Abstract

In this paper we investigate the local limit theorem for additive functionals of nonstationary Markov chains that converge in distribution. We consider both the lattice and the non-lattice cases. The results are also new in the stationary setting and lead to local limit theorems linked to convergence to stable distributions. The conditions are imposed to individual summands and are expressed in terms of lower psi-mixing coefficients.

1 Introduction

The local limit theorem for partial sums \((S_n)_{n \geq 1}\) of a sequence of random variables deals with the rate of convergence of the probabilities of the type \(P(c \leq S_n \leq d)\). Local limit theorems have been studied for the case of lattice random variables and the case of non-lattice random variables. A random variable is said to have a lattice distribution if there exists \(h > 0\) and \(\ell \in \mathbb{R}\) such that its values are concentrated on the lattice \(\{\ell + kh : k \in \mathbb{Z}\}\). The non-lattice distribution means that no such \(\ell\) and \(h\) exist.

This problem was intensively studied for sums of i.i.d. random variables. For i.i.d. random variables in the domain of attraction of a stable law the local limit theorem was solved by Stone (1965) and Feller (1967).
It should be mentioned that the local limit theorem is more delicate than its convergence in distribution counterpart and often requires additional conditions. An important counterexample is given by Gamkrelidze (1964), pointing out this phenomenon for independent summands and a variety of sufficient conditions were developed over the years. We mention especially papers by Rozanov (1957), Mineka-Silverman (1970), Maller (1978), Shore (1978) and Dolgopyat (2016).

In the dependent case, we mention early works on Markov chains by Kolmogorov (1962). On the other hand, Nagaev (1961) gives rates on convergence in the CLT for stationary $\psi-$mixing Markov chains. In the lattice case, Szewczak (2010) established a local limit theorem for continued fractions, which is an example of $\psi-$mixing Markov chains. Hafouta and Kifer (2016) proved a local limit theorem for nonconventional sums of stationary $\psi-$mixing Markov chains, while the case of infinite variance is analyzed in Aaronson and Denker (2001a). Also in the stationary case we mention the local limit theorems for Markov chains in the papers by Hervé and Pène (2010), Ferré et al. (2012). Recently, there are two additional works by Merlevède et al. (2021) and Dolgopyat and Sarig (2020), which cover several aspects of local limit theorems associated with the central limit theorem for $\psi-$mixing nonstationary Markov chains.

These results raise the natural question if a local limit theorem is valid for more general Markov chains. In this paper we positively answer this question and consider a class larger than $\psi-$mixing Markov chains defined by using the so called one sided lower $\psi-$mixing coefficient. The key tool in proving these results is a delicate factorization of the characteristic function of partial sums.

We shall comment that all the results obtained by Merlevède et al. (2021) for $\psi-$mixing nonstationary Markov chains are also valid for this larger class. Furthermore, we shall also obtain local limit theorems associated with other limiting distributions than the normal attraction, which is actually the attraction a stable distribution with index $p = 2$. More precisely we shall also obtain the local limit theorem associated to attraction to any stable distributions with index $1 < p < 2$. The key tools for obtaining these results are some general local limit theorems, which assume convergence to distributions with integrable characteristic functions.

Our paper is organized as follows. In Section 2 we present some preliminary considerations about the type of local limit theorems we shall obtain. In Section 3 we present the main results and provide some examples of classes of lower $\psi-$mixing Markov chains. Section 4 contains the proofs. We present first two general local limit theorems, then a bound on the characteristic function of sums and the proofs of the main results.

In the paper by $\Rightarrow$ we denote the convergence in distribution.

2 Preliminary considerations

We formulate first the conclusions of the local limit theorems. Let $(S_n)_n$ be a sequence of random variables and let $L$ be a random variable with characteristic function $f_L$. The basic assumption will be an underlying convergence in
distribution:

\[
\frac{S_n}{B_n} \Rightarrow L, \quad \text{where } f_L \text{ is integrable and } B_n \to \infty. \tag{1}
\]

Note that assuming that \( f_L \) is integrable implies that \( L \) has a continuous density we shall denote by \( h_L \) (see pages 370-371 in Billingsley, 1999).

In case when the variables \( (S_n) \) do not have values in a fixed minimal lattice we shall say that the sequence satisfies a local limit theorem if for any function \( g \) on \( \mathbb{R} \) which is continuous and with compact support,

\[
\lim_{n \to \infty} \sup_{u \in \mathbb{R}} \left| B_n \mathbb{E}g(S_n + u) - h_L \left( \frac{u}{B_n} \right) \int g(t) \lambda(dt) \right| = 0, \tag{2}
\]

where \( \lambda \) is the Lebesgue measure.

If all the variables have values in the same fixed lattice \( S = \{kh, k \in \mathbb{Z}\} \), by the local limit theorem we understand that for any function \( g \) on \( \mathbb{R} \) which is continuous and with compact support,

\[
\lim_{n \to \infty} \sup_{u \in S} \left| B_n \mathbb{E}g(S_n + u) - h_L \left( \frac{u}{B_n} \right) \int g(u) \mathcal{L}_h(du) \right| = 0, \tag{3}
\]

where \( \mathcal{L}_h \) is the measure assigning \( h \) to each point \( kh \).

By standard arguments, for any reals \( c \) and \( d \) we also have that (2) implies in the non-lattice case that

\[
\lim_{n \to \infty} \sup_{u \in \mathbb{R}} \left| B_n \mathbb{P}(c - u \leq S_n \leq d - u) - (d - c)h_L \left( \frac{u}{B_n} \right) \right| = 0, \tag{4}
\]

and in the lattice case

\[
\lim_{n \to \infty} \sup_{u \in S} \left| B_n \mathbb{P}(c - u \leq S_n \leq d - u) - h \sum_k I(c - u \leq kh \leq d - u)h_L \left( \frac{u}{B_n} \right) \right| = 0. \tag{5}
\]

In particular, since \( B_n \to \infty \) as \( n \to \infty \), then for fixed \( A > 0 \), in the non-lattice case

\[
\lim_{n \to \infty} \sup_{|u| \leq A} \left| B_n \mathbb{P}(c - u \leq S_n \leq d - u) - (d - c)h_L(0) \right| = 0, \tag{4}
\]

and in the lattice case

\[
\lim_{n \to \infty} \sup_{|u| \leq A, u \in S} \left| B_n \mathbb{P}(c - u \leq S_n \leq d - u) - h \sum_k I(c - u \leq kh \leq d - u)h_L(0) \right| = 0. \tag{5}
\]

If we further take \( u = 0 \) in (4), then, in the nonlattice case we have

\[
\lim_{n \to \infty} B_n \mathbb{P}(S_n \in [c, d]) = (d - c) h_L(0).
\]
In other words, the sequence of measures $B_n \mathbb{P}(S_n \in [c,d])$ of the interval $[c,d]$ converges to the Lebesgue measure.

In the lattice case we can take $u = 0$ in (5) and obtain,

$$\lim_{n \to \infty} B_n \mathbb{P}(S_n \in [c,d]) = h \sum_k I(c \leq kh \leq d)hL(0).$$

We assume now that $(\xi_k)_{k \geq 1}$ is a Markov chain defined on $(\Omega, \mathcal{K}, \mathbb{P})$ with values in $(\mathcal{X}, \mathcal{B}(\mathcal{X}))$ with regular transition probabilities:

$$Q_k(x, A) = \mathbb{P}(\xi_k \in A | \xi_{k-1} = x)$$

and marginal distributions denoted by

$$\mathbb{P}_k(A) = \mathbb{P}(\xi_k \in A).$$

Throughout the paper we shall assume that there is a constant $a > 0$ with the following property:

For all $k \geq 2$ there is $S'_k \in \mathcal{B}(S)$ with $\mathbb{P}_{k-1}(S'_k) = 1$ such that for all $A \in \mathcal{B}(S)$ and $x \in S'_k$ we have

$$Q_k(x, A) > a\mathbb{P}_k(A).$$

Triangular arrays $(\xi_{kn})_{k \geq 1}$ can also be considered. In this case $a$ should be replaced by $a_n$ which may be different from line to line.

Let $(g_j)$ be real-valued measurable functions and define

$$X_j = g_j(\xi_j)$$

and set

$$S_n = \sum_{k=1}^n X_k.$$

In order to obtain our results we shall combine several techniques, specifically designed for obtaining local limit theorems, with a suitable bound on the characteristic function facilitated by condition (8).

### 3 Main Results

In the sequel, we shall denote by $f_k(t)$ the Fourier transform of $X_k$,

$$f_k(t) = \mathbb{E}(\exp(itX_k)).$$

We shall introduce two useful conditions that will provide a version of the local limit theorem under conditions imposed to the characteristic function.

Let $a$ be as in (8).

**Condition A.** There is $\delta > 0$ and $n_0 \in N$ such that for $1 \leq |u| \leq \delta B_n$ and $n > n_0$

$$\frac{a^2}{2^4} \sum_{k=1}^n (1 - |f_k(u)B_n|^2) > g(u)$$

and $\exp(-g(u))$ is integrable.  \hfill (10)
Condition B. For $u \neq 0$ there is an $\varepsilon = \varepsilon(u)$, $c(u)$ and a $n_0 = n_0(u)$ such that for all $t$ with $|t - u| \leq \varepsilon$ and $n > n_0$

$$\frac{a^4}{2^4 \ln B_n} \sum_{k=1}^{n} (1 - |f_k(t)|^2) \geq c(u) > 1. \quad (11)$$

Our general local limit theorem is the following:

**Theorem 1** Let $(X_j)_{j \geq 1}$ be defined by (9) and satisfying (8). Assume that conditions (1), A and B are satisfied. If not all the variables have values in a fixed lattice, then (2) holds. If all the variables have the values in a fixed lattice $S = \{kh, k \in \mathbb{Z}\}$, under the same conditions with the exception that we assume now that Condition B holds for $0 < |u| \leq \pi/h$, then (3) holds.

The conditions of Theorem 1 are verified in many situations of interest. Merlevède et al. (2021) provided sufficient conditions for Conditions A and B when second moment is finite and obtained the local limit theorems in the nonlattice case under a more restrictive condition than (8). Namely it was assumed there that there are two constant $a > 0$ and $b < \infty$ with the following property:

For all $k \geq 2$ there is $S'_k \in \mathcal{B}(S)$ with $P_{k-1}(S'_k) = 1$ such that for all $A \in \mathcal{B}(S)$ and $x \in S'_k$ we have

$$a \mathbb{P}(A) \leq Q_k(x, A) \leq b \mathbb{P}(A). \quad (12)$$

By using our Proposition 10 all the results in Merlevède et al. (2021) also hold for a larger class of Markov chains satisfying only the one sided conditions (8). Therefore in all that results in Merlevède et al. (2021) the condition $b < \infty$ is superfluous. Furthermore, because of Theorem 8 below, all the results in Merlevède et al. (2021) can also be formulated for the lattice case. We shall not repeat all the results there and mention only that our results are also new in the stationary setting. In this particular case the results have a simple formulation.

The first theorem deals with local limit theorem in case of attraction to normal distribution, which is stable with index $p = 2$.

**Theorem 2** Assume that $(\xi_k)_{k \in \mathbb{Z}}$ is a strictly stationary Markov chain satisfying (8). Define $(X_k)_{k \in \mathbb{Z}}$ by $X_k = g(\xi_k)$ and assume $E(X_0) = 0$ and $H(x) = E(X_0^2 I(|X_0| \leq x)$ is a slowly varying function as $x \to \infty$. Then, there is $B_n \to \infty$ such that in the nonlattice case (3) holds and in the lattice case (3) holds with $h_L(x) = (2\pi)^{-1/2} \exp(-x^2/2)$.

**Remark 3** In case where $E(X_0^2) < \infty$, we can take $B_n^2 = E(S_n^2)$, and there are two constants $C_1$ and $C_2$ such that $C_1 E(X_0^2) \leq E(S_n^2) \leq C_2 E(X_0^2) n$. Furthermore, since in this case $E(S_n^2)/n \to c^2 > 0$, we can also take $B_n^2 = c^2 n$. In case $E(X_0^2) = \infty$ we can take $B_n^2 = \sqrt{\pi/2}E\{|S_n|\}$.

We move now to other types of limiting distributions $L$ in (1).
Let $0 < p < 2$. Assume that $(\xi_k)_{k \in \mathbb{Z}}$ is a strictly stationary Markov chain and let $(X_k)$ be defined by $X_k = g(\xi_k)$, with a nondegenerate marginal distribution satisfying the following condition:

$$
P(|X_1| > x) = x^{-p} \ell(x),$$  \hfill (13)

where $\ell(x)$ is a slowly varying function at $\infty$,  

$$
\frac{\mathbb{P}(X_1 > x)}{\mathbb{P}(|X_1| > x)} \to c^+ \quad \text{and} \quad \frac{\mathbb{P}(X_1 < -x)}{\mathbb{P}(|X_1| > x)} \to c^- \quad \text{as} \quad x \to \infty  \hfill (14)
$$

with $0 \leq c^+ \leq 1$ and $c^+ + c^- = 1$.

These conditions practically mean that the distribution of $X_1$ is in the domain of attraction of a stable law with index $p$. The convergence in distribution of a mixing sequence of random variables in the domain of attraction of a stable law is a delicate problem, which was often studied in the literature, starting with papers by Davis (1983), Jakubowski (1991), Samur (1987), Denker and Jakubowski (1989), Kobus (1995), Tyran-Kamińska (2010), Cattiaux and Manou-Abi (2014) El Machkouri et al. (2020), among many others. In general an additional "non clustering" assumption is relevant for this type of convergence. We shall assume that for every $x > 0$ and for all $k \geq 2$

$$
\lim_{n \to \infty} \mathbb{P}(|X_k| > xB_n \mid |X_1| > xB_n) = 0, \hfill (15)
$$

where $B_n$ is such that

$$
\frac{n}{B_n^p} \ell(B_n) = n \mathbb{P}(|X_1| > B_n) \to 1. \hfill (16)
$$

In the context of $\varphi$--mixing sequences, for this type of condition we refer to Corollary 5.9 of Kobus (1995) and Corollary 1.3 in Tyran-Kamińska (2010), where the necessity of the condition (15) for such a type of result is also discussed.

**Theorem 4** Assume $0 < p < 2$ and (13) and (14) are satisfied. When $1 < p < 2$ we assume $\mathbb{E}(X_1) = 0$ and when $p = 1$ we assume $X_1$ has a symmetric distribution. Also assume (6) and (17). Then in the nonlattice case (2) holds and in the lattice case (3) holds with $B_n$ defined by (17) and $h_L$ the density of a strictly stable distribution $L$ with index $p$.

Note that condition (15) of Theorem 4 is satisfied if we assume that there is $b \leq \infty$ such that the right hand side of (12) holds. Therefore we obtain:

**Corollary 5** Assume that $(X_k)$ is as in Theorem 4, (12) (13) and (14) are satisfied. Then the conclusions of Theorem 4 hold.
3.1 Examples

Example 1. The following is an example of a strictly stationary Markov chain satisfying (8) but not the right hand side of (12) (see Bradley (1997), Remark 1.5). The Markov chain \((\xi_k)_{k \in \mathbb{Z}}\) is such that the marginal distribution of \(\xi_0\) is uniformly distributed on \([0, 1]\) and the one step transition probabilities are as follows:

For each \(x \in [0, 1]\), let

\[P(\xi_1 = x | \xi_0 = x) = 1/2\]

and

\[P(\xi_1 \in B | \xi_0 = x) = (1/2)\lambda(B),\]

where \(B \subset [0, 1] - x\) and \(\lambda\) is the Lebesgue measure on \([0, 1]\). Then (8) holds with \(a = 1/2\). However no such \(b\) as in the right hand side of (12) exists.

Example 2. (Generalized Gibbs Markov chains). Let \(S\) be a countable set, \(p : S \times S \to [0, 1]\) be an aperiodic, irreducible stochastic matrix and \(\pi_s > 0\) for all \(s \in S\), \(\sum_{s \in S} \pi_s = 1\). Let \(T : S^N \to S^N\) be the shift and define the Markov chain in a canonical way on \(S^N\) by

\[P(X_1 = x_1, ..., X_n = x_n) = \pi_{x_1} p(x_1, x_2) ... p(x_{n-1}, x_n).\]

Let \(\Omega = \{x \in S^N : P(X_1 = x_1, ..., X_n = x_n) > 0\}\). We assume that there is \(0 < m < 1\) such that for all \(s, t \in S\)

\[p(s, t) \geq m \pi_t\]

(17)

Then our condition (8) is satisfied with \(a = m\). This is a larger class than the so called Gibbs-Markov maps as defined in Aaronson and Denker (2001b).

Example 3. In the context of Example 2, a fairly large class of countable state Markov processes satisfying condition (17) can be constructed by defining for \(i, j \in \mathbb{N}^*\)

\[p(i, j) = \pi_j + (\delta_{i,j} - \delta_{i+1,j}) \varepsilon_i,\]

where for all \(i \in \mathbb{N}^*\), \(\delta_{i,i} = 1\) and for \(j \neq i\) we have \(\delta_{i,j} = 0\). We take \(0 \leq \varepsilon_i \leq \min(1 - \pi_i, \pi_{i+1})\). In addition we assume that there is \(0 < m < 1\) such that

\[\varepsilon_i \leq (1 - m) \pi_{i+1}.\]

For example, let \(m = 1/2, \pi_j = 2^{-j}\) and set \(p(i, j) = 2^{-j} + (\delta_{i,j} - \delta_{i+1,j})2^{-(2+i)}\).

Example 4. Here is an example where \(a\) and \(b\) in condition (12) can be estimated. For every irrational number \(x\) in \((0, 1)\) there is a unique sequence of positive integers \(x_1, x_2, x_3, ...\) such that the following continued fraction expansion holds:

\[x = \frac{1}{x_1 + \frac{1}{x_2 + \frac{1}{x_3 + ...}}}.\]
If we introduce on $[0, 1]$ the Gauss probability measure with the density $f(x) = (\ln 2)^{-1}(1+x)^{-1}$, then the sequence $(x_1, x_2, x_3, \ldots)$ is a strictly stationary Markov chain. We know from Lemma 2.1 in Philipp (1988) that one can take for $a$ and $b$ which appear in condition $[12]$ the following values: $a = 0.2$ and $b = 1.8$.

4 Relation to mixing coefficients

Relation to lower $\psi-$mixing coefficient.

We introduce now a mixing condition which is equivalent to condition $[8]$. Following Bradley (2007), for any two sigma algebras $\mathcal{A}$ and $\mathcal{B}$ define the lower $\psi-$mixing coefficient by

$$\psi'(\mathcal{A}, \mathcal{B}) = \inf_{\mathcal{A} \in \mathcal{A}, \mathcal{B} \in \mathcal{B}} \frac{\mathbb{P}(\mathcal{A} \cap \mathcal{B})}{\mathbb{P}(\mathcal{A})\mathbb{P}(\mathcal{B})} > 0.$$ 

Obviously $0 \leq \psi' \leq 1$ and $\psi' = 1$ if and only if $\mathcal{A}$ and $\mathcal{B}$ are independent.

For a sequence $(\xi_k)_{k \geq 1}$ of random variables we shall denote by $\mathcal{F}_n^m = \sigma(\xi_i, m \leq i \leq n)$ and by

$$\psi'_k = \inf_{m \geq 1} \psi'(\mathcal{F}_1^m, \mathcal{F}_{k+m}^k).$$

In the Markov setting, by the Markov property,

$$\psi'_k = \inf_{m \geq 1} \psi'(\sigma(\xi_m), \sigma(\xi_{k+m})).$$

Notice that, in terms of conditional probabilities defined by $[5]$, we also have the following equivalent definition:

$$\psi'_1 = \inf_k \inf_{x \in \mathcal{B}(\mathcal{X})} \inf_{\xi_k \in \mathcal{A}} Q_k(x, A)/\mathbb{P}(\xi_k \in A).$$

Our condition $[8]$ is equivalent to

$$\psi'_1 = a > 0.$$ 

For Markov chains, by Theorem 7.4 (d) in Bradley (2007):

$$1 - \psi'_{k+m} \leq (1 - \psi'_k)(1 - \psi'_m).$$ 

(18)

So, by condition $[8]$, we have $1 - \psi'_n \leq (1 - a)^n \to 0$, and in this case, $(\xi_k)_{k \geq 1}$ is called lower $\psi-$mixing.

It should be mentioned that the condition on the coefficient $\psi'_1$ is quite natural for obtaining large deviation results for stationary Markov chains (Bryc and Smolenski, 1993).

Relation to $\rho-$mixing coefficients.
Define the maximal coefficient of correlation
\[ \rho(A, B) = \sup_{X \in L_2(A), Y \in L_2(B)} |\text{corr}(X, Y)|. \]

By Lemma 10 in Merlevède et al. (2021) (which is actually due to R. Bradley), we know that
\[ \rho(A, B) \leq 1 - \psi'(A, B). \] (19)

For a sequence \((\xi_k)_{k \geq 1}\) of random variables \(\rho_k = \sup_{m \geq 1} \rho(F_m^{f_1}, F_m^{f_\infty})\), and in the Markov case \(\rho_k = \sup_{m \geq 1} \rho(\sigma(\xi_m), \sigma(\xi_{k+m}))\). In this latter case we also have the equivalent definition for \(\rho_1\),
\[ \rho_1 = \sup_k \sup_{\|f\|_2 = 1, \mathbb{E}f = 0} \|Q_k f\|_2, \]
where
\[ Q_k f(x) = \int f(y)Q_k(x, dy). \]

According to (19), condition (8) implies
\[ \rho_1 \leq 1 - a < 1. \] (20)

By Theorem 7.4 (a) in Bradley, (2017) it follows that \(\rho_n \leq (1 - a)^n \to 0\). Therefore, a Markov chain satisfying condition (8) is also \(\rho\)-mixing.

Define now \((X_k)\) by (9). Assume the variables \((X_k)\) are centered and have finite second moments. Denote \(\tau_n^2 = \sum_{j=1}^n \text{var}(X_j)\) and \(\sigma_n^2 = \mathbb{E}(S_n^2)\). From Proposition 13 in Peligrad (2012) we know that
\[ \frac{1 - \rho_1}{1 + \rho_1} \leq \frac{\sigma_n^2}{\tau_n^2} \leq \frac{1 + \rho_1}{1 - \rho_1}. \]

By combining this inequality with (20), we obtain
\[ \frac{a}{2 - a} \leq \frac{\sigma_n^2}{\tau_n^2} \leq \frac{2 - a}{a}. \] (21)

If the Markov chain is stationary define \(X_k = g(\xi_k)\) and assume that the variables have second moment and are centered. Then by the definition of \(\rho_k\) and (20), for all \(k > 0\), \(|\mathbb{E}(X_0X_k)| \leq (1 - a)^k \mathbb{E}(X_k^2)\) and therefore it follows that there is \(c > 0\) such that
\[ \frac{\sigma_n^2}{n} \to c^2. \] (22)

Relation to \(\varphi\)-mixing coefficients

Relevant to our paper is also the relation with \(\varphi\)-mixing coefficient defined by
\[ \varphi(A, B) = \sup \frac{\mathbb{P}(A \cap B) - \mathbb{P}(A)\mathbb{P}(B)}{\mathbb{P}(A)}; A \in \mathcal{A} \text{ and } B \in \mathcal{B}, \mathbb{P}(A) > 0. \]
By Proposition 5.2 (III)(b) in Bradley (1997)

\[ \varphi(A, B) \leq 1 - \psi'(A, B). \]  

(23)

In the Markov case

\[ \varphi_k = \sup_{m \geq 1} \varphi(\sigma(\xi_m), \sigma(\xi_{k+m})). \]

Then, if condition (8) is satisfied, by (23) and by (18), for any \( k \geq 1 \)

\[ \varphi_k \leq 1 - \psi'_k \leq (1 - a)^k \to 0 \text{ as } n \to \infty, \]

(24)

and so, our Markov chain is also \( \varphi \)-mixing, at least exponentially fast.

Relation to \( \psi \)-mixing coefficient.

The class of \( \psi' \)-mixing Markov chains is strictly larger that the class of \( \psi \)-mixing. To see this we mention that the \( \psi \)-mixing coefficient is defined in the following way. For any two sigma algebras \( A \) and \( B \), define the \( \psi \)-mixing coefficient by

\[ \psi(A, B) = \sup \frac{\mathbb{P}(A \cap B) - \mathbb{P}(A)\mathbb{P}(B)}{\mathbb{P}(A)\mathbb{P}(B)}; \quad A \in A \text{ and } B \in B, \quad \mathbb{P}(A)\mathbb{P}(B) > 0. \]

It is well-known that

\[ \psi(A, B) = \max[\psi^*(A, B) - 1, 1 - \psi'(A, B)], \]

where

\[ \psi^* = \sup \frac{\mathbb{P}(A \cap B)}{\mathbb{P}(A)\mathbb{P}(B)}; \quad A \in A \text{ and } B \in B, \quad \mathbb{P}(A)\mathbb{P}(B) > 0. \]

For a sequence \( (\xi_k)_{k \geq 1} \) of random variables \( \psi_k = \sup_{m \geq 1} \psi(F^{m}_{1}, F^{k+m}_{1}) \) and in the Markovian case \( \psi_k = \sup_{m \geq 1} \psi(\sigma(\xi_m), \sigma(\xi_{k+m})). \) Note that \( \psi_1 < 1 \) implies \( \psi'_1 > 0 \). Therefore all our results also hold for \( \psi \)-mixing Markov chains with \( \psi_1 < 1 \).

Furthermore the \( \psi \)-mixing class of Markov chains is strictly smaller than \( \psi' \)-mixing (see example Remark 1.5 in Bradley, 2007 and Example 1). Therefore, clearly, the conclusions of our results also holds for smaller class of \( \psi \)-mixing Markov chains with \( \psi_1 < 1 \).

Note that condition (12) is equivalent to \( \psi'_1 = a > 0 \) and \( \psi^* = b < \infty \).

5 Proofs

5.1 Preliminary general local CLT

Here we give two general local limit theorems.
Theorem 6 We require that convergence in distribution in (1) holds. In addition, suppose that for each \( D > 0 \)

\[
\lim_{{T \to \infty}} \limsup_{{n \to \infty}} \int_{{T < |t| \leq DB_n}} \left| \mathbb{E} \exp \left( \frac{i}{B_n} \right) \right| dt = 0. \tag{25}
\]

Then (2) holds.

Remark 7 By decomposing the integral in (25) into two parts, on \( \{ T \leq |u| \leq \delta B_n \} \) and on \( \{ \delta B_n \leq |u| \leq DB_n \} \), and changing the variable in the second integral we easily argue that in order to prove this theorem it is enough to show that for each \( D \) fixed there is \( 0 < \delta < D \) such that

\[
(D_1) \quad \lim_{{T \to \infty}} \limsup_{{n \to \infty}} \int_{{T < |t| \leq B_n \delta}} \left| \mathbb{E} \exp \left( \frac{i}{B_n} \right) \right| dt = 0
\]

and

\[
(D_2) \quad \lim_{{n \to \infty}} B_n \int_{{\delta < |t| \leq D}} |\mathbb{E} \exp(itS_n)| dt = 0.
\]

If all the variables \((S_n)\) have the values in a fixed lattice, we impose a different condition and the result we obtain is the following:

Theorem 8 Assume now that all the variables \((S_n)\) have values in a fixed lattice

\[
S = \{ kh, k \in \mathbb{Z} \}
\]

and (1) holds. Suppose in addition that

\[
\lim_{{T \to \infty}} \limsup_{{n \to \infty}} \int_{{T < |t| \leq \frac{\pi}{h}B_n}} \left| \mathbb{E} \exp \left( \frac{i}{B_n} \right) \right| dt = 0. \tag{26}
\]

Then, the conclusion in (3) holds.

Remark 9 By decomposing the integral in (26) into two parts, on \( \{ T \leq |u| \leq \delta B_n \} \) and on \( \{ \delta B_n \leq |u| \leq \pi B_n / h \} \), the conclusion on Theorem 8 holds if for some \( \delta > 0 \)

\[
(D'_1) \quad \lim_{{T \to \infty}} \limsup_{{n \to \infty}} \int_{{T < |t| \leq B_n \delta}} \left| \mathbb{E} \exp \left( \frac{i}{B_n} \right) \right| dt = 0
\]

and

\[
(D'_2) \quad \lim_{{n \to \infty}} B_n \int_{{\delta < |t| \leq \pi / h}} |\mathbb{E} \exp(itS_n)| dt = 0.
\]

Proof of Theorems 6 and 8 The proofs of these theorems can be deduced from the corresponding arguments in Hafouta and Kifer (2016), who assumed convergence to normal distribution and normalization \( \sqrt{n} \). Since the proof of
Theorem 6 is given in Peligrad et al. (2021) we shall give here only the proof of Theorem 8.

The proof is based on the inverse Fourier formula for the sum $S_n$. According to Lemma 4.5 and arguments in Section VI.4 in Hennion and Hervé (2001) (see also Theorem 10.7 in Breiman (1982) and Section 10.4 there), it suffices to prove (2) for all continuous complex valued functions $g$ defined on $\mathbb{R}$, $|g| \in L^1(\mathbb{R})$ such that its Fourier transform

$$\hat{g}(t) = \int_{\mathbb{R}} e^{-itx} g(x) \, dx$$

has compact support contained in some finite interval $[-D, D]$.

The inversion formula gives:

$$g(x) = \frac{1}{2\pi} \int_{\mathbb{R}} e^{ixs} \hat{g}(s) \, ds.$$ 

Therefore, using a change of variables and taking the expected value, we obtain

$$\mathbb{E}[g(S_n + u)] = \frac{1}{2\pi B_n} \int_{\mathbb{R}} \hat{g}\left(\frac{t}{B_n}\right) f_{S_n}\left(\frac{t}{B_n}\right) \exp\left(\frac{itu}{B_n}\right) \, dt,$$

where we have used the notation

$$f_X(v) = \mathbb{E}(\exp(ivX)).$$

Denote

$$r(v) = \sum_{k=-\infty}^{\infty} \hat{g}(v + 2\pi \frac{k}{h}).$$

Since $\hat{g}$ has compact support included in an interval $[-D, D]$, the sum is finite. So, with the notation $M_v = h(D + |v|)/2\pi$, clearly

$$|r(v)| \leq \sum_{|k| \leq M_v} |\hat{g}(v + 2\pi \frac{k}{h})| \leq 2M_v \sup_{|u| \leq D} |\hat{g}(u)|. \quad (27)$$

Now,

$$\int_{\mathbb{R}} \hat{g}\left(\frac{t}{B_n}\right) f_{S_n}\left(\frac{t}{B_n}\right) \exp(\frac{itu}{B_n}) \, dt$$

$$= \sum_{k=-\infty}^{\infty} \int_{\frac{2k+1}{h}B_n}^{\frac{2k+1}{h}B_n} \hat{g}\left(\frac{t}{B_n}\right) f_{S_n}\left(\frac{t}{B_n}\right) \exp(\frac{itu}{B_n}) \, dt.$$ 

We change the variable from $t$ to $v$ according to:

$$\frac{t}{B_n} = \frac{v}{B_n} + \frac{2\pi k}{h}.$$

Because $u = k'h$, $k' \in \mathbb{Z}$,

$$\exp\left(\frac{itu}{B_n}\right) = \exp\left(iu \frac{v}{B_n} + ik'h \frac{2\pi k}{h}\right) = \exp\left(iu \frac{v}{B_n}\right).$$

12
Since $S_n$ has values in $\mathcal{S}$ we note that

$$f_{S_n}(\frac{t}{B_n} + \frac{2k}{h}) = f_{S_n}(\frac{t}{B_n}) \text{ for all } k \in \mathbb{Z}.$$ 

Therefore, by using the definition of $r(v)$,

$$\mathbb{E}[g(S_n + u)] = \frac{1}{2\pi B_n} \int_{-\frac{\pi}{B_n}}^{\frac{\pi}{B_n}} f_{S_n}(\frac{v}{B_n}) \exp\left(i\frac{vu}{B_n}\right) r\left(\frac{v}{B_n}\right) dv.$$ 

By the Fourier inversion formula we also have

$$h_L\left(\frac{u}{B_n}\right) = \frac{1}{2\pi} \int f_L(t) \exp\left(i\frac{tu}{B_n}\right) dt.$$ 

We evaluate

$$2\pi \left| B_n \mathbb{E}[g(S_n + u)] - h_L\left(\frac{u}{B_n}\right) \sum_{k=-\infty}^{\infty} hg(kh) \right|$$

$$= \left| \int_{-\frac{\pi}{B_n}}^{\frac{\pi}{B_n}} f_{S_n}(\frac{v}{B_n}) \exp\left(i\frac{vu}{B_n}\right) r\left(\frac{v}{B_n}\right) dv - \int f_L(v) \exp\left(i\frac{vu}{B_n}\right) dv \int g d\mathcal{L}_h \right|$$

$$= |I_n + II_n + III_n| \leq |I_n| + |II_n| + |III_n|,$n

where the terms $I_n$, $II_n$, and $III_n$ are given below and their modules analyzed:

$$|I_n| = \left| \int_{-T}^{T} \left( f_{S_n}(\frac{t}{B_n}) r\left(\frac{t}{B_n}\right) - f_L(t) \int g d\mathcal{L}_h \right) \exp\left(i\frac{tu}{B_n}\right) dt \right|$$

$$\leq \int_{-T}^{T} \left| f_{S_n}(\frac{t}{B_n}) r\left(\frac{t}{B_n}\right) - f_L(t) \int g d\mathcal{L}_h \right| dt,$$

and

$$|II_n| \leq \int |f_L(t)| dt \left( \int |g d\mathcal{L}_h| \right),$$

and

$$|III_n| \leq \int_{T<|v| \leq \frac{\pi}{B_n}} \left| f_{S_n}(\frac{v}{B_n}) \right| \left| r\left(\frac{v}{B_n}\right) \right| dv.$$ 

To deal with $|I_n|$, we further decompose the sum and use the triangle inequality,

$$|I_n| \leq \int_{-T}^{T} \left| f_{S_n}(\frac{v}{B_n}) r\left(\frac{v}{B_n}\right) - f_{S_n}(\frac{v}{B_n}) \int g d\mathcal{L}_h \right| dv$$

$$+ \int_{-T}^{T} \left| f_{S_n}(\frac{v}{B_n}) \int g d\mathcal{L}_h - f_L(v) \int g d\mathcal{L}_h \right| dv.$$ 

The first term in the right hand side of the above inequality tends to 0 because by Ch 10 in Breiman (1992) and since $B_n \to \infty$, we have

$$r\left(\frac{v}{B_n}\right) \to \int g d\mathcal{L}_h.$$
The second term in the right hand side converges to 0 because, by our hypotheses

\[ f_{S_n}\left(\frac{v}{B_n}\right) \to f_L(v), \]

uniformly on compacts.

The term \(|H_n|\) converges to 0 as \(T \to \infty\), because \(f_L(t)\) is integrable.

Next, for \(|III_n|\) we have

\[ |III_n| \leq \sup_{T < |v| \leq \frac{\pi}{2}B_n} |r(u)| \int_{T < |v| \leq \frac{\pi}{2}B_n} |f_{S_n}(\frac{v}{B_n})| dv. \]

The result follows by condition (26) and the fact that by (27) we have

\[ \sup_{|u| \leq D} |\hat{g}(u)| \leq [(Dh + \pi)/2\pi] \sup_{|u| \leq D} |\hat{g}(u)|. \]

\[ \square \]

5.2 Bounds on the characteristic function

The bound on the characteristic function of a Markov chain is inspired by Lemma 1.5 in Nagaev (1961). It is given in the following proposition. Recall the definition of \(a\) in (3).

Proposition 10 Let \((X_j)_{j \geq 1}\) be defined by (9). Then, for all \(n,\)

\[ |E(\exp(iuS_n))| \leq \exp \left[ -\frac{a^4}{16} \sum_{j=1}^{n} (1 - |f_j(u)|^2) \right]. \]

For proving this proposition we need some preliminary considerations.

For a complex measure \(\mu\), denote by \(\text{Var}\mu\) its total variation. This is, for all measurable \(A\) we have

\[ \text{Var}\mu(A) = \sup \sum_{k=1}^{n} |\mu(A_k)|, \]

where the supremum is taken over all \(n \in \mathbb{N}\), and all \(A_1, A_2, ..., A_n\), measurable disjoins sets of \(S\) with \(A = \bigcup_{k=1}^{n} A_k\).

The property we shall use below is that for complex functions and complex measures:

\[ |\int h(y)d\mu| \leq \int |h(y)| d(\text{Var}\mu). \]

For \(u\) fixed let us introduce the operator \(T_k = T_{u,k}\) defined on complex-valued bounded functions by:

\[ T_k(h)(x) = \int h(y) \exp(iug_k(y)) Q_k(x, dy). \]
So,
\[ T_k(h)(\xi_{k-1}) = \mathbb{E}(h(\xi_k) \exp(iuX_k)|\xi_{k-1}) . \]
Notice that the values are also complex-valued bounded functions.

For an operator \( T \) on \( L_1(S, \mathcal{B}(S)) \) denote by \( ||T||_1 = \sup_{||f||_1 \leq 1} ||T(f)||_1 \).

**Lemma 11** For any \( k \in \mathbb{N}, u \in \mathbb{R} \) we have for all \( k \geq 2 \),
\[ ||T_{k-1} \circ T_k||_1 \leq 1 - \frac{a^4}{8}(1 - |\mathbb{E}(\exp(iuX_{k-1})|^2)). \]

**Proof.** Let \( x \in S' \), where \( S' \in \mathcal{B}(S) \) such that \( \mathbb{P}_{k-1}(S') = 1 \), for which condition \[12\] holds. By the definition of \( T_k \)'s,
\[ T_{k-1} \circ T_k(h)(x) = \int \exp(iug_{k-1}(y)) \int h(z) \exp(iug_k(z))Q_k(y, dz)Q_{k-1}(x, dy). \]

Changing the order of integration
\[ T_{k-1} \circ T_k(h)(x) = \int h(z) \exp(iug_k(z)) \int \exp(iug_{k-1}(y))Q_{k-1}(x, dy)Q_k(y, dz) = \int h(z) \exp(iug_k(z))m_x(dz), \]
where, for \( x \) fixed in \( S' \), \( m_x \) is the measure defined on \( \mathcal{B}(S) \) by the formula
\[ m_x(A) = \int \exp(iug_{k-1}(y))Q_k(y, A)Q_{k-1}(x, dy). \]

Note that
\[ \int |T_{k-1} \circ T_k(h)(x)|\mathbb{P}_{k-2}(dx) = \int \left| \int h(z) \exp(iug_k(z))m_x(dz) \right| \mathbb{P}_{k-2}(dx) \]
\[ \leq \int \int |h(z)|\text{Var}(m_x(dz)) \mathbb{P}_{k-2}(dx) := \int |h(z)|m(dz), \]
where
\[ m(A) = \int \text{Var}(m_x(A)) \mathbb{P}_{k-2}(dx). \]

To analyze \( m(A) \), we start by noting that for an increasing sequence of measurable partitions \( \mathcal{P}_n \) of \( A \), by the monotone convergence theorem,
\[ m(A) = \lim_{n \to \infty} \sum_{A_i \in \mathcal{P}_n} \int |m_x(A_i)|\mathbb{P}_{k-2}(dx). \]
In order to find an upper bound for $|m_x(A)|$, we start from the following estimate, where we have used at the end condition (30):

$$
\left( \int Q_k(y, A)Q_{k-1}(x, dy) \right)^2 - \left( \int \exp(iug_{k-1}(y))Q_k(y, A)Q_{k-1}(x, dy) \right)^2
= \int \int (1 - \cos(u (g_{k-1}(y) - g_{k-1}(y')))) Q_k(y, A)Q_{k-1}(x, dy)Q_k(y', A)Q_{k-1}(x, dy')
= \int \int 2 \sin^2 \left( \frac{u}{2} (g_{k-1}(y) - g_{k-1}(y')) \right) Q_k(y, A)Q_{k-1}(x, dy)Q_k(y', A)Q_{k-1}(x, dy')
\geq a^4 P^2_k(A) M,
$$

where

$$
M = 2 \int \sin^2 \left( \frac{u}{2} (g_{k-1}(y) - g_{k-1}(y')) \right) \mathbb{P}_{k-1}(dy)\mathbb{P}_{k-1}(dy').
$$

Because

$$
|m_x(A)| = \int Q_k(y, A)Q_{k-1}(x, dy) - \int Q_k(y, A)Q_{k-1}(x, dy)
+ \left| \int \exp(iug_{k-1}(y))Q_k(y, A)Q_{k-1}(x, dy) \right|,
$$

we have

$$
|m_x(A)| = \int Q_k(y, A)Q_{k-1}(x, dy)
- \left( \int Q_k(y, A)Q_{k-1}(x, dy) \right)^2 - \left( \int \exp(iug_{k-1}(y))Q_k(y, A)Q_{k-1}(x, dy) \right)^2
\int Q_k(y, A)Q_{k-1}(x, dy) + \left| \int \exp(iug_{k-1}(y))Q_k(y, A)Q_{k-1}(x, dy) \right|
\leq 2 \int Q_k(y, A)Q_{k-1}(x, dy).
$$

But

$$
\int Q_k(y, A)Q_{k-1}(x, dy) + \left| \int \exp(iug_{k-1}(y))Q_k(y, A)Q_{k-1}(x, dy) \right|
\leq 2 \int Q_k(y, A)Q_{k-1}(x, dy).
$$

Therefore, by the above considerations,

$$
|m_x(A)| \leq \int Q_k(y, A)Q_{k-1}(x, dy) - \frac{a^4 P^2_k(A) M}{2 \int Q_k(y, A)Q_{k-1}(x, dy)}.
$$

With the notation

$$
Y_{k-2}(x) = \int Q_k(y, A)Q_{k-1}(x, dy) = \mathbb{P}(X_k \in A | X_{k-2} = x),
$$

by integrating the above inequality with respect to $\mathbb{P}_{k-2}(dx)$ we obtain

$$
\int |m_x(A)|\mathbb{P}_{k-2}(dx) \leq \int Y_{k-2}(x)\mathbb{P}_{k-2}(dx)
- \frac{a^4 P_k(A) M}{2Y_{k-2}(x)} \mathbb{P}_{k-2}(dx).
$$

(30)
By the Markov inequality,
\[ \Pr_{k-2}(Y_{k-2} > 2 \Pr_k(A)) \leq \frac{\int Y_{k-2}(x) \Pr_{k-2}(dx)}{2 \Pr_k(A)} = \frac{\Pr_k(A)}{2 \Pr_k(A)} = \frac{1}{2}. \]

So
\[ \Pr_{k-2}(Y_{k-2} \leq 2 \Pr_k(A)) \geq \frac{1}{2}. \]

Therefore
\[ \int \frac{\Pr_k(A)}{Y_{k-2}(x)} \Pr_{k-2}(dx) \geq \int_{Y_{k-2} \leq 2 \Pr_k(A)} \frac{\Pr_k(A)}{Y_{k-2}(x)} \Pr_{k-2}(dx) \geq \frac{1}{2} \Pr_{k-2}(Y_{k-2} \leq 2 \Pr_k(A)) \geq \frac{1}{4}. \]

Combining the last two inequalities with (30) we obtain
\[ \int |m_x(A)| \Pr_{k-2}(dx) \leq \Pr_k(A) - \frac{1}{8} a^4 \Pr_k(A) M \]
\[ = \left( 1 - \frac{1}{8} a^4 M \right) \Pr_k(A). \]

At this moment, this representation allows to estimate \( m(A) \) defined in (29),
\[ m(A) = \lim_n \sum_{A_i \in \mathcal{P}_n} \int |m_x(A_i)| \Pr_{k-2}(dx) \]
\[ \leq \lim_n \sum_{A_i \in \mathcal{P}_n} \left( 1 - \frac{1}{8} a^4 M \right) \Pr_k(A_i) \]
\[ = \left( 1 - \frac{1}{8} a^4 M \right) \Pr_k(A). \]

Whence, by (28), we obtain
\[ \int |T_{k-1} \circ T_k(h)(x)| \Pr_{k-2}(dx) = \int \int |h(z)| m(dz) \]
\[ \leq \left( 1 - \frac{1}{8} a^4 M \right) \int |h(z)| \Pr_k(dz), \]
and Lemma 11 follows by noting that
\[ M = 1 - |f_{k-1}(u)|^2. \]

\[ \square \]

**Lemma 12** For any two random variables \( X \) and \( Y \) we have
\[ |\mathbb{E}(\exp(iuX)|Y)|^2 \leq 1 - (\psi')^2 (1 - |\mathbb{E}(\exp(iuX)|^2) \ a.s. \]
where \( \psi' = \psi'(\sigma(Y), \sigma(X)) \).
Proof: We start by noticing that
\[ |\mathbb{E}(\exp(iuX)|Y))|^2 = \mathbb{E}(\exp(iuX)|Y)) \cdot \mathbb{E}(\exp(-iuX)|Y)). \]
Also, this equals
\[
\int \int \exp(iu(x - x'))\mathbb{P}_{X|Y}(dx)\mathbb{P}_{X|Y}(dx')
= \int \int \cos(u(x - x'))\mathbb{P}_{X|Y}(dx)\mathbb{P}_{X|Y}(dx')
= 1 - 2 \int \int \sin^2\left(\frac{u}{2}(x - x')\right)\mathbb{P}_{X|Y}(dx)\mathbb{P}_{X|Y}(dx').
\]
By the definition of \( \psi \) we have that, for \( k \)
\[ \psi^k(X|Y) = \mathbb{P}(X|Y)^{\psi^k}. \]
Hence, by Lemma 11 we have that, for \( k \)
\[ \mathbb{P}(X|Y) = \mathbb{P}(X|Y)^{\psi} \mathbb{P}(X)\ a.s., \]
therefore
\[ \int \int \sin^2\left(\frac{u}{2}(x - x')\right)\mathbb{P}_{X|Y}(dx)\mathbb{P}_{X|Y}(dx') \geq (\psi)^2 \int \int \sin^2\left(\frac{u}{2}(x - x')\right)\mathbb{P}_{X}(dx)\mathbb{P}_{X}(dx'). \]
and the result follows. \( \square \)

We are now in the position to prove Proposition 10.

Proof of Proposition 10

Note that
\[ \mathbb{E}(\exp(iuS_{2k})|\xi_0) = T_1 \circ T_2 \circ ... \circ T_{2k}(1). \]
So
\[ ||\mathbb{E}(\exp(iuS_{2k})|\xi_0)||_1 \leq ||T_1 \circ T_2||_1 ... ||T_{2k-1} \circ T_{2k}||_1. \]
Hence, by Lemma 11 we have that, for \( k \geq 1, \)
\[ ||\mathbb{E}(\exp(iuS_{2k})|\xi_0)||_1 \leq \prod_{j=1}^{k} [1 - a^4(1 - ||\mathbb{E}(\exp(iuX_{2j-1})^2||)/8] \]
Also, by Lemma 11 and Lemma 12
\[ ||\mathbb{E}(\exp(iuS_{2k})|\xi_0)||_1 \leq ||T_2 \circ T_3||_1 ... ||T_{2k-2} \circ T_{2k-1}||_1 ||T_{2k}(1)||_1 \leq \prod_{j=1}^{k} [1 - a^4(1 - ||\mathbb{E}(\exp(iuX_{2j})^2||)/8] \]
and so, by multiplying these two inequalities we get
\[ ||\mathbb{E}(\exp(iuS_{2k})|\xi_0)||_1^2 \leq \prod_{j=1}^{2k} [1 - a^4(1 - ||\mathbb{E}(\exp(iuX_j)^2)||)/8] \]
A similar result can be obtain for \( ||\mathbb{E}(\exp(iuS_{2k+1})|\xi_0)||_1, \) and since \( \mathbb{E}(\exp(iuS_n)) = \mathbb{E}(\mathbb{E}(\exp(iuS_n)|\xi_0)), \) by Jensen’s inequality we have
\[ ||\mathbb{E}(\exp(iuS_n))||_1^2 \leq \prod_{j=1}^{n} [1 - a^4/8(1 - |f_j(u)|^2)]. \]
Now, for any \( x \) real \( 1 + x \leq \exp(x) \) and the result in Proposition 10 follows. \( \square \)
5.3 Proof of Theorem 1

According to Remark 7, it remains to verify conditions (D1) and (D2). By Proposition 10 combined with Condition A, for any 1 ≤ |u| < δBn,

\[|\mathbb{E}\exp\left(iu\frac{S_n}{B_n}\right)| \leq \exp\left[-\frac{a^4}{16} \sum_{j=1}^{n} (1 - |f_j(u)|^2)\right]\]

\[\leq \exp(-g(u)).\]

Integrating both sides of this inequality on the intervals \(T \leq |u| \leq \delta B_n\) we obtain

\[
\int_{T \leq |u| \leq \delta B_n} |\mathbb{E}\exp\left(iu\frac{S_n}{B_n}\right)| \, du \leq \int_{T \leq |u| \leq \delta B_n} \exp(-g(u)) \, du
\]

\[
\leq \int_{|u| \geq T} \exp(-g(u)) \, du.
\]

Whence, taking first lim supn and then \(T \to \infty\), condition (D1) is verified.

We move now to verify (D2). Because the interval \([\delta, D]\) is compact, (D2) is verified if we can show that for any \(|u|\) fixed in \([\delta, D]\) we can find an open interval \(O_u\) such that

\[\mathbb{E}\exp(itS_n)| \to 0 \text{ as } n \to \infty.\]

By Proposition 10 for any \(t\),

\[B_n|\mathbb{E}\exp(itS_n)| \leq B_n \exp\left[-\frac{a^4}{16} \sum_{j=1}^{n} (1 - |f_j(t)|^2)\right]\]

\[\leq \exp\left[\ln B_n - \frac{a^4}{16} \sum_{k=1}^{n} (1 - |f_k(t)|^2)\right].\]

Now (D2) is satisfied provided that

\[\ln B_n \left(1 - \inf_{|t| \leq O_u} \frac{1}{\ln B_n} \frac{a^4}{16} \sum_{k=1}^{n} (1 - |f_k(t)|^2)\right) \to -\infty.\]

Since \(B_n \to \infty\), we obtain in this case that (D2) follows from Condition B.

The proof of the lattice case is similar. □

5.4 Proof of Theorem 2 and Remark 3

The proof of Theorem 2 is similar with the proof of the corresponding result in Merlevède et al. (2021) replacing Proposition 8 there by Proposition 10 here. In case \(\mathbb{E}(X^2) < \infty\), the identification of normalizer \(B_n\) in Remark 3 follows by 21 and 22.
When $\mathbb{E}(X^2) = \infty$, we shall invoke Theorem 2.1 in Peligrad (1990) to decide that $B_n$ can be taken $\sqrt{\pi/2\mathbb{E}|S_n|}$. To apply this theorem, note that by [24] we have $\varphi_1 < 1$, and also that fact that $X_1$ in the domain of attraction of the stable law with $\mathbb{E}(X^2) = \infty$, is equivalent to (1.2) in Peligrad (1990). Moreover, by Lemma 5.2 and Corollary 5.1 in Peligrad (1990) it follows that $B_n \to \infty$.

5.5 Proof of Theorem 4

We shall verify first condition (1).

We shall apply Corollary 5.9 in Kobus (1995). Note that, by arguments in Section 4, our Markov chain is $\varphi-$mixing with exponential rate of convergence to 0 of the $\varphi$-mixing coefficients. Since we assumed that the distribution of $X_1$ satisfies conditions (13) and (14), it follows that Condition (5.10) in Corollary 5.9 in Kobus (1995), is satisfied.

Therefore the convergence in distribution

$$\frac{S_n}{B_n} \Rightarrow L,$$

with $L$ strictly stable with exponent $p$, is equivalent to the condition: for any $x > 0$ and any $k \in \mathbb{N}$ we have

$$\lim_{n \to \infty} n \mathbb{P}\left(\frac{|X_1|}{B_n} \geq x, \frac{|X_j|}{B_n} \geq x \right) = 0.$$

Clearly, by conditions (13) we can write

$$x^p n \mathbb{P}\left(\frac{|X_1|}{B_n} \geq x\right) = \frac{n}{B_n^p} \ell(B_n) \frac{\ell(xB_n)}{\ell(B_n)}.$$

From the properties of slowly varying functions and from (16) we deduce that for any $x > 0$,

$$\lim_{n \to \infty} n \mathbb{P}\left(\frac{|X_1|}{B_n} \geq x\right) = \frac{1}{x^p}.$$

Therefore we can find a constant $C_x$ such that

$$n \mathbb{P}\left(\frac{|X_1|}{B_n} \geq x, \frac{|X_j|}{B_n} \geq x \right) \leq C_x \mathbb{P}\left(\frac{|X_j|}{B_n} \geq x \mid \frac{|X_1|}{B_n} \geq x \right).$$

and the result follows by condition (16).

Also note that a stable distribution with index $p \neq 1$ and symmetric for $p = 1$, has an integrable characteristic function. This can be seen by the form of the modulus of the characteristic function for these situations, namely for a constant $c_p$:

$$|f_L(t)| = \exp(-|c_pt|^p).$$

(Lévy, 1954). Therefore condition (1) holds.

To prove the results, according to Theorems 6 and 8, it remains to verify conditions A and B.
We shall invoke relation (7.9) in Feller (1967), which states that under (13) and (14), there are constants \( \delta > 0, n_0 \in \mathbb{N} \) and \( c > 0 \) such that for \( 0 < |u| \leq \delta B_n \) and \( n > n_0 \)

\[
n \left( 1 - |f_1 \left( \frac{u}{B_n} \right)|^2 \right) > cu^p.
\]

Clearly Condition A is satisfied.

In the stationary setting Condition B reads: For \( u \neq 0 \) there is an \( \varepsilon = \varepsilon(u) \), \( c(u) \) and a \( n_0 = n_0(u) \) such that for all \( t \) with \( |t - u| \leq \varepsilon \) and \( n > n_0 \)

\[
\frac{na^4}{2^4 (\ln B_n)} (1 - |f_1(t)|^2) \geq c(u) > 1.
\]

By the definition of \( B_n \), it is well known that \( B_n > C n^{p'} \) for some \( p' < 1/p \) and \( n \) large enough.

If \( X \) does not have a lattice distribution, then for every \( u, f_1(u) < 1 \), and by the continuity of \( f_1 \) for any \( u \neq 0 \) we can certainly find an \( \varepsilon > 0 \) and \( c < 1 \), such that for all \( t \) with \( |t - u| \leq \varepsilon \) we have \( |f_1(t)| < c \). Therefore, in this case, for such \( t \),

\[
\frac{na^4}{(\ln B_n)} (1 - |f_1(t)|^2) \geq \frac{na^4}{p \ln n} (1 - c^2) \to \infty
\]

and Condition B is satisfied.

In the nonlattice case we use a similar argument on the interval \( 0 < u < \frac{x}{p} \).

\[ \square \]
