ symmetry will in general specify a cocycle representative $\omega_2$, not just its cohomology class $[\omega_2]$.

A (2+1)D topological phase with symmetry group $G_f$ may have a ’t Hooft anomaly, that is, there may be an obstruction to gauging the $G_f$ symmetry. If there is such an anomaly, then the (2+1)D topological phase can only be realized (with the symmetry generated on-site) on the surface of a (3+1)D fermionic SPT. The rest of this paper is concerned with determining the ’t Hooft anomaly of a given fermionic SET from its symmetry fractionalization data; we therefore seek to match our results with data specifying a fermionic SPT. Wang and Gu [24] have, using the decorated domain wall construction, classified (3+1)D fermionic SPTs for generic $G_f$, and their classification is consistent with results from cobordism theory [33, 34]. Wang and Gu showed that (3+1)D fermionic SPTs are

\(^3\) We note that the results on fermionic symmetry fractionalization reviewed here also appeared in [32], which appeared on the arXiv at the same time as both the first version of this paper and [29].
specified by four pieces of data, \( \{n_1, n_2, n_3, n_4\} \in \mathbb{Z}^4(G_b, \mathbb{Z}_T) \times C^2(G_b, \mathbb{Z}_2) \times C^3(G_b, \mathbb{Z}_2) \times C^4(G_b, U(1)) \), where \( C^k \) and \( \mathbb{Z}^k \) denote \( k \)-cochains and \( k \)-coycles, respectively. These data obey various consistency equations and equivalence relations, whose precise form is unimportant for our purposes. The relevant fact is that if \( n_i \) is trivial, then the equivalence class of \( n_{i+1} \) is such that \([n_{i+1}] \in H^{i+1}(G_b, X_{i+1})\) for the appropriate coefficient group \( X_{i+1} \). On the other hand, if \( n_i \) is non-trivial, then \( n_{i+1} \) is generally an \( H^{i+1}(G_b, X_{i+1}) \)-torsor. We therefore expect this structure to appear in the obstruction theory for gauging \( G_f \).

**B. Fermionic symmetry fractionalization**

The first step of defining \( G_f \) symmetry fractionalization is to assign an autoequivalence \([\rho_g] \) of \( \mathcal{C} \) to each element \( g \in G_b \). Topological autoequivalences are well-defined for any BFC regardless of modularity, so autoequivalences of a super-modular category \( \mathcal{C} \) are also well-defined. This assignment defines the \( U \)-symbols as given in Eq. 22.

There is, however, a physical constraint on the choice of autoequivalence. The symmetry operator \( R_g \) is defined on the physical, microscopic Hilbert space, and we will be seeking to localize \( R_g \). Then if \( \gamma_{i,r} \) is a basis of (Majorana) fermion operators at position \( r \), the Hilbert space defines matrices \( \hat{U}_{ij}(g, r) \) such that

\[
R_g \gamma_{i,r} R_g^{-1} = \sum_j \hat{U}_{ij}(g, r) \gamma_{j,r},
\]

where \( i \) and \( j \) label elements of the basis of fermionic operators.

As shown in [29], compatibility of a representative autoequivalence \( \rho_g \) of \( \mathcal{C} \) with Eq. 42 constrains

\[
\rho_g(\ket{\psi, \psi; 1}) = \ket{\psi, \psi; 1},
\]

or equivalently, for all \( g \in G_b \),

\[
U_g(\psi, \psi; 1) = +1.
\]

In the bosonic case, the topological autoequivalence may be redefined by a natural isomorphism of the form \( U \) in Eq. 20. Clearly we have less freedom in the fermionic case; maintaining Eq. 44 requires natural isomorphisms to have \( \gamma_\psi \in \{\pm 1\} \). In fact, as shown in [29], modifying \( R_g \) with a natural isomorphism with \( \gamma_\psi = -1 \) amounts to redefining \( R_g \rightarrow (-1)^F R_g \), which, as discussed in Sec. IV A, is a physical change to the system and not a gauge redundancy. Therefore, the redundancy in topological autoequivalences for fermionic symmetries is not given by arbitrary natural isomorphisms, but instead “locality-respecting” natural isomorphisms which have \( \gamma_\psi = +1 \). We denote the group of topological autoequivalences of \( \mathcal{C} \) which obey Eq. 44, modulo locality-respecting natural isomorphisms, as \( \text{Aut}_{LR}(\mathcal{C}) \).

As such, fermionic symmetry actions are specified by a group homomorphism

\[
[\rho_g] : G_b \rightarrow \text{Aut}_{LR}(\mathcal{C}).
\]

There is some subtlety in demanding that locality-respecting natural isomorphisms have \( \gamma_\psi = +1 \) because of the redundancy Eq. 21 in natural isomorphisms. Define an Abelian group \( K(\mathcal{C}) \) consisting of maps \( \zeta_a \) that obey the fusion rules, that is,

\[
K(\mathcal{C}) = \{ \zeta : \text{anyon labels } \rightarrow U(1) \mid \zeta_a \zeta_b = \zeta_c \text{ whenever } N_{ab}^c > 0 \}.
\]

Clearly \( \zeta_\psi \in \{\pm 1\} \), which provides a natural \( \mathbb{Z}_2 \) grading on \( K(\mathcal{C}) \):

\[
K(\mathcal{C}) = K_+(\mathcal{C}) \oplus K_-(\mathcal{C})
\]

where \( K_+ (\mathcal{C}) \) consists of maps with \( \zeta_\psi = \pm 1 \). It was proven in [29] that, given any minimal modular extension \( \tilde{\mathcal{C}} \) of \( \mathcal{C} \), every element \( \zeta_a \) of \( K(\mathcal{C}) \) can be written

\[
\zeta_a = M_{a,x}
\]

---

4 It is not hard to show that every element of \( \text{Aut}(\mathcal{C}) \) has a representative which obeys Eq. 44. Accordingly, one can check that, depending on details which will be discussed shortly, as a group \( \text{Aut}_{LR}(\mathcal{C}) \) is either isomorphic to \( \text{Aut}(\mathcal{C}) \) or double-covers \( \text{Aut}(\mathcal{C}) \).
for some $x \in \mathcal{C}$, and in particular, $x \in \mathcal{A}$ if $\zeta \in K_+(\mathcal{C})$. Hence
\[ K_+(\mathcal{C}) \cong \mathcal{A}/\{1, \psi\}, \tag{49} \]
where $\mathcal{A} \subset \mathcal{C}$ is the group of Abelian anyons of $\mathcal{C}$ and $\{1, \psi\}$ is the $\mathbb{Z}_2$ subgroup generated by the transparent fermion $\psi$.

If $K_-(\mathcal{C})$ is nonempty, then every natural isomorphism which preserves Eq. 44 is equivalent to a locality-respecting natural isomorphism.

There is a canonical natural isomorphism $\Upsilon_\psi$ of the same form as Eq. 20 with
\[ \gamma_a = \begin{cases} -1 & \text{if } a = \psi \\ 1 & \text{else} \end{cases} \tag{50} \]
We immediately see that $\Upsilon_\psi$ respects locality if and only if $K_-(\mathcal{C})$ is nonempty. If $\Upsilon_\psi$ does not respect locality, then $[\Upsilon_\psi] \neq [1]$ as elements of $\text{Aut}_{LR}(\mathcal{C})$.

Many of the results and casework in this paper depend on whether or not $\Upsilon_\psi$ respects locality, so it is useful to summarize some characterizations from [29] of when $\Upsilon_\psi$ respects locality. The following are equivalent:

- $\Upsilon_\psi$ respects locality
- $K(\mathcal{C})/K_+(\mathcal{C}) \cong \mathbb{Z}_2$ (which means $K_-(\mathcal{C})$ is nonempty)
- As groups, $\text{Aut}(\mathcal{C}) \cong \text{Aut}_{LR}(\mathcal{C})$
- There exists a minimal modular extension of $\mathcal{C}$ which contains an Abelian fermion parity vortex
- There exists a set of phases $\zeta_a$ which obey the fusion rules and have $\zeta_\psi = -1$.

Conversely, the following are also equivalent:

- $\Upsilon_\psi$ violates locality
- $K(\mathcal{C}) = K_+(\mathcal{C}) \cong \mathcal{A}/\{1, \psi\}$
- As groups, $\text{Aut}_{LR}(\mathcal{C})/\mathbb{Z}_2 \cong \text{Aut}(\mathcal{C})$
- Any set of phases $\zeta_a$ which obey the fusion rules must have $\zeta_\psi = +1$.

Also, if elements of $\text{Aut}(\mathcal{C})$ are uniquely determined by their permutation action on the anyons (as is true in many theories of physical interest), then the same holds for $\text{Aut}_{LR}(\mathcal{C})$ if and only if $\Upsilon_\psi$ respects locality.

After specifying the group homomorphism, one must compute the obstruction to symmetry localization. There are two obstructions. The first is the “bosonic” obstruction to defining any $G_b$ symmetry fractionalization whatsoever on $\mathcal{C}$ and is valued in $\mathcal{H}^3(G_b, K(\mathcal{C}))$; if $\Upsilon_\psi$ violates locality, then we may characterize $K(\mathcal{C}) \cong \mathcal{A}/\{1, \psi\}$, but if $\Upsilon_\psi$ respects locality, there is nothing further to say in general. The derivation is very similar to the bosonic case; see [29] for details.

At this point one may define symmetry fractionalization data $\eta_a(g, h)$ subject to the usual consistency conditions Eqs. 31-32. However, compatibility of the symmetry localization ansatz with Eq. 42 and the full $G_f$ symmetry in Eq. 40 requires [29] the constraint
\[ \eta_\psi(g, h) = \omega_2(g, h) \in \mathbb{Z}_2^2(G_b, \mathbb{Z}_2). \tag{51} \]
Regarding autoequivalences as gauge-equivalent only if they differ by locality-respecting natural isomorphisms means that gauge transformations preserve Eq. 51.

The existence of a symmetry fractionalization pattern obeying Eq. 51 is subject to a “fermionic” symmetry localization obstruction which is valued in $\mathbb{Z}_2^2(G_b, \mathbb{Z}_2)$ if $\Upsilon_\psi$ violates locality and is valued in $\mathcal{H}^3(G_b, K_+(\mathcal{C})) = \mathcal{H}^3(G_b, \mathcal{A}/\{1, \psi\})$ in $\Upsilon_\psi$ respects locality.

To summarize, symmetry fractionalization of a fermionic symmetry group $G_f$ on a super-modular category $\mathcal{C}$ is given by a homomorphism $[\rho_G] : G_b \to \text{Aut}_{LR}(\mathcal{C})$ (which defines the $U$-symbols $U_g(a, b; c)$) and a choice of data $\eta_a(g, h)$, subject to the same consistency conditions Eqs. 23,24,31,32 as in the bosonic case. This data is subject to the constraints
\[ U_g(\psi, \psi; 1) = +1 \tag{52} \]
\[ \eta_\psi(g, h) = \omega_2(g, h), \tag{53} \]
and symmetry action gauge transformations are restricted to be locality-respecting, in that they must have

\[ \gamma_{\psi}(g) = +1. \]  

(54)

The existence of consistent symmetry fractionalization requires two obstructions to vanish: a bosonic symmetry localization obstruction \([\mathcal{O}_b] \in \mathcal{H}^1(G_b, \mathcal{A}/\{1, \psi\})\) and a fermionic symmetry localization obstruction \([\mathcal{O}_f] \) which is valued in \(Z^2(G_b, \mathbb{Z}_2)\) if \(\Upsilon_{\psi}\) violates locality and which is valued in \(\mathcal{H}^1(G_b, \mathcal{A}/\{1, \psi\})\) if \(\Upsilon_{\psi}\) respects locality.

V. \(\mathcal{H}^1(G_b, \mathbb{Z}_T)\) OBSTRUCTION

We prove Theorem 1.3.

Proof. Using the Gauss sum,

\[ c_{\nu_2} = -c_{\nu_1} \mod 8. \]  

(55)

We have defined

\[ c_{\nu_2} = c_{\nu_1} + o_1(g)/2 \mod 8 \]  

(56)

where \(o_1(g)\) must, by the 16-fold way, be an integer. Hence

\[ o_1(g) = -4c_{\nu_1} \mod 16. \]  

(57)

Hence \(c_{\nu_1} = 0 \mod 1/4\). Now, suppose that \((\nu_3, \nu_4)\) also satisfy Eq. 56 with a different integer \(n'(g)\). Then we could run the same argument to obtain

\[ o'_1(g) = -4c_{\nu_3} \mod 16. \]  

(58)

But \(c_{\nu_3} - c_{\nu_1} \in \mathbb{Z}/2\) by the 16-fold way, which means

\[ o'_1(g) - o_1(g) \in 2\mathbb{Z}. \]  

(59)

\[ \square \]

It immediately follows that if \(o_1(g) = 1 \mod 2\), then it is not possible to have a lift \(\rho_g : \tilde{\mathcal{C}}_{\nu_0} \to \tilde{\mathcal{C}}_{\nu_0}\). This is a rather familiar statement because \(o_1(g) = 1\) implies \(c_{\nu_1} \in \mathbb{Z} \pm 1/4\), which can never be left invariant by an anti-unitary symmetry. Hence \([o_1] \in \mathcal{H}^1(G_b, \mathbb{Z}_T)\) obstructs the ability to lift \(\rho_g\) to a map which is a true symmetry of a minimal modular extension \(\tilde{\mathcal{C}}\), rather than a map between two distinct minimal modular extensions. Conjecture 1.5 states that \([o_1]\) is the only such obstruction.

VI. \(\mathcal{H}^2(G_b, \ker r)\) OBSTRUCTION

Given a group homomorphism \([\rho_g] : G_b \to \text{Aut}_{L,R}(\mathcal{C})\), we assume that the \(\mathcal{H}^1(G_b, \mathbb{Z}_T)\) obstruction vanishes. Then for each \(g \in G_b\), one can define a consistent lift \([\tilde{\rho}_g]\) on a fixed minimal modular extension \(\tilde{\mathcal{C}}\), that is, \(r([\tilde{\rho}_g]) = [\rho_g]\), where \(r\) is the restriction map

\[ r : \text{Aut}_{L,R}(\tilde{\mathcal{C}}) \to \text{Aut}_{L,R}(\tilde{\mathcal{C}})|_\mathcal{C} \subseteq \text{Aut}_{L,R}(\mathcal{C}). \]

(60)

However, the lifted map \([\tilde{\rho}_g]\) may not be a group homomorphism. Our aim is to show that there is an obstruction to finding a lift \([\tilde{\rho}_g]\) which is a group homomorphism \(G_b \to \text{Aut}_{L,R}(\tilde{\mathcal{C}})\), and this obstruction is valued in \(\mathcal{H}^2(G_b, \ker r)\). We then relate this obstruction to the \(\mathcal{H}^2(G_b, \mathbb{Z}_2)\) part of the ’t Hooft anomaly for fermionic SETs.
A. Defining the obstruction

Suppose we have a lift \( \tilde{\rho}_g \) of a general autoequivalence \( [\rho_g] \) of \( \mathcal{C} \). In general \( r \) may have a nontrivial kernel, so \( \tilde{\rho}_g \) can be composed with any element of ker \( r \) to obtain another, equally valid lift. Although \( \rho_g \) and \( \tilde{\rho}_g \) may in general be antiunitary, elements of ker \( r \) are automatically unitary.

We will show in Sec. VI B that the permutation action of all elements of ker \( r \) on anyon labels commute with each other, although they in general need not commute with \( [\rho_g] \). In the case where elements of Aut(\( \tilde{\mathcal{C}} \)) are completely determined by their permutation action on the anyons, then this implies that ker \( r \) is Abelian. We will assume that ker \( r \) is Abelian in general.

Let us consider

\[
o_2(g, h)^{-1} := \tilde{\rho}_g \tilde{\rho}_h \tilde{\rho}_{gh}^{-1}. \tag{61}\]

By inspection, modifying a representative lift \( \tilde{\rho}_g \) by a locality-respecting natural isomorphism modifies \( o_2 \) by a locality-respecting natural isomorphism, so this equation is also well-defined in Aut\(_{LR}(\tilde{\mathcal{C}})\). Since \( [\rho_g] \) is a group homomorphism \( G_b \to \text{Aut}_{LR}(\mathcal{C}) \), \( o_2 \) restricts to a trivial map in Aut\(_{LR}(\mathcal{C})\), i.e., \( o_2(g, h) \in \text{ker} \). However, it may be a nontrivial element of ker \( r \). In general, \( o_2(g, h) \in \mathcal{C}^2(G_b, \text{ker} r) \) defines a \( (\text{ker} r) \)-valued 2-cocohain on \( G_b \).

Demanding that the \( \tilde{\rho}_g \) be associative, we find by decomposing \( \tilde{\rho}_{ghk} \) in two distinct ways that

\[
\tilde{\rho}_{ghk} = o_2(gh, k)\tilde{\rho}_{gh}\tilde{\rho}_k \tag{62}
= o_2(g, k)o_2(h, g)\tilde{\rho}_g\tilde{\rho}_h\tilde{\rho}_k \tag{63}
= o_2(g, hk)\tilde{\rho}_g\tilde{\rho}_{hk} \tag{64}
= o_2(g, hk)\tilde{\rho}_{g\tilde{\rho}_h\tilde{\rho}_k}. \tag{65}
\]

where we have defined

\[
o_2(h, k) = o_2(\tilde{\rho}_g(2)h, k)\tilde{\rho}_g^{-1} \tag{66}.
\]

For these two decompositions of \( \tilde{\rho}_{ghk} \) to be equal, we need \( o_2(g, h) \in Z^2(G_b, \text{ker} r) \).

Clearly \( \tilde{\rho}_g \) is only a group homomorphism if \( o_2 = 1 \). This condition is not generically satisfied, but we may obtain another lift by modifying each \( \tilde{\rho}_g \) by an element of ker \( r \). Such a modification changes \( o_2(g, h) \) by \( (\text{ker} r) \)-valued 2-coboundary. Therefore, the lift can be modified to obtain a group homomorphism \( G_b \to \text{Aut}_{LR}(\tilde{\mathcal{C}}) \) if and only if \( [o_2] \in H^2(G_b, \text{ker} r) \) is cohomologically trivial. That is, \( [o_2] \) is the obstruction to lifting the permutation action of \( G_b \) on \( \mathcal{C} \) to \( \tilde{\mathcal{C}} \).

In the case where \( \text{ker} r = \mathbb{Z}_2 \), we will see that \( \text{ker} r \) commutes with all of Aut\(_{LR}(\tilde{\mathcal{C}})\). Accordingly, \( [o_2] \) defines a group extension \( \tilde{G}_b \) of \( G_b \) by \( \mathbb{Z}_2 \). In fact, if we enlarge the symmetry to \( \tilde{G}_b \), then there is a consistent lift to \( \tilde{\rho}_g \in \text{Aut}_{LR}(\tilde{\mathcal{C}}) \).

Let ker \( r = \{1, \psi\} \), and with \( \tilde{G}_b = G_b \times \mathbb{Z}_2 \) as sets, define

\[
\tilde{\rho}_{(g, p)} = \tilde{\rho}_g^p \tag{67}
\]

with \( g \in G_b \) and \( p \in \{0, 1\} \simeq \mathbb{Z}_2 \). Then

\[
\tilde{\rho}_{(g, p)}\tilde{\rho}_{(h, q)} = o_2(g, h)\tilde{\rho}_{gh} \tag{68}
= \tilde{\rho}_{(gh, p+q+\tilde{o_2}(g, h))} \tag{69}
= \tilde{\rho}_{(g, p)}\tilde{\rho}_{(h, q)}. \tag{70}
\]

where \( \tilde{o_2} \in \{0, 1\} \simeq \mathbb{Z}_2 \) means we are interpreting \( o_2 \in \text{ker} r \simeq \mathbb{Z}_2 \) as an element of additive \( \mathbb{Z}_2 \) instead of ker \( r \). Hence these symmetry actions are a group homomorphism \( \tilde{\rho}_{(g, p)} : \tilde{G}_b \to \text{Aut}_{LR}(\tilde{\mathcal{C}}) \) as claimed.

As an example, let us consider the semion-fermion theory with \( G_b = \mathbb{Z}_2^T \). The modular extension of this theory is \( \tilde{\mathcal{C}} = U(1)_2 \times U(1)_{-4} \). The simple objects of \( \tilde{\mathcal{C}} \) can labeled \((a, b)\) for \( a = 0, 1 \) and \( b = 0, 1, 2, 3 \). Here, \( v = (0, 1) \) is the fermion parity vortex, \( \psi = (0, 2) \) is the fermion, and \( s = (1, 0) \) is the semion. It is clear that ker \( r = \mathbb{Z}_2 \) in this case; its nontrivial element \( [\alpha_v] \) takes \( v \leftrightarrow v \times \psi \). Under \( T, \mathcal{C} \) transforms as follows:

\[
T \psi = \psi \tag{71}
\]

\[
T \psi = \psi
\]
There are two possible lifts $[\tilde{\rho}_T]$ to the modular extension which differ by the action of $[\alpha_{\psi}]$; we may take either

$$T_v = s \times v \text{ or } T_v = s \times \psi \times v$$

(72)

For the first choice

$$T(T_v) = T(s \times v) = (s \times \psi) \times (s \times v) = \psi \times v.$$  

(73)

That is,

$$[\tilde{\rho}_T]^2 = [\alpha_{\psi}] = \alpha_2(T, T)$$  

(74)

One can check straightforwardly that the second choice of $[\tilde{\rho}_T]$ leads to the same $\alpha_2$. Therefore $[\alpha_2] \neq +1 \in \mathcal{H}^2(\mathbb{Z}_4^T, \mathbb{Z}_2)$. Thus there is no way to have the permutations faithfully act on the modular extension as $G_b = \mathbb{Z}_4^T$. However we can have them act as $G_b = \mathbb{Z}_4^T$.

B. Characterizing $\text{ker } r$

In order to understand $[\alpha_2]$ better, we need to characterize $\text{ker } r$. In the following, we first define two important maps, denoted $[\tilde{\Upsilon}_\psi]$, and $[\alpha_{\psi}]$. We will see that $[\alpha_{\psi}]$ always generates a $\mathbb{Z}_2 \subseteq \text{ker } r$.

1. $[\tilde{\Upsilon}_\psi]$

$\tilde{\Upsilon}_\psi$ is defined to be the lift of $\Upsilon_\psi$ to $\tilde{\mathcal{C}}$, and is defined by the following action:

$$\tilde{\Upsilon}_\psi(a, b; c) = \gamma_a \gamma_b \gamma_c |a, b, c\rangle \text{ with } \gamma_a = \begin{cases} -1 & a = \psi \\ 1 & \text{else} \end{cases}$$

(75)

for $a, b, c \in \tilde{\mathcal{C}}$. Clearly $r([\tilde{\Upsilon}_\psi]) = [\Upsilon_\psi]$, so $[\tilde{\Upsilon}_\psi] \in \text{ker } r$ if and only if $\Upsilon_\psi$ respects locality. If $[\tilde{\Upsilon}_\psi] \in \text{ker } r$ and $\tilde{\Upsilon}_\psi$ violates locality, then it forms a $\mathbb{Z}_2$ subgroup of $\text{ker } r$. On the other hand, if $\tilde{\Upsilon}_\psi$ respects locality, then it is a trivial element of $\text{ker } r$.

2. $[\alpha_{\psi}]$

Next, we consider a map $\alpha_{\psi}$, with the following permutation action:

$$\alpha_{\psi}(a) = a \text{ if } a \in \tilde{\mathcal{C}}_0 \simeq \mathcal{C}$$

$$\alpha_{\psi}(a) = a \times \psi \text{ if } a \in \tilde{\mathcal{C}}_1.$$  

(76)

This permutation preserves the fusion rules, twists, and modular $S$-matrix of the theory. One can check in a range of examples that there indeed exists a braided autoequivalence $\alpha_{\psi}$ of $\tilde{\mathcal{C}}$ with this permutation action. In fact, Ref. [32] (which appeared simultaneously on the arXiv with the first version of this work) gave an explicit formula the $U$-symbols of exactly such a braided autoequivalence as follows:

$$U_{\alpha_{\psi}}(a', b'; c'; \mu, \nu) = \sum_{\lambda} \left[ (F_{c' c}^{- \psi \times a, b'} F_{c' c}^{\psi \times a, b'})^{-1} \right]_{(b, s, \lambda), (a, x \times \psi), (b, \lambda)} R_{\psi \times a, b'}^{\psi \times a, b'} \left[ (F_{c' c}^{\psi \times a, b'} F_{c' c}^{\psi \times a, b'})^{-1} \right]_{(c, \lambda), (a', \nu)}$$

(77)

where we use the shorthand $a' = \alpha_{\psi}(a)$ and define

$$f_x = \begin{cases} 0 & x \in \tilde{\mathcal{C}}_0 \\ 1 & x \in \tilde{\mathcal{C}}_1. \end{cases}$$

(78)

Consider the case where (i) every permutation of simple objects of $\tilde{\mathcal{C}}$ which preserves the modular data corresponds to a unique element $\text{Aut}(\tilde{\mathcal{C}})$, and similarly (ii) every permutation of simple objects in $\mathcal{C}$ preserving the modular data...
corresponds to a unique element of $\text{Aut}(\mathcal{C})$. Then $[\alpha_\psi]$ generates a $\mathbb{Z}_2$ subgroup of $\ker r$ as long as $\tilde{\mathcal{C}}_r$ is non-empty. In more general situations, Ref. [32] demonstrated that as a braided autoequivalence, it is always true that $[\alpha_\psi] \in \ker r$, commutes with all of $\text{Aut}_{LR}(\tilde{\mathcal{C}})$, and squares to the identity.

If $\tilde{\mathcal{C}}_r$ is non-empty, then $[\alpha_\psi]$ is clearly non-trivial. If $\tilde{\mathcal{C}}_\sigma$ is non-empty, then we can calculate the gauge-invariant (in $\text{Aut}_{LR}(\tilde{\mathcal{C}})$) quantity

$$U_{\alpha_\psi}(\sigma,\psi;\sigma) = (F^{\psi \alpha_\psi})^{-1} R^{1\sigma} (F^{\psi \sigma \alpha_\psi})^{-1}$$

(79)

(80)

where the last equality follows from a straightforward use of the hexagon equation. Hence $[\alpha_\psi]$ is non-trivial in this case as well, and so $[\alpha_\psi]$ always generates a central $\mathbb{Z}_2$ subgroup of $\ker r$. Note that Eq. 77 provides a definition of a non-trivial $[\alpha_\psi]$ even when $\tilde{\mathcal{C}}_r$ is empty, in which case $\alpha_\psi$ always has trivial permutation action on the objects in $\tilde{\mathcal{C}}$.

For a familiar example, consider $\mathcal{C} = \{1, \psi\}$; then there is a modular extension $\tilde{\mathcal{C}} = \{1, \psi, e, m\}$ which is equivalent to $\mathbb{Z}_2$ gauge theory, where we are viewing $\tilde{\mathcal{C}}_r = \{e, m\}$. Then the map $\alpha_\psi$ permutes $e \leftrightarrow m$, implementing electromagnetic duality.

If $\tilde{\mathcal{C}}_r$ is empty, then $[\alpha_\psi]$ may or may not equal $[\tilde{\mathcal{C}}_\psi]$. Certainly this equality is only possible when $\Upsilon_\psi$ respects locality so that both maps are in $\ker r$. These two maps are equal for, e.g., $\tilde{\mathcal{C}} = \text{Ising}$. We do not have any example where $\tilde{\mathcal{C}}_r$ is empty and $[\alpha_\psi]$ and $[\tilde{\mathcal{C}}_\psi]$ are inequivalent maps, which raises the natural question of whether $[\alpha_\psi] = [\tilde{\mathcal{C}}_\psi]$ whenever $\tilde{\mathcal{C}}_r$ is empty [35].

3. Permutation actions of elements of $\ker r$

Fully characterizing $\ker r$ is a non-trivial task in general. We can, however, determine the allowed permutation action of all elements of $\ker r$ by proving Theorem 1.6:

**Proof.** We may apply the Verlinde formula to $\tilde{\mathcal{C}}$, which is modular:

$$N_{\mathcal{C},\psi}^{\tilde{p}(v)} + N_{\mathcal{C},\psi}^{\tilde{p}(v)} = \sum_{x \in \tilde{\mathcal{C}}} (S_{\psi,x} + S_{1x}) S_{\psi,x}^* S_{\tilde{p}(v)x}$$

(81)

$$= \sum_{x \in \tilde{\mathcal{C}}_0} (S_{\psi,x} + S_{1x}) S_{\psi,x}^* S_{\tilde{p}(v)x} + \sum_{x \in \tilde{\mathcal{C}}_1} (S_{\psi,x} + S_{1x}) S_{\psi,x}^* S_{\tilde{p}(v)x}.$$  

(82)

By Eq. 15, $S_{\psi,x} = \pm S_{1,x}$ with the upper sign for $x \in \tilde{\mathcal{C}}_0$ and the lower sign for $x \in \tilde{\mathcal{C}}_1$. Therefore,

$$N_{\mathcal{C},\psi}^{\tilde{p}(v)} + N_{\mathcal{C},\psi}^{\tilde{p}(v)} = \sum_{x \in \tilde{\mathcal{C}}_0} 2 S_{\psi,x} S_{\tilde{p}(v)x} + 0$$

(83)

$$= \sum_{x \in \tilde{\mathcal{C}}_0} 2|S_{\psi,x}|^2 > 0,$$

(84)

where we have used the fact that $S$ is invariant under $\tilde{p}$ and that $\tilde{p}(x) = x$ if $x \in \tilde{\mathcal{C}}_0$. Therefore either $\tilde{p}(v) = v$ or $\tilde{p}(v) = \psi \times v$, and in particular, if $v \in \tilde{\mathcal{C}}_\sigma$, $\tilde{p}(v) = v$.

Next, suppose $v_1, v_2 \in \tilde{\mathcal{C}}_r$. Then

$$S_{v_1,v_2} = \tilde{p}(S_{v_1,v_2}) = S_{\tilde{p}(v_1),\tilde{p}(v_2)} = S_{v_1,v_2}(-1)^{m_1+m_2}$$

(85)

where

$$m_i = \begin{cases} 0 & \tilde{p}(v_i) = v_i \\ 1 & \tilde{p}(v_i) = v_i \times \psi \end{cases}$$

(86)

Hence if $S_{v_1,v_2} \neq 0$, then $m_1 = m_2$, that is, $\tilde{p}$ changes the fermion parity of both $v_1$ and $v_2$ or of neither. If $S_{v_1,v_2} = 0$ but $v_1, v_2$ are in the same one of the $k$ blocks of the $S_{a_i,a_j}$ part of the $S$-matrix, then there exists a sequence of $\psi$-type vortices $a_1, a_2, \ldots, a_p$ such that $S_{v_1,a_j} \neq 0, S_{v_1,a_j} \neq 0, \ldots, S_{a_p,v_2} \neq 0$. Applying the above argument to each pair in the sequence, we conclude that if $v_1, v_2$ belong to the same block of the $S$-matrix, $\tilde{p}$ acts the same way on both vortices, i.e. it either changes the fermion parity of both or of neither.

4. \( \ker r \) when permutations determine \( \text{Aut}(\tilde{C}) \) and \( \text{Aut}(C) \)

In many well-studied examples, every permutation of the simple objects of a BFC \( B \) uniquely determines an element of \( \text{Aut}(B) \). We can fully characterize \( \ker r \) as long as \( \tilde{C} \) and \( C \) obey slightly weaker properties:

**Theorem VI.1.** Let \( k \) be as in Theorem I.6. Suppose that every permutation of vortices in \( \tilde{C} \) given in Theorem I.6 uniquely determines an element of \( \text{Aut}(\tilde{C}) \) (but not necessarily a unique element of \( \text{Aut}_{LR}(\tilde{C}) \)), and further suppose that there is a unique element of \( \text{Aut}(C) \) which does not permute anyons. Then \( \ker r = \mathbb{Z}_2^{\max(k,1)} \).

**Proof.** Let \( [\tilde{p}] \in \ker r \). According to Theorem I.6, there are \( 2^{\max(k,1)} \) possible permutation actions for \( [\tilde{p}] \), given by \( k \) independent choices of whether or not \( [\tilde{p}] \) changes the fermion parity of the \( v \)-type vortices in each block, and each permutation action squares to the identity. If \( k = 0 \), then \( [\tilde{p}] \) acts as the identity permutation.

We first claim that all of these possible permutation actions commute with each other. This statement is only nontrivial for \( k > 1 \). To prove this claim, it suffices to show that \( v \) and \( v \times \psi \) belong to the same block.

Suppose first that for some \( w \neq v, v \) and \( w \) belong to the same one of the \( k \) blocks of the \( S \)-matrix. Then there is a sequence of \( v \)-type anyons vortices \( a_1, a_2, \ldots, a_p \) such that \( S_{v,a_1} \neq 0, S_{a_1,a_2} \neq 0, \ldots, S_{a_{p-1},w} \neq 0 \). But \( S_{v \times \psi, a_1} = -S_{a_1,v} \neq 0 \) as well. Hence \( v \times \psi \) is also in the same block as \( w \), so \( v \) and \( v \times \psi \) are in the same block, namely the block containing \( w \).

We claim that such a \( w \) must exist. Suppose by way of contradiction that no such \( w \) exists, i.e., \( S_{v,w} = 0 \) for all \( w \in C_1 \), in which case \( v \) is in a block by itself. It follows that \( S_{v \times \psi, w} = -S_{v,w} = 0 \) for all \( w \in C_1 \), and since \( S_{v \times \psi, a} = S_{v,a} \) for all \( a \in C_0 \), we must have \( S_{v,w} = S_{v \times \psi, a} \) for all \( a \in C \). Hence \( S \) has two identical rows and is not invertible, which is a contradiction since \( \tilde{C} \) is modular. This proves that all of the aforementioned permutation actions commute.

By assumption, the permutation action of \( \tilde{p} \) defines a unique element of \( \text{Aut}(\tilde{C}) \), but may or may not uniquely determine an element of \( \text{Aut}_{LR}(\tilde{C}) \). Whether or not it does depends on the properties of \( [\tilde{\psi}] \), which is the one possibly-nontrivial element of \( \text{Aut}_{LR}(\tilde{C}) \) which does not permute anyons.

We need to consider three possible cases, depending on whether \( \tilde{\psi} \) and \( \tilde{\psi} \) respect locality.

**Case 1:** \( \tilde{\psi} \) respects locality in \( \tilde{C} \). Then \( \tilde{\psi} \) respects locality in \( C \), and also \( \tilde{C} \) contains an Abelian fermion parity vortex. Hence \( \tilde{C} \) is nonempty; \( k > 0 \), \( \text{Aut}_{LR}(\tilde{C}) = \text{Aut}(\tilde{C}) \), and \( \text{Aut}_{LR}(C) = \text{Aut}(C) \). Therefore, each of the \( 2^k \) anyon permutations defined above determines a unique element of \( \text{Aut}_{LR}(\tilde{C}) \) which restricts to the identity in \( \text{Aut}_{LR}(C) \) (since the restricted permutation action is trivial). Furthermore, if \( [\tilde{p}] \in \ker r \), \( [\tilde{p}]^2 = [1] \) because \( [\tilde{p}]^2 \) does not permute anyons. Thus \( \ker r = \mathbb{Z}_2^k \).

**Case 2:** \( \tilde{\psi} \) does not respect locality in \( \tilde{C} \), but \( \tilde{\psi} \) respects locality in \( C \). Then some minimal modular extension of \( C \) contains an Abelian fermion parity vortex, but \( \tilde{C} \) does not; according to a result of [29], that this implies that \( \tilde{C} \) has no \( v \)-type vortices, i.e., \( k = 0 \). According to Theorem I.6, \( [\tilde{p}] \) must therefore act as the identity permutation. Exactly two elements of \( \text{Aut}_{LR}(\tilde{C}) \) implement the trivial permutation, namely \( [\tilde{\psi}] \neq [1] \) in \( \tilde{C} \). In particular, \( [\tilde{\psi}] \) restricts to \( [\tilde{\psi}] = [1] \) in \( C \). Hence \( [\tilde{\psi}] \in \ker r \), and \( \ker r = \mathbb{Z}_2^{\max(k,1)} = \mathbb{Z}_2 \).

**Case 3:** Neither \( \tilde{\psi} \) nor \( \tilde{\psi} \) respect locality in their respective categories. In this case, \( r([\tilde{\psi}]) = [\tilde{\psi}] \neq [1] \), so \( [\tilde{\psi}] \notin \ker r \). But \( [\alpha \psi] \) is a non-trivial element of \( \ker r \), and thus must not equal \( [\tilde{\psi}] \). Therefore, \( [\alpha \psi] \) has a non-trivial permutation action, that is, \( \tilde{\psi} \) is non-empty and \( k > 0 \). Now consider any braided autoequivalence \( [\tilde{p}] \in \text{Aut}_{LR}(\tilde{C}) \) which implements one of the anyon permutation actions given above. \( [\tilde{p}] \) must restrict to either \( [1] \) or \( [\tilde{\psi}] \) on \( C \), and \( [\tilde{\psi}] \cup [\tilde{p}] \) will restrict to \( [\tilde{\psi}] \) or \( [1] \) respectively. Hence exactly one of \( [\tilde{p}] \) and \( [\tilde{\psi}] \cup [\tilde{p}] \) is in \( \ker r \), that is, each of the \( 2^k \) permutation actions above defines a unique element of \( \ker r \). If \( [\tilde{p}] \in \ker r \), then \( r([\tilde{p}]^2) = [1] \), so \( [\tilde{p}]^2 = 1 \) as well. Hence \( \ker r = \mathbb{Z}_2^k \), concluding our proof.

One can check that all of the cases we considered above can actually occur. For an example where \( \tilde{\psi} \) respects locality, we can take \( C = B \square \{1, \psi\} \) for any modular \( B \) and \( \tilde{C} = B \square D(\mathbb{Z}_2) \), where \( D(\mathbb{Z}_2) \) is the quantum double of \( \mathbb{Z}_2 \), also known as the toric code topological order. Here \( \square \) is the Deligne product and physically corresponds to stacking decoupled topological orders. Instead taking \( \tilde{C} = B \square \text{Ising} \) gives an example where \( \tilde{\psi} \) does not respect locality but \( \tilde{\psi} \) does. For an example where neither \( \tilde{\psi} \) nor \( \tilde{\psi} \) respects locality, we can take \( C = \text{SO}(3)_3 \); an example minimal modular extension is \( \tilde{C} = \text{SU}(2)_6 \).

It is true but not immediately obvious that one can have \( k > 1 \) decoupled blocks of the \( v \times v \) part of the \( S \)-matrix; we consider an explicit example with \( k = 2 \) in Sec. VI E.
5. ker $r$ when permutations do not uniquely determine $\text{Aut}(\tilde{C})$ and $\text{Aut}(C)$

If there is not a one-to-one correspondence between elements of $\text{Aut}(\tilde{C})$ (resp. $\text{Aut}(C)$) and anyon permutations which preserve the fusion rules and modular data of $\tilde{C}$ (resp. $C$), then we are not generally able to give any further characterization of ker $r$ as a group. All we have is our prior statements: ker $r$ always contains a $\mathbb{Z}_2$ subgroup generated by $[\alpha_y]$, and if $\Upsilon_y$ respects locality but $\tilde{\Upsilon}_y$ does not, then $[\tilde{\Upsilon}_y]$ also generates a $\mathbb{Z}_2$ subgroup of ker $r$ which may or may not equal the subgroup generated by $[\alpha_y]$.

We do know that Theorem I.6 still applies; the anyon permutations of all elements of ker $r$ are still restricted. However, three possibilities could further complicate the analysis of ker $r$:

1. There could be an anyon permutation which preserves the modular data of $\tilde{C}$ but does not correspond to any braided autoequivalence of $\tilde{C}$. In this case, there must be a map $\tilde{\rho}$ from $\tilde{C}$ to an inequivalent theory with the same modular data as $\tilde{C}$, that is, $\tilde{C}$ must have a “modular isotope.” This can occur in general $[36, 37]$. In this situation, ker $r$ may contain fewer than $2^k$ distinct permutation actions.

2. There could be a non-trivial but non-permuting element of $\text{Aut}_{LR}(\tilde{C})$. If such an autoequivalence exists and is in ker $r$, then each allowed permutation action may determine many elements of ker $r$, and each allowed permutation action may give rise to a subgroup of ker $r$ which is larger than $\mathbb{Z}_2$. UMTCs can in general have non-trivial non-permuting autoequivalences $[38]$.

3. There could be a non-trivial but non-permuting element of $\text{Aut}_{LR}(C)$. If such an autoequivalence exists, then there may be some permutation actions allowed by Theorem I.6 which, nevertheless, do not determine an element of ker $r$ because any braided autoequivalence which implements such a permutation action necessarily restricts to a non-trivial but non-permuting element of $\text{Aut}_{LR}(C)$. In this situation, ker $r$ may again contain fewer than $2^k$ distinct permutation actions.

We have not found any example where we know that a particular one of the above possibilities is relevant for characterizing ker $r$. In Section VI.E, we study an example involving two copies of $\text{SO}(3)_3$, for which we suspect one of the above possibilities is occurring.

C. Relation to Arf invariant on torus

Let us consider the case where ker $r = \mathbb{Z}_2$, generated by $[\alpha_y]$. According to the classification of fermion SPTs reviewed in Sec. IV.A, if an FSPT has $[n_1] = 0$, then there is a piece of data $[n_2] \in H^2(G_b, \mathbb{Z}_2)$ in the specification of a (3+1)D fermionic SPT. In the present case, our obstruction $[\alpha_2]$ is also valued in $H^2(G_b, \mathbb{Z}_2)$. It is therefore natural to expect that the $H^2(G_b, \text{ker } r)$ obstruction is, in this case, a ‘t Hooft anomaly which can be canceled by a (3+1)D fermionic SPT with $[n_2] = [\alpha_2]$. In this section, and the next, we give two arguments that these anomalies match.

First, we demonstrate that the action of the symmetry on the torus Hilbert space of the SET is sensitive to the Arf invariant in a way which agrees with the results of $[26]$ for the ‘t Hooft anomaly in the case of $\mathbb{Z}_4^{T,F}$. In Sec. V.D., we give a second argument by explicitly describing anomaly inflow using the decorated domain wall construction for fermion SPTs.

Consider the ground states of the TQFT on a spatial torus, $T^2$. As described in Sec. II.A, the Hilbert space breaks up into four sectors $H_{\mu,\nu}$, where $\{\mu, \nu\} \in \{0,1\}$ specify a spin structure. Here $\mu = 0$ refers to anti-periodic (Neveu-Schwarz) boundary conditions and 1 refers to periodic (Ramond) boundary conditions. These are sometimes also referred to as bounding and non-bounding spin structures, respectively.

Here $H_{\mu,\nu}$ is a $\mathbb{Z}_2$ graded Hilbert space which includes both even and odd fermion number sectors. That is, we can think of this as the TQFT Hilbert space allowing for the possibility of a $\psi$ puncture. We will use the basis Eq. 17 and the description Eq. 18 for the torus Hilbert space. Since the torus Hilbert space of the fermionic theory is defined via states of the minimal modular extension $\tilde{C}$ on the 3-punctured sphere (i.e. its states are defined using simple objects in $\tilde{C}$), only a (representative) lift $\tilde{\rho}_g$ has a well-defined action on the torus Hilbert space.

Our aim is to show that if there is an $H^2$ anomaly, then the action of $\tilde{\rho}_g$ on the torus Hilbert space is necessarily deformed by the Arf invariant

$$\text{Arf}(\mu, \nu) = \mu \nu$$

(87)

of the spin structure. More precisely, given a state $|\Psi\rangle_{\mu,\nu} \in H_{\mu,\nu}$, the $G_b$ group law of the lift is deformed in the sense

$$\tilde{\rho}^{-1}_{g h} \tilde{\rho}_g \tilde{\rho}_h |\Psi\rangle_{\mu,\nu} = o_2(g, h) |\Psi\rangle_{\mu,\nu} = (-1)^{\gamma_2(g, h) \text{Arf}(\mu, \nu)} |\Psi\rangle_{\mu,\nu}.$$  

(88)
The notation $\partial_2(g, h) \in \mathbb{Z}_2 \cong \{0, 1\}$ distinguishes when we are viewing $\sigma_2$ as an element of $\mathbb{Z}_2$ as an additive group from when we view $\sigma_2 \in \mathbb{Z}_2 \cong \ker r$. Eq. 88 extends and sharpens the results of [26], which considered only the special case $G_f = \mathbb{Z}_4^\langle r \rangle$.

Since $o_2(g, h)$ acts trivially on fusion spaces $V^{c}_{ab}$ with $a, b, c \in \tilde{C}_0$, it is immediate that Eq. 88 holds for $\mu = 0$.

Now fix a $v$-type vortex $v$ and consider $|v, \sigma; 1 \rangle \in V^1_{v \sigma}$; then

$$o_2(g, h) \left( |v, \sigma; 1 \rangle \right) = U_{o_2(g, h)} \left( v \times \psi \bar{g}^2, \bar{v} \times \psi \bar{g}^2; 1 \right) |v \times \psi \bar{g}^2, \bar{v} \times \psi \bar{g}^2; 1 \rangle.$$  \hspace{1cm} (89)

The $U$ factors obtained from the action of $o_2$ on $V^1_{v \sigma}$ and its dual $V^1_{v \sigma}^*$ are complex conjugates and thus will always cancel out, so the action of $o_2(g, h)$ is either trivial or simply interchanges $(V^1_{v \sigma} \otimes V^1_{v \sigma}^*)$ and $(V^1_{v \sigma} \otimes V^1_{v \sigma}^*)$. Said differently,

$$o_2(g, h) |v \rangle = |v \times \psi \bar{g}^2 \rangle$$  \hspace{1cm} (90)

where $|v \rangle$ is a torus state of definite topological charge $v$ piercing the $\sigma$ cycle. Therefore, using Eq. 17, we find

$$o_2(g, h) |v \rangle_{1,0} = |v \rangle_{1,0}$$  \hspace{1cm} (91)

$$o_2(g, h) |v \rangle_{1,1} = (-1)^{o_2(g, h)} |v \rangle_{1,1}$$  \hspace{1cm} (92)

which verifies Eq. 88 for the present case.

Finally, we must consider states built from a $\sigma$-type vortex. The above argument immediately generalizes to the unpunctured states to show that

$$o_2(g, h) |\sigma \rangle_{1,0} = |\sigma \rangle_{1,0}$$  \hspace{1cm} (93)

Running a similar argument on the states with a puncture, we find that

$$o_2(g, h) |\sigma; \psi \rangle = U_{o_2(g, h)}|\sigma, \sigma; 1 \rangle U_{o_2(g, h)}^*|\sigma, \sigma; \psi \rangle |\sigma, \psi \rangle$$  \hspace{1cm} (94)

Since $o_2$ does not permute $\sigma$, and $\sigma \times \psi = \sigma$, one can show from the consistency conditions that

$$U_{o_2(g, h)}|\sigma, \sigma; 1 \rangle U_{o_2(g, h)}^*|\sigma, \psi; \psi \rangle = U_{o_2(g, h)}|\sigma, \psi; \sigma \rangle$$  \hspace{1cm} (95)

This last quantity was computed in Eq. 80; combining it with Eqs. 94 and 95, we obtain Eq. 88 for this last class of states.

### D. Anomaly inflow from bulk (3+1)D FSPT

Again restricting to $\ker r = \mathbb{Z}_2$, we will make an anomaly inflow argument directly relating the $[o_2] \in \mathcal{H}^2(G_b, \mathbb{Z}_2)$ anomaly discussed above and the $[n_2] \in \mathcal{H}^2(G_b, \mathbb{Z}_2)$ that arises in the classification of (3+1)D fermionic SPTs.

First, we note that the physical meaning of the 2-cocycle $n_2(g, h)$ that characterizes a (3+1)D bulk SPT is as follows. The (3+1)D fermionic SPT state can be considered to be a superposition of all possible networks of codimension-1 domain walls. A non-trivial $n_2(g, h)$ means that the codimension-2 junction of three codimension-1 $G_b$ domain walls labeled $g, h$, and $gh \in G_b$ are decorated with a (1+1)D Kitaev chain if $n_2(g, h)$ is non-trivial. Therefore, we can consider our system on a 3-dimensional space with boundary, and with a particular choice of domain wall junction, as shown in Fig. 1.

Second, we note that an important property of a (1+1)D Kitaev chain is that it can be coupled to a $\mathbb{Z}_2^d$ gauge field, and we can insert a $\mathbb{Z}_2^d$ symmetry defect (flux). For the Kitaev chain defined on a ring, the $\mathbb{Z}_2^d$ symmetry defect changes the spin structure; that is, it changes the boundary conditions from periodic to anti-periodic (or vice versa). It is well-known that changing the spin structure changes the fermion parity of the ground state. To see this concretely, we can consider the Hamiltonian for the Kitaev chain:

$$H_K = -i \sum_j (u_{\gamma_j} \gamma_{j+1} \sigma_{j,j+1} + v_{\gamma_j} \gamma_{j+1}).$$  \hspace{1cm} (96)

Here $\gamma_j, \gamma_j'$ are independent Majorana fermion operators on site $j$ (i.e. $\{\gamma_j, \gamma_k\} = \{\gamma_j', \gamma_k'\} = 2 \delta_{jk}$ and $\{\gamma_j, \gamma_k'\} = 0$. Note that this system can also be written in terms of complex fermions $c_i = \gamma_i + i \gamma_i'$. Furthermore, we have coupled the system to a $\mathbb{Z}_2$ gauge field $\sigma_{j,j+1} = \pm 1$ on the links $(j, j + 1)$. 

Setting $\sigma_{j,j+1} = 1$ for all $j$, the limits $u/v \ll 1$ and $u/v \gg 1$ realize topologically distinct phases. When the system originates from a model of hopping and pairing of complex fermions $c_i$, it is natural to identify the $u/v \ll 1$ to be the trivial phase and $u/v \gg 1$ to be the topological phases. A hallmark of the topological phase is that the the fermion parity of the ground state changes in the presence of a $\mathbb{Z}_2$ symmetry defect on the link $(j, j + 1)$ (which corresponds to setting $\sigma_{j,j+1} = -1$). This can be seen easily in the limit $v = 0$, where the ground state is simply $i\gamma^j_0 \gamma_{j+1} = \sigma_{j,j+1}$. Therefore taking $\sigma_{j,j+1} \rightarrow -\sigma_{j,j+1}$ changes the local fermion parity $i\gamma^j_0 \gamma_{j+1}$ by one.

Next, let us consider fermion parity vortices at the (2+1)D surface, which are endpoints of fermion parity vortex lines that go into the (3+1)D bulk. Let us consider a process, shown in Fig. 1, where a fermion parity vortex $v$ at the surface encircles the trijunction where the defects $g, h, gh$ all meet. Importantly, to come back to the original configuration, the vortex line in the bulk sweeps across a membrane that must necessarily intersect the Kitaev chain on the codimension-2 junction in the bulk. This changes the fermion parity of the Kitaev chain, which must be compensated for by a change in fermion parity on the vortex line. This can then be interpreted as a transformation $v \rightarrow v \times \psi$ in the surface theory. Therefore we see that we indeed obtain the symmetry action $\tilde{\mathcal{F}}(g, h) \times \psi = \tilde{\mathcal{F}}(gh) \times \psi$, where here we take $\tilde{\mathcal{F}}(g, h) = 1, \psi$, which is consistent with the action $\tilde{\mathcal{F}}(g, h) \times v$. If $v \in \mathbb{C}_2$, this process does not permute the vortices but instead changes the fusion channel of two $\sigma$-type vortices, which is expected because they are braiding with a Majorana zero mode.

E. On the possibility $\ker r \neq \mathbb{Z}_2$

As discussed in Sec. VI.B.5, we cannot presently exclude the possibility that $\ker r$ is different from $\mathbb{Z}_2$. This might happen because the number of blocks in the $v - v$ portion of the $S$-matrix of $\hat{C}$ is $k > 1$, or because certain permutations of $\hat{C}$ which preserve the modular data do not uniquely determine an element of $\text{Aut}(\hat{C})$. If $\ker r \neq \mathbb{Z}_2$, it is not immediately obvious how to connect the ’t Hooft anomaly $[n_2] \in \mathcal{H}^2(G_b, \mathbb{Z}_2)$ to the obstruction $o_2(G_b, \ker r)$. We do know, however, that $\ker r$ contains a $\mathbb{Z}_2$ subgroup generated by $[\alpha_v]$.

Our anomaly arguments in Secs. VI.C, VI.D are quite general and physical, so we expect that there should be a fully general connection between the ’t Hooft anomaly and the $\mathcal{H}^2(G_b, \ker r)$ obstruction. We therefore conjecture the following:

**Conjecture VI.2.** In all cases, $\ker r = \mathbb{Z}_2 = \{[1], [\alpha_v]\}$, and $[o_2] \in \mathcal{H}^2(G_b, \mathbb{Z}_2)$ is equal to the ’t Hooft anomaly $[n_2]$ of the (2+1)D fermionic topological phase in question.
modular data of block formed by \( \rho \), where the particle content is labeled as in Appendix C. The other two possible lifts of \( k \) of the results of [26]; the un-generalized results are reviewed in Appendix A.

Examining the set of permutations which preserve the modular data, one would naively conclude that \( \ker r \) is trivial and so there would be no connection between \( n_2 \) and \( o_2 \). This is in tension with the physical arguments for Conjecture VI.2. We give a well-defined but difficult in practice way to test Conjecture VI.2 in this case.

Consider the theory \( \mathcal{C} = \text{SO}(3)_3 \boxtimes \text{SO}(3)_3/\{\psi \psi \sim 1\} \), where the quotient means we condense the bound state of the transparent fermions from each copy of the theory. We take \( G_b = \mathbb{Z}_2^T \) and \( G_f = \mathbb{Z}_2^{T,f} \). It is easy to check that this theory is super-modular. For this \( G_f \), the 3+1D FSPT classification is \( \mathbb{Z}_{16} \), and it is known that \( \text{SO}(3)_3 \) has a \( \nu = 3 \) anomaly in this \( \mathbb{Z}_{16} \) classification [23]. Hence \( \mathcal{C} \) has a \( \nu = 6 \) anomaly which is associated with the nontrivial element \( [n_2] \in \hat{H}^2(\mathbb{Z}_2^T, \mathbb{Z}_2) = \mathbb{Z}_2 \).

The minimal modular extension we consider is \( \tilde{\mathcal{C}} = \text{SU}(2)_6 \boxtimes \text{SU}(2)_6 \boxtimes \mathcal{I}(-9)/\{\psi \psi \sim 1\} \), where \( \mathcal{I}(-9) \) is the \( c_- = -9/2 \) minimal modular extension of \( \{1, \psi\} \) and the quotient means we condense all pairs of Abelian fermions from the different theories. The particle content, topological twists, quantum dimensions, and possible actions of \( T \) are listed in Table I, while the \( S \)-matrix is given in Appendix C. The data were derived from a slight generalization of the results of [26]; the un-generalized results are reviewed in Appendix A.

Examining the set of permutations which preserve the modular data, one would naively conclude that \( \ker r = \mathbb{Z}_2^2 \) because there are \( k = 2 \) distinct blocks of the \( \tilde{\mathcal{C}} \), part of the \( S \)-matrix, namely one block formed by \( (1, 3, \sigma)_{\pm} \) and one block formed by \( (3, 1, \sigma)_{\pm} \). There are thus four possible lifts of the permutation action of \( \rho_T \) to \( \tilde{\mathcal{C}} \) which preserve the modular data of \( \mathcal{C} \). Two form a group homomorphism \( \mathbb{Z}_2^T \rightarrow \text{Aut}_{LR}(\mathcal{C}) \): their actions are given by a choice of signs:

\[
(1, 3, \sigma)_{\pm} \leftrightarrow (3, 1, \sigma)_{\mp}
\]
\[
(1, 3, \sigma)_{\pm} \leftrightarrow (3, 1, \sigma)_{\mp}
\]
\[
(1, 1, \sigma) \leftrightarrow (3, 3, \sigma),
\]

where the particle content is labeled as in Appendix C. The other two possible lifts of \( \rho_T \) form a group homomorphism \( \mathbb{Z}_4^T \rightarrow \text{Aut}_{LR}(\tilde{\mathcal{C}}) \):

\[
(1, 3, \sigma)_{\pm} \rightarrow (3, 1, \sigma)_{\pm} \rightarrow (1, 3, \sigma)_{\mp} \rightarrow (3, 1, \sigma)_{\mp} \rightarrow (1, 3, \sigma)_{\pm}
\]
\[
(1, 1, \sigma) \leftrightarrow (3, 3, \sigma)
\]

This implies that if \( k > 1 \), then for at least one of \( \tilde{\mathcal{C}} \) and \( \mathcal{C} \), not every permutation of simple objects that preserves the modular data defines a unique braided autoequivalence. According to the discussion of Sec. VI.B.5, we expect that \( \tilde{\mathcal{C}}, \mathcal{C} \), or both have a modular isotope or have a non-trivial autoequivalence which does not permute simple objects.

We give a well-defined but difficult in practice way to test Conjecture VI.2 in this case.
Within each pair, the two possible lifts differ by the permutation action of \( \alpha_\phi \).

Choosing a lift in Eq. 97, the permutation action of \( o_2 \in \ker r \) is trivial. One can check that \( \Upsilon_\psi \) does not respect locality in this theory, so \( \Upsilon_\psi \) is not in \( \ker r \); accordingly, if we assume that permutations which preserve the modular data uniquely determine an element of \( \text{Aut}(\bar{C}) \), \( [o_2] \) is trivial. However, as argued above, \( [n_2] \) is non-trivial. We therefore expect that permutations do not uniquely determine an element of \( \text{Aut}(\bar{C}) \) in this theory.

In the cases in Eq. 98 where the lift is not a group homomorphism \( \bar{C}_\alpha \to \text{Aut}_{LR}(\bar{C}) \), we see explicitly that, as permutations,

\[
\tilde{\rho}_g^{(2)} = \alpha_\psi.
\] (99)

Therefore, if only the permutations in Eq. 98 define valid autoequivalences of \( \bar{C} \) and \( \ker r = \mathbb{Z}_2 \), we would indeed obtain \( [o_2] = [n_2] \) for \( C = \text{SO}(3)_3 \). We speculate that this is the case; in order to check this speculation, one would need to solve for the \( F \)- and \( R \)-symbols of \( \bar{C} \), which is a non-trivial task, and then directly attempt to solve for the \( U \)-symbols for each permutation action. We expect that a solution for the \( U \)-symbols exists only for the permutations in Eq. 98.

F. Independence of modular extension

In the special case that \( G_b \) contains anti-unitary symmetries, we give a proof of Conjecture I.7, which can be roughly summarized as claiming that the \( \mathcal{H}^2 \) anomaly is independent of the choice of modular extension, and then give partial results in the case where all elements of \( G_b \) are unitary.

**Theorem VI.3.** Suppose \( G_b \) contains at least one anti-unitary symmetry. Then the obstruction \( [o_2] \in \mathcal{H}^2(G_b, \ker r) \) is identical for every \( \nu \) for which there exists, for every \( g \in G_b \), a lift \( \tilde{\rho}_g^{(2)}: \bar{C}_\nu \to \bar{C}_\nu \) of \( \rho_g \).

**Proof.** Suppose that lifts of \( \rho_g \) exist for two modular extensions \( \bar{C}_{\nu_1} \) and \( \bar{C}_{\nu_2} \). Let \( r_i \) be the restriction map \( r_i: \text{Aut}_{LR}(\bar{C}_{\nu_i}) \to \text{Aut}_{LR}(\bar{C}_{\nu_i}) \mid \text{ker} \). Suppose we have a particular lift \( \tilde{\rho}_g^{(1)} \) of \( \rho_g \) to \( \bar{C}_{\nu_1} \). Since \( G_b \) contains anti-unitary symmetries, the only possible \( \bar{C}_{\nu_2} \) are obtained from \( \bar{C}_{\nu_1} \) by stacking the invertible phase with central charge \( c = 4 \mod 8 \).

Upon gauging fermion parity, this \( c = 4 \) phase is equivalent to the 3-fermion topological order. Stacking such a phase has the effect of changing the topological twist of the fermion parity vortices by a minus sign:

\[
\theta_x \to -\theta_x \quad \text{if} \quad x \in (\bar{C}_{\nu_1})_1,
\] (100)

while keeping invariant the fusion rules, \( S \)-matrix, and \( F \)-symbols. Therefore, we can use the same anyon labels for \( \bar{C}_{\nu_1} \) and \( \bar{C}_{\nu_2} \) and define the action of \( \tilde{\rho}_g^{(2)} \) on basis states by

\[
\tilde{\rho}_g^{(2)} |a, b; c\rangle_{\bar{C}_{\nu_2}} = \tilde{U}_g^{(1)}(g_a, g_b; g_c) |a, b; c\rangle_{\bar{C}_{\nu_2}}
\] (101)

where the permutation actions on the anyon labels and the \( U \)-symbols are given by interpreting the anyon labels in \( \bar{C}_{\nu_2} \). The action of \( \tilde{\rho}_g^{(2)} \) is extended to the full Hilbert space by (anti)-linearity. Similarly, \( \ker r_1 = \ker r_2 \) and the permutation action and \( U \)-symbols for each element of \( \ker r_1 \) can be reinterpreted as valid data for the corresponding element of \( \ker r_2 \). It follows immediately that \( \tilde{\rho}_g^{(2)} \) defines the same cocycle \( o_2(g, h) \in \mathbb{Z}^2(G_b, \mathbb{Z}_2) \) and thus the same cohomology class \( [o_2(g, h)] \).

We can prove a weaker result in the case where \( G_b \) is unitary. Let \( P(\bar{C}) \) be the group of anyon permutations of \( \bar{C} \) which preserve the modular \( S \)- and \( T \)-matrices of \( \bar{C} \).

**Proposition VI.4.** Let \( \tilde{\rho}_g^{(1)} \) be a lift of \( \rho_g \) to \( \text{Aut}_{LR}(\bar{C}_{\nu_1}) \) which defines the obstruction \( o_2^{(1)} \in \mathcal{H}^2(G_b, \ker r) \). If \( G_b \) is unitary, then there is a permutation \( \tilde{\rho}_g^{(2)} \in P(\bar{C}_{\nu_1}) \) which lifts \( \rho_g \) as an element of \( P(\bar{C}) \). Furthermore, \( \tilde{\rho}_g^{(2)} \) defines a permutation \( o_2^{(2)} \) by Eq. 61; if \( \delta \nu = \nu_2 - \nu_1 \) is even, then \( o_2^{(2)} = o_2^{(1)} \) as permutations, while if \( \delta \nu \) is odd, then \( o_2^{(2)} \) is the trivial permutation.

The proof is quite technical, so we briefly sketch it here and defer the details to Appendix B. The main idea is to use the 16-fold way theorem [28], which states that a generic minimal modular extension may be derived from a given on \( \bar{C}_{\nu_1} \) by layering \( \bar{C}_{\nu_1} \) with a minimal modular extension \( \mathcal{I}(\delta \nu) \) of \( \{1, \psi\} \) and condensing the bound state of the
fermions in the two layers. Using results on anyon condensation [26], we can derive the modular data of a generic minimal modular extension from the given one \( \tilde{C} \). This step is straightforward when \( \delta \nu \) is even because \( I(\delta \nu) \) is Abelian, but it is quite involved when \( \delta \nu \) is odd so that \( I(\delta \nu) \) is non-Abelian. From the new modular data, we can explicitly construct an element of \( P(\tilde{C}_{v_2}) \) for each \( \rho^{(1)}_q \) and then calculate the permutation action of compositions of these permutations.

Prop. VI.4 has the rather surprising corollary:

**Corollary VI.5.** Suppose that in every minimal modular extension of \( C \), every lift of \( \rho_q \) as a permutation action from \( P(C) \) to \( P(\tilde{C}) \) defines a lift of the autoequivalence class \([\rho_q]\) from \( \text{Aut}_{LR}(C) \) to \( \text{Aut}_{LR}(\tilde{C}) \). Then if \( \Upsilon_\psi \) violates locality, given any lift of the symmetry to \( \tilde{C}_{v_1} \), we can construct a non-anomalous lift to all \( \tilde{C}_{v_2} \) for any \( v_2 \), that is, \( [\sigma_2] = 0 \) independent of the modular extension. If \( \Upsilon_\psi \) respects locality, then we can construct a non-anomalous lift to exactly half of the minimal modular extensions.

**Proof.** (Corollary VI.5) First consider the case where \( \Upsilon_\psi \) violates locality. Then \( \tilde{\Upsilon}_\psi \) also violates locality for all minimal modular extensions \( \tilde{C}_{v_1} \), and all nontrivial elements of ker \( r \) have a nontrivial permutation action. But according to Proposition VI.4, for \( v_2 - v_1 \) odd, \( o_2(2) \) has trivial permutation action, so it must be the identity as an autoequivalence. Now repeat the argument starting from the permutation action \( \rho^{(2)}_q \) to see that for \( v_3 - v_2 \) odd, that is, \( v_3 - v_1 \) even, we can again construct a \( \rho^{(3)}_q \) such that \( o_2(3) \) is also trivial.

If \( \Upsilon_\psi \) respects locality, then for some \( v_0 \), for all minimal modular extensions \( \tilde{C}_v \) of \( C \) with \( v = v_0 \) mod 2 contain only \( \sigma \)-type fermion parity vortices, and while all minimal modular extensions with \( v = v_0 + 1 \) mod 2 contain only \( \nu \)-type fermion parity vortices (at least two of which are Abelian). We may assume without loss of generality that the extension \( \tilde{C}_{v_1} \) for which we are given a symmetry action obeys \( v_1 = v_0 \) mod 2. If this is not the case, then use Prop. VI.4 to construct a symmetry action on \( \tilde{C}_{v_1+1} \) (which must have only \( \sigma \)-type fermion parity vortices) and reindex \( v_1 \rightarrow v_1 - 1 \) mod 16. Now applying the \( \delta \nu \) odd case of Prop. VI.4, we obtain a symmetry action on \( \tilde{C}_{v_1+1} \) with \( o_2(v_1+1) \) a nonpermuting element of ker \( r \); since \( \tilde{C}_{v_1+1} \) has only \( \nu \)-type vortices, all non-trivial elements of ker \( r \) are permuting (see Sec. VII B), and thus \( o_2(v_1+1) \) is the identity. Using the \( \delta \nu \) even case of Prop. VI.4, we obtain a non-anomalous lift for all \( v_2 = v_1 + 1 \) mod 2.

We comment that the above argument does not extend to \( v_1 = v_0 \) mod 2, since ker \( r \) contains a nontrivial nonpermuting element \( \tilde{\Upsilon}_\psi \).

Since \( \tilde{C}_{v+1} \) can be obtained from \( \tilde{C}_v \) by stacking a \( p + ip \) superconductor before gauging fermion parity, it would be very surprising if the anomaly depends on \( \nu \). Prop. VI.4 is thus strong evidence that any theory with an \( H^2 \) anomaly must violate its assumptions; in particular, following a very similar discussion in Sec. VIE, we expect that a nontrivial \( H^2 \) anomaly with \( G_b \) unitary can only occur in theories with modular isotopes or with some nontrivial autoequivalence which does not permute the anyons.

**VII. \( H^3(G_b, \mathbb{Z}_2) \) OBSTRUCTION**

Suppose that the \( H^2(G_b, \text{ker} \ r) \) obstruction vanishes, so that we may lift a group homomorphism \([\rho_q] : G_b \rightarrow \text{Aut}_{LR}(C)\) to a group homomorphism \([\tilde{\rho}_q] : G_b \rightarrow \text{Aut}_{LR}(\tilde{C})\). Given a symmetry fractionalization pattern on \( C \), we ask whether or not that fractionalization pattern can be lifted to \( \tilde{C} \). We will show that there is an obstruction to this process valued in \( H^3(G_b, \mathbb{Z}_2) \). Our discussion will very similar to that of Ref. [25], but [25] assumed \( G_f = G_b \times \mathbb{Z}_2 \) and made some technical assumptions which are known to fail in certain cases. We will use our general understanding of fermionic symmetry fractionalization to remove those technical assumptions.

Note also that \([\tilde{\rho}_q]\) defines a \( G_b \) symmetry action on a UMTC \( \tilde{C} \), so there may be an obstruction to localizing \([\tilde{\rho}_q]\), that is, to finding any symmetry fractionalization on \( \tilde{C} \) irrespective of whether it matches the symmetry fractionalization on \( C \). This obstruction is valued in \( H^3(G_b, \tilde{A}) \) and can be computed in the standard way for bosonic SETs, see [1]. We will show that this obstruction is in fact determined by the \( H^3(G_b, \mathbb{Z}_2) \) obstruction.

**A. \( H^3(G_b, \mathbb{Z}_2) \) anomaly**

We start with symmetry fractionalization data, which we choose to characterize by \( \omega(a, g, h) \in C^2(G_b, K(C)) \) satisfying Eq. 33. In the present language, \( \Omega_a \in Z^3(G_b, K(C)) \). The gauge freedom \( \nu_a \) appearing in Eq. 37 is an element of \( K(C) \), so only \( [\Omega_a] \in H^3(G_b, K(C)) \) is gauge-invariant.
We are also given a lift \( \tilde{\omega} \) of the symmetry action \( \rho \) to \( \tilde{C} \), which determines a specific (unambiguous) lift \( \tilde{\Omega}_a(\mathbf{g}, \mathbf{h}, \mathbf{k}) \in H^3(G_b, K(\tilde{C})) \). One can naively think of the lift condition as simply taking a cocycle representative \( \tilde{\Omega}_a \) and demanding that it match \( \Omega_a \) when \( a \in C \), but as we will see, we will need to weaken this condition slightly. There is a restriction map \( r : K(\tilde{C}) \to K(C) \) given by restricting to \( \tilde{C}_0 = C \). The map \( r \) induces a map on cohomology, which we will also call \( r \), and we have

\[
r([\tilde{\Omega}]) = [\Omega]
\]  

(102)

Certainly a cocycle representative \( \tilde{\Omega}_a \) of \( [\tilde{\Omega}] \) restricts to some representative \( \Omega_a \), but as we will see later, it may be that not all representatives \( \Omega_a \) lift to a representative \( \tilde{\Omega}_a \). We only demand that the cohomology class lift, that is, that given representatives \( \Omega_a \) and \( \omega_a \), some gauge-equivalent representatives lift.

We now ask whether or not there exists a lift \( \tilde{\omega}_a \in C^2(G_b, K(\tilde{C})) \) such that

\[
\tilde{\Omega}_a = d\tilde{\omega}_a
\]

(103)

for all \( a \in \tilde{C} \) and such that \( r(\tilde{\omega}_a) = \omega_a \).

The first step is to show that there always exists exactly two lifts \( \tilde{\omega}_a \) of \( \omega_a \). Suppose first that such a lift exists. There always exists an element \( p_a \in K(\tilde{C}) \) defined by

\[
p_a = M_a,\psi = \begin{cases} 1 & \text{if } a \in \tilde{C}_0 \\ -1 & \text{if } a \in C_1 \end{cases}
\]

(104)

Hence, given a lift \( \tilde{\omega}_a(\mathbf{g}, \mathbf{h}) \), there is always another one \( \tilde{\omega}_a p_a^\alpha(\mathbf{g}, \mathbf{h}) \) with \( \alpha \in C^2(G_b, \mathbb{Z}_2) \) (here \( \mathbb{Z}_2 = \{0, 1\} \)). Also, we may always write

\[
\tilde{\Omega}_a = M_a,\tilde{\psi}
\]

(105)

\[
\tilde{\omega}_a = M_a,\tilde{\psi}
\]

(106)

for some \( \tilde{\psi}, \tilde{\Omega} \in \tilde{A} \) because \( \tilde{C} \) is modular; the \( p_a \) freedom mentioned above amounts to changing \( \mathbf{w} \to \tilde{\mathbf{w}} \times \psi \). By super-modularity of \( C \), the only element of \( \tilde{C} \) which braids trivially with all of \( \tilde{C}_0 \) is \( \psi \), so the two lifts defined by \( \tilde{\mathbf{w}} \) and \( \mathbf{w} \times \psi \) are the only ones which restrict to \( \omega_a \) on \( C \). Hence, if a lift exists, there are exactly two such lifts.

The reason that some lift exists at all depends on whether \( \Upsilon_\psi \) and \( \tilde{\Upsilon}_\psi \) respect or violate locality. We will prove this in casework after completing the rest of the argument for the \( H^3 \) obstruction.

Assuming some lift exists, choose one, which we call \( \tilde{\omega}_a \). We must ask if Eq. 103 is satisfied. Define

\[
\tilde{\Omega}_a(\mathbf{g}, \mathbf{h}, \mathbf{k}) = \tilde{\Omega}_a(\mathbf{g}, \mathbf{h}, \mathbf{k}) (d\tilde{\omega}_a(\mathbf{g}, \mathbf{h}, \mathbf{k}))^{-1}.
\]

(107)

Clearly Eq. 103 is satisfied for all \( a \in \tilde{C} \) if and only if \( \tilde{\Omega}_a = 1 \in Z^3(G_b, K(\tilde{C})) \). This will not generally be the case; however, by definition Eq. 103 is satisfied if \( a \in C \). Hence \( \tilde{\Omega}_a = 1 \) for all \( a \in C \) and therefore \( \tilde{\Omega}_a \in C^3(G_b, \mathbb{Z}_2) \) where we have identified \( \{1, p_a\} = \mathbb{Z}_2 \). By straightforward computation, \( d\tilde{\Omega}_a = 1 \). We have the freedom to choose a different lift \( \tilde{\omega}_a(\mathbf{g}, \mathbf{h}) p_a^\alpha(\mathbf{g}, \mathbf{h}) \), which modifies \( \tilde{\Omega}_a \to \tilde{\Omega}_a p_a^\alpha \), that is, it changes \( \tilde{\Omega}_a \) by a \( \mathbb{Z}_2 \)-coboundary. Therefore, \( [\tilde{\Omega}] \in H^3(G_b, \mathbb{Z}_2) \) is a well-defined cohomology class independent of the choice of lift, and if \( [\tilde{\Omega}] = 1 \), there exists a representative \( \tilde{\Omega}_a = 1 \), i.e., some lift satisfies Eq. 103. We therefore see that \( [\tilde{\Omega}] \in H^3(G_b, \mathbb{Z}_2) \) is the obstruction to lifting symmetry fractionalization from \( C \) to all of \( \tilde{C} \).

Note that we do not need to make any explicit reference to \( G_f \), which is encoded via the constraint \( \eta_\psi = \omega_g \). The lifted symmetry fractionalization data automatically agrees with the symmetry fractionalization data on \( C \) and therefore also obeys the constraint.

The above argument is merely a reformulation of that of Ref. [25]. However, Ref. [25] assumes that \( \Omega_a \) and \( \omega_a \) can always be written as double braids of \( a \) with some element of \( \tilde{C} \); rephrased in the present language, they assume that \( \Omega_a \) and \( \omega_a \) have some lifts \( \tilde{\Omega}_a \) and \( \tilde{\omega}_a \). This assumption is only obviously true if \( \tilde{\Upsilon}_\psi \) respects locality. In what follows, we justify this assumption in different cases depending on whether \( \tilde{\Upsilon}_\psi \) and \( \Upsilon_\psi \) respect locality. We will heavily rely on results from [29] summarized in Sec. IV B which relate whether or not \( \Upsilon_\psi \) respects locality to various properties of \( C \) and \( \tilde{C} \).

One might ask separately if there could be an \( H^3(G_b, \tilde{A}) \) obstruction to defining any \( G_b \) symmetry fractionalization pattern on \( \tilde{C} \), whether it agrees with the symmetry fractionalization on \( C \) or not. Obviously if the \( H^3(G_b, \mathbb{Z}_2) \) obstruction \( [\tilde{\Phi}] \) vanishes, there cannot be any such obstruction. We claim more generally that \( [\tilde{\Phi}] \) actually determines the \( H^3(G_b, \tilde{A}) \) obstruction, and in the following we explain the relationship in each case.
1. Case: $\Upsilon_\psi$ violates locality

If $\Upsilon_\psi$ violates locality, then $K(\mathcal{C}) = K_+(\mathcal{C})$, that is, every set of phases which obey the fusion rules on $\mathcal{C}$ are +1 on the fermion, and also $\tilde{A} = A$. Hence $\Omega_a$ and $\omega_a$ are in $K_+(\mathcal{C})$, so

$$\Omega_a = M_{a,\phi}$$
$$\omega_a = M_{a,\omega}$$

(108)

for $\mathcal{O} \in \mathbb{Z}^3(G_b, \mathcal{A}/\{1, \psi\})$ and $\mathbf{w} \in C^2(G_b, \mathcal{A}/\{1, \psi\})$. We can then lift $\Omega_a$ and $\omega_a$ to $\tilde{\mathcal{C}}$ straightforwardly by extending Eq. 108 to all $a \in \tilde{\mathcal{C}}$. The lifted symmetry action $[\tilde{p}]$ on $\tilde{\mathcal{C}}$, which we have already taken as a given, determines the lift $\Omega_a$, while there is freedom in choosing a lift of $\omega_a$ using $p_a$, as discussed previously.

Having proven that a lift exists, we now discuss the $\mathcal{H}^3(G_b, K(\tilde{\mathcal{C}}))$ obstruction. The short exact sequence

$$1 \to \mathbb{Z}_2 = \{1, \psi\} \to \mathcal{A} \to \mathcal{A}/\{1, \psi\} \to 1$$

(109)

induces a map

$$i : \mathcal{H}^3(G_b, \mathbb{Z}_2) \to \mathcal{H}^3(G_b, \mathcal{A})$$

(110)

that is part of the long exact sequence

$$\cdots \to H^2(G_b, \mathcal{A}/\{1, \psi\}) \xrightarrow{\delta} H^3(G_b, \mathbb{Z}_2) \xrightarrow{i} H^3(G_b, \mathcal{A}) \xrightarrow{q} H^3(G_b, \mathcal{A}/\{1, \psi\}) \to \cdots$$

(111)

The fact that $\Upsilon_\psi$ violates locality means that no minimal modular extension of $\mathcal{C}$ contains an Abelian parity vortex; therefore, $\tilde{A} = A$. By construction, then, $i([\mathcal{O}]) = [\tilde{\mathcal{O}}]$, which is the actual $\mathcal{H}^3(G_b, \tilde{A})$ obstruction to symmetry localization. Therefore, the $\mathcal{H}^3(G_b, \mathbb{Z}_2)$ obstruction actually determines the $\mathcal{H}^3(G_b, \tilde{A})$ obstruction of the lifted theory; either $[\tilde{\mathcal{O}}] \in \ker i$, in which case symmetry localization is not obstructed on $\tilde{\mathcal{C}}$ even if the lift of the particular symmetry fractionalization pattern in question is obstructed, or $i([\mathcal{O}])$ is nontrivial, in which case there is an obstruction to lifting the given symmetry fractionalization pattern on $\mathcal{C}$ to $\tilde{\mathcal{C}}$ simply because there is no consistent symmetry fractionalization pattern on $\tilde{\mathcal{C}}$ at all.

We note that the fact that symmetry fractionalization is unobstructed on $\mathcal{C}$, i.e. that $[\mathcal{O}] = q([\tilde{\mathcal{O}}])$ is trivial, means that $[\tilde{\mathcal{O}}] \in \ker q = \im i$, which is why we could find $[\tilde{\mathcal{O}}] \in \mathcal{H}^3(G_b, \mathbb{Z}_2)$ with $i([\mathcal{O}]) = [\tilde{\mathcal{O}}]$.

2. Case: $\Upsilon_\psi$ and $\tilde{\Upsilon}_\psi$ respect locality

We show that every element of $K(\mathcal{C})$ has a lift to $K(\tilde{\mathcal{C}})$, which implies that $\Omega_a$ and $\omega_a$ lift to $K(\tilde{\mathcal{C}})$. First suppose that $\zeta_a \in K_+(\mathcal{C})$; then

$$\zeta_a = M_{a,\chi}$$

(112)

for some $x \in \mathcal{A}/\{1, \psi\}$. By simply choosing a representative of $x \in \mathcal{A}$, we obtain a lift of $\zeta_a$ by extending Eq. 112 to all $a \in \tilde{\mathcal{C}}$. As usual, there is another lift related by sending $x \to x \times \psi$, or equivalently by modifying the lift by $p_a$.

Suppose instead that $\zeta_a \in K_-(\mathcal{C})$. Since $\tilde{\Upsilon}_\psi$ respects locality, $\tilde{\mathcal{C}}$ contains an Abelian fermion parity vortex; call such a parity vortex $\nu$, and define $\lambda_a = M_{a,v} \in K_-(\mathcal{C})$ and $\tilde{\lambda}_a = M_{a,\nu} \in K_-(\mathcal{C})$. Then $\lambda_a^{-1}\zeta_a \in K_+(\mathcal{C})$ and, as we have already shown, has exactly two possible lifts $(\tilde{\lambda}_a) = M_{a,\tilde{x}}$, where the two possible choices of $\tilde{x} \in \mathcal{A}$ differ by a fermion, to $K_+(\tilde{\mathcal{C}})$. Hence there are exactly two (distinct) possible lifts $\tilde{\lambda}_a(\lambda_a^{-1}\zeta_a) = M_{a,\tilde{x} \times \nu}$ of $\zeta_a$ to $K_-(\tilde{\mathcal{C}})$. These two lifts differ by changing $\tilde{x} \times \nu$ by a fermion, or equivalently by modifying the lift by $p_a$.

This proves that every element of $K(\mathcal{C})$ lifts to $K(\tilde{\mathcal{C}})$, as desired.

Our argument that the $\mathcal{H}^3(G_b, \mathbb{Z}_2)$ obstruction determines the $\mathcal{H}^3(G_b, \tilde{A})$ obstruction for general symmetry fractionalization on $\tilde{\mathcal{C}}$ carries through from the case where $\Upsilon_\psi$ violates locality. The only difference is that we start from a short exact sequence

$$1 \to \mathbb{Z}_2 \to K(\tilde{\mathcal{C}}) = \tilde{A} \to K(\mathcal{C}) \to 1.$$  

(113)

Using the fact that the (bosonic) obstruction to symmetry fractionalization on $\mathcal{C}$ is valued in $H^3(G_b, K(\mathcal{C}))$, the rest of the argument carries through mutatis mutandis.
3. Case: $\Upsilon_\psi$ respects locality but $\tilde{\Upsilon}_\psi$ does not

This case is a bit trickier than the others because $\tilde{C}$ does not contain an Abelian fermion parity vortex; hence $\tilde{A} = \mathcal{A}$, and every element of $K(\tilde{C})$ restricts to an element of $K_+(\mathcal{C})$. As such, $K_+(\tilde{C})/\mathbb{Z}_2 = K_+(\mathcal{C})$, where the $\mathbb{Z}_2$ subgroup is generated by $p_a = M_{a,\psi}$.

In general, $\Omega_a$ and $\omega_a$ take values in $K(\mathcal{C})$, not necessarily in $K_+(\mathcal{C})$, so they need not have lifts to $K(\tilde{C})$. However, there is gauge freedom of the form Eq. 37 we claim that there is a gauge choice in which both $\Omega_a$ and $\omega_a$ lift.

Since $\Upsilon_\psi$ respects locality, there exists some $\lambda_a \in K(\mathcal{C})$ with $\lambda_\psi = -1$; define a gauge transformation

$$\nu_a(g, h) = \begin{cases} 1 & \text{if } \omega_\psi(g, h) = +1 \\ \lambda_a & \text{if } \omega_\psi(g, h) = -1 \end{cases} \quad (114)$$

Then the gauge-transformed $\omega'_a$ must have $\omega'_\psi(g, h) = +1$ for all $g, h$, that is, $\omega'_a \in K_+(\mathcal{C})$. Since the gauge transformation preserves Eq. 33, we must also have $\Omega'_a(g, h, k) = +1$, that is, $\Omega'_a \in K_+(\mathcal{C})$. Hence Eq. 108 applies for $\Phi \in Z^3(G_b, \mathcal{A}/\{1, \psi\})$ and $w \in C^3(G_b, \mathcal{A}/\{1, \psi\})$. As in the previous cases, then, we may lift both $\Omega_a$ and $\omega_a$ to $K(\tilde{C})$ by extending Eq. 108 to all of $\tilde{C}$, with no freedom in $\Omega_a$, but a $C^2(G_b, \mathbb{Z}_2)$ choice for $\tilde{w}_a$.

We have therefore proven that even if some particular representatives $\Omega_a$ and $\omega_a$ of given symmetry fractionalization data do not lift to $K(\tilde{C})$, some gauge-equivalent representative does.

The argument that the $\mathcal{H}^3(G_b, \mathbb{Z}_2)$ obstruction determines the $\mathcal{H}^4(G_b, \tilde{A})$ obstruction is identical to the case in which $\Upsilon_\psi$ violates locality; the argument in the latter case really only used the fact that $\tilde{A} = \mathcal{A}$ for the minimal modular extension in question, which is true whenever $\tilde{\Upsilon}_\psi$ violates locality.

B. Dependence on symmetry fractionalization class

We can see explicitly how the $\mathcal{H}^3(G_b, \mathbb{Z}_2)$ anomaly depends on the symmetry fractionalization class on $\mathcal{C}$ as follows. As discussed in [29], symmetry fractionalization on $\mathcal{C}$ is an $\mathcal{H}^2(G_b, \mathcal{A}/\{1, \psi\})$ torsor, that is, changing symmetry fractionalization classes on $\mathcal{C}$ amounts to shifting $w(g, h) \rightarrow w'(g, h) = w(g, h) \times t(g, h)$ with $t \in Z^2(G_b, \mathcal{A}/\{1, \psi\})$. The new symmetry fractionalization pattern depends only on the cohomology class $[t]$. Given a particular lift $\tilde{w}$ of $w$, then, we can pick a particular lift $\tilde{t}$ of $t$ to obtain a lift $\tilde{w}'$ of $w'$. A representative of the obstruction class $[\tilde{\Phi}']$ corresponding to $\tilde{w}'$ is thus

$$\tilde{\Phi}' = \tilde{\Phi} \times \tilde{d} \tilde{w}' = \tilde{\Phi} \times \tilde{d} \tilde{t} \quad (115)$$

Changing $t$ by a coboundary in $\mathcal{A}/\{1, \psi\}$ leaves $\tilde{d}t$ invariant and thus can affect $\tilde{\Phi}'$ only through the choice of lift to $\tilde{d}t$. Changing the lift $\tilde{t}$ changes $\tilde{\Phi}$ by a $\mathbb{Z}_2$-coboundary, so $[\tilde{\Phi}']$ is independent of the lift. Certainly $\tilde{d}t \not\in B^3(G_b, \mathcal{A})$, but generically $\tilde{d}t \not\in B^3(G_b, \mathbb{Z}_2)$. As such, $[\tilde{d}t]$ is not generally trivial in $\mathcal{H}^3(G_b, \mathbb{Z}_2)$ and thus can change the obstruction class.

C. Example: doubled semion-fermion

We consider doubled semion-fermion topological order with $G_f = \mathbb{Z}_4^T \cdot f = \mathbb{Z}_2^T \times \mathbb{Z}_2^f$ symmetry. The particles in $\mathcal{C}$ are generated by two Abelian semions $s_1, s_2$ with $\theta_{s_i} = +i$ and trivial mutual braiding and a transparent fermion $\psi$. Time-reversal acts as $T s_i = \psi s_i$.

Up to gauge transformations, one can check that, with the anyons ordered $1, s_1, s_2, s_1 s_2, \psi, \psi s_1, \psi s_2, \psi s_1 s_2$, then

$$U_T(a, b; a \times b) = \left( \begin{array}{cccccccc} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 & 1 & 1 & 1 & -1 \\ 1 & -1 & 1 & -1 & 1 & 1 & 1 & -1 \\ 1 & -1 & 1 & -1 & 1 & 1 & -1 & 1 \\ 1 & -1 & -1 & 1 & -1 & -1 & 1 & -1 \\ 1 & 1 & -1 & 1 & -1 & 1 & 1 & -1 \\ 1 & 1 & -1 & 1 & -1 & 1 & 1 & -1 \end{array} \right) \quad (116)$$
and \( \eta_a(T, T) = \{1, i, i, 1, -1, -i, -i, -1\} \) in the same order. There is also a solution with \( \eta_a \rightarrow \eta^*_a \), but it behaves similarly. We can calculate \( \kappa \) from \( U \) by

\[
\kappa_{T, T}(a, b; a \times b) = U_T^*(a, b; a \times b) U_T^+(T_a, T_b; T(a \times b))
\]

from which we obtain \( \beta_a(T, T) = \{1, i, i, 1, -1, -i, -i, -1\} \) in our preferred gauge. From this we find

\[
\omega_a(T, T) = \frac{\beta_a(T, T)}{\eta_a(T, T)} = +1 \text{ for all } a
\]

We now need to obtain \( \Phi \) of the modular extension. The modular extension we consider is the tensor product \( U(1)_2 \times U(1)_2 \times U(1)_{-2} \times U(1)_{-2} \), whose quasiparticles are generated by \( s_1, s_2, v, \psi \), where \( v \) is a semionic fermion-parity vortex with \( \theta_v = -i \). Note that \( \theta_{\psi v} = -i \) as well due to the nontrivial braiding. Coincidentally this theory is two copies of the double-semion theory, but that fact plays no role here.

Our earlier expression for \( \omega \) can now be written

\[
\omega_a = M_{a, 1},
\]

for \( a \in C \), up to a fermion. That is, \( \omega(T, T) = 1 \).

There are two options for the extension of the action of time-reversal. Note that \( s_1 s_2 \) is a fermion, so \( v s_1 s_2 \) and \( \psi s_1 s_2 \) are both semions with \( \theta = +i \). Either we can set \( v \rightarrow v s_1 s_2 \) or \( v \rightarrow \psi s_1 s_2 \). We choose the latter permutation action first.

Solving the \( U - F \) and \( U - R \) consistency equations by computer, with the anyons ordered

\[1, s_1, s_2, v, v s_1, v s_2, v s_1 s_2, \psi, v \psi s_1, v \psi s_2, v \psi s_1 s_2, \psi, \psi s_1, \psi s_2, \psi s_1 s_2,\]

we obtain

\[
\begin{pmatrix}
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\
1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\
1 & 1 & -1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\
1 & 1 & 1 & -1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 \\
1 & 1 & -1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\
1 & 1 & 1 & 1 & -1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\
1 & 1 & -1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
1 & -1 & -1 & 1 & -1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\
1 & -1 & -1 & 1 & -1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\
1 & 1 & -1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\
1 & 1 & -1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\
1 & 1 & -1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1
\end{pmatrix}
\]

from which we obtain \( \kappa \) and

\[
\beta_a = \{1, i, i, 1, -1, -i, -i, -1\}
\]

up to a gauge transformation. Then

\[
\Omega_a = \{1, 1, 1, 1, -1, -1, -1, -1, -1, -1, -1, -1, 1, 1, 1, 1\} = M_{a, \psi}
\]

so \( \bar{\Phi} = \psi \). Note that \( \bar{\Phi} \) is not ambiguous by a fermion since it is defined for all of \( \mathcal{C} \). We can now compute, whether we choose \( w(T, T) = 1 \) or \( \psi \),

\[
\bar{\Phi}(T, T) = \bar{\Phi}(T, T) d w(T, T) = \psi \times 1 = \psi
\]

Hence \( [\bar{\Phi}] \in H^3(\mathbb{Z}_2^T, \mathbb{Z}_2) \) is nontrivial and the symmetry fractionalization is obstructed.

One can check that choosing the other action \( v \rightarrow v s_1 s_2 \) under time-reversal leads to the same result.
There is a shortcut to see that there is an inconsistency here. We stated above that
\[ \eta_{s_1 s_2} = +1 = -\theta_{s_1 s_2} \quad \text{and} \quad \eta_{\psi s_1 s_2} = -1 = -\theta_{\psi s_1 s_2} \] (124)

One can show on general grounds that,
\[ \eta_a = \theta_a \text{ if } a = b \times T(b) \] (125)

for some \( b \) in the category in question. For \( a = s_1 s_2 \) or \( \psi s_1 s_2 \), we have \( \eta_a \neq \theta_a \) for this fractionalization pattern. Eq. 125 is satisfied in \( C \) because, for the \( a \) in question, there is no \( b \in C \) for which \( a = b \times T(b) \). However, in the modular extension \( \tilde{C} \), such a \( b \) does exist: \( s_1 s_2 = v s_1 s_2 \times T(v s_1 s_2) \) if we use the permutation action \( v \rightarrow v s_1 s_2 \), and \( \psi s_1 s_2 = v s_1 s_2 \times T(v s_1 s_2) \) under the permutation action \( v \rightarrow v \psi s_1 s_2 \). Therefore, there is an inconsistency between the consistency of fractionalization in the modular extension and the fractionalization pattern in \( C \).

VIII. ADDITIONAL EXAMPLES

A. T-Pfaffian

T-Pfaffian is the surface theory for the \( G_f = U(1) \times \mathbb{Z}_2^T \) topological insulator, where \( G_f = [U(1) \times \mathbb{Z}_2^T] / \mathbb{Z}_2 \). It consists of a subcategory \( C \) of the Ising \( \times U(1) \) state as follows. Labeling elements of Ising \( \times U(1) \) by \( a_j \) with \( a \in \{ I, \psi, \sigma \} \) and \( j = 0, 1, \ldots, 7 \), the quasiparticle content of \( C \) consists of the twelve quasiparticles \( \{ I_{2k}, \psi_{2k}, \sigma_{2k+1} \} \) for \( k = 0, 1, 2, 3 \). The transparent fermion of the category is \( \psi = \psi_4 \) (caution with the notation; \( \psi \) alone means the physical fermion of \( C \), and \( \psi_k \) is a label in Ising \( \times U(1) \)). Time reversal \( [\rho_T] \) interchanges \( I_2 \leftrightarrow \psi_2 \) and \( I_6 \leftrightarrow \psi_6 \).

It is not hard to check that \( Y_\psi \) respects locality in this theory; therefore, \( \text{Aut}(C) = \text{Aut}_{LR}(C) \), and one can check that \( [\rho_g] \) is determined entirely by its permutation action. In particular, writing \( g = (e^{i\theta_b} T^a) \) for \( a \in \{ 0, 1 \} \), then \( [\rho_g] \) is the identity if \( a_g = 0 \) and is nontrivial and equal to \( [\rho_T] \) if \( a_g = 1 \), independent of \( \theta_g \).

The minimal modular extensions of this theory have \( c_- = 1/2 \). The minimal modular extension \( \tilde{C} \) which is compatible with time reversal, i.e., with \( c_+ = 0 \) can be written
\[ \tilde{C} = (C \boxtimes \text{Ising}) \setminus \{ \psi \psi' \sim 1 \}, \] (126)

where the denominator means condensing the bound state of the physical fermion \( \psi \) in \( C \) with the fermion \( \psi' \) in the additional copy of Ising. One can check that \( \tilde{C} \) has only \( \sigma \)-type fermion parity vortices and admits a permutation action of \( T \) which lifts the permutation action of \( \rho_T \) as shown in Refs. [12, 39, 40]. Since \( C \) has no modular isotopes\([41]\), the aforementioned permutation must define a full autoequivalence \( \{ \rho_T \} \) of \( C \), so the \( H^1(G_b, \mathbb{Z}_T) \) anomaly vanishes:
\[ [a_1] = 0 \in H^1(G_b, \mathbb{Z}_T). \] (127)

Since all the vortices are \( \sigma \)-type, \( Y_\psi \) does not respect locality and is therefore the nontrivial element of \( \ker r = \mathbb{Z}_2 \). This permutation action squares to the identity permutation, although this does not guarantee that the \( H^2(G_b, \mathbb{Z}_2) \) anomaly vanishes because \( Y_\psi \) is non-permuting.

Physically, we expect that the anomaly arises because the physical fermion \( \psi \) carries nontrivial \( U(1)^f \) quantum numbers, but the fermion parity vortices are all \( \sigma \)-type, that is, they absorb \( \psi \). The fact that \( \psi \) carries nontrivial \( U(1)^f \) quantum numbers enters through \( \eta_\psi \), which appears at the level of the \( H^3(G_b, \mathbb{Z}_2) \) obstruction. We therefore conjecture the following:

**Conjecture VIII.1.** The T-Pfaffian state has \( [a_2] = 0 \), but \( [a_3] \neq 0 \).

Checking this conjecture explicitly would require knowledge of the full \( F \)- and \( R \)-symbols of the gauged T-Pfaffian state, which we do not know in general how to compute from the decomposition Eq. 126.

We contrast the present picture with a more typical argument \([42]\). One can use a decorated domain wall construction wherein the bulk (3+1)D topological insulator can be understood in terms of decorating \( T \) domain walls with a (2+1)D integer quantum Hall state with Chern number 1. This construction assumes \( U(1)^f \) symmetry from the outset and requires a \( c_- = 1/2 \mod 1 \) minimal modular extension on the boundary so that \( T \) domain walls on the boundary carry a chiral mode arising from the integer quantum Hall state in the bulk. However, \( c_- = 1/2 \mod 1 \) is manifestly incompatible with time reversal symmetry in isolation. In this context, then, the anomaly is characterized as a nontrivial element of \( H^1(\mathbb{Z}_2^T, \mathbb{Z}_T) \). Another way to state this latter construction is that we gauge \( U(1)^f \) symmetry first, and then attempt to lift the \( G_f/U(1)^f = \mathbb{Z}_2^T \) symmetry to the gauged theory. In this context, the T-Pfaffian
TABLE II: Quantum dimensions, topological twists, and time-reversal actions for $\tilde{\mathcal{C}} = \text{Sp}(3)_3 \boxtimes \mathcal{I}(2)$. All other data can be determined from the tabulated data; e.g. $\theta_{(n, \psi)} = -\theta_{(n, 1)}$, and $\mathbf{T}((n, \overline{\pi})) = \mathbf{T}((n, a)) \times (1, \psi)$. The action of $\mathbf{T}$ on $\mathcal{C} = \text{Sp}(3)_3 \boxtimes \{1, \psi\}$ is uniquely determined and squares to the identity. Its lift to $\mathcal{C}$ is ambiguous by $\alpha_\psi$ and squares to $\alpha_\psi$. Quantum dimensions can be written exactly in terms of 56th roots of unity, but we do not do so here.

anomaly appears as an $\mathcal{H}^1(G_f/U(1)_\mathbb{F}, \mathbb{Z}_T)$ obstruction. By comparison, in our framework, we gauge fermion parity first and then attempt to lift the $G_f/\mathbb{Z}_4 = G_b$ symmetry to the gauged theory. In the latter case, the $\mathcal{H}^1(G_b, \mathbb{Z}_T)$ anomaly vanishes, and $T$-Pfaffian fits into a higher level of the anomaly cascade. Both perspectives correspond to valid ways of calculating the same anomaly; they simply decompose the classification differently. Our perspective is more general, since fermionic systems always have $\mathbb{Z}_4^T$ symmetry but need not have $U(1)_T$ symmetry.

B. $\text{Sp}(3)_3 \times \{1, \psi\}$

$\mathcal{C} = \text{Sp}(3)_3 \boxtimes \{1, \psi\}$ gives an example of a $\nu = 6$ phase of the $\mathbb{Z}_{16}$ classification for $G_f = \mathbb{Z}_4^T$. $\text{Sp}(3)_3$ has central charge $c = 1 \mod 8$, so we should consider $\text{Sp}(3)_3 \times U(1)_{-1}$ to get a time-reversal invariant theory. $\text{Sp}(3)_3$ itself has 20 particles, so $\mathcal{C} = \text{Sp}(3)_3 \boxtimes \{1, \psi\}$ has 40 particles. The modular data of $\text{Sp}(3)_3$ were obtained by computer using SageMath. We tabulate the quantum dimensions and topological twists of $\text{Sp}(3)_3$ in Table II: the $S$-matrix is large and enunlightening, so we do not write it explicitly here. The particles will be labeled from 1 to 20, where particle 1 is the identity and the others are ordered by increasing quantum dimension but otherwise arbitrarily. We can label a particle in $\mathcal{C}$ by a pair $(n, x)$ with $n$ from 1 to 20 and $x \in \{1, \psi\}$. There is a unique action of time reversal which preserves the modular data up to complex conjugation, with the corresponding permutation given in Table II.

The time-reversal invariant modular extension is $\tilde{\mathcal{C}} = \text{Sp}(3)_3 \boxtimes \mathcal{I}(-2)$. We label the parity vortices of $\mathcal{I}(-2)$ by $a$ and $\overline{\sigma}$, with $a \times \psi = \overline{\sigma}$ and $a \times \overline{\sigma} = 1$. It is clear that $\tilde{\mathcal{C}}$ has $\nu$-type vortices, and furthermore that $\tilde{\mathcal{C}}$ respects locality, so $\text{Aut}(\tilde{\mathcal{C}}) = \text{Aut}_{LR}(\mathcal{C})$ and $\ker r = \{1, \alpha_\psi\} = \mathbb{Z}_2$ where $\alpha_\psi$ fuses a fermion into each parity vortex. The modular data of this product theory can be computed straightforwardly from the modular data of the constituents. Labeling the particles in $\mathcal{C}$ as $(n, x)$ with, again, $n = 1, 2, \ldots, 20$, and this time $x \in \{1, \psi, \overline{\sigma}\}$, one can check directly that there are exactly two lifts of the action of time reversal on $\mathcal{C}$ to $\tilde{\mathcal{C}}$. One is tabulated in Table II, and the other is given by composing with $\alpha_\psi$ (which switches $a \leftrightarrow \overline{\sigma}$). It is clear by inspection that these actions do not square to the identity; for example, under time reversal,

\[
(1, a) \rightarrow (2, \overline{\sigma}) \rightarrow (1, \overline{\sigma}) \rightarrow (2, a) \rightarrow (1, a)
\]

which yields a representation of $\mathbb{Z}_4^T$, not of $\mathbb{Z}_2^T$. Composition with $\alpha_\psi$ does not change this fact, so we conclude that, as expected, this theory has an $\mathcal{H}^2(\mathbb{Z}_2^T, \mathbb{Z}_2)$ obstruction.
IX. DISCUSSION

We have systematically characterized the set of obstructions which appear in lifting symmetry fractionalization data from a super-modular category \( \mathcal{C} \) to a minimal modular extension \( \tilde{\mathcal{C}} \). We found that this data is in good correspondence with the Wang-Gu classification of fermionic SPTs and gave a physical meaning for each obstruction:

1. The \( \mathcal{H}^1(G_b, \mathbb{Z}_2) \) piece is the obstruction to defining a lift of the autoequivalence \( [\rho_b] \) to \( [\tilde{\rho}_b] \in \text{Aut}_{LR}(\tilde{\mathcal{C}}) \) for some minimal modular extension \( \tilde{\mathcal{C}} \).

2. The \( \mathcal{H}^2(G_b, \ker r) \) piece is the obstruction to choosing a lift which is a group homomorphism \( [\tilde{\rho}_b] : G_b \rightarrow \text{Aut}_{LR}(\tilde{\mathcal{C}}) \).

3. The \( \mathcal{H}^3(G_b, \mathbb{Z}_2) \) piece is the obstruction to lifting the symmetry fractionalization data on \( \mathcal{C} \) to \( \tilde{\mathcal{C}} \).

4. The \( \mathcal{H}^4(G_b, U(1)) \) piece is the obstruction to lifting \( \tilde{\mathcal{C}} \), together with its symmetry fractionalization data, to a \( G_b \)-crossed modular tensor category.

Our work raises a number of open questions. We have given physical and formal motivation for a large number of conjectures regarding the different obstructions described in this work. One major theme of our conjectures is that the anomalies are, roughly speaking, independent of the choice of minimal modular extension \( \tilde{\mathcal{C}} \). We were able to make partial progress on some of these conjectures by using the results of Ref. [26] to relate the \( S \)-matrices of different minimal modular extensions via anyon condensation; a full proof will likely require an understanding of how to use a given minimal modular extension to obtain the \( F \)- and \( R \)-symbols of all minimal modular extensions, perhaps using a generalized “zesting” construction [28]. Such an understanding would likely alleviate the tension between our general results characterizing \( \ker r \) and anomaly considerations for the doubled SU(2)_b theory considered in Sec. VI.E.

We have given an inflow argument for the \( \mathcal{H}^2 \) contribution to the anomaly using the decorated domain wall construction; it would be useful to gain a similar understanding for the other contributions.

Our formalism naturally allows us to determine the obstruction \([\rho_k] \in \mathcal{H}^k(G_b, X_k)\) (for the appropriate coefficient group \( X_k \)) when \([o_j]\) vanishes for \( j < k \). It would be very interesting to derive the full Wang-Gu equations for the anomaly purely from BFC and symmetry fractionalization data. For example, if \([o_1] \neq 0\), then the symmetry action cannot be lifted from \( \mathcal{C} \) to an autoequivalence of any modular extension \( \tilde{\mathcal{C}} \); in this case, how might one define a cochain \( o_2 \) which generalizes the idea of the failure of such a lift to be a group homomorphism?

Our formalism suggests a very general way of understanding mixed anomalies. We have shown that the data characterizing the anomaly, namely, a spectral sequence decomposition into the Wang-Gu data of the bordism group \( \Omega^k(BG_b) \), where \( \xi \) is a kind of twisted spin structure, can be interpreted by first gauging fermion parity and then considering a sequence of obstructions to lifting the \( G_b \) symmetry. Consider instead a bosonic SET with symmetry group \( G = G_1 \times G_2 \). Then there is a spectral sequence decomposition of the \( \mathcal{H}^4(G, U(1)) \) bosonic SET anomaly via the K"unneth decomposition. Our procedure might be applied to understand the mixed anomaly between \( G_1 \) and \( G_2 \) in terms of a “two-step” gauging process, where one first gauges \( G_1 \) and then determines a cascade of obstructions to lifting the \( G_2 \) symmetry to the \( G_1 \)-gauged theory. More generally, if \( G \) is given by a short exact sequence

\[
1 \rightarrow G_1 \rightarrow G \rightarrow G_2 \rightarrow 1,
\]

there is again a spectral sequence decomposition of \( \mathcal{H}^4(G, U(1)) \) and a similar construction may apply.

X. ACKNOWLEDGEMENTS

We thank Parsa Bonderson, Meng Cheng, and Zhenghan Wang for discussions. In particular, MB thanks Parsa Bonderson for detailed comments on the first version of this paper posted to the arXiv. We also thank Ryohei Kobayashi and Srivatsa Tata for collaboration on related projects. This work is supported by NSF CAREER (DMR-1753240) and JQI-PFC-UMD.

Note added in v2: When the first version of this paper was posted to the arXiv, a simultaneous posting, Ref. [32], also appeared, which independently arrives at many of the same results as this paper. Ref. [32] in particular included a result for the map \( \alpha_\psi \), reproduced here in Eq. 77, which is used here to prove a conjecture from the first version of this paper, which is now Eq. 80. Ref. [32] also used Eq. 77 to give the most general proof that \( \{\alpha_\psi\} \) always generates a \( \mathbb{Z}_2 \) subgroup of \( \ker r \), a fact which we use to remove the dependence of Theorem VI.1 on a technical conjecture stated in the first version of this paper.
Appendix A: $S$-matrix of a condensed theory

We presently reproduce, with additional detail, the derivation from [26] of the $S$-matrix $\hat{S}$ of the theory obtained by condensing an Abelian boson $\phi$ in a theory with $S$-matrix $S$. Our main addition to [26] is a careful discussion of gauge invariance. Specifically, $\hat{S}$ should be gauge-invariant under vertex basis transformations, a fact which is in tension with the expression of $\hat{S}$ in terms of the gauge-dependent punctured $S$-matrix of the uncondensed theory.

Assume that $\delta^k = 1$ for some $n > 1$; we will specialize to $n = 2$ later. Then we can view the Wilson lines for $\phi$ as generating a $\mathbb{Z}_n$ 1-form symmetry of the theory; condensing $\phi$ corresponds to gauging that symmetry. We perform this gauging to understand the Hilbert space of the condensed theory on the torus.

In the path integral picture, gauging the symmetry means that we sum over all insertions of the symmetry generator on nontrivial cycles of the 3-torus. We begin by considering insertions of a $\phi$ Wilson line through the time circle. Then at every spatial slice, we are summing over states with no insertion and with all possible insertions of $\phi^k$, that is, we consider an expanded Hilbert space of the original theory consisting of the Hilbert space on the torus and the Hilbert spaces on the punctured torus with punctures labeled $\phi^k$. We presently reproduce, with additional detail, the derivation from [26] of the $S$-matrix of the theory obtained.

States on the punctured Hilbert space with puncture $\phi^k$ are labeled $|a;\phi^k\rangle$ where $N_{a,\bar{a}} > 0$. Physically, these states correspond to ones where an $a,\bar{a}$ pair is created from vacuum, wrapped around a given spatial cycle of the torus (which we will call cycle $\beta$ for concreteness), and then fused into $\phi^k$ at the puncture. Under a basis transformation $\Gamma_{\alpha}^{ab}$ of the fusion spaces $V_{c,ab}$, these states transform as

$$|a;\phi^k\rangle \rightarrow \Gamma_{\phi^k}^{a\bar{a}} (\Gamma_{\phi^k}^{a\bar{a}})^* |a;\phi^k\rangle \quad (A1)$$

and are thus gauge-invariant (in this sense) only when $k = 0$.

Also, observe that each anyon $a$ must have a $\mathbb{Z}_n$ orbit of some length $\ell_a$ which divides $n$. By definition, if $|a;\phi^k\rangle$ is a nonzero state, then $N_{a,\bar{a}}^a = N_{a,\bar{a}}^k > 0$, that is, $a \times \phi^k = a$. Hence $k$ is a multiple of $\ell_a$. Hence the total number of distinct states in the expanded Hilbert space that are associated to the anyon $a$ is $n/\ell_a$.

Next consider inserting a Wilson loop for $\phi^k$ around cycle $\alpha$ of the torus. Let $W_a(\phi^k)$ be the operator which does this; then since $\phi$ is Abelian,

$$W_a(\phi^k) |a;\phi^m\rangle = M_{a,\phi} |a;\phi^m\rangle \quad (A2)$$

with $M$ the mutual statistics. Since $\phi$ is Abelian,

$$M_{a,\phi} = e^{2\pi i k q/n} \quad (A3)$$

for some integer $q$. Summing over all of these insertions,

$$\sum_{k=0}^{n-1} W_a(\phi^k) |a;\phi^m\rangle = \left( \sum_{k=0}^{n-1} e^{2\pi i k q/n} \right) |a;\phi^m\rangle = \delta_{q,0} |a;\phi^m\rangle \quad (A4)$$

That is, we require $a$ to braid trivially with $\phi$ to keep its corresponding states in the condensed theory.

Finally, we consider inserting a Wilson loop of $\phi^k$ Wilson loops around cycle $\beta$ of the torus. Clearly this takes the state $|a;\phi^m\rangle \rightarrow |a \times \phi^k;\phi^m\rangle$, so the only states we should consider are

$$|[a];\phi^m\rangle = \frac{1}{\sqrt{\ell_a}} \sum_{k=0}^{\ell_a} |a \times \phi^k;\phi^m\rangle \quad (A6)$$

where here $[a]$ labels the orbit of $a$ under fusion with $\phi$.

The Hilbert space therefore consists of states $|[a];\phi^m\rangle$ such that $a$ braids trivially with $\phi$ and $m = 0, 1, \ldots, n/\ell_a - 1$ (that is, there are $n/\ell_a$ states per anyon). In particular, there is a unique state associated to $[a]$ if $a$ has orbit length $\ell_a = n$ but the orbit $[a]$ splits to $n/\ell_a$ states after condensation if $a \times \phi^a = a$ for some $\ell_a < n$.

Now consider the transformation of these states under modular transformations. By definition, in this basis, if $S$ and $T$ are the operators which implement $S$ and $T$ modular transformations,

$$\langle a;\phi^m | S | b;\phi^n \rangle = \delta_{m,n} S_{ab} \quad (A7)$$

$$\langle a;\phi^m | T | b;\phi^n \rangle = \delta_{m,n} T_{ab} \quad (A8)$$

$$\langle a;\phi^m | \bar{T} | b;\phi^n \rangle = \delta_{m,n} \bar{T}_{ab} \quad (A9)$$
where $S^{(\phi)}_{ab}$ and $T^{(\phi)}_{ab}$ are the punctured $S$- and $T$-matrices. Note that all elements of $T^{(\phi)}$ and diagonal elements $S^{(\phi)}_{aa}$ of the punctured $S$-matrix are gauge-invariant under vertex basis transformations, while off-diagonal elements of the punctured $S$-matrix (for $m > 0$) are not generally gauge-invariant.

It is diagrammatically straightforward to check that

$$S^{(\phi)}_{a,\phi,b} = S^{(\phi)}_{a,b,\phi} = S^{(\phi)}_{a,b}$$

(A10)

provided $[a]$ and $[b]$ are both deconfined particles, i.e., $a$ and $b$ both braid trivially with $\phi$), and that

$$T^{(\phi)}_{ab} = \theta_{ab}$$

(A11)

Hence

$$\hat{S}_{(a,m),(b,s)} = \langle [a]; \phi^m | S | [b]; \phi^s \rangle = \frac{1}{\sqrt{\ell_a \ell_b}} \sum_{a \in [a], b \in [b]} \delta_{m,s} S^{(\phi)}_{ab}$$

(A12)

$$\hat{T}_{(a,m),(b,s)} = \langle [a]; \phi^m | T | [b]; \phi^s \rangle = \delta_{m,s} T^{(\phi)}_{ab}$$

(A13)

(A14)

(A15)

are well-defined expressions independent of the representatives of $[a]$ and $[b]$ we choose and are the $S$- and $T$-matrices of the condensed theory in this basis for the torus Hilbert space.

We now discuss gauge freedom very carefully. In the uncondensed theory, there is a preferred basis $|a; \phi^m\rangle$ of the Hilbert space, where $a$ is any anion. For $m = 0$, these states are invariant under gauge transformations of the fusion spaces. However, there is still some gauge freedom, in the sense that we could send $|a; 1\rangle \to e^{i\alpha_a} |a; 1\rangle$ for some phases; this gauge freedom modifies the $S$-matrix. We can canonically fix this gauge freedom up to a global phase rotation (physically, a gauge choice for the vacuum state) by demanding that $S_{1a}$ be real and positive for all $a$ and also that $S_{ab}$ be symmetric. Another way to say this is that we could be handed some phase-rotated states $|a; 1\rangle$ from the outset; we would observe that we have the “wrong” basis because the resulting $S$-matrix would not have these nice properties, and this could be corrected with a (diagonal) basis transformation.

For $m > 0$, there is no such canonical basis for these states. The situation is in some sense worse, because changing the basis of the fusion spaces induces a particular change of basis on the punctured torus Hilbert space, of the form Eq. A1, and therefore changes the punctured $S$-matrix of the uncondensed theory. This naively seems disturbing because the $S$-matrix of the condensed theory appears to depend on a fusion space basis in the original theory. However, from the above perspective, there is no such problem; such a change of basis of fusion spaces in the uncondensed theory is just a particular special case of changing the basis for the torus Hilbert space of the condensed theory. We simply imagine that we are handed the states $|a; \phi^m\rangle$ in some fixed but non-canonical basis, and then inspect the $S$-matrix of the condensed theory; if it does not have the intended properties, we were handed the “wrong” basis and should perform a torus Hilbert space basis transformation to fix it.

There is one subtlety here if $1 < \ell_a < n$, which is that we must gauge-fix

$$W_{\beta}(\phi) |a; \phi^m\rangle = |a \times \phi; \phi^m\rangle$$

in the uncondensed theory. This is needed in order to ensure that the state $|[a]; \phi^m\rangle$ in Eq. A6 is indeed symmetric under insertion of $\phi$ Wilson loops.

Having discussed gauge freedom, we now need to check if our states in the condensed theory are in the canonical gauge. For $\ell_a = \ell_b = n$, then $S_{[a],[b]} = \delta_{a,b}$, so $\hat{S}$ inherits its nice properties from $S$; these states are in the correct gauge. For $\ell_a < n$, however, we are certainly not in the correct gauge since in this basis

$$\hat{S}_{1,([a],k)} = \begin{cases} \sqrt{2} S_{1,a} & k = 0 \\ 0 & \text{else} \end{cases}$$

(A17)

On general grounds, quasiparticles must correspond to some superposition of states $|[a]; \phi^m\rangle$ with fixed $[a]$, so we may restrict our attention to a fixed-$[a]$ sector.

At this point we restrict ourselves to $n = 2$. Then if $\ell_a = 1$, we have $a \times \phi = a$ and a general basis transformation is of the form

$$
\begin{pmatrix}
|a; +\rangle \\
|a; -\rangle
\end{pmatrix} = U^{(a)}
\begin{pmatrix}
|a; 1\rangle \\
|a; \phi\rangle
\end{pmatrix} = e^{i\alpha_a}
\begin{pmatrix}
e^{-i(\beta_a + \delta_a)/2} \cos(\gamma_a/2) & -e^{-i(\beta_a - \delta_a)/2} \sin(\gamma_a/2) \\
e^{i(\beta_a - \delta_a)/2} \sin(\gamma_a/2) & e^{i(\beta_a + \delta_a)/2} \cos(\gamma_a/2)
\end{pmatrix}
\begin{pmatrix}
|a; 1\rangle \\
|a; \phi\rangle
\end{pmatrix}
$$

(A18)
Strictly speaking $U^{(a)}$ is a diagonal block in the transformation of the entire Hilbert space; the state $|1; 1\rangle$ does not transform in this basis transformation. Accordingly,

$$\begin{align*}
(\hat{S}_{1,(a,+)}, \hat{S}_{1,(a,-)}) &= (\hat{S}_{1,(a,1)}, \hat{S}_{1,(a,\vec{a})}) 
&= \sqrt{2} S_{1,a} e^{-i(\alpha - \delta/2)} \left( e^{i\beta/2} \cos(\gamma/2), e^{-i\beta/2} \sin(\gamma/2) \right)

\text{(A19)}
\end{align*}$$

We require that

$$d_{(a,+)} + d_{(a,-)} = \frac{\hat{S}_{1,(a,+)}}{\hat{S}_{1,1}} + \frac{\hat{S}_{1,(a,-)}}{\hat{S}_{1,1}} = S_{1,a} = d_a
\text{(A21)}$$

following the usual rules for preserving the quantum dimension of split particles. Using $\hat{S}_{1,1} = 2S_{1,1}$, equating the magnitudes leads to

$$\cos \beta_a \sin \gamma_a = 1
\text{(A22)}$$

That is, $\gamma = \pi/2$ and $\beta = 0$ or $\gamma = 3\pi/2$ and $\beta = \pi$. We now ensure that $\hat{S}_{1,(a,\pm)}$ are real and positive. In the first solution, we find this requires $\alpha - \delta/2 = 0 \mod 2\pi$, while in the second we find $\alpha - \delta/2 = 3\pi/2 \mod 2\pi$. Substituting back, we find that these two solutions are related by switching the rows of $U^{(a)}$, so that up to a basis reordering the only solutions for $U^{(a)}$ are

$$U^{(a)} = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & e^{i\delta_a} \\ 1 & -e^{i\delta_a} \end{pmatrix}
\text{(A23)}$$

Note that $\delta_a$ is exactly the gauge freedom in $|a; \phi\rangle$.

Next, we demand that $\hat{S}$ is symmetric. In this basis,

$$\begin{align*}
\hat{S}_{(a,\pm),(b,\pm)} &= U^{(a)} \begin{pmatrix} S_{ab} & 0 \\ 0 & S_{ab}^{(\phi)} \end{pmatrix} (U^{(b)})^\dagger 
&= \frac{1}{2} \begin{pmatrix} S_{ab} + e^{i(\delta_a - \delta_b)} S_{ab}^{(\phi)} & S_{ab} - e^{i(\delta_a - \delta_b)} S_{ab}^{(\phi)} \\ S_{ab} - e^{i(\delta_a - \delta_b)} S_{ab}^{(\phi)} & S_{ab} + e^{i(\delta_a - \delta_b)} S_{ab}^{(\phi)} \end{pmatrix}
\text{(A24)}
\end{align*}$$

For $a = b$ this is clearly symmetric and independent of our remaining gauge freedom. If $a \neq b$, then symmetry of $\hat{S}$ amounts to a choice

$$e^{2i(\delta_a - \delta_b)} = \frac{S_{ba}^{(\phi)}}{S_{ab}^{(\phi)}}
\text{(A25)}$$

Equivalently, we may think of this as fixing a gauge so that the uncondensed punctured $S$-matrix $S_{ab}^{(\phi)}$ is symmetric in $a$ and $b$. If we are already in such a gauge, then we may choose $\delta_a = \delta_b = 0$, which reduces to the results of Ref. [26].

To prove that such a gauge exists, we perform the diagrammatic manipulation in Fig. 2 to show

$$S_{ab}^{(\phi)} = \frac{d_a F_{a,\phi,1}^{a,\pi} a F_{\phi,a,1}^{\phi,\pi}}{d_b F_{b,\phi,1}^{b,\phi} b F_{\phi,b,1}^{\phi}} S_{ba}^{(\phi)}
\text{(A26)}$$

Letting

$$e^{2i\delta_a} = \frac{d_a F_{a,\phi,1}^{a,\pi} a F_{\phi,a,1}^{\phi,\pi}}{d_b F_{b,\phi,1}^{b,\phi} b F_{\phi,b,1}^{\phi}}
\text{(A27)}$$

we obtain the gauge transformation which symmetrizes the punctured $S$-matrix.

Notice that there is some residual gauge freedom preserving the symmetry of the uncondensed punctured $S$-matrix; we may send $e^{i\delta_a} \to -e^{i\delta_a}$. This gauge transformation simply flips the role of the rows in $U^{(a)}$ and thus corresponds to relabeling $(a, \pm) \to (a, \mp)$.

### Appendix B: Proof of Proposition VI.4

The proof is quite involved, so we begin with an outline of the strategy. First, for $\delta \nu \in \mathbb{Z}_{16}$, let $\mathcal{I}(\delta \nu)$ be the minimal modular extension of $\{1, \psi\}$ with chiral central charge $c_- = \delta \nu/2 \mod 8$. Then the 16-fold way tells us that, given $\mathcal{C}_{\nu_1}$, the minimal modular extension $\mathcal{C}_{\nu_2}$ is constructed as

$$\mathcal{C}_{\nu_2} = \mathcal{C}_{\nu_1} \otimes \mathcal{I}(\delta \nu)/\{\psi \psi \sim 1\}
\text{(B1)}$$
FIG. 2: Diagrammatic manipulation in the standard BFC graphical calculus (see, e.g., [41] or [1] for reviews and [36, 37] for graphical representations of the punctured S-matrix) leading to Eq. A26. Blue lines are a or b, orange are b or b*, and green is φ. We are assuming φ × φ = 1 and that a × φ = a, b × φ = b. “Inverse for b” means to repeat the same process as the first three steps, but in reverse and moving the φ line attached to the |b, b; φ> vertex. In the step labeled “isotopy”, we use the fact that the double braid of φ is trivial with both a and b.

where the quotient means that we condense the bound state of the preferred fermions in \( \tilde{\mathcal{C}}_{\nu_1} \) and \( \mathcal{I}(\delta \nu) \). The proof goes in four steps:

Step 1: Use the results of [26], which we review in expanded detail in Appendix A, to derive the anyon content and the S- and T-matrices of the condensed theory \( \tilde{\mathcal{C}}_{\nu_2} \).

Step 2: Directly construct an anyon permutation \( \tilde{\rho}^{(2)}_g \) on \( \tilde{\mathcal{C}}_{\nu_2} \) that lifts the permutation action of \( \rho_g \).

Step 3: Show that \( \tilde{\rho}^{(2)}_g \) preserves the S- and T-matrices of \( \tilde{\mathcal{C}}_{\nu_2} \).

Step 4: Compute the permutation action of \( \tilde{\alpha}^{(2)}_2 (g, h) \).

Step 1: According to [26], the anyon content of \( \tilde{\mathcal{C}}_{\nu_1+1} \) can be labeled by equivalence classes of anyons \( (a, x) \in \tilde{\mathcal{C}}_{\nu_1} \otimes \mathcal{I}(\delta \nu) \) and, in some cases, a sign. In all cases, the anyon sector \( \tilde{\mathcal{C}}_{\nu_1} \otimes \mathcal{I}(\delta \nu) \) consists of the equivalence classes \( (a_0, 1) \sim (a_0 \times \psi, \psi) \) for \( a_0 \in \tilde{\mathcal{C}}_{\nu_1} \). The behavior of the fermion parity vortex sector depends on the parity of \( \delta \nu \).

If \( \delta \nu \) is even, then \( \mathcal{I}(\delta \nu) \) is Abelian, and its particles can be labeled \( \{1, \psi, v, v \times \psi\} \). Then the fermion parity vortices of \( \tilde{\mathcal{C}}_{\nu_2} \) are as follows:

1. \( (a_v, v) \sim (a_v \times \psi, v \times \psi) \) for \( a_v \in \tilde{\mathcal{C}}_{\nu_2} \). These form the sector \( \tilde{\mathcal{C}}_{\nu_2} \).

2. \( (a_\sigma, v) \sim (a_\sigma \times \psi, v \times \psi) \) for \( a_\sigma \in \tilde{\mathcal{C}}_{\nu_2} \). These form the sector \( \tilde{\mathcal{C}}_{\nu_2} \).

Notice that anyon labels in \( \tilde{\mathcal{C}}_{\nu_2} \) are in one-to-one correspondence with anyon labels in \( \tilde{\mathcal{C}}_{\nu_2} \).

If \( \delta \nu \) is odd, the particles of \( \mathcal{I}(\delta \nu) \) obey Ising fusion rules. Labeling the particles by \( \{1, \psi, \sigma\} \), the fermion parity vortices of \( \tilde{\mathcal{C}}_{\nu_2} \) are as follows:

1. \( (a_v, \sigma) \sim (a_v \times \psi, \sigma) \) for \( a_v \in \tilde{\mathcal{C}}_{\nu_2} \). These form the sector \( \tilde{\mathcal{C}}_{\nu_2} \).

2. \( (a_\sigma, \sigma)_\pm \) for \( a_\sigma \in \tilde{\mathcal{C}}_{\nu_2} \). These form the sector \( \tilde{\mathcal{C}}_{\nu_2} \) with \( (a_\sigma, \sigma)_+ \times \psi = (a_\sigma, \sigma)_- \). We say in this case that \( (a_\sigma, \sigma)_\sigma \) splits after condensation.

where the quotient means that we condense the bound state of the preferred fermions in \( \tilde{\mathcal{C}}_{\nu_1} \) and \( \mathcal{I}(\delta \nu) \). The proof goes in four steps:

Step 1: Use the results of [26], which we review in expanded detail in Appendix A, to derive the anyon content and the S- and T-matrices of the condensed theory \( \tilde{\mathcal{C}}_{\nu_2} \).

Step 2: Directly construct an anyon permutation \( \tilde{\rho}^{(2)}_g \) on \( \tilde{\mathcal{C}}_{\nu_2} \) that lifts the permutation action of \( \rho_g \).

Step 3: Show that \( \tilde{\rho}^{(2)}_g \) preserves the S- and T-matrices of \( \tilde{\mathcal{C}}_{\nu_2} \).

Step 4: Compute the permutation action of \( \tilde{\alpha}^{(2)}_2 (g, h) \).

Step 1: According to [26], the anyon content of \( \tilde{\mathcal{C}}_{\nu_1+1} \) can be labeled by equivalence classes of anyons \( (a, x) \in \tilde{\mathcal{C}}_{\nu_1} \otimes \mathcal{I}(\delta \nu) \) and, in some cases, a sign. In all cases, the anyon sector \( \tilde{\mathcal{C}}_{\nu_1} \otimes \mathcal{I}(\delta \nu) \) consists of the equivalence classes \( (a_0, 1) \sim (a_0 \times \psi, \psi) \) for \( a_0 \in \tilde{\mathcal{C}}_{\nu_1} \). The behavior of the fermion parity vortex sector depends on the parity of \( \delta \nu \).

If \( \delta \nu \) is even, then \( \mathcal{I}(\delta \nu) \) is Abelian, and its particles can be labeled \( \{1, \psi, v, v \times \psi\} \). Then the fermion parity vortices of \( \tilde{\mathcal{C}}_{\nu_2} \) are as follows:

1. \( (a_v, v) \sim (a_v \times \psi, v \times \psi) \) for \( a_v \in \tilde{\mathcal{C}}_{\nu_2} \). These form the sector \( \tilde{\mathcal{C}}_{\nu_2} \).

2. \( (a_\sigma, v) \sim (a_\sigma \times \psi, v \times \psi) \) for \( a_\sigma \in \tilde{\mathcal{C}}_{\nu_2} \). These form the sector \( \tilde{\mathcal{C}}_{\nu_2} \).

Notice that anyon labels in \( \tilde{\mathcal{C}}_{\nu_2} \) are in one-to-one correspondence with anyon labels in \( \tilde{\mathcal{C}}_{\nu_2} \).

If \( \delta \nu \) is odd, the particles of \( \mathcal{I}(\delta \nu) \) obey Ising fusion rules. Labeling the particles by \( \{1, \psi, \sigma\} \), the fermion parity vortices of \( \tilde{\mathcal{C}}_{\nu_2} \) are as follows:

1. \( (a_v, \sigma) \sim (a_v \times \psi, \sigma) \) for \( a_v \in \tilde{\mathcal{C}}_{\nu_2} \). These form the sector \( \tilde{\mathcal{C}}_{\nu_2} \).

2. \( (a_\sigma, \sigma)_\pm \) for \( a_\sigma \in \tilde{\mathcal{C}}_{\nu_2} \). These form the sector \( \tilde{\mathcal{C}}_{\nu_2} \) with \( (a_\sigma, \sigma)_+ \times \psi = (a_\sigma, \sigma)_- \). We say in this case that \( (a_\sigma, \sigma)_\sigma \) splits after condensation.
The $T$-matrix of the condensed theory is simple: the topological spin of $(a, x)$ (including the split case $(a, \sigma_\pm)$ is $\theta_a \theta_x$.

Next consider the $S$-matrix $\tilde{S}_{\nu^2}$ of $\tilde{C}_{\nu^2}$, and let $S^{(\nu)}$ be the punctured $S$-matrix for the product theory $\tilde{C}_{\nu^1} \boxtimes \mathcal{J}(\delta \nu)$. As discussed in Appendix A, we can choose a gauge for the uncondensed theory such that $S_{ab}^{(\nu, \psi)}$ is symmetric. With that gauge-fixing, we can write down the following expression for the $S$-matrix of the condensed theory [26]. If $(a, x)$ and $(b, y)$ do not split under condensation, then

$$S_{(a,x),(b,y)}^{\tilde{C}_{\nu^2}} = 2S_{(a,x),(b,y)}^{(1)} \tag{B2}$$

If only $(a, x)$ splits or only $(b, y)$ splits, then

$$S_{(a,x),(b,y)}^{\tilde{C}_{\nu^2}} = S_{(a,x),(b,y)}^{(1)} \tag{B3}$$

independent of the sign. Finally, if both $(a, x)$ and $(b, y)$ both split, then

$$S_{(a,x),(b,y)}^{\tilde{C}_{\nu^2}} = \frac{1}{2} \left( S_{(a,x),(b,y)}^{(1)} + S_{(a,x),(b,y)}^{((\nu, \psi))} - S_{(a,x),(b,y)}^{((\nu, \psi))} - S_{(a,x),(b,y)}^{((\nu, \psi))} \right) \tag{B4}$$

where the matrix rows correspond to the sign for $(a, x)_\pm$ and the columns correspond to the sign for $(b, y)_\pm$. In this last case, $x = y = \sigma$ and we can calculate further using the fact that $x = y = \sigma$ and the punctured $S$-matrix for the product theory is the product of punctured $S$-matrices. We know that $S_{\sigma, \sigma}^{(1)} = 0$ in the Ising theory (and $S_{a, \sigma, b, \sigma}^{(1)} = 0$ in $\tilde{C}_{\nu^1}$ as well), so those terms all drop. By direct computation in the gauge of, e.g., [41], we find the only nonzero element of the punctured $S$-matrix in the Ising theory

$$S_{\sigma, \sigma}^{(\delta \nu, \psi)} = \sqrt{2} e^{-2\pi i \delta \nu / 8} \tag{B5}$$

Hence when both $(a, x)$ and $(b, y)$ split,

$$S_{(a,x),(b,y)}^{\tilde{C}_{\nu^2}} = e^{-2\pi i \delta \nu / 8} \frac{S_{a,b}^{(\nu, \psi)}}{\sqrt{2}} \begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix} \tag{B6}$$

where $S_{a,b}^{(\nu, \psi)}$ is the punctured $S$-matrix of $\tilde{C}_{\nu^1}$. Thanks to our gauge fixing for the punctured $S$-matrix in the uncondensed theory, $S_{\nu^2}$ is symmetric.

Step 2: Define the permutation action $\tilde{\rho}_{g}^{(2)}$ as follows:

$$\tilde{\rho}_{g}^{(2)}((a, x)) = (\tilde{\rho}_{g}^{(1)}(a), x) \quad \text{if} \quad (a, x) \text{ does not split}$$

$$\tilde{\rho}_{g}^{(2)}((a, x)_\pm) = (\tilde{\rho}_{g}^{(1)}(a), x)_\pm \times \psi_{\nu}(g) \quad \text{if} \quad (a, x) \text{ splits} \tag{B7}$$

where $s_a(g) \in \{0, 1\} \approx \mathbb{Z}_2$ must be defined for each $a \in \tilde{C}_{\nu^1}$. It is immediate that $\tilde{\rho}_{g}^{(2)}$ lifts the permutation action $\rho_{g}$ as long as $\tilde{\rho}_{g}^{(1)}$ does as well.

In order to define $s_a(g)$, first calculate directly

$$\tilde{\rho}_{g}(S_{a,b}^{\tilde{C}_{\nu^1},(\psi)}) = U_g(\sigma_a, \sigma_b, \psi)U_g^*(\sigma_a, \sigma_b; 1)U_g^*(\sigma_b, \sigma_b; \psi)U_g^*(\sigma_b, \sigma_b; 1)S_{a,b}^{\tilde{C}_{\nu^1},(\psi)} = S_{a,b}^{\tilde{C}_{\nu^1},(\psi)} \tag{B8}$$

In our particular gauge, the punctured $S$-matrix is symmetric in $a$ and $b$. Hence we can write

$$\tilde{\rho}_{g}(S_{a,b}^{\tilde{C}_{\nu^1},(\psi)}) = \tilde{\rho}_{g}(S_{a,b}^{\tilde{C}_{\nu^1},(\psi)}) = U_g(\sigma_b, \sigma_b; \psi)U_g^*(\sigma_b, \sigma_b; 1)U_g^*(\sigma_a, \sigma_a; \psi)U_g^*(\sigma_a, \sigma_a; 1)S_{a,b}^{\tilde{C}_{\nu^1},(\psi)} \tag{B9}$$

But $S_{a,b}^{\tilde{C}_{\nu^1},(\psi)} = S_{a,b, \sigma}^{\tilde{C}_{\nu^1},(\psi)}$, so Eqs. B8, B9 combine to

$$[U_g(\sigma_b, \sigma_b; \psi)U_g^*(\sigma_b, \sigma_b; 1)]^2 = [U_g(\sigma_a, \sigma_a; \psi)U_g^*(\sigma_a, \sigma_a; 1)]^2 \tag{B10}$$

Equivalently, if we fix a reference $\sigma$-type vortex $r_\sigma$, then we must have

$$s_a(g) = \frac{U_g(\sigma_a, \sigma_a; 1)U_g^*(\sigma_a, \sigma_a; \psi)}{U_g(\sigma_r, \sigma_r; 1)U_g^*(\sigma_r, \sigma_r; \psi)} \in \mathbb{Z}_2 \tag{B11}$$
where we are slightly abusing notation; the above defines \( s_a(g) \notin \{1, -1\} \cong \mathbb{Z}_2 \) instead of \( \{0, 1\} \cong \mathbb{Z}_2 \). We emphasize that the entire analysis above requires \( a \) be a \( \sigma \)-type vortex.

The above proof actually does not apply if \( S^{\bar{C}\nu_1}_{ab}(\psi) = 0 \). As in Sec. VIB, we can break the \( S \)-matrix of \((\bar{C}\nu_2)_v\) into \( k \) blocks and apply the above argument to each block separately; we have a separate choice of \( r_\sigma \) for each block.

We choose \( r_\sigma \) to be \( g \)-independent. As we will see, such a choice will lead to a permutation \( o^{(2)}(g, h) \) which is exactly the identity; instead choosing a \( g \)-dependent \( r_\sigma \) in each block will amount to modifying the permutation action of \( o^{(2)}(g, h) \) by a ker \( r \)-valued coboundary.

**Step 3:** It is immediately obvious that \( \tilde{r}^{(2)}_g \) preserves the \( T \)-matrix provided \( \tilde{r}^{(1)}_g \) does. Also, given the fact that \( \tilde{r}^{(1)}_g \) preserves the \( S \)-matrix of \( \bar{C}_m \), Eqs. B2,B3 immediately imply that \( \tilde{r}^{(2)}_g \) preserves \( S^{\bar{C}\nu_2}_{(a,x),(b,y)} \) when at most one of \((a, x)\) and \((b, y)\) split. The case where both split requires some calculation.

From Eq. B8, we see that

\[
\tilde{r}^{(1)}_g(S^{\bar{C}\nu_1}_{a,b}(\psi)) = s_a(g)s_b(g)S^{\bar{C}\nu_1}_{a,b}(\psi) = S^{\bar{C}\nu_1}_{a,b}(\psi).
\]

Hence

\[
\tilde{r}^{(2)}_g\left(S^{\bar{C}\nu_2}_{(a,x),(b,y)}(\psi)\right) = e^{-2\pi i \nu/8} \sqrt{2} \times s_a(g)s_b(g)\tilde{S}^{\bar{C}\nu_1}_{a,b}(\psi) \times \left( \begin{array}{cc} 1 & -1 \\ -1 & 1 \end{array} \right)
\]

(B12)

On the other hand, \( \tilde{r}^{(2)}_g((a, \sigma)) = (a, \sigma)_{\pm} \). Hence,

\[
S^{\bar{C}\nu_2}_{\mp}\left(S^{\bar{C}\nu_2}_{(a,x),(b,y)}(\psi)\right) = S^{\bar{C}\nu_2}_{(a,x),(b,y)}(\psi) = e^{-2\pi i \nu/8} \sqrt{2} \times s_a(g)s_b(g)\tilde{S}^{\bar{C}\nu_1}_{a,b}(\psi) \times \left( \begin{array}{cc} 1 & -1 \\ -1 & 1 \end{array} \right) = \tilde{r}^{(2)}_g(S^{\bar{C}\nu_2}_{(a,x),(b,y)}(\psi))
\]

where the factor of \( s_a(g) \) is interpreted as permuting the rows of the matrix if it is \(-1\) and the factor of \( s_b(g) \) should be interpreted as permuting the columns if it is \(-1\). Hence \( \tilde{r}^{(2)}_g \) indeed preserves the \( S \)-matrix.

**Step 4:** By direct computation,

\[
\left( \begin{array}{c} r^{(2)}_g \\ r^{(2)}_g \end{array} \right)^{-1} \tilde{r}^{(2)}_g \circ \left( \begin{array}{c} r^{(2)}_g \\ r^{(2)}_g \end{array} \right) ((x, a)) = \left( \begin{array}{c} o^{(1)}_g(g, h)(a), x \\ o^{(1)}_g(g, h)(a), x \end{array} \right) \text{ if } (a, x) \text{ does not split}
\]

\[
\left( \begin{array}{c} r^{(2)}_g \\ r^{(2)}_g \end{array} \right)^{-1} \tilde{r}^{(2)}_g \circ \left( \begin{array}{c} r^{(2)}_g \\ r^{(2)}_g \end{array} \right) ((x, a)_\pm) = (a, x)_\pm \times \psi^{s(a) + s(h) - s(ph)} \text{ if } (a, x) \text{ splits}
\]

(B14)

If \( \delta \nu \) is even, then no particles split, and \( (o^{(1)}_g(g, h)(a), x) = \psi \times (a, x) \) if and only if \( o^{(2)}_g(g, h)(a) = \psi \times a \). Hence \( o^{(2)}_g \) and \( o^{(2)}_g \), as permutations, are identical on the cochain level.

If \( \delta \nu \) is odd, then \( (o^{(1)}_g(g, h)(a), x) \sim (a, x) \) for all \( a \in \bar{C}_{\nu_1} \). In particular, if \( o^{(2)}_g \) acts nontrivially on \( a \), then \( a \in \bar{C}_{\nu_1} \), and we saw that in such a case \((a, \sigma) \sim (a \times \psi, \sigma) \). Hence the only permutation action comes from split particles, and by inspection, modifying the reference vortex \( r_\sigma \) in a \( g \)-dependent way changes \( o^{(2)}_g(g, h) \) by a ker \( r \)-valued coboundary. We can directly calculate from Eq. 61 that

\[
o^{(2)}_g(g, h)((a_\sigma, \sigma)_\pm) = \frac{U_{g}(gh_{a_\sigma}, gh_{a_\sigma}, 1)\tilde{U}_{h}(gh_{a_\sigma}, gh_{a_\sigma}, \psi) \times U_{gh}(gh_{a_\sigma}, gh_{a_\sigma}, 1)\tilde{U}_{gh}(gh_{a_\sigma}, gh_{a_\sigma}, \psi)}{U_{gh}(gh_{a_\sigma}, gh_{a_\sigma}, 1)\tilde{U}_{gh}(gh_{a_\sigma}, gh_{a_\sigma}, \psi)}
\]

(B15)

\[
\times \frac{U_{gh}(gh_{r_\sigma}, gh_{r_\sigma}, 1)\tilde{U}_{gh}(gh_{r_\sigma}, gh_{r_\sigma}, \psi) \times U_{gh}(gh_{r_\sigma}, gh_{r_\sigma}, 1)\tilde{U}_{gh}(gh_{r_\sigma}, gh_{r_\sigma}, \psi)}{U_{gh}(gh_{r_\sigma}, gh_{r_\sigma}, 1)\tilde{U}_{gh}(gh_{r_\sigma}, gh_{r_\sigma}, \psi)}
\]

(B16)

\[
= \frac{\kappa_{g,h}(gh_{a_\sigma}, gh_{a_\sigma}, 1)\kappa_{g,h}(gh_{a_\sigma}, gh_{a_\sigma}, \psi)}{\kappa_{g,h}(gh_{r_\sigma}, gh_{r_\sigma}, 1)\kappa_{g,h}(gh_{r_\sigma}, gh_{r_\sigma}, \psi)} + 1
\]

(B17)

where the last line comes from decomposing \( \kappa \) as a product of anyon-dependent factors \( \beta \). Hence \( \tilde{r}^{(2)}_g \) is a group homomorphism \( G_b \to P(\bar{C}_{\nu_2}) \).

**Appendix C: Doubled SU(2)_6**

We write down the UMTC data for \( \bar{C} = SU(2)_6 \times SU(2)_6 \times Ising_{-9/2}/(\psi\psi \sim 1) \). Here Ising_{-9/2} is the minimal modular extension of \( \{1, \psi\} \) with central charge \( c_- = -9/2 \). The quotient means that we condense pairs of preferred fermions in these three spin modular theories, i.e., we condense \((6, 0, 0), (0, 0, \psi), \) and \((6, 0, \psi), \) where the first two labels label particles in the two copies of \( SU(2)_6 \) and the third labels particles in the Ising theory.
\( \tilde{C} \) contains 14 particles. Labeling the particles of \( SU(2)_6 \) by integers from 0 to 6 in the usual way, and labeling elements of Ising as \( \{0, \sigma, \psi\} \), the deconfined particles of the theory, their topological twists, and quantum dimensions are given in Table I.

The particle \((6, 0, 0)\) is the preferred fermion of this spin modular theory. All labels are redundant under fusion with \((6, 6, 0), (0, 6, \psi), \) and \((6, 0, \psi)\) in the product theory before condensation. We have

\[
\tilde{C}_v = \{(1, 3, \sigma)\pm, (3, 1, \sigma)\pm\} \quad \text{(C1)}
\]

\[
\tilde{C}_\sigma = \{(1, 1, \sigma), (3, 3, \sigma)\} \quad \text{(C2)}
\]

and all other particles are in \( \tilde{C}_0 \). The total quantum dimension is \( D = 4(2 + \sqrt{2}) \).

With \( d = 1 + \sqrt{2} \) and the quasi-particles ordered as in Table I, the modular data of \( \tilde{C} \) is:

\[
S = \frac{1}{D} \begin{pmatrix}
1 & d & d & d & d^2 & d^2 & 1 & \sqrt{2}d & \sqrt{2}d & \sqrt{2}d & \sqrt{2}d & 2d & 2d \\
-d & d^2 & -1 & d^2 & -d & -d & d & \sqrt{2}d & \sqrt{2}d & -\sqrt{2}d & -\sqrt{2}d & 2d & -2d \\
-d & d & -1 & d^2 & -d & -d & d & -\sqrt{2}d & -\sqrt{2}d & \sqrt{2}d & \sqrt{2}d & 2d & -2d \\
-d & -1 & d^2 & -1 & d^2 & -d & -d & -\sqrt{2}d & -\sqrt{2}d & -\sqrt{2}d & -\sqrt{2}d & 2d & 2d \\
d^2 & -d & -d & -d & -d & 1 & 1 & d^2 & -\sqrt{2}d & -\sqrt{2}d & -\sqrt{2}d & -\sqrt{2}d & 2d & 2d \\
d^2 & -d & -d & -d & -d & 1 & 1 & d^2 & \sqrt{2}d & \sqrt{2}d & \sqrt{2}d & \sqrt{2}d & -2d & -2d \\
1 & d & d & d & d & d & d & 1 & -\sqrt{2}d & -\sqrt{2}d & -\sqrt{2}d & -\sqrt{2}d & -2d & -2d \\
\sqrt{2}d & \sqrt{2}d & -\sqrt{2}d & -\sqrt{2}d & \sqrt{2}d & \sqrt{2}d & \sqrt{2}d & 2\sqrt{2}d & -2\sqrt{2}d & 0 & 0 & 0 & 0 \\
\sqrt{2}d & -\sqrt{2}d & -\sqrt{2}d & -\sqrt{2}d & \sqrt{2}d & -\sqrt{2}d & \sqrt{2}d & -2\sqrt{2}d & 2\sqrt{2}d & 0 & 0 & 0 & 0 \\
\sqrt{2}d & -\sqrt{2}d & \sqrt{2}d & \sqrt{2}d & -\sqrt{2}d & -\sqrt{2}d & \sqrt{2}d & 0 & 0 & 0 & 0 & 0 & 0 \\
2d & 2d & 2d & -2d & -2d & 2d & -2d & 0 & 0 & 0 & 0 & 0 & 0 \\
2d & -2d & -2d & 2d & -2d & -2d & -2d & 0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix}
\]

\[
T = \operatorname{diag}(1, i, i, -i, -1, 1, 1, 1, 1, e^{5\pi i/4}, e^{3\pi i/4}) \quad \text{(C3)}
\]

There are two permutation actions on the anyons which lift the action of \( T \) on \( C \), complex conjugate the modular
data, and square to the identity. Listed as a 14x14 matrix acting on anyon labels, these permutations are

\[ P_1 = \begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1
\end{pmatrix}, \quad (C5) \]

\[ P_2 = \begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
