ABUNDANCE FOR SLC SURFACES OVER ARBITRARY FIELDS

QUENTIN POSVA

Abstract. We prove the abundance conjecture for projective slc surfaces over arbitrary fields of positive characteristic. The proof relies on abundance for lc surfaces over arbitrary fields, proved by H. Tanaka, and on the technique of C. Hacon and C. Xu to descend semi-ampleness from the normalization. We also present applications to dlt threefold pairs, and to mixed characteristic families of surfaces.

1. Introduction

The Minimal Model Program (MMP) predicts that a variety with mild singularities $X$ admits a birational model $X'$ such that either $K_{X'}$ is nef, or such that there is a fibration $X' \to Y$ whose general fiber is a Fano variety. In the first case, the MMP is completed by the Abundance conjecture: if $K_{X'}$ is nef, then it should also be semi-ample.

In the case of surfaces, both the MMP and the Abundance conjecture are established in many cases. For smooth surfaces over the complex numbers, this goes back to the work of the Italian school at the beginning of the twentieth century and to the subsequent work of Kodaira, although the results were formulated in different terms: see [Mat02, §1] for an exposition of these results. These classical methods were extended by Mumford [Mum69] to surfaces over algebraically closed fields of positive characteristic. Since then, MMP and Abundance were proved more generally for log canonical surface pairs over the complex numbers by Fujino [Fuj12] and over algebraically closed fields of positive characteristic by Tanaka [Tan14].

The work of Kollár and Shepherd-Barron on the moduli space of canonically polarized smooth complex surfaces [KSB88] has demonstrated that in order to have a good moduli theory of such surfaces, we should consider the larger class of so-called semi-log canonical (slc) surfaces. Hence it is natural to ask whether the MMP and the Abundance theorem can be extended to that class of surfaces. As a matter of fact, the usual MMP does not work [Fuj14, Example 5.4]. On the other hand, Abundance holds for slc surface pairs in characteristic zero by [Fli92, §8 and §12] and over algebraically closed fields of positive characteristic by [Tan16].
The purpose of this article is to extend the Abundance theorem to slc surfaces over any field of positive characteristic. We prove:

**Theorem 1.** Let \((S, \Delta)\) be an slc surface pair and \(f: S \to B\) a projective morphism where \(B\) is separated of finite type over a field \(k\) of positive characteristic. Assume that \(K_S + \Delta\) is \(f\)-nef; then it is \(f\)-semi-ample.

Let us sketch the proof in the case \(B\) is the spectrum of a field. Abundance holds over arbitrary fields for slc surface pairs by the work of Tanaka [Tan20a]. Thus if \((S, D + \Delta)\) is the normalization of \((S, \Delta)\), since \(K_S + \Delta\) pullbacks to \(K_{\overline{S}} + \overline{D} + \overline{\Delta}\) the latter is semi-ample. We have to find a way to descend semi-ampleness along the normalization.

Our strategy is similar to the one of [HX16]. Let \(\tau\) be the involution of \(D^n\) induced by the normalization, and let \(\varphi: \overline{S} \to \overline{T}\) be the fibration given by a sufficiently divisible multiple of \(K_{\overline{S}} + \overline{D} + \overline{\Delta}\). One shows that the set theoretic equivalence relation on \(T\) induced by \((\varphi, \varphi \circ \tau): D^n \to T\) is finite using finiteness of \(B\)-representations. It follows that the quotient \(T := T/(D^n \to T)\) exists and similar arguments show that the hyperplane divisor of \(\overline{T}\) descends to \(T\). Then it is not difficult to show that the composition \(\overline{S} \to \overline{T} \to T\) factors through \(S\) and that a multiple of \(K_{\overline{S}} + \overline{\Delta}\) is the pullback of the hyperplane divisor of \(T\).

In [HX16] the authors use the theory of sources and springs of a crepant log structure developed by Kollár (see [Kol13, §4.3]) to prove finiteness of the equivalence relation and descent of the hyperplane divisor. We have not placed our proof on such axiomatic ground, since the few cases of crepant log structures \(S \to \overline{T}\) that arise in our situation can be quite explicitly described. However our proof is an illustration of Kollár’s theory: the technical details are easier, yet we encounter its main steps and subtleties. We highlight the correspondences in Remark 3.1.14.

There is another approach to slc abundance, developed in characteristic zero by Fujino [Fuj99, Fuj00] and used by Tanaka to prove slc abundance for surfaces over algebraically closed fields of positive characteristic [Tan16]. This approach is actually closely related to that of Hacon and Xu, and to Kollár’s theory of crepant log structures: the finiteness of \(B\)-representations plays a crucial role (see [Fuj99, Conjecture 4.2]), and the geometric properties of \(S \to \overline{T}\) that are relevant in Fujino’s approach (see [Fuj99, Proposition 3.1]) can be understood in terms of sources, springs and \(\mathbb{P}^1\)-links (see [Kol13, §4.3]).

The set-up of [HX16] may also be applied to the relative setting \(f: S \to B\). However, instead of adapting all the previous steps to this relative setting, we choose to reduce to the absolute case as in [Tan20a]. The main step is to compactify both \(S\) and \(B\) while preserving the properties of \(S\) and \(f\). This is achieved using a carefully chosen MMP and some gluing theory.

1.1. Applications

We give two applications of Theorem 1. The first one is about families of slc surfaces in mixed characteristic. In positive characteristic, relative semi-ampleness is a property of fibers by [CT20]. The recent work of Witaszek [Wit21] shows that a similar statement holds for relative semi-ampleness in mixed characteristic. Combining our main result with abundance for threefolds in characteristic zero, we therefore obtain:

**Theorem 2 (Theorem 4.0.1).** Let \(S\) be an excellent regular Noetherian one-dimensional scheme of mixed characteristic, \(f: (X, \Delta) \to S\) a dominant flat projective morphism of relative dimension two. Assume that \((X, \Delta + X_s)\) is slc for every closed point \(s \in S\), and that every fiber \(X_s\) is \(S_2\).

Then if \(K_X + \Delta\) is \(f\)-nef, it is \(f\)-semi-ample.

The second application is about dlt threefolds of general type over arbitrary fields:

**Theorem 3 (Theorem 3.3.4).** Let \((X, \Delta)\) be a projective \(\mathbb{Q}\)-factorial dlt threefold over an arbitrary field \(k\) of characteristic \(p > 5\). Assume that \(K_X + \Delta\) is nef. Then \((K_X + \Delta)|_{\Delta = 1}\) is semi-ample.
This theorem is a generalization of [Wal18, Theorem 1.3], which is a key step for the existence of good minimal models for lc threefolds over algebraically closed fields of characteristic $p > 5$ [Wal18, Theorem 1.1]. In a forthcoming note, I plan to combine Theorem 3.3.4, the techniques of [Wal18] and the tools of [DW19], to obtain the existence of good minimal models for lc threefolds over imperfect fields.

1.2. Acknowledgements

I am grateful to Jakub Witaszek for several suggestions. Financial support was provided by the European Research Council under grant number 804334.

2. Preliminaries

2.1. Conventions and notations

We work over an arbitrary field $k$ of positive characteristic, except in Section 4 where we work over a excellent Noetherian base scheme $S$. We use the same terminology in the more general case, replacing $k$ by $S$ in the definitions below.

A variety is a connected separated reduced equidimensional scheme of finite type over $k$. Note that a variety in our sense might be reducible. A curve (resp. a surface, resp. a threefold) is a variety of dimension one (resp. two, resp. three).

Let $X$ be an integral scheme. A coherent $O_X$-module $F$ is $S_2$ if it satisfies the condition $\text{depth}_{O_{X,x}} F_x \geq \min\{2, \dim F_x\}$ for all $x \in X$.

If $X$ is a reduced Noetherian scheme, its normalization is defined to be its relative normalization along the structural morphism $\bigsqcup \text{Spec}(k(\eta)) \to X$ where $\eta$ runs through the generic points of $X$. Recall that $X$ is normal if and only if it is regular in codimension one and $O_X$ is $S_2$.

Given a normal variety $X$, we denote by $K_X$ any Weil divisor on $X$ associated to the invertible sheaf $\omega_{X,reg}$. A $\mathbb{Q}$-Weil divisor $D$ on $X$ is $\mathbb{Q}$-Cartier if for some $m > 0$ the reflexive sheaf $O_X(mD)$ is invertible.

A pair $(X, \Delta)$ is the data of a normal variety $X$ together with a $\mathbb{Q}$-Weil divisor $\Delta$ whose coefficients belongs to $[0; 1]$, such that $K_X + \Delta$ is $\mathbb{Q}$-Cartier. The divisor $\Delta$ is called the boundary of the pair.

We follow the standard terminology of [Kol13, §2.1] for the birational geometry of pairs. In particular, we refer the reader to loc. cit. for the notions of log canonical (lc) and divisorially log terminal (dlt) pairs, and for the definition of log canonical model.

Let $(X, \Delta + D)$ be a pair, where $D$ is a reduced divisor with normalisation $D^n$. Then there is a canonically-defined $\mathbb{Q}$-divisor $\text{Diff}_{D^n} \Delta$ on $D^n$ such that restriction on $D^n$ induces an isomorphism $\omega_{X,m}^{[m]}(m\Delta + mD)|_{D^n} \cong \omega_{D^n,m}(m\text{Diff}_{D^n} \Delta)$ for $m$ divisible enough. Singularities of $(X, \Delta + D)$ along $D$ and singularities of $(D^n, \text{Diff}_{D^n} \Delta)$ are related by so-called adjunction theorems. We refer to [Kol13, §4.1] for fundamental theorems of adjunction theory.

Let $X$ be a variety and $C \subset X$ a curve proper over a field $k'$. For a Cartier divisor $L$ on $X$, we define the intersection number $L \cdot C = \deg_{k'} O_C(L|_{C})$. By linearity, this definition extends to $\mathbb{Q}$-Cartier divisors.

Let $X$ be a variety and $D$ be a $\mathbb{Q}$-divisor. We denote by $\text{Aut}_k(X, D)$ the group of $k$-automorphisms $\sigma$ of $X$ with the property that $\sigma(D) = D$. Similarly, if $L$ is a $\mathbb{Q}$-line bundle then $\text{Aut}_k(X, L)$ is the group of $k$-automorphisms $\sigma$ of $X$ such that $\sigma^* L = L$.

2.2. Quotients by finite equivalence relations

The theory of quotients by finite equivalence relations is developped in [Kol12] and [Kol13, §9]. For convenience, we recall the basic definitions and constructions that we will need.

Let $S$ be a base scheme, and $X, R$ two reduced $S$-schemes. An $S$-morphism $\sigma = (\sigma_1, \sigma_2) : R \to X \times_S X$ is a set theoretic equivalence relation if, for every geometric point $\text{Spec} \; K \to S$, the induced map

$$\sigma(\text{Spec} \; K) : \text{Hom}_S(\text{Spec} \; K, R) \to \text{Hom}_S(\text{Spec} \; K, X) \times \text{Hom}_S(\text{Spec} \; K, X)$$
is injective and an equivalence relation of the set $\text{Hom}_S(\text{Spec} K, X)$. We say in addition that $\sigma: R \to X \times_S X$ is finite if both $\sigma_i: R \to X$ are finite morphisms.

Suppose that $\sigma: R \to X \times_S X$ is a reduced closed subscheme. Then there is a minimal set theoretic equivalence relation generated by $R$; see [Kol13, 9.3]. Even if both $\sigma_i: R \to X$ are finite morphisms, the resulting pro-finite relation may not be finite: achieving transitivity can create infinite equivalence classes.

Let $(\sigma_1, \sigma_2): R \to X \times_S X$ be a finite set theoretic equivalence relation. A geometric quotient of this relation is an $S$-morphism $q: X \to Y$ such that

(a) $q \circ \sigma_1 = q \circ \sigma_2$,
(b) $(Y, q: X \to Y)$ is initial in the category of algebraic spaces for the property above, and
(c) $q$ is finite.

The most important result for us is that quotients by finite equivalence relation usually exist in positive characteristic: if $X$ is essentially of finite type over a field $k$ of positive characteristic and $R \to X$ is a finite set theoretic equivalence relation, then the geometric quotient $X/R$ exists and is a $k$-scheme [Kol12, Theorem 6, Corollary 48].

2.3. Demi-normal varieties and slc pairs

We recall the definitions of demi-normal varieties and of slc pairs. We refer the reader to [Pos21, §3] for basic properties worked out in the generality we need.

Definition 2.3.1. A one-dimensional Noetherian local ring $(R, \mathfrak{m})$ is called a node if there exists a ring isomorphism $R \cong S/(f)$, where $(S, \mathfrak{n})$ is a regular two-dimensional local ring and $f \in \mathfrak{n}^2$ is an element that is not a square in $\mathfrak{n}^2/\mathfrak{n}^3$.

A locally Noetherian integral scheme (or ring) is called nodal if its codimension one local rings are regular or nodal. It is called demi-normal if it is $S_2$ and nodal.

Let $X$ be a reduced scheme with normalization $\pi: \bar{X} \to X$. The conductor ideal of the normalization is defined as

$$\mathfrak{I} := \mathfrak{Hom}_X(\pi_*, \mathcal{O}_{\bar{X}}, \mathcal{O}_X).$$

It is an ideal in both $\mathcal{O}_X$ and $\mathcal{O}_{\bar{X}}$. We let

$$D := \text{Spec}_X \mathcal{O}_X/\mathfrak{I}, \quad \bar{D} := \text{Spec}_X \mathcal{O}_{\bar{X}}/\mathfrak{I},$$

and call them the conductor subschemes.

Lemma 2.3.2. Notations as above. Assume that $X$ is a demi-normal germ of variety. Then:

(a) $D$ and $\bar{D}$ are reduced of pure codimension 1.
(b) If $\eta \in D$ is a generic point such that $\text{char } k(\eta) \neq 2$, the morphism $\bar{D} \to D$ is étale of degree 2 in a neighborhood of $\eta$.
(c) $X$ has a dualizing sheaf which is invertible in codimension one. In particular, it has a well-defined canonical divisor $K_X$.
(d) Let $\Delta$ be a $\mathbb{Q}$-divisor on $X$ with no component supported on $D$, and such that $K_X + \Delta$ is $\mathbb{Q}$-Cartier. If $\bar{\Delta}$ denotes the divisorial part of $\pi^{-1}(\Delta)$, then there is a canonical isomorphism

$$\pi^* \omega_X^{[m]}(m\Delta) \cong \omega_{\bar{X}}^{[m]}(m\bar{D} + m\bar{\Delta})$$

for $m$ divisible enough.

Proof. See [Pos21, 2.2.3].

Definition 2.3.3. We say that $(X, \Delta)$ is an semi-log canonical (slc) pair if: $X$ is demi-normal, $\Delta$ is a $\mathbb{Q}$-divisor with no components along $D$, $K_X + \Delta$ is $\mathbb{Q}$-Cartier, and the normalization $(X, \bar{D} + \bar{\Delta})$ is an lc pair.

Definition 2.3.4. Notations as in Lemma 2.3.2. Assume that $\eta \in D$ is a generic point. Then $\bar{D} \to D$ is either purely inseparable (that can only happen if $\text{char } k(\eta) = 2$) or generically étale. In the first case, we call $(\eta \in X)$ an inseparable node; in the second case, we call it a separable node.
Lemma 2.3.5. Notations as above. Assume that $X$ has only separable nodes. Then:

(a) the induced morphism of normalizations $\overline{D^n} \to D^n$ is the geometric quotient by a Galois involution $\tau$;

(b) if $K_X + \Delta$ is $\mathbb{Q}$-Cartier, then $\tau$ is a log involution of $(\overline{D^n}, \text{Diff}_{\overline{D^n}} \Delta)$.

Proof. See [Pos21, 2.2.5]. □

Proposition 2.3.6. Let $X$ be a demi-normal variety over a field $k$ of positive characteristic, and $\pi: \overline{X} \to X$ its normalization. Then we have a factorization

$$\pi = \left( \overline{X} \xrightarrow{\nu} \bar{X} \xrightarrow{F} X \right)$$

where

(a) $\nu$ is the geometric quotient of $\bar{X}$ by the finite set-theoretic equivalence relation induced by the separable nodes of $X$;

(b) $F$ is a purely inseparable morphism induced by the inseparable nodes of $X$ (see [Pos21, §3.5]), and $F = \text{id}$ if $\text{char } k \neq 2$.

Proof. [Pos21, 2.3.6]. □

If a scheme fails to be satisfy the property $S_2$, in many cases it has a finite alteration that is $S_2$:

Proposition 2.3.7. Let $X$ be a reduced equidimensional excellent Noetherian scheme. Then the locus $U$ where $X$ is $S_2$ is an open subset with $\text{codim}_X(X \setminus U) \geq 2$, and there exists a morphism $g: X' \to X$ such that

(a) $X'$ is $S_2$ and reduced,

(b) $g$ is finite and an isomorphism precisely above $U$, and

(c) the normalization $X'^n \to X$ factorizes through $g$.

We call $g: X' \to X$, the $S_2$-ification of $X$.

Proof. The morphism $g: X' \to X$ is the one given by [Gro65, 5.10.16] (see [Gro65, 5.10.13] for the definition of the $Z^{(2)}$ appearing in the definition). The first two items also follow from [Gro65, 5.10.16] granted that $g$ is finite, which holds by [Gro65, 5.11.1]. The fact that $g$ factors the normalization follows from finiteness of $g$ and from [Sta, 035Q]. □

2.4. Preliminary results

The following results will be useful in the next sections. While they are probably well-known, we include sketches of proof for convenience of the reader.

Proposition 2.4.1. Let $C$ be a regular projective curve over $k$, and $D$ a boundary such that $K_C + D$ is ample. Then $\text{Aut}_k(C, D)$ is finite.

Proof. We may replace $D$ by $[D] = \sum_{i=1}^m p_i$. Since $K_C + D$ is ample and preserved by the elements of $\text{Aut}_k(C, D)$, we can describe the latter group as the group of $k$-points of the linear algebraic group

$$G := \{ \Phi \in \text{PGL}_k H^0(C, m(K_C + D)) \mid \Phi(C) = C, \Phi(D) = D \}, \quad m \text{ divisible enough.}$$

The tangent space of $G$ at the identity morphism is given by $H^0(C, T_C \otimes I_D)$ [Deb01, §2.9], which is trivial since $T_C \otimes I_D = \mathcal{O}(-K_C - D)$ is anti-ample. It follows that $G$ is a finite group scheme, and thus $\text{Aut}_k(C, D)$ is a finite group. □

Lemma 2.4.2. Let $(S, \Delta)$ be a dlt surface. Then $S$ is $\mathbb{Q}$-factorial and the irreducible components of $|\Delta|$ are normal.

Proof. The $\mathbb{Q}$-factoriality is proved in [Tan18, 4.11]. Hence to show that the components of $|\Delta|$ are normal, we may assume that $\Delta = |\Delta|$ is irreducible. Then we can repeat the proof of [KM98, 5.51], using [Tan18, 3.2] instead of [KM98, 2.68]. □
The next two results study the pluricanonical representations on regular curves of genus zero.

**Lemma 2.4.3.** Let $X$ a proper variety over $k$ and $L$ a line bundle on $X$. Write $K := H^0(X,\mathcal{O}_X)$. If the natural representation $\rho_K: \text{Aut}_K(X, L) \to \text{GL}_K H^0(X, L)$ has finite image, then so does $\rho_k: \text{Aut}_k(X, L) \to \text{GL}_k H^0(X, L)$.

**Proof.** If $\varphi \in \text{Aut}_k(X)$, then $\varphi^*: K \to K$ is a $k$-linear field automorphism. This gives a partition
\[
\text{Aut}_k(X, L) = \bigsqcup_{\sigma \in \text{Aut}_k(K)} \text{Aut}_k^\sigma(X, L)
\]
which is finite since $k \subset K$ is a finite field extension. Notice that if $\varphi \in \text{Aut}_K^\sigma(X, L)$, then $\varphi^{-1} \in \text{Aut}_K^{-1}(X, L)$.

For each $\sigma$, fix an element $\varphi_\sigma \in \text{Aut}_K^\sigma(X, L)$ (if that subset is not empty). If we have another element $\psi \in \text{Aut}_K^\sigma(X, L)$ then the automorphism
\[
\rho_k(\varphi_\sigma^{-1} \circ \psi): H^0(X, L) \to H^0(X, L)
\]
is $K$-linear. Therefore we get a map
\[
\iota_\sigma: \text{Aut}_K^\sigma(X, L) \to \text{GL}_K H^0(X, L), \quad \psi \mapsto \rho_k(\varphi_\sigma^{-1} \circ \psi).
\]
Since $\varphi_\sigma^{-1} \circ \psi \in \text{Aut}_K(X, L)$, we see that $\text{im}(\iota_\sigma) \subseteq \text{im}(\rho_K)$. Thus $\text{im}(\iota_\sigma)$ is finite. Moreover
\[
|\text{im}(\iota_\sigma)| = |\rho_k(\varphi_\sigma^{-1}) \circ \text{im}(\rho_k|_{\text{Aut}_K^\sigma(X, L)})| = |\text{im}(\rho_k|_{\text{Aut}_K^\sigma(X, L)})|
\]
so $\rho_k|_{\text{Aut}_K^\sigma(X, L)}$ has finite image. Since
\[
\text{im}(\rho_k) = \bigsqcup_{\sigma \in \text{Aut}_k(K)} \text{im}(\rho_k|_{\text{Aut}_K^\sigma(X, L)})
\]
the lemma is proved. \qed

**Proposition 2.4.4.** Let $C$ be a regular proper curve of genus zero over an arbitrary field $k$, and $E$ an effective $\mathbb{Q}$-divisor such that $K_C + E \sim_\mathbb{Q} 0$. Then for $m$ divisible enough, the natural representation $\text{Aut}_k(C, \omega_C^m(mE)) \to \text{GL}_k(H^0(C, \omega_C^m(mE)))$ has finite image.

**Proof.** If $C$ is smooth over $k$, then we may assume that $k$ is algebraically closed and the result is well-known. For the rest of the proof, we assume that $C$ is non-smooth over $k$.

Since $K_C \sim_\mathbb{Q} -E$ we have $E > 0$ and so $h^0(C, \omega_C) = 0$. By Lemma 2.4.3 we may replace $k$ by $H^0(C, \mathcal{O}_C)$ to prove the result.

By [Tan20b, 9.8, 9.10] it holds that char $k = 2$ and we can find degree 2 purely inseparable extensions $k \subset l \subset k'$ such that $C_l = C \times_k l$ is integral with non-isomorphic normalization $B \cong \mathbb{F}_{k'}^1$.

Moreover there is $P \in B(k')$ such that $K_B + P \sim g^*K_C$. If $m$ is such that $mE$ is a $\mathbb{Z}$-divisor, then $mK_B + mP + g^{-1}mE \sim 0$. Since $C_l$ is reduced we have an inclusion $\mathcal{O}_{C_l} \subset \nu_\ast \mathcal{O}_B$. Tensoring with $f^\ast \omega_C^m(mE)$ and using the projection formula, we obtain an inclusion $f^\ast \omega_C^m(mE) \subset \nu_\ast g^\ast \omega_C^m(mE)$. Taking global section, we get a sequence of inclusions
\[
(2.4.4.a) \quad H^0(C, \omega_C^m(mE)) \subset H^0(C, \omega_C^m(mE) \otimes_k l \subset H^0(B, \omega_B^m(mP + g^{-1}mE)).
\]

On the other hand, extending scalars along $k \subset l$ gives a natural map
\[
f^\ast: \text{Aut}_k(C, \omega_C^m(mE)) \to \text{Aut}_l(B, \omega_B^m(mP + g^{-1}mE)),
\]
whose image respects the flag (2.4.4.a). Therefore it is sufficient to show that the action of $\text{Aut}_l(B, \omega_B^m(mP + g^{-1}mE))$ on $H^0(B, \omega_B^m(mP + g^{-1}mE))$ is finite. By Lemma 2.4.3, it is sufficient to prove finiteness after replacing $l$ by $k'$. By [Tan20b, 9.8] we may choose the
extensions \( k \subset l \subset k' \) so that \( P \) does not belong to the support of \( g^{-1}mE \). Thus the support of \( mP + g^{-1}mE \) contains at least two points, and we may apply the usual argument (see [Pos21, 5.1.15]).

\[ \square \]

3. Abundance in Positive Characteristic

3.1. Absolute case

We begin with abundance in the absolute case:

**Theorem 3.1.1.** Let \( (S_0, \Delta_0) \) be a projective slc surface pair over an arbitrary field \( k \) of positive characteristic. Assume that \( KS_0 + \Delta_0 \) is nef; then it is semi-ample.

For the duration of the proof we fix \( (S_0, \Delta_0) \) and let \( (S, D + \Delta) \) be its normalization. Write \( D = D_G + D_I \), where \( D_G \) is the preimage of the separable nodes of \( S_0 \), and \( D_I \) is the preimage of the inseparable ones. Let \( \tau \) be the induced log involution of \( (D_G, \text{Diff}_{D_G}(\Delta + D_I)) \).

We emphasize that \( S_0 \) is not assumed to be irreducible. Thus \( (S, \Delta + D) = \bigsqcup_{i=1}^n (S_i, \Delta + D_i) \) is the disjoint union of its normal irreducible components.

We divide the proof in several steps.

3.1.1. Reduction to separable nodes. This step is only necessary if \( \text{char } k = 2 \). Applying Proposition 2.3.6, we get a factorization

\[
(S, D + \Delta) \longrightarrow (S', D'_I + \Delta') \xrightarrow{\mu} (S_0, \Delta_0)
\]

where \( \mu \) is finite purely inseparable and \( (S', D'_I + \Delta') \) is slc with only separable nodes. In other words, \( \mu \) resolves only the inseparable nodes. It factorises some \( k\)-Frobenius of \( S' \), say

\[
F_k^e : S' \xrightarrow{\mu} S_0 \xrightarrow{\nu} S'
\]

(we can actually take \( e = 1 \)). Assume that \( L := m(KS' + D'_I + \Delta') \) is base-point free. Then since \( \nu \) is a universal homeomorphism, \( \nu^*\mathcal{O}(L) \sim \mathcal{O}(mp^e(KS_0 + \Delta_0)) \) is also base-point free. Therefore semi-ampleness of \( K_{S'} + D'_I + \Delta' \) implies semi-ampleness of \( K_{S_0} + \Delta_0 \). Thus it suffices to study \( (S', D'_I + \Delta') \) and so we may assume that \( S_0 \) has only separable nodes.

3.1.2. Quotienting the fibration. The pullback \( KS + D + \Delta \) is nef by assumption, so it is semi-ample by [Tan20a]. Choose \( m > 0 \) even such that \( m(KS + D + \Delta) \) is base-point free, and let \( \varphi : S \rightarrow T \) be the corresponding fibration onto a normal projective variety. We let \( H \) be the hyperplane Cartier divisor on \( T \) with the property that \( \varphi^*\mathcal{O}(H) = \mathcal{O}(m(KS + D + \Delta)) \).

Since \( S_0 \) has only separable nodes, it is the geometric quotient of its normalization \( S \) by the finite equivalence relation induced by the involution \( \tau \) on \( (D^n, \text{Diff}_{D^n}(\Delta)) \). This equivalence relation is generated by the two morphisms \((\iota, \iota' = \iota \circ \tau) : D^n \rightrightarrows S \). Let \( \psi : D^n \rightarrow E \) be the fibration corresponding to the base-point free divisor \( m(KS + D + \Delta)|_{D^n} \). Then we have a diagram

\[
\begin{array}{ccc}
D^n & \xrightarrow{\iota} & S \\
\downarrow \psi & & \downarrow \varphi \\
E & \xrightarrow{j'} & T
\end{array}
\]

where \((\psi, j)\) (resp. \((\psi, j')\)) is the Stein factorization of \( \varphi \circ \iota \) (resp. of \( \varphi \circ \iota' \)). The two morphisms \((j, j') : E \rightrightarrows T \) are finite, and they generate a pro-finite equivalence relation on \( T \). (We only care about the reduced image of this relation in \( T \times_k T \): see the comment after [Kol13, 9.1].)

We claim that this relation is actually finite, and that \( H \) descends to the quotient. We prove both claims below: for the moment assume they hold. Let \( q : T \rightarrow T_0 := T/(E \rightrightarrows T) \) be the quotient. Since both compositions \( q \circ \varphi \circ \iota \) and \( q \circ \varphi \circ \iota' \) are equal, we obtain a morphism
\( \varphi_0 : S_0 \to T_0 \) such that the diagram

\[
\begin{array}{c}
S \\ \downarrow \varphi \\
S_0 \\
\end{array}
\begin{array}{c}
\Downarrow n \\
\Downarrow \varphi_0 \\
T_0 \\
\end{array}
\begin{array}{c}
T \\
\downarrow \gamma \\
T_0 \\
\end{array}
\]

commutes. Moreover there is an ample Cartier divisor \( H_0 \) such that \( q^*H_0 = H \).

**Claim 3.1.2.** \( \varphi_0^*H_0 = m(K_{S_0} + \Delta_0) \). In particular \( K_{S_0} + \Delta_0 \) is semi-ample.

**Proof.** Tensoring the inclusion \( O_{S_0} \subset n_*O_S \) by \( \varphi_0^*O(H_0) \) and using the projection formula, we obtain

\[
\varphi_0^*O_{T_0}(H_0) \subset n_*O_S(m(K_S + D + \Delta)).
\]

By commutativity of \((3.1.1.b)\) and the definition of \( \varphi \) and \( q \), for \( s \in O(H_0) \) we see that its pullback \( \varphi_0^*s \in n_*O(m(K_S + D + \Delta)) \) is a log pluricanonical section whose restriction to \( D^n \) is \( \tau \)-invariant. Thus \( \varphi_0^*O(H_0) \subset O(m(K_{S_0} + \Delta_0)) \) by [Pos21, 3.2.6]. Let \( Q \) be the cokernel: it has the property that \( n^*Q = 0 \). We claim that \( Q = 0 \) to begin with, and this will conclude the proof.

The question is local on \( S_0 \), so let us consider an integral excellent demi-normal ring \( A \) with only separable nodes, with integral closure \( B \) and conductor ideal \( I \), and two locally projective finitely generated \( A \)-modules \( L_1 \subset L_2 \) such that \( M := L_2/L_1 \) satisfies \( M \otimes_A B = 0 \). Then \( M \) is supported on the non-normal locus and \( M \otimes_A B = M \otimes_A/I B/I \). But \( A/I \to B/I \) is generically étale, hence generically faithfully flat, and this implies that \( \text{Supp}(M) \) has codimension \( \geq 2 \). Since \( L_1 \) and \( L_2 \) are reflexive, the inclusion \( L_1 \subset L_2 \) is an equality.

**Remark 3.1.3.** In the diagram \((3.1.1.b)\), the Stein factorisation of \( S_0 \to T_0 \) need not be demi-normal.

For example, consider the product \( T := E \times \mathbb{P}^1 \) of an elliptic curve with a rational smooth curve over an algebraically closed field. Let \( \Delta_T \) be the sum of one section of \( p_E \) and of three distinct sections of \( p_{E'} \). Then \( K_T + \Delta_T \) is ample and \((T, \Delta_T)\) is dlt. Let \( \varphi : S \to T \) be the blow-up of two distinct points \( p \) and \( q \) that are \( 0 \)-dimensional strata of \( \Delta \), and let \( E_p, E_q \) be the corresponding \( \varphi \)-exceptional divisors. Then \( \varphi^*(K_T + \Delta_T) = K_S + \Delta_S + E_p + E_q \). So \( \varphi : S \to T \) is the ample model of \((S, \Delta_S + E_p + E_q)\).

Let \( \tau : E_p \cong E_q \) be an isomorphism that sends \( \Delta_S|E_p \) to \( \Delta_S|E_q \). Then the quotient \( r : S \to S_0 := S/R(\tau) \) exists, \((S_0, \Delta_{S_0} + F)\) is slc with normalization \((S, \Delta_S + E_p + E_q), \) where \( F = r(E_p) = r(E_q) \). On the other hand, the induced involution \( E \equiv T \) is given by \( p \sim q \), and so the fibration given by \( m(K_{S_0} + \Delta_{S_0} + F) \) is \( S_0 \to T_0 := T/(p \sim q) \).

However, \( T_0 \) is not demi-normal since it is not \( S_2 \).

**3.1.3. Finiteness.** It remains to show finiteness and descent, and we begin by the former. It is convenient to reduce to the case where (each component) of \((S, \Delta + D)\) is dlt:

**Claim 3.1.4.** In order to show that the equivalence relation induced by \( E \equiv T \) is finite, we may assume that \((S, D + \Delta)\) is dlt.

**Proof.** Indeed, let \( \phi : (S_{\text{dlt}}, D_{\text{dlt}} + \Delta_{\text{dlt}} + E) \to (S, D + \Delta) \) be a crepant dlt blow-up where \( D_{\text{dlt}} = \phi_*^{-1}D \) and \( E = \text{Exc}(\phi) \) [Tan18, 4.7, 4.8]. Then \( K_{S_{\text{dlt}}} + D_{\text{dlt}} + \Delta_{\text{dlt}} + E \) is semi-ample, and the corresponding fibration is just \( \varphi \circ \phi : S_{\text{dlt}} \to S \to T \). Moreover \( (D^n, \text{Diff}_{D^n} \Delta) = (D^n_{\text{dlt}}, \text{Diff}_{D^n_{\text{dlt}}} (\Delta_{\text{dlt}} + E)) \), so we recover the involution \( \tau \) on the dlt model. Notice that \( D^n_{\text{dlt}} \) is just the disjoint union of its irreducible components by Lemma 2.4.2.

Now let us write \( T = \bigsqcup_{i \geq 1} T_i \) and \( \varphi = \prod_i \varphi_i \) where \( \varphi_i : S_i \to T_i \) is the fibration given by \( m(K_{S_i} + \Delta_i + D_i) \). Let \( \kappa_i := \kappa(S_i, \Delta_i + D_i) \geq 0 \) be the respective Kodaira dimensions, it holds that \( \dim T_i = \kappa_i \). We let \( \mathcal{C} \) be the collection of irreducible components of \( D^n \). For \( \Gamma \in \mathcal{C} \) we write \( \Delta_{\Gamma} := \text{Diff}_{\Gamma}(\Delta + D - \Gamma) \).

The following claim follows immediately from the construction.

**Claim 3.1.5.** The two morphisms \((j, j') : E \equiv T \) come from an involution \( B^* \) on \( E \) defined as follows: if \( \tau(\Gamma) = \Gamma' \), then \( B^* : \psi(\Gamma) \cong \psi(\Gamma') \) is induced by the isomorphism \( \tau^* : H^0(\Gamma', m(K_{\Gamma'} + \Delta_{\Gamma'})) \cong H^0(\Gamma, m(K_{\Gamma} + \Delta_{\Gamma})) \).
It is possible that two components of $D^n$ are conjugated under $\tau$ but do not belong to the same irreducible component of $S$. However we have the following:

**Claim 3.1.6.** A component $\Gamma$ of $D^n$ is $\varphi$-exceptional if and only if $\tau(\Gamma)$ is. Moreover, $\Gamma$ is non-$\varphi$-exceptional if and only if $K_{\Gamma} + \Delta_{\Gamma}$ is ample.

**Proof.** The one-dimensional component $\Gamma$ is $\varphi$-exceptional if and only if $\psi(\Gamma)$ is a point. Moreover $\psi(\Gamma)$ is a point if and only if $K_{\Gamma} + \Delta_{\Gamma}$ has Kodaira dimension zero. Since $\tau$ sends $K_{\Gamma} + \Delta_{\Gamma}$ to $K_{\tau(\Gamma)} + \Delta_{\tau(\Gamma)}$, we obtain the result.

We need to understand the non-$\varphi$-exceptional components of $D^n$, and how they relate. The informations we need are given by the next three claims.

**Claim 3.1.7.** Let $(S_i, \Delta_i + D_i)$ be such that $\kappa_i = 2$. Then $(T_i, (\varphi_i)_*(\Delta_i + D_i))$ is the log canonical model of $(S_i, \Delta_i + D_i)$. If $\Gamma$ is a non-$\varphi_i$-exceptional irreducible component of $D_i$, then $\Gamma$ is the normalization of a component of $(\varphi_i)_*D_i$.

**Proof.** For simplicity, we drop the index $i$ for the duration of the proof. It follows from [Bö1, 7.3] and [Gro65, 4.5.9, 4.6.1] that a general fiber $F$ of $\varphi$ is a geometrically integral proper curve. Since $T$ is regular, $F$ is a complete intersection in $S$. We may assume that $F$ is disjoint from Sing$(S)$, and therefore $F$ is Gorenstein.

Let $K = H^0(F, \mathcal{O}_F)$. We have

$$\deg_K K_F = (K_S + F) \cdot_K F = (-\Delta - D) \cdot_K F \leq -\Gamma \cdot_K F < 0.$$ 

Thus $h^0(F, \omega_F) = h^1(F, \mathcal{O}_F) = 0$. By [Kol13, 10.6] we deduce that $\deg_K K_F = -2$. Hence $\Gamma \cdot_K F \leq 2$, which means that $\Gamma$ has at most two irreducible components.

Say that $F = \varphi^{-1}(t)$. Then we have the exact sequence

$$\mathcal{O}_T = \varphi_* \mathcal{O}_S \to K = \varphi_* \mathcal{O}_F \to R^1 \varphi_* \mathcal{O}_S \otimes \mathcal{O}_T(-t).$$

Since $-K_S - \Delta \sim_{Q. \tau} D$, by [Tan18, 3.3] the sheaf $R^1 \varphi_* \mathcal{O}_S$ vanishes on the open set of $T$ over which the fibers of $\varphi$ are integral. By the choice of $F$ we obtain that $\mathcal{O}_T \to \varphi_* \mathcal{O}_F$ is surjective. Hence the field extension $k(t) \subseteq K$ is an equality.

If $\Gamma_j$ is a component of $\Gamma$ that satisfies $1 = \Gamma_j \cdot_K F = \Gamma_j \cdot(k(t)F)$, then $\varphi|_{\Gamma_j} : \Gamma_j \to T$ is generically an isomorphism by [Pos21, 5.1.7]. Both $\Gamma_j$ and $T$ are normal, so it is an isomorphism. This completes the proof.

**Claim 3.1.9.** In the situation of Claim 3.1.8, if $\Gamma \to T_i$ is separable of degree 2, then there exists a non-trivial log involution of $(\Gamma^n, \text{Diff}_{\Gamma^n}(\Delta + D - \Gamma))$ over $T_i$.

**Proof.** Assume first that $\Gamma = \Gamma^n$ is irreducible. Then $\varphi|_{\Gamma}$ is Galois: let $\xi : \Gamma \cong \Gamma$ be the corresponding involution over $T_i$. We claim that $\xi$ preserves $m(K_{\Gamma} + \Delta_{\Gamma})$. Indeed, fix any global meromorphic form $\omega \in H^0(S_i, \mathcal{O}(m(K_S + D + \Delta)))$ and take $s \in H^0(T_i, \mathcal{O}(H))$ such that $\varphi_*s = \omega$. Then since $\xi$ commutes with $\varphi|_{\Gamma}$ we have

$$\omega|_{\Gamma} = (\varphi|_{\Gamma})^* s = (\varphi|_{\Gamma} \circ \xi)^* s = \xi^* \omega|_{\Gamma}.$$ 

Since the global sections of $\mathcal{O}(m(K_S + D + \Delta))$ generate, our claim is proved.

Now assume that $\Gamma = \Gamma_1 + \Gamma_2$ and that both $\varphi|_{\Gamma_i}$ are isomorphisms. Then one proves as above that

$$\xi := \varphi|_{\Gamma_2}^{-1} \circ \varphi|_{\Gamma_1} : (\Gamma_1, \Delta_{\Gamma_1}) \to (\Gamma_2, \Delta_{\Gamma_2})$$

is a log isomorphism.

We are ready to show finiteness of the relation generated by $E \Rightarrow T$. 

Claim 3.1.10. The equivalence relation defined by \((j,j')\): \(E \rightrightarrows T\) is finite.

Proof. We study the pullback of the equivalence relation \(R(B^r) \rightrightarrows T\) through the finite structural morphism \(j: E \to T\). It is the equivalence relation given by two types of relations:

(a) the fibers of \(j: E \to T\), and

(b) the isomorphisms \(B^\phi: E \cong E\), with \(\phi \in \langle \tau, \{\xi\} \rangle \subset \text{Aut}_k(D^n, \text{Diff}_{D^n} \Delta)\) where the \(\xi\)'s are the isomorphisms described in Claim 3.1.9. Indeed, any such \(\phi\) is a log isomorphism and so it induces an automorphism \(\phi^*\) of \(H^0(D^n, \m(K_{D^n} + \text{Diff}_{D^n} \Delta))\) which gives the isomorphism \(B^\phi\). In other words, the isomorphism \(B^\phi\) is given by the action of \(\phi\) on the vector space \(\bigoplus_{\Gamma \in E} H^0(\Gamma, \m(K_{\Gamma} + \Delta_{\Gamma}))\).

If we can show that this equivalence relation on \(E\) is finite, it will follow that the equivalence relation \(R(B^r) \rightrightarrows T\) is finite.

First we claim that the subgroup \(G := \langle B^r, \{B^\xi\} \rangle \leq \text{Aut}_k(E)\) is finite. Actually, since the map \(\langle \tau, \{\xi\} \rangle \to G, \quad \phi \mapsto B^\phi\)
satisfies \(B^\phi \circ B^{\phi'} = B^{\phi \circ \phi'}\), it suffices to show that \(\langle \tau, \{\xi\} \rangle \subset \text{Aut}_k(D^n, \text{Diff}_{D^n} \Delta)\) is finite. We reduce to show that the stabilizer of each \(\Gamma \in E\) is finite. Recall that the \(\xi\)'s are isomorphisms between non-\(\phi\)-exceptional curves. Thus by Claim 3.1.8 the stabilizer of a \(\phi\)-exceptional \(\Gamma\) is of order at most two. On the other hand, the stabilizer of a non-\(\phi\)-exceptional \(\Gamma\) is contained in \(\text{Aut}_k(\Gamma, \Delta_{\Gamma})\), which is finite by Proposition 2.4.1 since \(K_{\Gamma} + \Delta_{\Gamma}\) is ample.

Now we must also declare to be equivalent those points that belong the same fibers of the structural morphism \(j\). There are finitely many closed points \(z \in j(E)\) such that \(j^{-1}(z)\) is not contained in a \(G\)-orbit. For the moment it is sufficient to know that the set \(Z\) of those is finite, we will describe it more precisely below. Since the new relations we must add are supported on \(G \cdot j^{-1}(Z) \times_k G \cdot j^{-1}(Z)\), which is finite over \(k\), we obtain that the pullback equivalence relation on \(E\) is finite.

\(\Box\)

3.1.4. Descent. To conclude we must show that the Cartier divisor \(H\) descends to the quotient \(T_0 = T/R(B^r)\). We use the method of [Kol13, 5.38], and keep the notations of Claim 3.1.10.

First of all, we study the special set \(Z\) considered at the end of the proof of Claim 3.1.10. Recall that it is the finite set of those \(z \in j(E)\) such that \(j^{-1}(z)\) is not contained in a \(G\)-orbit.

Observation 3.1.11. These \(z\) are of three types:

(a) \(z \in T_i\) with \(\dim T_i = 2\). By Claim 3.1.7 \(z\) is a singular point of \((\varphi_i)_* D_i\). Thus by [Kol13, 2.31.1] it is a node of \((\varphi_i)_* D_i\), with two preimages \(p\) and \(q\) in \(D_i\).

(b) \(z \in T_i\) with \(\dim T_i = 1\). By Claim 3.1.8 it follows that \(z\) is the contraction of a \(\varphi\)-exceptional component of \(D_i\).

(c) \(z \in T_i\) with \(\dim T_i = 0\). Then \(z\) is the contraction of a \(\varphi\)-exceptional component of \(D_i\).

We note that in any case \(z\) is the image of an lc center \(W\) of \((S, \Delta + D)\).

Claim 3.1.12. For each \(z\) as above, let \(W\) and \(W'\) be two lc centers of \((S, \Delta + D)\) that is minimal for the property that \(\varphi(W) = z = \varphi(W')\). Then there is a log isomorphism \((W, \text{Diff}^*_W(\Delta + D)) \cong (W', \text{Diff}^*_W(\Delta + D))\).

Proof. If \(z \in T_i\) with \(\dim T_i = 2\), then by Claim 3.1.7 there is a proper curve \(C\) passing through \(p\) and \(q\) that is contracted by \(\varphi_i\). By [Kol13, 2.31.2], the curve \(C\) belongs to the reduced boundary \(\Delta^p_{S_i} + D_i\). Since \((K_{S_i} + \Delta_i + D_i) \cdot C = 0\) it follows by the adjunction formula that \(k(p) = H^0(C, \m_C) = k(q)\).

If \(z \in T_i\) with \(\dim T_i \leq 1\) we follow the last part of the proof of [Pos21, 5.2.12]. This part only uses the MMP for surfaces, available in our generality thanks to [Tan18], and [Pos21, 5.2.9] where it is assumed that \(p > 2\). This assumption is only used to apply [Pos21, 5.1.6] in order to prove that some curves are smooth rational, which we do not need (notice that the displayed calculation in [Pos21, 5.2.9] can be performed on the generic fiber).

\(\Box\)

Claim 3.1.13. Moreover, in the case \(z \in T_i\) with \(\dim T_i = 1\), if one minimal \(W\) above \(z\) is a curve a genus one, then it is the unique minimal center over \(z\).
Proof. Let us drop the index $i$, write $D + \Delta^{<1} = \Theta$ and $\Delta^{<1} = \Upsilon$. Then $(S, \Upsilon)$ is klt and $K_S + \Upsilon \sim_{Q, \varphi} -\Theta$.

By the argument in the proof of [Pos21, 5.2.12], if $\Theta$ does not dominate $T$ then $\varphi^{-1}(z) \cap \Theta$ is connected. By adjunction this implies that $W = \varphi^{-1}(z) \cap \Theta$.

Assume that $\Theta$ dominates $T$. By adjunction $W$ is isolated in the support of $\Theta$. We run a few steps of the $(K_S + \Upsilon)$-MMP over $C$, and stop when the tranform of $\Theta$ intersects $W$. Since $K_S + \Theta + \Upsilon \sim_{Q, T} 0$, each step is crepant for $(S, \Theta + \Upsilon)$ (see [Pos21, 5.1.14]). It follows that $\text{Diff}_W^*(\Theta + \Upsilon) \neq 0$, contradicting adjunction. Thus $\varphi^{-1}(z) \cap \Theta$ does not contain a genus one curve. □

Now let $T_H := \text{Spec}_T \sum_{\tau \geq 0} H^0(T, rH)\Rightarrow$ be the total space of $H$, and similarly

$$E_H := T_H \times_T E = \bigcup_{\tau \in \mathcal{C}} \text{Spec}_{\tau} \sum_{r \geq 0} H^0(\Gamma, rm(K_{\Gamma} + \Delta_{\Gamma})) \xrightarrow{\text{j}_H} T_H$$

Since $\tau$ is a log isomorphism of $(D^n, \text{Diff}_D, \Delta)$, the involution $B^\tau: E \cong E$ lifts to an involution $B^\tau_H: E_H \cong E_H$. The Cartier divisor $H$ descends to the quotient $T/R(B^\tau)$ if the equivalence relation $R(B^\tau_H) \Rightarrow T_H$ is finite.

As in the proof of Claim 3.1.10, we consider the pullback of $R(B^\tau_H) \Rightarrow T_H$ to $E_H$. It is generated by two types of relations:

(a) the fibers of the structural morphism $j_H: E_H \rightarrow T_H$, and

(b) the isomorphisms $B^\phi_H: E_H \cong E_H$ induced by the $B^\phi: E \cong E$, where as in Claim 3.1.10 we take $\phi \in \{\tau, \{\xi\}\}$. More precisely, each $\phi: E \cong E$ induces an automorphism of the graded section ring $\bigoplus_{\Gamma \in \mathcal{C}} \sum_{r \geq 0} H^0(\Gamma, rm(K_{\Gamma} + \Delta_{\Gamma}))$ which gives $B^\phi_H$.

We have seen in Claim 3.1.10 that the group $G = \langle B^\tau, \{B^\xi\} \rangle \subset \text{Aut}_k(E)$ is finite, and it follows the orbits of $G_H := \langle B^\tau_H, \{B^\xi_H\} \rangle$ are finite.

Now we must take in account the fibers of $j_H: E_H \rightarrow T_H$. The new relations we get are supported on the fibers of $E_H \rightarrow T$ over the closed finite subset $Z \subset j(E)$. By Claim 3.1.12 we see that the new relations come from some isomorphisms between the $W$’s, inducing isomorphisms between the section rings of the Cartier divisors $m(K_S + \Delta + D)|_W$, where $W$ runs through the minimal lc centers of $(S, \Delta + D)$ over the points of $Z$. As in [Kol13, 5.38], it suffices to show that the pluricanonical representations

$$\text{Aut}_k(W, \text{Diff}_W^*(\Delta + D)) \rightarrow \text{GL}_k H^0(W, m(K_W + \text{Diff}_W^*(\Delta + D)))$$

are finite.

Recall that we are trying to descend the Cartier divisor $H$ to the quotient $T_0 = T/R(B^\tau)$. Since the $T_i$ of dimension 0 gets glued to closed points of $T_0$, there is no problem to descend $H$ there. So we only have to care about the $z \in j(E)$ that belong to components $T_i$ with $\dim T_i \geq 1$.

If a minimal lc center above $z$ is a genus one curve, then by Claim 3.1.13 we see that $j^{-1}(z)$ is contained in a $G$-orbit. Thus we may assume that the minimal lc centers $W$ above $z$ are either 0-dimensional, or genus one curves.

If $W$ is 0-dimensional then it is the spectrum of a finite field extension of $k$, and thus $\text{Aut}_k(W)$ is finite. If $W$ is a genus zero curve then finiteness of pluricanonical representations is proved in Proposition 2.4.4. This concludes the proof. □

Remark 3.1.14. The discussion above is a simple illustration of some key features of Kollár’s theory of sources and springs for crepant log structures:

(a) In Kollár’s terminology, $\varphi: (S, \Delta + D) \rightarrow T$ is a crepant log structure, the components of $D$ are the sources (of their images in $T$) and the components of $E$ are the springs (of their images in $T$).

(b) In Claim 3.1.9, in case $\Gamma = \Gamma_1 + \Gamma_2$, the fact that $(\Gamma_1, \Delta_{\Gamma_1})$ and $(\Gamma_2, \Delta_{\Gamma_2})$ are log-isomorphic to each other corresponds to the uniqueness of the source up to crepant birational map [Kol13, 4.45.1].
(c) In Claim 3.1.9, in case $\Gamma \to T$, is a separable double cover, the fact that the extension of function fields is Galois and that the Galois involution can be realised by a log-automorphisms of $(\Gamma, \Delta_f)$ corresponds to the Galois property of springs [Kol13, 4.45.5].

(d) In Claim 3.1.9, in case $\Gamma = \Gamma_1 + \Gamma_2$, we have that $(S, \Gamma_1 + \Gamma_2 + (\Delta - \Gamma)) \to T$ is a weak $\mathbb{P}^1$-link [Pos21, 5.2.10]. Indeed, the general fiber $F = f^{-1}(t)$ is an integral Gorenstein proper curve over $k(t)$ with $H^0(F, \mathcal{O}_F) = k(t)$ and has an invertible sheaf $\Gamma_i|_F$ of degree $\Gamma_i \cdot k(t) F = 1$ (since $(S, D + \Delta)$ is dlt, the components of the reduced boundary are Cartier). Thus $F \cong \mathbb{P}^1_{k(t)}$ by [Sta, 0C6U].

(e) To show finiteness and descent, we have reduced both times to a question about representation of a group of log automorphisms of $E$ on the space of pluricanonical sections of $H$. This corresponds to the crucial role that pluricanonical representations have in [Kol13, 5.36-38]. Our case is easily manageable, since the groups of log automorphisms that appear are finite to begin with, so finiteness of the representation is automatic.

3.2. Relative case

We prove abundance in the relative setting. We deduce the relative version from the absolute version, following the strategy of [Tan20a].

Assumption 3.2.1. Let $(S_0, \Delta_0)$ be a slc surface, $f_0: S_0 \to B_0$ a projective morphism where $B_0$ is separated of finite type over a field $k$ of positive characteristic. We assume that $K_{S_0} + \Delta_0$ is $f_0$-nef.

We aim to show that $K_{S_0} + \Delta_0$ is $f_0$-semi-ample.

3.2.1. Reduction to the projective case. First we reduce to the projective case. The statement is local over $B_0$, so we may assume it is affine and irreducible. Then by Chow lemma [Sta, 0200] we see that we can embed $B_0$ as a subscheme of a projective $k$-scheme $B$ (we take $B_0$ affine and irreducible so that we can take $B_0$ as the $U$ that appears in the second paragraph of the proof of [Sta, 0200]).

We look for a projective slc compactification of $(S_0, \Delta_0)$ over $B$. By [Pos21, 3.7.1] there is a commutative diagram

$$
\begin{array}{ccc}
S_0 & \xrightarrow{j} & S \\
\downarrow f_0 & & \downarrow f \\
B_0 & \xrightarrow{f} & B
\end{array}
$$

where $S$ is a demi-normal surface, $j$ is a dense open embedding, the singular codimension one points of $S$ are contained in $S$, and $f$ is a projective morphism.

We have obtained a projective compactification. Ensuring the slc property is slightly more delicate: we combine MMP and gluing techniques to improve the boundary $S \backslash S_0^\circ$, we may assume that:

(a) the scheme $\bar{S}$ is regular at the points of $Z$;

(b) $\Delta \cap \bar{D}$ is contained in $S_0^\circ$;

(c) if $\bar{E}$ is the divisorial part of $Z$, then $\text{Supp}(\Delta) + \bar{D} + \bar{E}$ is simple normal crossing at the points of $Z$.

In particular $(\bar{S}, \bar{\Delta} + \bar{E})$ is lc. However $K_{\bar{S}} + \bar{\Delta} + \bar{E}$ might not be nef over $B$. To remedy to this situation, we run a $(K_{\bar{S}} + \bar{\Delta} + \bar{E} + \bar{D})$-MMP over $B$, and call $\varphi: \bar{S} \to \bar{S}'$ the resulting birational contraction:

$$
\begin{array}{ccc}
\bar{S}_0 & \xrightarrow{j} & \bar{S} \\
\downarrow \varphi & & \downarrow \varphi \\
\bar{S}_0' & \to & \varphi(\bar{S}_0')
\end{array}
$$

Note that $(\bar{S}, \bar{\Delta} + \bar{E})$ is a demi-normal surface, the singular codimension one points of $\bar{S}$ are contained in $\bar{S}$, and $\varphi$ is a projective morphism.
This MMP exists by [Tan18].

Claim 3.2.2. With the notations as above:

(a) \( \dim S' = 2 \),
(b) \( \varphi(S_0^n) \) is an open subset of \( S' \) and \( S_0^n \to \varphi(S_0^n) \) is an isomorphism,
(c) \( \bar{D} \) is the closure of the conductor divisor of \( S_0^n \),
(d) \( \bar{D}^n \cong (\bar{D}')^n \),
(e) if \( \tau \) is the involution on \( \bar{D}^n \) induced by the separable nodes of \( S_0 \), then \( R(\tau) \Rightarrow S' \) is a finite equivalence relation,
(f) \( \tau \) preserves the pullback of \( K_{S'} + \Delta' + \bar{E}' + \bar{D}' \) to \( (\bar{D}')^n \).

Proof. Since \( K_S + \Delta + \bar{D} \) is nef on the generic fiber over \( B \), the MMP ends with a minimal model, so \( \dim S' = 2 \) and \( \varphi \) is birational. The MMP contracts finitely many proper curves over \( B \), and none of them is contained in \( S_0^n \). Thus we see that \( \varphi(S_0^n) \) is open and that \( S_0^n \to \varphi(S_0^n) \) is finite birational. Since the target is normal, it must be an isomorphism.

We also see that \( \bar{D} \) is finite birational, thus their normalizations are isomorphic. Hence we can transport \( \tau \) to \( (\bar{D}')^n \). The relation \( R(\tau) \Rightarrow S' \) is finite over \( \varphi(S_0^n) \cong S_0^n \), since it is the relation that arises from the normalization of \( S_0 \). The complement \( \bar{D}' \setminus \varphi(S_0^n) \) is finite, so we deduce that \( R(\tau) \Rightarrow S' \) is finite.

By construction \( (\bar{S}, \bar{E} + \bar{D}) \) is dlt in a neighbourhood of \( \bar{S} \setminus S_0^n \). Thus \( \varphi \) is a crepant in a neighborhood of \( \bar{D} \to \bar{D}' \). Hence to prove that \( \tau \) preserves \( (K_{S'} + \Delta' + \bar{D}')|_{(\bar{D}')^n} \), it suffices to show that \( \tau \) preserves \( \Gamma := \text{Diff}_{\bar{P}}(\Delta + \bar{E}) \). It does so over \( S_0^n \), and by construction for every \( P \in \bar{D}^n \setminus D_0^n \) we have coeff \( \Gamma = 1 \). Thus \( \tau \) preserves the different divisor \( \Gamma \).

By the two last items of Claim 3.2.2 and by [Pos21, Theorem 1] we can de-normalize \( S' \) along the gluing data given by \( S_0^n \to S_0 \). We obtain a lc surface pair \((S', \Delta' + \bar{E}')\), which contains \((S_0, \Delta_0)\) as an open subset (notice that \( \bar{E}'|_{S_0} \) is empty), and such that \( K_{S'} + \Delta' + \bar{E}' \) is nef over \( B \). The proof that \( (S', \Delta' + \bar{E}') \) is projective over \( B \) is similar to the analog statement in [Pos21, 3.7.1].

Claim 3.2.3. With the notations as above, it is sufficient to show that \( K_{S'} + \Delta' + \bar{E}' \) is semi-ample over \( B \).

Proof. More generally, consider a proper scheme morphism \( g : X \to T \), a line bundle \( L \) on \( X \), and open subschemes \( T_0 \subset T \) and \( V \subset X_{T_0} \):

\[
\begin{array}{ccc}
V & \xleftarrow{i} & X_{T_0} \\
\downarrow{h} & & \downarrow{g_{T_0} =: m} \\
T_0 & & \\
\end{array}
\]

We claim that if the functorial morphism \( \epsilon_L : g^*g_*L \to L \) is surjective, then so is \( \epsilon_{LV} : h^*h_*LV \to LV \). Write \( L_0 := L_{X_{T_0}} \). We have a commutative diagram

\[
\begin{array}{ccc}
i^*m^*m_*L_0 & \xrightarrow{\alpha} & i^*m^*m_*i_*i^*L_0 \\
\downarrow{\beta} & & \downarrow{\cong} \\
i^*L_0 = LV & \xleftarrow{\epsilon_{LV}} & h^*h_*LV \\
\end{array}
\]

where \( \alpha = i^*m^*m_*L_0 \to i_*i^*L_0 \) and \( \beta = i^*\epsilon_{L_0} \). If \( \epsilon_L \) is surjective then \( \epsilon_{L_0} \) is surjective [CT20, 2.12], so \( \beta \) is surjective and by commutativity of the diagram we deduce that \( \epsilon_{LV} \) is surjective.

We apply this result to \( (X, T, T_0, V, L) = (S', B, B_0, S_0, \mathcal{O}(r(K_{S'} + \Delta' + \bar{E}'))) \) for \( r \) divisible enough to prove the claim.

3.2.2. Conclusion of the proof. We assume from now on that \( B_0 \) is projective over \( k \), and \((S_0, \Delta_0)\) slc projective over \( B_0 \) with normalization \((S_0, \Delta_0 + \bar{D})\). Let \( A \) be an Cartier ample divisor on \( B_0 \). By [Tan20a, 4.11] the divisor \( K_{S_0} + \Delta_0 + \bar{D} + n^*f_0^*(mA) \) is nef for \( m \) large enough. Thus \( K_{S_0} + \Delta_0 + f_0^*(mA) \) is nef, hence semi-ample by Theorem 3.1.1. In particular
it is \(f_0\)-semi-ample, say that \(L := \mathcal{O}(\rho(K_{S_0} + \Delta_0 + f_0^*(mA)))\) defines a morphism over \(B_0\). Tensoring the surjection \(f_0^*(f_0)_*L \to L\) by \(f_0^*\mathcal{O}(-mA)\) we see that \(K_{S_0} + \Delta_0\) is \(f_0\)-semi-ample.

This completes the proof of Theorem 1. \(\square\)

3.3. Applications to threefolds

Lemma 3.3.1. Let \((X, B)\) be a plt pair defined over an arbitrary field \(k\). Let \(l \subset k\) be a subfield and \((X_l, B_l)\) a pair such that \((X_l, B_l) \otimes_k k = (X, B)\). Then \((X_l, B_l)\) is plt.

Proof. Since \(\mu : X \to X_l\) is faithfully flat, \(X_l\) is normal [Sta, 033G]. Now let \(f_l : Y_l \to X_l\) be a birational proper morphism with \(K_{Y_l} + B_{Y_l} = f_l^*(K_X + B)\). We must show that the coefficients of \(B_{Y_l}\) along exceptional divisors are strictly less than 1. Let \((f : Y \to X) := (f_l : Y_l \to X_l) \otimes_l k\).

As in the proof of [DW19, 6.17] one sees that \(Y\) is integral. Let \(Y^n \to Y\) be its normalization:

\[
\begin{array}{ccc}
Y^n & \xrightarrow{\nu} & Y_l \\
\downarrow & & \downarrow \mu_Y \\
Y & \xrightarrow{\mu} & X_l
\end{array}
\]

Then

\[K_{Y^n} + B_{Y^n} = n^*f^*(K_X + B) = \nu^*(K_{Y_l} + B_{Y_l}).\]

Let \(E_l\) be a prime divisor on \(Y_l\) that is exceptional over \(X_l\), and \(E\) the strict transform of \(E_l \otimes_k k\). Then \(E\) is exceptional over \(X\), thus \(\text{coeff}_E B_{Y^n} < 1\) by the plt condition on \((X, B)\).

Since \(\text{coeff}_E B_{Y^n} \geq \text{coeff}_{E_l} B_{Y_l}\), we deduce that \(\text{coeff}_{E_l} B_{Y_l} < 1\). This shows that \((X_l, B_l)\) is plt. \(\square\)

Lemma 3.3.2. Let \((X, \Delta)\) be a \(\mathbb{Q}\)-factorial dlt threefold defined over an arbitrary field \(k\) of characteristic \(p > 5\). If \(E \subset \Delta = 1\) is an irreducible component, then \(E\) is normal.

Proof. The first paragraph of the proof of [Kol13, 4.16] works over any field, and shows that the lc centers of a dlt pair are amongst the strata of its reduced boundary. Therefore \((X, E)\) is plt in a neighbourhood of \(E\).

Assume that \(k\) is \(F\)-finite. Then we obtain that \(E\) is normal by [DW19, 6.3].

If \(k\) is not \(F\)-finite, then we can find a subfield \(l \subset k\) that is finitely generated over \(\mathbb{F}_p\) and such that \((X, E)\) is defined over \(l\), say \((X_l, E_l) \otimes_l k = (X, E)\). By Lemma 3.3.1 the pair \((X_l, E_l)\) is plt, and by [DW19, 6.18] \(X_l\) is \(\mathbb{Q}\)-factorial (it is assumed there that \(l\) must be infinite: since \(k\) is not \(F\)-finite it is not contained in \(\mathbb{F}_p\), and so we may indeed choose \(l\) infinite). Then \(E_l\) is normal. This implies that \(E\) is normal. Indeed, if it is not, then we can find a finitely generated intermediate extension \(l \subset l' \subset k\) such that \(E_l \otimes_l l'\) is not normal. But \(l'\) is still \(F\)-finite and we could have worked with \((X_l, E_l) \otimes_l l'\) to begin with, thus we get a contradiction. \(\square\)

Lemma 3.3.3. Let \((X, \Delta)\) be a \(\mathbb{Q}\)-factorial dlt threefold defined over an arbitrary field \(k\) of characteristic \(p > 5\). Let \(\pi : Z \to \Delta = 1\) be the \(S_2\)-fication. Then \(\pi\) is a finite universal homeomorphism and \(Z\) is semi-normal.

Proof. The \(S_2\)-fication is characterized in Proposition 2.3.7. In particular \(\pi\) is finite and an isomorphism above the codimension one points. Thus by [Kol13, 2.31] and the fact that \(Z\) is \(S_2\), we obtain that \(Z\) is semi-normal.

It remains to show that \(\pi\) is a universal homeomorphism. It is surjective since it factors the normalization, and universally closed since it is finite. Thus it suffices to show that \(\pi\) is injective on geometric points. This is proved as in [Wal18, 5.1], using Lemma 3.3.2 instead of [Wal18, 2.11]. \(\square\)

Theorem 3.3.4. Let \((X, \Delta)\) be a projective \(\mathbb{Q}\)-factorial dlt threefold over an arbitrary field \(k\) of characteristic \(p > 5\). Assume that \(K_X + \Delta\) is nef. Then \((K_X + \Delta)|_{\Delta = 1}\) is semi-ample.
Proof. Let \( \pi : Z \rightarrow \Delta^{=1} \) be the \( S_2 \)-fiction. Then \( Z \) is semi-normal by Lemma 3.3.3, by adjunction \((Z, K_Z + \text{Diff}_Z \Delta^{<1})\) is a projective slc surface and \( K_Z + \text{Diff}_Z \Delta^{<1} = (K_X + \Delta)|_Z \) is nef. Then by Theorem 3.1.1 \((K_X + \Delta)|_Z\) is semi-ample. By Lemma 3.3.3 the morphism \( \pi \) is a universal homeomorphism, hence it factors a \( k \)-Frobenius of \( Z \), and we deduce that \((K_X + \Delta)|_{\Delta^{=1}}\) is also semi-ample.

\[ \square \]

4. ABUNDANCE FOR SURFACES IN MIXED CHARACTERISTIC

Theorem 4.0.1. Let \( S \) be an excellent regular Noetherian one-dimensional scheme of mixed characteristic, \( f : (X, \Delta) \rightarrow S \) a dominant flat projective morphism of relative dimension two. Assume that \((X_s, \Delta_s)\) is slc for every closed point \( s \in S \), and that every fiber \( X_s \) is \( S_2 \).

Then if \( K_X + \Delta \) is \( f \)-ample.

Proof. By abundance for slc threefolds in characteristic 0 [Fli92, HX16], \( K_X + \Delta \) is semi-ample on the generic fiber. By assumption \((X_s, \Delta_s)\) is slc, thus by Theorem 3.1.1 we see that \( K_X + \Delta \) is semi-ample on every closed fiber. We conclude by [Wit21, Theorem 1.2].
