(Dated: October 20, 2021)

Hexagonal boron nitride (h-BN) is a promising platform for quantum information processing due to its potential to host optically active defects with attractive optical and spin properties. Recent studies suggest that carbon trimers might be the defect responsible for single-photon emission in the visible spectral range in h-BN. In this theoretical study, we combine group theory together with density functional theory (DFT) calculations to predict the properties of the neutral $C_2C_N$ carbon trimer defect. We find the multi-electron states of this defect along with possible radiative and non-radiative transitions assisted by the spin-orbit and the spin-spin interactions. We also investigate the Hamiltonian for external magnetic field and ground-state hyperfine interactions. Lastly, we use the results of our investigation in a Lindblad master equation model to predict an optically detected magnetic resonance (ODMR) signal and the $g^2(\tau)$ correlation function. Our findings can have important outcomes in quantum information applications such as quantum repeaters used in quantum networks and quantum sensing.

I. INTRODUCTION

Color centers as solid-state artificial atoms in systems such as diamond, silicon carbide, and Van der Waals materials, have potential applications in quantum technology [1, 2]. Many of these color centers are single-photon sources and have good spin properties [3]. Single-photon emitters (SPE) are a vital part of photonic quantum technologies [4, 5], also spins with good spin-photonic interfaces are promising candidates for storing information [6]. These make color centers important for various quantum applications, including quantum communication, quantum sensing, and distributed quantum computing.

Ultra-bright and polarized single-photon emission from color centers in two-dimensional (2D) hexagonal boron nitride (h-BN) has been recently observed at room temperature [7]. h-BN has attracted attention for several reasons. Firstly, it has a relatively large bandgap of around 6 eV [8–10] which allows it to host many defects [11–15]. However, the true atomic structure of most of these emitters remains unknown [16, 17]. Secondly, because of its 2D nature, it is promising for heterogeneous assembly and on-chip integration into devices [18, 19]. Thirdly, some defects in h-BN might have high sensitivity to the environment because of their location at the surface, which is advantageous for quantum sensing applications [20]. Finally, defects in h-BN are the only known solid-state sources that can display Fourier transform limited lines at room temperature [21]. If the Fourier transform of an emitter’s temporal profile matches its spectral line-shape, then the emitter resonance does not fluctuate during the timescale of emission. This implies that quantum coherence is maintained so that the emitter can be used for many quantum protocols.

It has been shown that visible range SPEs in h-BN originate from carbon-related defects [16]. Jara et al. [22] suggest that the neutral $C_2C_N$ and $C_2B_N$ carbon trimer defects might have zero-phonon line (ZPL) energies of 1.62 eV and 1.65 eV, respectively, and a phonon sideband of around 160 meV, which is typically found in many experiments [16, 23]. However, a new study suggests that the $C_2B_N$ defect might have a ZPL energy of 1.36 eV [24]. This energy is too far from the visible range, and so we focus only on the $C_2C_N$ defect where both studies agree on a ZPL energy of around 1.6 eV.

In this study, we explore the electronic structure of the $C_2C_N$ defect in 2D h-BN and find the possible radiative and non-radiative transitions to model the observed lines. To do so, we combine group theory analysis with density functional theory (DFT) calculations [25, 26]. We determine the symmetry-adapted molecular orbitals (MO) using group theory analysis. Then, we use DFT results to determine the relative energy ordering of these orbitals [27]. Next, we obtain the total orbital and spin multi-electron states by filling the lowest energy MOs, which gives us the ground state. Exciting electrons to the higher energy MOs gives us the excited states [28]. We calculate the total energy of the electronic structures with DFT, and the difference between these energies gives us the transition energies between defect states.

We then consider the spin-orbit, the spin-spin, and external magnetic field interactions and find matrix elements of the Hamiltonian, where group theory decreases the complexity by reducing the number of non-zero elements. Furthermore, we look at the interaction between the defect and the electromagnetic field and find non-vanishing matrix elements to derive the optical transitions. Combining this with the spin-orbit and the spin-spin Hamiltonians gives us possible non-radiative transi-
tions assisted by the spin-orbit and the spin-spin interactions [17]. We also examine the hyperfine interaction of the ground state with a possible nearby nuclear spin [29]. Finally, we look at the dynamics of this system and simulate the optically detected magnetic resonance (ODMR) signal predicted by the Lindblad master equation [30].

This paper is organized as follows. In Sec. II we discuss the symmetry of the $C_2C_N$ defect and determine the symmetry-adapted MOs. Then we investigate multi-electron states (Sec. III), the spin-orbit interaction (Sec. IV), the spin-spin interaction (Sec. V), spin-orbit and spin-spin mediated transitions (Sec. VI), selection rules for the transitions (Sec. VII), external magnetic field effect (Sec. VIII), and hyperfine interaction (Sec. IX). In Sec. X we simulate the ODMR spectra and the $g^2(\tau)$ second-order correlation function. Next, we provide a summary in Sec. XII. Finally, we discuss computational methods in Sec. XI. Matrix elements of all of the interactions and more configurations for the ODMR simulations are given in the Supplementary Material I.

**II. MOLECULAR ORBITALS**

The atomic configuration of the $C_2C_N$ defect is shown in Fig. 1(a), where $C_2$ denotes the $C_{6h}C_N$ carbon dimer, and $C_N$ denotes a substitution of a nitrogen atom with a carbon atom. In order to find the symmetry group of the defect, it is important to know if the defect is in- or out-of-plane, as some defects might be distorted out of the plane [31]. A recent study suggests that distortion from the plane for the $C_2C_N$ defect is negligible and that it has a planar structure [24]. Thus, this defect has $C_{2v}$ symmetry, which is supported by defect wave functions as in Fig. 2(a).

The ground-state configuration of carbon is $1s^22s^22p^2$. The planarity of the defect implies that carbon atoms will have $sp^2$ hybridization. In $sp^2$ hybridization, the $2s$ orbital is mixed with only two of the three available $2p$ orbitals. The third $2p$ orbital remains unhybridized and out of the plane and in the $\hat{y}$ direction, which is also confirmed by our DFT calculations shown in Fig. 2(a).

Each carbon atom of the $C_2C_N$ defect shares three of its valence electrons with nearby atoms in the lattice; therefore, they each have one unpaired electron. Thus, the dangling bonds of the defect are $\pi$ bonds, and they are denoted by $\{\pi_1, \pi_2, \pi_3\}$.

Now, we need to find the symmetry-adapted MOs of this defect. The MOs are eigenfunctions of the Coulombic Hamiltonian. We apply the projection operator,

$$\phi_\tau = P^{(\tau)}\sigma_i = \frac{l_r}{h} \sum_\epsilon \chi_\epsilon^{(\tau)} R_\epsilon \pi_i,$$

with a specific irreducible representation (IR) on our dangling bonds to find symmetrized MOs [32]. Here, $P^{(\tau)}$ is the projection to the representation $\tau$, $l_r$ is the dimension of the representation $r$, $h$ is the number of symmetry group members, $\chi_\epsilon^{(\tau)}$ is the character of the operator $\epsilon$ in the representation $\tau$, $R_\epsilon$ is the symmetry operator, and $\pi_i$ is the dangling bond $i$. According to the character table of $C_{2v}$ point group (Table I), $b$ and $b'$ MOs transform according to IR $B_2$. They are defined as

$$b = \alpha \pi_2 + \frac{\beta}{\sqrt{2}} (\pi_1 + \pi_3),$$

$$b' = \beta \pi_2 + \frac{\alpha}{\sqrt{2}} (\pi_1 + \pi_3),$$

where $\alpha$ and $\beta$ are overlap integrals and $|\alpha|^2 + |\beta|^2 = 1$. There is another MO that transforms as IR $A_2$, defined as

$$a = \frac{1}{\sqrt{2}} \{\pi_1 - \pi_3\}.$$

**III. MULTI-ELECTRON STATES**

We use DFT to find the energy of each of the MOs discussed above and their energy ordering. The defect wave functions in Fig. 2(a) obtained from the DFT calculations show that the MO with the lowest energy transforms as IR $B_2$, so it represents the $b$ MO. This is because, according to the symmetry operators in Fig. 1(b), this MO is anti-symmetric under $C_2(z)$ and $\sigma_v(xz)$, and symmetric under $E$ and $\sigma_v(yz)$. The next MO with higher

energy transforms as IR \(A_2\), because it is anti-symmetric under \(\sigma_v(xz)\) and \(\sigma_v(yz)\), and symmetric under \(E\) and \(C_2(z)\). Therefore, it represents the \(a\) MO. Finally, the one with the highest energy transforms as IR \(B_2\) similar to the first one, and thus it represents the \(b'\) MO. Based on a previous study, the MOs in the ground state and the first excited state lie inside the bandgap [22]. Our \textit{ab initio} calculations show that the MOs in the next two excited states are also in the bandgap.

Multi-electron states are composed by filling the MOs with three unpaired electrons of the defect, starting from the lowest energy \(b\) MO. The \(b\) MO will be fully occupied with two electrons in the ground state, and the \(a\) MO will be half occupied. This configuration will form a spin doublet because the half occupied \(a\) MO can be either spin up or down. So its spin multiplicity will be equal to 2. This lowest multi-electron state has the configuration \([b]^1[a]^1[b']^0\) which transforms as IR \(A_2\). Other excited multi-electron states are produced by exciting each of these electrons to higher MOs. The \([b]^1[a]^2[b']^0\) and \([b]^2[a]^0[b']^1\) configurations are also spin doublets, similar to the ground state, and transform according to IR \(B_2\). But the other excited state \([b]^1[a]^1[b']^1\) needs careful consideration. Since it is the addition of three spin 1/2 orbitals, it will have three irreducible spin representations, including one quartet state and two doublet states with multiplicities 4, 2, and 2, respectively. These states all transform as IR \(A_2\). The corresponding electronic configurations of these states are given in Table II and the energy levels of the first four single-configuration states are given in Fig. 2(b).

TABLE II. Configuration of total wave functions. Some of these states are entangled states which need careful consideration when calculating their energy using DFT. Spin-down electrons in an orbital are shown with a line over them. In the label column, calligraphic letters \(A\) and \(B\) represent IRs \(A_2\) and \(B_2\), respectively. Also, \(d\) and \(q\) in the superscript stand for doublet and quartet states, respectively. Prime and double prime in IRs of each state is used just to distinguish them with other states with the same IR.

IV. SPIN-ORBIT INTERACTION

The spin-orbit interaction is the sum of the Larmor and Thomas interaction energy which is given by [28]

\[
H_{\text{SO}} = \sum_k \frac{\hbar}{2m_e^2c^2} \left( \nabla_k V \times p_k \right) \cdot \left( \frac{s_k}{\hbar} \right)
\]

\[
= \sum_k l_k \cdot \left( \frac{s_k}{\hbar} \right),
\]  

where \(V\) is the electric potential energy of the nucleus, \(\hbar\) is the reduced Planck constant, \(m_e\) is the electron rest
mass, \( c \) is the speed of light in vacuum, \( s_k \) is the spin of electron \( k \), \( p_k \) is the momentum of electron \( k \), and \( k \) sums over all electrons. By utilizing group theory, we omit the vanishing components of the matrix elements of \( l_k \). The elements \( \langle \phi_i | l | \phi_j \rangle \) are non-vanishing only if \( \Gamma(\phi_i) \otimes \Gamma(l_k) \otimes \Gamma(\phi_j) \supset \Gamma^{A1} \), where \( \Gamma \) is the irreducible representation. Since \( I \) is proportional to \( r \times p \), it transforms as \( (B_2, B_1, A_2) \). Based on Table III, only \( l_{y} \), which transforms as \( \text{IR} \ B_{1} \), will have non-zero values. Therefore,

\[
H_{SO} = \sum_{k} \sum_{k'} \left( s_{k} \langle \phi_{i} | l_{y} | \phi_{j} \rangle \right) .
\]

VI. SPIN-ORBIT AND SPIN-SPIN INDUCED TRANSITIONS

For the spin-orbit interaction, as we discussed before, only the matrix elements in the form of \( \langle B_2 | H_{so} | A_2 \rangle \) and their complex conjugate will be non-zero. This indicates that there are no matrix elements in degenerate manifolds of \( \{ A_{0,d}, B_{1,d}, B_{2,d}, A_{3,q} \} \). Therefore, there is no mixing due to the spin-orbit coupling. However, we have possible spin-orbit induced transitions between the states in these manifolds, which are \( B_{1,d} \leftrightarrow A_{0,d}, B_{2,d} \leftrightarrow A_{0,d}, B_{1,d} \leftrightarrow A_{3,q} \), and \( B_{2,d} \leftrightarrow A_{3,q} \). As discussed in Ref. [35, 36], these types of transitions can happen in two steps. First, spin-orbit assisted transition occurs for example from \( B_{2,d} \) to a vibrational excited state of \( A_{3,q} \). This is followed by a relaxation to the vibrational ground-state, for example, via the emission of one or more phonons. Such a process will be possible if there is an overlap between the initial vibrational level of \( B_{2,d} \) and the excited vibrational level of \( A_{3,q} \).

Similarly and based on the findings of the previous section, the spin-spin interaction has no matrix element in the degenerate manifold of \( \{ A_{0,d}, B_{1,d}, B_{2,d} \} \). However, there are non-zero matrix elements of the spin-spin interaction in the quartet state manifold. \( D_{ij} \) is the diagonal, and \( E_{3} \) is the off-diagonal term. Hence, spin-spin interaction breaks the degenerate quartet states into two states and separates them by \( 2D_{0} \). Also, the non-diagonal terms in the same manifold mix these two states. There are also possible spin-spin induced transitions between the states in these manifolds, which are \( A_{0,d} \leftrightarrow A_{3,q}, B_{1,d} \leftrightarrow A_{3,q}, B_{2,d} \leftrightarrow A_{3,q} \).

VII. SELECTION RULES

Here we look at the dominant transition allowed by the interaction of the electron with the electromagnetic field, which is the electric dipole transition. The electric dipole interaction is defined as

\[
H_{dipole} = E \cdot d = \sum_{k} e E \cdot r_k ,
\]

where \( E \) is the electric field, \( d \) is the electric dipole moment, \( r_k \) is the position of \( k \) electron with respect to the nucleus, and \( e \) is the elementary electric charge. The position \( r \) in the \( C_{2v} \) group transforms like \( (B_1, B_2, A_1) \). Thus, according to Table III, the allowed transitions are induced by either \( eE_{x}x \) or \( eE_{z}z \) and the dipole moment
lies completely in the plane. The dipole allowed transitions and the matrix elements are given in the appendix (Sec. A 3). These results are summarized in Fig. 3(a), which shows radiative and non-radiative transitions along with the energy levels of the states.

VIII. EXTERNAL MAGNETIC FIELD

In the presence of an external magnetic field, there will be another term for the Zeeman interaction of the magnetic field with spin and orbital angular momentum [27]. This interaction is given by

\[ H_B = \frac{e}{2me} \sum_k (l_x + g_e s_k) \cdot B, \]  

(10)

where \( g_e \) is the electron spin g-factor, \( s \) is the electron spin, \( l \) is electron orbital angular momentum, \( B \) is the external magnetic field, and \( k \) sums over all electrons. But since \( l_x \) transforms as IR \( A_2 \) and transforms as IR \( B_2 \) according to Table III, they do not contribute to the Hamiltonian. Therefore, the Zeeman interaction will be simplified to \( H_B = \frac{e}{2me} \sum_k (B_x g_e s_x + B_y l_y + g_e s_y + B_z g_e s_z) \). The matrix elements of the Hamiltonian above are given in the appendix (Sec. B).

A. Quartet state anticrossing

As we discussed previously, the spin-spin interaction splits and mixes the quartet state eigenvalues and the spin-orbit interaction does not affect them. Adding a magnetic field perpendicular to the h-BN sheet (\( y \)), modifies the energy eigenvalues of the quartet state. We add the matrix elements of the interactions for the quartet state from preceding sections and find its eigensystem. The energy eigenvalues are given by

\[ E_1 = \tilde{B}_y - \nu_1, \]
\[ E_2 = \tilde{B}_y + \nu_1, \]
\[ E_3 = -\tilde{B}_y - \nu_1, \]
\[ E_4 = -\tilde{B}_y + \nu_1, \]

(11)

and eigenvalues are given by

\[ |\Phi_1\rangle = \mu_1 |A^{3,q}_{-1/2}\rangle + i \nu_1 |A^{3,q}_{+1/2}\rangle \]
\[ + i |A^{3,q}_{-3/2}\rangle + |A^{3,q}_{+3/2}\rangle, \]
\[ |\Phi_2\rangle = -\mu_2 |A^{3,q}_{-1/2}\rangle - i \nu_2 |A^{3,q}_{+1/2}\rangle \]
\[ + i |A^{3,q}_{-3/2}\rangle + |A^{3,q}_{+3/2}\rangle, \]
\[ |\Phi_3\rangle = -\nu_1 |A^{3,q}_{-1/2}\rangle + i \nu_1 |A^{3,q}_{+1/2}\rangle \]
\[ - i |A^{3,q}_{-3/2}\rangle + |A^{3,q}_{+3/2}\rangle, \]
\[ |\Phi_4\rangle = -\nu_2 |A^{3,q}_{-1/2}\rangle + i \nu_2 |A^{3,q}_{+1/2}\rangle \]
\[ - i |A^{3,q}_{-3/2}\rangle + |A^{3,q}_{+3/2}\rangle, \]

(12)

where the coefficients are defined as

\[ \kappa_1 = \sqrt{4\tilde{B}_y^2 + \tilde{D}_0^2 + \tilde{E}_3^2 - 2\tilde{B}_y (\tilde{D}_0 + \sqrt{3}\tilde{E}_3)}, \]
\[ \kappa_2 = \sqrt{4\tilde{B}_y^2 + \tilde{D}_0^2 + \tilde{E}_3^2 + 2\tilde{B}_y (\tilde{D}_0 + \sqrt{3}\tilde{E}_3)}, \]
\[ \mu_1 = \frac{3\tilde{B}_y^2 - \tilde{E}_3^2}{3\tilde{B}_y^2 - \tilde{D}_0^2 - \tilde{E}_3^2}, \]
\[ \mu_2 = \frac{\tilde{D}_0 + \sqrt{3}\tilde{E}_3}{\tilde{D}_0 + \sqrt{3}\tilde{E}_3}, \]
\[ \nu_1 = \frac{(\tilde{E}_3 - \sqrt{3}\tilde{B}_y) - \kappa_1 + \tilde{B}_y + \tilde{D}_0}{\tilde{E}_3^2 - 3\tilde{B}_y^2}, \]
\[ \nu_2 = \frac{(\tilde{E}_3 - \sqrt{3}\tilde{B}_y) - \kappa_2 + \tilde{B}_y + \tilde{D}_0}{\tilde{E}_3^2 - 3\tilde{B}_y^2} \]

The variables with tilde are defined as below to simplify the equations.

\[ \tilde{B}_y = \frac{\gamma_e \hbar}{2} B_y \]
\[ \tilde{D}_0 = \frac{\mu_0 \sqrt{2} \hbar^2}{16\pi} D_0 \]
\[ \tilde{E}_3 = \frac{\mu_0 \sqrt{2} \hbar^2}{16\pi} E_3 \]

Based on these results and as shown in Fig. 3(b), an anticrossing happens between \( |\Phi_1\rangle \) and \( |\Phi_2\rangle \) when the magnetic field compensates the spin-spin splitting at \( \tilde{B}_y \) near \( \sqrt{\tilde{D}_0^2 + \tilde{E}_3^2}/2 \). The \( |\Phi_3\rangle \) state remains unmixed as it is diverging from other states. The \( |\Phi_4\rangle \) state is not mixed too, despite the fact that the \( |\Phi_2\rangle \) state passes it at \( \tilde{B}_y \) near \( \sqrt{\tilde{D}_0^2 + \tilde{E}_3^2} \).

IX. GROUND-STATE HYPERFINE INTERACTION

Nuclear spins in solids are a promising candidate for storing information and using them as quantum memories due to their long coherence time [37]. Nuclear spin quantum memories have been demonstrated experimentally for the orbital ground state of the negatively-charged nitrogen-vacancy center in diamond [38, 39]. In this section, we will investigate the effect of the presence of a carbon-13 nuclear spin in the defect, which is given by \( \tilde{H} = \tilde{H}_{13C} + \tilde{V}_{mhf} + \tilde{V}_{ehf} \). The first term is Zeeman interaction of the nuclear spin with an external magnetic field, which is given by \( \tilde{H}_{13C} = -\gamma_{13C} B \cdot \tilde{I} \), where \( \tilde{I} \) is the nuclear spin and \( \gamma_{13C} \) is the magnetic gyromagnetic ratio of \( ^{13}C \). The second (third) term is the magnetic (electric) component of the hyperfine interaction of the ground electronic state of the defect with the \( ^{13}C \) nuclear.
spin [29, 40]. We only have to look at the magnetic component since $^{13}\text{C}$ has a nuclear spin of $I = 1/2$, and the electric component is due to the quadrupole moment of nuclei with spin $I \geq 1$ [41]. Also, we ignored the nuclear spin-spin interactions in this paper.

The magnetic hyperfine Hamiltonian accounts for the interaction between the nuclear spin and the electronic orbital magnetic moment in addition to the dipole-dipole interaction between the nuclear spin and the electron spin. The component of the hyperfine interaction that is related to the orbital angular momentum is given by

$$
\hat{V}_{\text{mhf}} = C_{\text{mhf}} \sum \left\{ \frac{8\pi}{3} \delta(\hat{r}_{iC}) - \frac{1}{r_{iC}^3} \right\} \hat{s}_i \cdot \hat{I} + \frac{3(\hat{s}_i \cdot \hat{r}_{iC})(\hat{I} \cdot \hat{r}_{iC})}{r_{iC}^5}
$$

$$
= -C_{\text{mhf}} \sum \hat{s}_i \cdot \hat{A}^{(2)}_i \cdot \hat{I}
$$

$$
= -C_{\text{mhf}} \sum \hat{j}^{(2)}_i \otimes \hat{A}^{(2)}_i^{(0)},
$$

where $C_{\text{mhf}} = g_I \mu_N g_e \mu_B \frac{\mu B}{4\pi}$, and $\hat{A}^{(2)}_i$ is a second rank tensor. The Fermi contact term contributes to the energy of orbitals with non-zero value of the wave function at the position of the nucleus. However, based on our DFT calculations (Fig. 2(a)), the wave functions are zero at the position of the carbon nuclei and we can ignore the Dirac delta term. Consequently, the second order tensor $\hat{A}^{(2)}_i$ is given by

$$
\hat{A}^{(2)}_i = \frac{1}{r_{iC}^7} \begin{pmatrix}
    r_{iC}^2 - 3x_{iC}^2 & -3x_{iC}y_{iC} & -3x_{iC}z_{iC} \\
    -3x_{iC}y_{iC} & r_{iC}^2 - 3y_{iC}^2 & -3y_{iC}z_{iC} \\
    -3x_{iC}z_{iC} & -3y_{iC}z_{iC} & r_{iC}^2 - 3z_{iC}^2
\end{pmatrix}.
$$

For simplifying further calculations, we define $\hat{j}^{(2)}_i = \hat{s}_i \otimes \hat{I}$ and write the interaction in the compound tensor form.
According to Table III, for the ground states $|A_{\pm 1/2}^0\rangle$, only the operators of the form $O^{A_1}$ contribute to the hyperfine interaction. Thus, only the diagonal terms of $A_{\pm 2}^{(2)}$ in Eq. (16) transform as IR $A_1$ contribute to the hyperfine interaction of the ground state, and the off-diagonal terms do not contribute. We write the basis of the ground state of the defect coupled to a $^{13}$C nuclear spin as

$$
|\Psi_1^g; 1, +1\rangle = |A_{+1/2}^{0,d}\rangle |+\rangle_I,
$$

$$
|\Psi_2^g; 1, 0\rangle = \frac{1}{\sqrt{2}}(|A_{+1/2}^{0,d}\rangle |+\rangle_I + |A_{-1/2}^{0,d}\rangle |-\rangle_I),
$$

$$
|\Psi_3^g; 1, -1\rangle = |A_{-1/2}^{0,d}\rangle |-\rangle_I,
$$

$$
|\Psi_4^g; 0, 0\rangle = \frac{1}{\sqrt{2}}(|A_{+1/2}^{0,d}\rangle |-\rangle_I - |A_{-1/2}^{0,d}\rangle |+\rangle_I).
$$

(17)

Based on the symmetry of the system, there can only be non-zero hyperfine matrix elements for states that have $\Delta S \in \{0, \pm 2\}$. The results of the calculations for matrix elements are shown in the appendix (Sec. C2).

X. ODMR SIGNAL

There have been reports of ODMR signal for defects in h-BN. One of them is known to originate from the $V_{\parallel}$ defect [42], while the origins of the other observed ODMR signals are not established yet [19, 43]. Here, we present our results for the ODMR simulation using the model in Fig. 4. We used the Lindblad master equation to derive the second-order correlation function $g^{(2)}$ and the ODMR contrast.

We simulate a coherent pulse to excite the ground doublet state $\{|1\rangle, |2\rangle\}$ to one of the two excited doublet states $\{|3\rangle, |4\rangle\}$ or $\{|5\rangle, |6\rangle\}. All of these electronic states are spin 1/2 states, and we assumed that their spin states are split due to an external magnetic field. We also simulate a coherent microwave pulse to probe the ODMR signal by changing its energy around the spin-splitting energy.

If the quartet dark states $\{|7\rangle, |8\rangle, |9\rangle, |10\rangle\}$ do not overlap with the phonon sideband of the first excited states $\{|3\rangle, |4\rangle\}$, they can act as a meta-stable manifold during the decay of the second excited states $\{|5\rangle, |6\rangle\}$. Since we predict that the quartet energy of around 4.1 eV is far above the 1.6 eV of the first excited doublet, it is unlikely that there is an overlap with the phonon sideband, which is typically smaller than about 500 meV for defects in h-BN [16]. In addition, the decay to the quartet state from the quartet state to the first excited state can depend on the spin, and hence the system could produce an ODMR signal. To see this signal, one should excite the ground-state levels to the second excited state doublet $\{|5\rangle, |6\rangle\}$, after which a spin-independent non-radiative transition can occur into the quartet manifold.

The $^2B_2$ state is the most promising candidate because its energy is very close to the quartet state, and most likely, it will overlap with its phonon sideband, allowing for fast non-radiative transitions to the meta-stable state. Thus, we restricted the model to the $^2B_2$ level and ignored $^2A_2'$ and $^2A_2''$ levels because of their high energy. We also ignored non-radiative transitions related to $^2B_2' \leftrightarrow ^2A_2$, $^2B_2 \leftrightarrow ^2A_2$, and $^4A_2 \leftrightarrow ^2A_2$ because the energy difference between them is large and it is more likely that other non-radiative and radiative transitions will dominate the transitions between these states. In our simulation, the microwave Rabi frequency was chosen such that the ODMR signal had the highest value.

We simulate a coherent pulse to excite the ground doublet state $\{|1\rangle, |2\rangle\}$ to one of the two excited doublet states $\{|3\rangle, |4\rangle\}$ or $\{|5\rangle, |6\rangle\}. All of these electronic states are spin 1/2 states, and we assumed that their spin states are split due to an external magnetic field. We also simulate a coherent microwave pulse to probe the ODMR signal by changing its energy around the spin-splitting energy.

The results obtained by exciting the ground-state levels directly to the second excited state $\{|5\rangle, |6\rangle\}$, which is the $^2B_2'$ state, are given in Fig. 5. We have used the parameters in Table IV to predict this ODMR signal. The lifetime of excited states with energies around 2 eV has
been measured for many emitters, and they are around a few ns [44], which we have used for the optical decay rates in our model. The intersystem crossing rates and meta-stable decay rates for which we see ODMR signal are on the order of magnitude of the rates seen in other defects [45], but more calculations are needed to verify if the rates are in the proper range for the C\textsubscript{2}C\textsubscript{N} defect.

Varying the parameters used for this model shows that $k_{51}$, $k_{62}$, $k_{53}$, and $k_{64}$ have major effects on the ODMR signal. They should be on the order of the values specified in Table IV in order to cause an ODMR signal contrast around 1%. Their effect on the ODMR signal and $g^2$ correlation function is shown in Fig. 6 and Fig. 7, respectively. Also, the difference between $k_{74}$ and $k_{83}$ is essential for having an ODMR signal. Based on our calculations for the spin-orbit and the spin-spin interactions, the matrix elements responsible for these transitions are different for the spin up and down. The transition amplitudes are proportional to these matrix elements, allowing the defect to have spin-dependent decay rates from and to the quartet state. The effect of changing $k_{74}$ and $k_{83}$ on the ODMR signal and $g^2$ correlation function is shown in Fig. 8. Based on the matrix elements of the spin-orbit and spin-spin interactions, the $k_{74}$ and $k_{83}$ rates are related to the $k_{93}$ and $k_{104}$ rates. So changing each of them will affect the other two.

XI. COMPUTATIONAL DETAILS

The DFT calculations and post-processing were performed using the QUANTUM ESPRESSO open-source software package [46]. The calculations utilized a plane-wave basis set with a kinetic energy cutoff of 350 eV and projector augmented-wave pseudopotentials [47]. All relaxation calculations were performed with a force convergence threshold of $10^{-4}$ eV/Å. Experimental investigations of point defects in h-BN typically consider multi-layer samples; however, it has been shown that DFT calculations result in negligible differences between the electronic structure of defects in single- and multi-
FIG. 7. The effect of changing $k_{53}$ and $k_{64}$ on the optical signal, ODMR contrast, and the second-order correlation function. The grid line shows the Rabi frequency at 5 MHz. The results show that as $k_{53}$ and $k_{64}$ rates decrease, the magnitude of the ODMR signal increases.

layer systems [7]. Our supercell consists of 98 atoms and a vacuum separation of 15 Å between layers, corresponding to $7 \times 7$ unit cells of mono-layer h-BN. The atomic positions and in-plane lattice constant for the pristine h-BN structure were relaxed using the Perdew-Burke-Ernzerhof (PBE) exchange-correlation functional [48]. An in-plane lattice constant of $a = 2.5$ Å was obtained, consistent with previous findings [49]. The Heyd-Scuseria-Ernzerhof (HSE06) hybrid functional [50] was then used to optimize the direct bandgap at the $K$ high symmetry point [51] to the bulk value of $\approx 6$ eV [17]. A bandgap of 5.98 eV was obtained by setting the mixing parameter to 0.32 and fine-tuning the screening parameter to $0.086 \, \text{Å}^{-1}$.

The $C_2C_N$ defect was then added to the hexagonal lattice, the atomic positions were relaxed in-plane, and the ground-state wave functions of the single-particle defect levels were calculated. Next, the single-configuration excited states ($^2A_2^\prime$, $^2B_2$, $^2B_2^\prime$, and $^4A_2$) were created using the ∆SCF method [52], and the atomic positions of each excited state electronic configuration were relaxed in-plane. The transition energies between defect states were calculated by considering the difference in total energies of the structures, obtained via spin-polarized calculations performed within the Γ-point approximation. The HSE06 functional has been shown to provide accurate results for defects in h-BN which exhibit low correlation and charge transfer, and as such, it is expected that the error in the DFT calculations of the single-configuration states is on the order of 0.1 eV [22, 53]. The remaining states of interest ($^2A_2^\prime$ and $^2A_2^\prime$) are multi-configuration states which cannot be modeled in the DFT calculations using the ∆SCF method. Rough estimates for the corresponding transition energies were obtained following the method of Ref. [54, 55], making use of the single-configuration states $|bab^\prime\rangle$, $|bab^\prime\rangle$, and $|b\overline{a}b^\prime\rangle$ which were created within the ∆SCF procedure (see appendix Sec. D for detailed calculations).

FIG. 8. The effect of changing $k_{83}$ and $k_{74}$ on the optical signal, ODMR contrast, and the second-order correlation function. The grid line shows the Rabi frequency at 5 MHz. The results show that for some values of $k_{83}$ and $k_{74}$ rates, the sign of the ODMR contrast will change to positive.

XII. CONCLUSION

We have used group theory and DFT calculations to find the electronic structure and transitions of the $C_2C_N$ defect in 2D h-BN. The results are summarized...
in Fig. 3(a) which shows that there are several radiative transitions together with spin-orbit and spin-spin assisted non-radiative transitions. Also, the spin-spin interaction causes a splitting between quartet states \(^4A_2\). We studied the effect of an external magnetic field and found that in the presence of an external magnetic field perpendicular to the plane, there is an anticrossing between the states of the quartet manifold. We also looked at the ground-state hyperfine interactions, which can be useful in future studies. Finally, we simulated the system using the Lindblad master equation. Although our results indicate that it is unlikely for the \(C_2\) defect to be responsible for the ODMR signals that have been reported so far, we show that it could be possible to see an ODMR signal contrast of \(\sim 1\%\) for the configuration discussed in the text. Properties of the defect that we considered are essential for future applications, e.g., for quantum networks and quantum sensing.

ACKNOWLEDGMENTS

We thank Igor Aharonovich for valuable discussions. This work was supported by the Natural Sciences and Engineering Research Council (NSERC) of Canada through its Discovery Grant and Strategic Project Grants Programs, the Alberta Major Innovation Fund Quantum Technology project, Compute Canada, and Advanced Research Computing (ARC) IT team of the University of Calgary.

Appendix A: Matrix elements of the Hamiltonian

In this section, we provide the matrix elements of the interactions discussed in the main text.

1. Spin-orbit interaction

The matrix elements of the spin-orbit interaction are given below, where the variables \(\lambda\), and \(\lambda'\) are defined as

\[
\lambda = \langle a | l^{(9)} | b \rangle, \quad \lambda' = \langle b' | l^{(9)} | a \rangle.
\]  

\[
H_{so} = \frac{i}{2} \times \begin{pmatrix}
A^{0,d}_{+1/2} & A^{0,d}_{-1/2} & B^{1,d}_{+1/2} & B^{1,d}_{-1/2} & B^{2,d}_{+1/2} & B^{2,d}_{-1/2} & A^{3,q}_{+1/2} & A^{3,q}_{-1/2} & A^{3,q}_{+3/2} & A^{3,q}_{-3/2} & A^{3,d'}_{+1/2} & A^{3,d'}_{-1/2} & A^{3,d''}_{+1/2} & A^{3,d''}_{-1/2}
\end{pmatrix}
\]

\[
\begin{align*}
A^{0,d}_{+1/2} &= 0 \\
A^{0,d}_{-1/2} &= 0 \\
B^{1,d}_{+1/2} &= 0 \\
B^{1,d}_{-1/2} &= 0 \\
B^{2,d}_{+1/2} &= \lambda' \\
B^{2,d}_{-1/2} &= 0 \\
A^{3,q}_{+1/2} &= 0 \\
A^{3,q}_{-1/2} &= 0 \\
A^{3,q}_{+3/2} &= 0 \\
A^{3,q}_{-3/2} &= 0 \\
A^{3,d'}_{+1/2} &= 0 \\
A^{3,d'}_{-1/2} &= 0 \\
A^{3,d''}_{+1/2} &= 0 \\
A^{3,d''}_{-1/2} &= 0 \\
\end{align*}
\]

2. Spin-spin interaction

We can see from Table III that the only elements of D that transform as IRs \(A_1\) and \(B_1\) would yield non-zero values. These are

\[
\tilde{D}^{A_1} = \{\hat{D}_{xx}, \hat{D}_{yy}, \hat{D}_{zz}\} \quad \text{and} \quad \tilde{D}^{B_1} = (\hat{D}_{xx} + \hat{D}_{zz})/2.
\]  
In this interaction, we have the product of two rank-2 tensors. This product can be reduced to a
sum of rank 4, 3, 2, 1, and 0 irreducible tensor operators. Nevertheless, here we need a compound tensor operator of rank zero. This tensor product is given by the equation below [34].

\[
[\hat{s}^{(2)} \otimes \hat{D}^{(2)}]^{(0)}_{l_0} = \frac{1}{\sqrt{6}} \sum_{q=-2}^{+2} (-1)^{2-q} \hat{s}^{(2)}_{-q} \hat{D}^{(2)}_{q} \tag{A3}
\]

<table>
<thead>

<td>+1</td>
<td>\frac{1}{\sqrt{2}} (\hat{s}^{(1)}<em>{i+1} \hat{s}^{(1)}</em>{i} + \hat{s}^{(1)}<em>{i} \hat{s}^{(1)}</em>{i+1})</td>
</tr>
<tr>
<td></td>
<td>0</td>
<td>\frac{1}{\sqrt{6}} (\hat{s}^{(1)}<em>{i-1} \hat{s}^{(1)}</em>{i+1} + 2 \hat{s}^{(1)}<em>{i} \hat{s}^{(1)}</em>{0} + \hat{s}^{(1)}<em>{i+1} \hat{s}^{(1)}</em>{i-1})</td>
</tr>
<tr>
<td></td>
<td>-1</td>
<td>\frac{1}{\sqrt{2}} (\hat{s}^{(1)}<em>{i-1} \hat{s}^{(1)}</em>{i} + \hat{s}^{(1)}<em>{i} \hat{s}^{(1)}</em>{i-1})</td>
</tr>
<tr>
<td></td>
<td>-2</td>
<td>\hat{s}^{(1)}<em>{i} \hat{s}^{(1)}</em>{i+1}</td>
</tr>
</tbody>
</table>

TABLE V. Second rank spin tensor.

In order to use Eq. (A3), we need the spherical components of \( \hat{D} \). Spherical and Cartesian components of \( \hat{D} \) are related by the equations below.

\[
\hat{D}^{(2)}_{\pm 1} = \frac{(\hat{D}^{(2)}_{xx} - \hat{D}^{(2)}_{yy}) \pm i \hat{D}^{(2)}_{xy}}{\sqrt{2}} \tag{A4}
\]

\[
\hat{D}^{(2)}_{0} = (2\hat{D}^{(2)}_{zz} - \hat{D}^{(2)}_{xx} - \hat{D}^{(2)}_{yy}) / \sqrt{6}
\]

The components of \( \hat{s}^{(1)} \) in the notation of spherical tensor operators are given by

\[
\begin{align*}
\hat{s}^{(1)}_{+1} &= -\frac{1}{\sqrt{2}} (\hat{s}_x + i \hat{s}_y), \\
\hat{s}^{(1)}_{0} &= \hat{s}_z, \\
\hat{s}^{(1)}_{-1} &= \frac{1}{\sqrt{2}} (\hat{s}_x - i \hat{s}_y), \\
\hat{s}^{(1)}_{+1} &- \frac{1}{2} = -\frac{1}{\sqrt{2}} + \frac{1}{2}, \\
\hat{s}^{(1)}_{-1} + \frac{1}{2} &= \frac{1}{\sqrt{2}} - \frac{1}{2}.
\end{align*}
\]

Now that we have all the preliminary tools, we will derive the matrix elements. For the elements in the form of \( \langle A | H_{ss} | A' \rangle \) and \( \langle B | H_{ss} | B' \rangle \), according to Table III, only the parts of \( H_{ss} \) that transform as IR \( A_1 \) would yield non-zero values. \( |A \rangle \) and \( |A' \rangle \) can be any of states in Table II that transform as IR \( A_2 \) and similarly \( |B \rangle \) and \( |B' \rangle \) can be any of states in Table II that transform as IR \( B_2 \). \( \{\hat{D}_{xx}, \hat{D}_{yy}, \hat{D}_{zz}\} \) are the only components of \( \hat{D} \) that transform as IR \( A_1 \). In the spherical tensor form, \( \hat{D}_{0} \) transforms as IR \( A_1 \) and first two components of \( \hat{D}_{\pm 2} \) also transform as IR \( A_1 \). Therefore, just \( \hat{D}_{0} \), and \( \hat{D}_{\pm 2} \) contribute to non-zero values. At last, according to Eq. (A3), \( \Delta S \in \{0, \pm 2\} \). Similarly, for \( \langle A | H_{ss} | B \rangle \) according to Table III, only the parts of \( H_{ss} \) that transform as IR \( B_1 \) would yield non-zero values. \( \{\hat{D}_{xx}, \hat{D}_{yy}\} \) are the only components of \( \hat{D} \) that transform as IR \( B_1 \). Therefore, just \( \hat{D}_{\pm 1} \) contributes to non-zero values. For these matrix elements, according to Eq. (A3), we have \( \Delta S \in \{\pm 1\} \).

\[
\begin{align*}
\langle A | H_{ss} | A' \rangle \rightarrow A_1 &\rightarrow \hat{D}_{0}, \hat{D}_{\pm 2} \rightarrow \Delta S \in \{0, \pm 2\} \\
\langle B | H_{ss} | B' \rangle \rightarrow B_1 &\rightarrow \hat{D}_{\pm 1} \rightarrow \Delta S \in \{\pm 1\}
\end{align*}
\]

After doing all the calculations, we get the matrix elements for the spin-spin interaction, shown below.
The matrix elements used above are defined as

\[
\begin{bmatrix}
A_{-1/2}^{0.d} & A_{1/2}^{0.d} & B_{+1/2}^{1.d} & B_{-1/2}^{1.d} & B_{+1/2}^{2.d} & B_{-1/2}^{2.d} & A_{+1/2}^{3.q} & A_{-1/2}^{3.q} & A_{+1/2}^{3.d'} & A_{-1/2}^{3.d'} & A_{+1/2}^{3.d''} & A_{-1/2}^{3.d''}
\end{bmatrix}
\]

\[
H_{\text{so}} = \frac{\mu_0 \gamma^2 \hbar^2}{16\pi}
\]

\[
\begin{align*}
A_{-1/2}^{0.d} & = 0 \\
A_{1/2}^{0.d} & = 0 \\
B_{+1/2}^{1.d} & = 0 \\
B_{-1/2}^{1.d} & = 0 \\
B_{+1/2}^{2.d} & = 0 \\
B_{-1/2}^{2.d} & = 0 \\
A_{+1/2}^{3.q} & = \Delta_1 \\
A_{-1/2}^{3.q} & = \Phi
\end{align*}
\]

The matrix elements used above are defined as

\[
D_0 = \frac{1}{2\sqrt{3}} \left( \langle bb'| bb | \hat{D}_{zz}^{(2)} | ba - ab \rangle \\
+ \langle ba - ab | \hat{D}_{zz}^{(2)} | ba - ab \rangle \\
+ \langle ab' - b'a | \hat{D}_{zz}^{(2)} | ab' - b'a \rangle \right),
\]

\[
E_1 = \frac{1}{15} \left( \langle bb' - b'b | \hat{D}_{zz}^{(2)} | ba - ab \rangle \\
+ \langle ab' - b'a | \hat{D}_{zz}^{(2)} | ab' - b'a \rangle \right),
\]

\[
E_2 = \frac{1}{10} \left( \langle ab' - b'a | \hat{D}_{xx}^{(2)} - \hat{D}_{yy}^{(2)} | ab - ba \rangle \\
+ \langle ab - ba | \hat{D}_{xx}^{(2)} - \hat{D}_{yy}^{(2)} | ab - ba \rangle \right),
\]

\[
E_3 = \frac{1}{\sqrt{30}} \left( \langle ab' - b'a | \hat{D}_{xx}^{(2)} - \hat{D}_{yy}^{(2)} | ab' - b'a \rangle \\
+ \langle bb' - b'b | \hat{D}_{xx}^{(2)} - \hat{D}_{yy}^{(2)} | bb' - b'b \rangle \\
+ \langle ab - ba | \hat{D}_{xx}^{(2)} - \hat{D}_{yy}^{(2)} | ab - ba \rangle \right),
\]

\[
F_1 = \frac{\sqrt{3}}{2\sqrt{5}} \langle bb' - b'b | \hat{D}_{zz}^{(2)} | ab - ba \rangle,
\]

\[
F_2 = \frac{\sqrt{3}}{2\sqrt{5}} \langle ab' - b'a | \hat{D}_{zz}^{(2)} | bb' - b'b \rangle,
\]

\[
G = \frac{1}{\sqrt{30}} (bb' - b'b | D_{zz}^{(2)} | ba - ab),
\]

\[
H = \frac{1}{6\sqrt{10}} \left( \langle bb' - b'b | \hat{D}_{zz}^{(2)} | bb' - b'b \rangle \\
+ \langle ba - ab | \hat{D}_{zz}^{(2)} | ba - ab \rangle \\
- 2\langle ab' - b'a | \hat{D}_{zz}^{(2)} | ab' - b'a \rangle \right),
\]

\[
I = \frac{\sqrt{3}}{2\sqrt{10}} \left( -\langle bb' - b'b | \hat{D}_{zz}^{(2)} | bb' - b'b \rangle \\
+ \langle ab' - b'a | \hat{D}_{zz}^{(2)} | ab' - b'a \rangle \right),
\]

\[
J = -\frac{1}{2\sqrt{15}} \left( +\langle ab' - b'a | \hat{D}_{xx}^{(2)} - \hat{D}_{yy}^{(2)} | ab' - b'a \rangle \\
+ \langle bb' - b'b | (\hat{D}_{xx}^{(2)} - \hat{D}_{yy}^{(2)}) | bb' - b'b \rangle \\
- 2\langle ba - ab | (\hat{D}_{xx}^{(2)} - \hat{D}_{yy}^{(2)}) | ba - ab \rangle \right),
\]

\[
K = \frac{1}{2\sqrt{15}} \left( +\langle ab' - b'a | (\hat{D}_{xx}^{(2)} - \hat{D}_{yy}^{(2)}) | ab' - b'a \rangle \\
+ \langle bb' - b'b | (\hat{D}_{xx}^{(2)} - \hat{D}_{yy}^{(2)}) | bb' - b'b \rangle \\
- 2\langle ba - ab | (\hat{D}_{xx}^{(2)} - \hat{D}_{yy}^{(2)}) | ba - ab \rangle \right),
\]

\[
L = \frac{1}{\sqrt{5}} \left( -\langle ab' - b'a | (\hat{D}_{xx}^{(2)} - \hat{D}_{yy}^{(2)}) | ab' - b'a \rangle \\
+ \langle bb' - b'b | (\hat{D}_{xx}^{(2)} - \hat{D}_{yy}^{(2)}) | bb' - b'b \rangle \right).
\]

3. Dipole transitions

The dipole allowed transition rates would be proportional to the values defined below.
\[ \mu_x = eE_x \langle a | x | b \rangle \]
\[ \mu'_x = eE_x \langle a | x | b' \rangle \]
\[ \mu_{z,0} = eE_z \{ \langle b | z | b \rangle + \langle a | z | a \rangle + \langle b' | z | b' \rangle \} \]
\[ \mu_{z,1} = eE_z \{ 2 \langle b | z | b \rangle + \langle a | z | a \rangle \} \]
\[ \mu_{z,2} = eE_z \{ \langle b | z | b \rangle + 2 \langle a | z | a \rangle \} \]
\[ \mu_{z,3} = eE_z \{ 2 \langle b | z | b \rangle + \langle b' | z | b' \rangle \} \]
\[ \mu'_z = eE_z \{ b | z | b' \} \]

Furthermore, the matrix elements are as shown below.

Appendix B: Magnetic interaction

We define the following values for single molecular orbitals.

\[ \eta = \langle a | l_y | b \rangle \]
\[ \eta' = \langle a | l_y | b' \rangle \]
Appendix C: Hyperfine interaction

We can write the hyperfine interaction in the form of spherical components as below.

\[
\hat{V}_{\text{mhf}} = -C_{\text{mhf}} \sum_i [\hat{j}_{1}^{(2)} \otimes \hat{A}_{1}^{(2)}]^{(0)}
\]

\[
= -\frac{C_{\text{mhf}}}{\sqrt{3}} \sum_i \sum_{q=-2}^{q=+2} (-1)^{2q-2q} J_{1}^{(2)} J_{1}^{(2)} A_{1, q}^{(2)} \tag{C1}
\]

After doing the calculations, we end up with the following Hamiltonian for the ground state.

\[
V_{\text{mhf}} = -\frac{C_{\text{mhf}}}{12\sqrt{3}} \begin{pmatrix}
\Psi_1 & \Psi_2 & \Psi_3 & \Psi_4 \\
G_0 & 0 & -2G_0 & 0 \\
-3\sqrt{3}G_1 & 0 & G_0 & 0 \\
0 & -G_0 & 0 & 0
\end{pmatrix}, \tag{C2}
\]

where

\[
G_0 = (a|2A_{2z}^{(2)} - A_{zz}^{(2)} - A_{yy}^{(2)}|a),
\]

\[
G_1 = (a|A_{zz}^{(2)} - A_{yy}^{(2)}|a). \tag{C3}
\]

### Table VI.

### Table VII.

<table>
<thead>
<tr>
<th>Spin state</th>
<th>Energy</th>
</tr>
</thead>
<tbody>
<tr>
<td>(</td>
<td>\alpha\alpha\beta\rangle)</td>
</tr>
<tr>
<td>(</td>
<td>\beta\alpha\alpha\rangle)</td>
</tr>
<tr>
<td>(</td>
<td>\alpha\beta\alpha\rangle)</td>
</tr>
</tbody>
</table>

Since \(|\alpha\alpha\beta\rangle\) is also a quartet state, we have \(E_q = E[|\Psi_q\rangle] = E[|\alpha\alpha\alpha\rangle]\). By using the equation

\[
\frac{1}{\sqrt{3}} (|\Psi_q\rangle - \sqrt{2}|\Psi_{d'}\rangle) = |\alpha\alpha\beta\rangle, \tag{D2}
\]

we have \(E[|\alpha\alpha\beta\rangle] = \frac{1}{2}(E_q + 2E[|\Psi_{d'}\rangle]). \) Thus, 
\(E_{d'} = E[|\Psi_{d'}\rangle] = (3E[|\alpha\alpha\beta\rangle] - E_q)/2\). Based on our DFT calculations in Table VII, \(E[|\alpha\alpha\beta\rangle] = 4.7\) eV and \(E_q = 4.1\) eV, which implies that 
\(E_{d'} = (3 \times 4.7 - 4.1)/2 = 5\) eV.
Next, we define auxiliary state $\phi$:

$$
|\phi\rangle = \frac{1}{2\sqrt{3}} \begin{pmatrix} \sqrt{3} |\Psi_d\rangle' + 3 |\Psi_d\rangle'' \end{pmatrix} = \frac{1}{2\sqrt{6}} \begin{pmatrix} -2\beta\alpha + 4\alpha\beta\alpha - 2\alpha\alpha\beta \end{pmatrix} \quad (D3)
$$

By using this auxiliary state, we show that

$$
\frac{1}{\sqrt{3}} (|\Psi_q\rangle + \sqrt{2} |\phi\rangle) = |\alpha\beta\alpha\rangle. \quad (D4)
$$

Similar to previous calculation, we can show that

$$
E[|\alpha\beta\alpha\rangle] = \frac{1}{3} (E_q + 2E_\phi) = \frac{1}{3} \left\{ E_q + \frac{1}{6} (3E_{d''} + 9E_{d'''} + 3\sqrt{3} \langle \Psi_{d'''} | H | \Psi_{d''} \rangle + 3\sqrt{3} \langle \Psi_{d''} | H | \Psi_{d'''} \rangle) \right\} = \frac{1}{6} (2E_q + E_{d''} + 3E_{d'''}). \quad (D5)
$$

Therefore, we can calculate $E_{d'''}$ as below.

$$
E_{d'''} = \frac{1}{3} \left\{ 6E[|\alpha\beta\alpha\rangle] - 2E_q - E_{d''} \right\} = \frac{1}{3} (6 \times 5.5 - 2 \times 4.1 - 5) = 6.6 \text{ eV} \quad (D6)
$$

**Appendix E: ODMR signal**

In this section, we study the effect of changing parameters used for ODMR signal in Table IV. In each of the following figures, we change only one or two parameters to see their effect on our model. In Fig. 9, we checked the effect of changing the first and the second excited state spin splittings $\omega_e$ and $\omega_{e2}$. The result shows that although changing them would affect the magnitude of the ODMR signal, there is only one resonance in the ODMR signal, and it is because of the ground-state spin splitting $\omega_g$. This might be due to the high decay rates from the excited state compared to microwave driving, which makes the spin-flip rates in the excited state negligible compared to the ground state. All lines in Fig. 11 overlap indicating that changing $k_{31}$ and $k_{42}$ does not change the results. This is expected because the metastable and dark states, which have important roles in seeing the ODMR signal, are higher in energy than the first excited state. Therefore, changing the decay rates from the first excited state to the ground state does not affect the results.

FIG. 9. The effect of changing $\omega_e$ and $\omega_{e2}$ on the optical signal, ODMR contrast, and the second-order correlation function. The grid line shows the Rabi frequency at 5 MHz.

FIG. 10. The effect of changing $\Omega_{MW}$ on the optical signal, ODMR contrast, and the second-order correlation function. The grid line shows the Rabi frequency at 5 MHz.
FIG. 11. The effect of changing $k_{31}$ and $k_{42}$ on the optical signal, ODMR contrast, and the second-order correlation function.

FIG. 12. The effect of changing $\Omega_{\text{op}}$ on the optical signal, ODMR contrast, and the second-order correlation function. The grid line shows the Rabi frequency at 5 MHz.

FIG. 13. The effect of changing $k_{57}$ and $k_{68}$ on the optical signal, ODMR contrast, and the second-order correlation function. The grid line shows the Rabi frequency at 5 MHz. Based on the matrix elements of the spin-orbit and spin-spin interactions, the $k_{57}$ and $k_{68}$ rates are related to the $k_{510}$ and $k_{69}$ rates. So changing each of them will affect the other two.
