Abstract

George Boole first proposed the union bounding problem, which is a class of probabilistic satisfiability problems. Based on Hailperin’s linear programming formulation of the problem, a very large body of research was conducted to provide good bounds by considering a relaxation that is either polynomial dimension in \( n \) or is at least polynomially computable. We study monotone linear mappings \( L \) to a lower \( N \) dimensional space such that \( L(R^{n-1}_+) \subseteq R^N_+ \) and provide a complete characterization of the cone \( L_{\mathcal{E}}(R^{n-1}_+) \) for three aggregation models from the literature. This characterization leads to strictly improved bounds in two of these cases as a result. We also obtain an \( O(n^2) \) dimensional linear program that is equivalent with Hailperin’s model. An interesting side result is that there exists a connection between Hailperin’s model and the cut-polytope.

1 Boole’s Problem and our results

In his seminal works, George Boole \[1,2\] (see also \[3\]) introduced a difficult family of problems that turned out to be very important in numerous applications and became widely studied. In its simplest and most frequently studied form, we are given reals \( p_i, i = 1, \ldots, n \), and \( p_{i,j} \) for \( 1 \leq i < j \leq n \), for some positive integer \( n \), and the problems is to determine tight lower and upper bounds for the probability of the union of \( n \) events, \( A_i, i = 1, \ldots, n \), assuming the equalities \( \mathbb{P}(A_i) = p_i \) for \( i = 1, \ldots, n \) and \( \mathbb{P}(A_i \cap A_j) = p_{i,j} \) for all \( 1 \leq i < j \leq n \). This problem, known as the union bounding problem, turns out to be quite difficult. Hailperin \[17\] proposed a linear programming formulation. Note that the events

\[
\omega_S = \bigcap_{i \in S} A_i \cap \bigcap_{i \notin S} \bar{A}_i
\]
for $S \subseteq \{1, \ldots, n\}$ partition the probability space, and the events $A_i$ or $A_i \cap A_j$ or the union of all these events can be viewed as unions of some of these atomic events. Hailperin proposed to view

$$x_S = \mathbb{P}(\omega_S) \quad \text{for all } S \subseteq \{1, \ldots, n\}$$

as unknown variables, and formulated the union bounding problem as the linear optimization problem of the form

$$\begin{align*}
\max / \min \quad & \sum_{S \subseteq \{1, \ldots, n\}} x_S \\
\text{s.t.} \quad & \sum_{S \subseteq \{1, \ldots, n\}} x_S = p_Q \quad \forall \ Q \subseteq \{1, \ldots, n\}, |Q| \leq 2, \\
& x_S \geq 0 \quad \forall \ S \subseteq \{1, \ldots, n\}.
\end{align*}$$

Let us denote by $LB(H)$ and $UB(H)$ the optimum values of the minimization and maximization, respectively, of above linear program.

Let us add here a few remarks, to enhance clarity of our following discussions:

1. Note that $LB(H)$ and $UB(H)$ are sharp bounds, meaning that for an arbitrary real $Z$ with $LB(H) \leq Z \leq UB(H)$ there exists a probability space with events $A_i$, $i = 1, \ldots, n$ such that $Z = \mathbb{P}\left(\bigcup_{i=1}^{n} A_i\right)$.

2. From a computational point of view, the input size depends only on $n$. Thus, for a reasonably bounded rational input the input size is polynomially bounded by $n$, while the number of variables in (1) is exponential in $n$. This in itself of course is not an indication of computational hardness. However, it was shown that trying to use column generation leads, in every iteration, to a binary unconstrained quadratic optimization, that in general is known to be NP-hard [19]. It was also shown that the feasibility of (1) belongs to the family of probabilistic satisfiability problems, that are also known to be NP-hard, in general [20]. These indications are not a definitive proof of computational hardness. Nevertheless, the perceived hardness of (1) motivated a large amount of research to provide bounds that are close to $LB(H)$ from below and to $UB(H)$ from above and are computable in polynomial time in terms of the input size.

3. We can observe that variable $x_\emptyset$ appears only once, in the equality corresponding to $p_\emptyset = 1$. Thus, we can eliminate both $x_\emptyset$ and the first equality.
from our formulation yielding a somewhat simplified formulation:

$$\max \sum_{S \subseteq \{1, \ldots, n\}, S \neq \emptyset} x_S$$

s.t.  

$$\sum_{S \subseteq \{1, \ldots, n\}, S \supseteq Q} x_S = p_Q \quad \forall \ Q \subseteq \{1, \ldots, n\}, 1 \leq |Q| \leq 2,$$

$$x_S \geq 0 \quad \forall \ \emptyset \neq S \subseteq \{1, \ldots, n\}.$$  

(2)

This simplification may lead to a feasible formulation (2), even when problem (1) is infeasible [8]. Still, denoting by $Z^{\text{max}}$ and $Z^{\min}$ the optimum values in (2), we have the relations that (1) is infeasible if and only if $Z^{\min} > 1$, and for feasible inputs we have $\text{LB}(H) = Z^{\min}$ and $\text{UB}(H) = \min\{1, Z^{\max}\}$. Thus, problems (1) and (2) are equivalent.

There is a very large body of research on providing good bounds for (2), mostly by considering a relaxation that is either polynomial dimension in $n$ or is at least polynomially computable, due to some structural property. We refer the reader to [8] for a concise summary of these results. Many of these results are based on relaxations of (2) obtained by aggregating some of the variables of the original formulation (and sometimes, aggregating also some of the equalities of (2)). In fact such aggregations are monotone linear mappings $L$ to a lower $N$ dimensional space such that $L(\mathbb{R}_+^{2^n-1}) \subseteq \mathbb{R}_+^N$. A commonly overlooked fact is that one may have strict containment in this relation. In our paper we study such mappings, and provide a complete polyhedral characterization of $L(\mathbb{R}_+^{2^n-1})$ for a large family of aggregations. Our results allow us to provide new polynomially computable probability bounds that strictly improve on existing results of e.g., [27, 28]. We also obtain an $O(n^2)$ dimensional linear program that is equivalent with (2). An interesting side result is that there exists a somewhat surprising connection between problem (2) and the cut-polytope (a very different connection from the one pointed out by [15]).

2 Notation and terminology

For a positive integer $n$ let us define $V = [n] = \{1, 2, \ldots, n\}$, and define $\Omega = 2^V \setminus \{\emptyset\}$.

In this paper we focus on aggregations of the variables of (2) of the following type: To a hypergraph $\mathcal{E} = \{E_1, \ldots, E_N\} \subseteq 2^\Omega$ we associate

$$y^k = \sum_{S \in E_k} x_S \quad \text{for } k = 1, \ldots, N. \quad (3)$$

This defines a monotone linear mapping $L_{\mathcal{E}} : \mathbb{R}^\Omega \to \mathbb{R}^N$. In each of the following special cases, we choose $\mathcal{E}$ in such a way that the objective function and the
equality constraints in (2) are easily representable (sometimes after applying additional aggregations of some of the equalities). From the above definition it is also immediate that $L_{\mathcal{E}}(\mathbb{R}_+^\Omega) \subseteq \mathbb{R}_+^N$. A rarely recognized property in the literature is that many times we have $L_{\mathcal{E}}(\mathbb{R}_+^\Omega) \neq \mathbb{R}_+^N$. Thus, the obtained relaxation could frequently be tightened with additional inequalities corresponding to the facets of the cone $L_{\mathcal{E}}(\mathbb{R}_+^\Omega)$.

We consider three aggregation models from the literature and provide a complete characterization of the cone $L_{\mathcal{E}}(\mathbb{R}_+^\Omega)$. This characterization leads to strictly improved bounds in two of these cases.

In the subsequent sections variables will be associated to various subfamilies of $\Omega$. One of the dividing parameters used many times is the cardinality of the subsets. Accordingly, we introduce

$$\Omega^\ell = \{ S \in \Omega \mid |S| = \ell \}$$

for $\ell = 1, \ldots, n$, and therefore we have the partition $\Omega = \bigcup_{\ell=1}^n \Omega^\ell$.

Let us start first recalling some of the aggregations of this type from the literature, and see if one can improve on them by describing the image of the positive orthant.

### 3 The Binomial Moment Problem

Let us first consider the aggregation with the family $\mathcal{E}^0 = \{ E^0_k \mid k = 1, \ldots, n \}$, where $E^0_k = \{ S \subseteq V \mid |S| = k \}$ for $k = 1, \ldots, n$ resulting in the so called binomial moment problem:

$$\max \left\{ \sum_{k=1}^n y^k \left| \begin{array}{c} \sum_{k=1}^n k y^k = \sum_{i \in V} p_i \\ \sum_{k=1}^n \binom{k}{2} y^k = \sum_{i,j \in V \atop i < j} p_{i,j} \\ y^k \geq 0 \text{ for } k = 1, \ldots, n. \end{array} \right. \right\}$$

Numerous papers dealt with this problem ([7], [9], [11], [13], [15], [21], [23], [24], and [25]). As we noted above the nonnegativity of the $x_S$, $S \in \Omega$ variables simply replaced by the nonnegativity of the aggregated $y^k$, $k = 1, \ldots, n$ variables. It turns out that in this case this is correct:

**Theorem 1** For this aggregation we have

$$L_{\mathcal{E}^0}(\mathbb{R}_+^\Omega) = \mathbb{R}_+^n.$$
**Proof:** Assume $\alpha_0, \ldots, \alpha_1$ are real numbers such that

$$\alpha_0 + \sum_{k=1}^{n} \alpha_k y^k \geq 0$$

whenever $x = (x_S \mid S \in \Omega) \in \mathbb{R}_+^\Omega$.

Since $x = 0$ is such a nonnegative vector, for which $y = 0$, and thus $\alpha_0 \geq 0$ follows immediately.

Furthermore we can consider the vectors $x \in \mathbb{R}_+^\Omega$, in which $x_S = 0$ for all $S \in \Omega, |S| \neq k$. For this case we have $y^j = 0$ for all $j \neq k$, and $y^k$ can take arbitrary positive values. Since we must have $\alpha_0 + \alpha_k \cdot y^k \geq 0$ for all these substitutions, we must have $\alpha_k \geq 0$, too. Since all coefficients in the above inequality must be nonnegative, it is a trivial consequence of the nonnegativity of the $y^k, k = 1, \ldots, n$ variables. $\square$

### 4 The Aggregation by Prékopa and Gao

Prékopa and Gao [27] introduced an aggregation of (2) that corresponds to the case when

$$E_1 = \{E_i^k \mid i \in V, k = 1, \ldots, n\},$$

where

$$E_i^k = \{S \in \Omega^k \mid i \in S\}.$$  

Thus, $L_{E_1}$ is a mapping from $\mathbb{R}_+^\Omega$ to the space of the $n^2$ variables defined by

$$y_i^k = \sum_{S \in \Omega^k \atop i \in S} x_S \quad \text{for all } i \in V \text{ and } k = 1, \ldots, n. \quad (4)$$

Using these definitions, they considered the aggregation

$$\max \ (\min) \ \sum_{k=1}^{n} \frac{1}{k} \sum_{i \in V} y_i^k \quad s.t. \quad \sum_{k=1}^{n} y_i^k = p(i) \quad \forall \ i \in V, \quad (5)$$

$$\sum_{k=2}^{n} (k - 1) y_i^k = \sum_{R \in \Omega^2 \atop i \in R} p_R \quad \forall \ i \in V$$

$$y_i^k \geq 0 \quad \forall \ i \in V, \text{ and } k = 1, \ldots, n.$$

They proved that this maximization problem has the same maximum value as the upper bound by [24], and the minimization problem has the same value as
the lower bound by [22]. Let us denote by \( PG \) the linear programming problem formed by (5) and by \( \text{LB}(PG) \) and \( \text{UB}(PG) \) the corresponding minimum and maximum values.

We can observe that in this case however \( \text{LE}_1(\mathbb{R}_+^\Omega) \neq \mathbb{R}_+^{n^2} \), thus formulation (5) could potentially be tightened up.

To see this, let us observe first that by (4) we have the equalities

\[
\sum_{S \subseteq V \mid i \notin S} x_S = \sum_{j \in V \setminus \{i\}} y_j^k - (k - 1) \cdot y_i^k
\]

for all \( i \in V \) and \( k = 1, \ldots, n \). Thus, the inequalities

\[
\sum_{j \in V \setminus \{i\}} y_j^k - (k - 1) \cdot y_i^k \geq 0 \quad (6)
\]

are valid inequalities for \( \text{LE}_1(\mathbb{R}_+^\Omega) \), for all \( i \in V \) and \( 1 \leq k \leq n \), and they are not linear consequences of the nonnegativities in (5).

Let us introduce the convex cone

\[
U^1 = \left\{ y \in \mathbb{R}_+^{n^2} : \sum_{j \in V \setminus \{i\}} y_j^k - (k - 1) \cdot y_i^k \geq 0 \quad \forall \ i \in V \text{ and } k = 1, \ldots, n \right\}
\]

Then we have the relations

\[
\text{LE}_1(\mathbb{R}_+^\Omega) \subseteq U^1 \subsetneq \mathbb{R}_+^{n^2}. \quad (7)
\]

Let us pause for a moment, and note that by its definition \( \text{LE}_1(\mathbb{R}_+^\Omega) \) is a convex cone, however, it is far from obvious that it is a polyhedral convex cone. Our first result in this section is to prove that in fact it is a polyhedral convex cone, and we provide a full characterization of its facets.

For real numbers \( \alpha_0, \alpha_i^k, i \in V, k = 1, \ldots, n \) we call the inequality

\[
\alpha_0 + \sum_{k=1}^{n} \sum_{i \in V} \alpha_i^k \cdot y_i^k \geq 0 \quad (8)
\]

a valid inequality for \( \text{LE}_1(\mathbb{R}_+^\Omega) \) if it holds for all \( x \in \mathbb{R}_+^\Omega \) under the substitutions (4). Our first observation is that the tightest valid inequalities have a special format.

**Lemma 2** If (8) is a tightest valid inequality for \( \text{LE}_1(\mathbb{R}_+^\Omega) \), then we must have \( \alpha_0 = 0 \), and there exists an integer \( 1 \leq k \leq n \) such that \( \alpha_i^k = 0 \) for all \( i \in V \) and \( \ell \neq k \).

**Proof:** Let us note first that for \( x = 0 \in \mathbb{R}_+^\Omega \) we have \( y_i^k = 0 \) for all \( i \in V \) and \( k = 1, \ldots, n \). Thus, \( \alpha_0 \geq 0 \) follows.
We claim next, that for an arbitrary value of \( k \) \((1 \leq k \leq n)\) the inequality

\[
\sum_{i \in V} \alpha_i^k y_i^k \geq 0
\]

is also a valid inequality for \( L_{E_1}(\mathbb{R}^{\Omega_+}) \). For this let us denote the left hand side of the above inequality as \( F_k(x) \) for \( x \in \mathbb{R}^{\Omega_+} \), \( k = 1, \ldots, n \), assuming the substitutions \( (1) \). Let us also note that this expression depends only on variables \( x_S \) with \( |S| = k \). Consequently we can assume that \( x_S = 0 \) for all \( S \in \Omega \) with \( |S| \neq k \). Assume then indirectly that the above inequality is not valid, that is that there exits a vector \( x \in \mathbb{R}^{\Omega_+} \) with \( x_S = 0 \) for all \( S \in \Omega \) with \( |S| \neq k \) such that \( F_k(x) < 0 \). For such a vector, and for any positive real \( \lambda > 0 \) we have that the left hand side of \( (8) \) is equal to

\[
\alpha_0 + F_k(\lambda \cdot x) = \alpha_0 + \lambda \cdot F_k(x)
\]

which for large \( \lambda \) values would turn negative, contradicting the validity of \( (8) \). This contradiction, when applied for all values of \( k \), and the nonnegativity of \( \alpha_0 \) implies that \( (8) \) is a linear consequence of the inequalities

\[
\sum_{i \in V} \alpha_i^k y_i^k \geq 0 \quad \forall k = 1, \ldots, n.
\]

\( \square \)

**Lemma 3** Given reals \( \alpha_i, i \in V \), and a integer \( 1 \leq k \leq n \), the inequality

\[
\sum_{i \in V} \alpha_i^k y_i^k \geq 0 \quad (9)
\]

is valid for \( L_{E_1}(\mathbb{R}^{\Omega_+}) \) if and only if for all subsets \( S \in \Omega^k \) we have

\[
\sum_{i \in S} \alpha_i \geq 0.
\]

**Proof:** By Lemma \( \square \) all valid inequalities for \( L_{E_1}(\mathbb{R}^{\Omega_+}) \) have the form like in \( (9) \). Viewing the left hand side as a linear combination of the \( x_S, S \in \Omega^k \) variables, it is easy to see that

\[
\sum_{i \in S} \alpha_i
\]

is the coefficient of \( x_S \) in this linear combination, for all \( S \in \Omega^k \). Thus, if this quantity was negative for a subset \( S \in \Omega^k \), then changing the value of \( x_S \) to a larger value, while not changing the values of the other \( x_P, P \in \Omega^k, P \neq S \) variables would strictly decrease (at a linear rate) the left hand side of \( (9) \). Since \( x_S \) could take an arbitrarily large value, the claim follows. \( \square \)

Our main result in this section is the following equality:
Theorem 4

\[ L_{\mathcal{E}_1}(\mathbb{R}^\Omega_+) = U^1. \]

**Proof:** According to (7), \( U^1 \) is not smaller than \( L_{\mathcal{E}_1}(\mathbb{R}^\Omega_+) \). Assume indirectly that \( U^1 \neq L_{\mathcal{E}_1}(\mathbb{R}^\Omega_+) \), and choose a feasible solution \( y \in U^1 \setminus L_{\mathcal{E}_1}(\mathbb{R}^\Omega_+) \). This implies that \( y \) must violate one of the valid inequalities for \( L_{\mathcal{E}_1}(\mathbb{R}^\Omega_+) \). According to Lemmas 2 and 3 this (violated) inequality should look like

\[ \sum_{i \in V} \alpha_i \cdot y_i^k < 0. \] (10)

According to Lemma 3, permuting the coefficients in this inequality also yields a valid inequality for \( L_{\mathcal{E}_1}(\mathbb{R}^\Omega_+) \). Thus we can assume a permutation that yields the lowest left hand side in (10), i.e., we can assume that

\[
\begin{align*}
\alpha_1 &\leq \alpha_2 \leq \cdots \leq \alpha_n. \\
y^k_1 &\geq y^k_2 \geq \cdots \geq y^k_n.
\end{align*}
\] (11)

Note that by (10) we must have \( \alpha_1 < 0 \), and by Lemma 3 \( \alpha_1 + \cdots + \alpha_k \geq 0 \), implying \( \alpha_k > 0 \).

Note that after the sorting of the components as in (11), if we decrease \( \alpha_i \) by epsilon, and increase \( \alpha_j, j > i \) by the same \( \epsilon \), then the left hand side of (10) can only decrease. Let us perform this operations, decreasing \( \alpha_1 \) and increasing \( \alpha_j \) for \( 2 \leq j < k \) until we arrive to the vector

\[ \beta_i = \begin{cases} 
\alpha_1 - (k-2)\alpha_k + \alpha_2 + \cdots + \alpha_{k-1} & \text{if } i = 1, \\
\alpha_k & \text{if } 2 \leq i \leq k, \\
\alpha_i & \text{if } i > k.
\end{cases} \]

Note that we have \( \beta_1 \geq -(k-1)\alpha_k \), and \( \beta_i \geq \alpha_k \) for all \( i = 2, \ldots, n \). Thus we can write the chain of inequalities

\[
0 > \sum_{i \in V} \alpha_i \cdot y_i^k \geq \sum_{i \in V} \beta_i \cdot y_i^k \geq \alpha_k \left( -(k-1)y^k_1 + \sum_{i=2}^n y^k_i \right) \geq 0
\]

Here the last inequality follows since \( \alpha_k > 0 \) and \( y \in U^1 \). The derived contradiction proves that \( U^1 = L_{\mathcal{E}_1}(\mathbb{R}^\Omega_+) \), as claimed. \( \square \)

Now, we fully characterize facets of a polyhedral convex cone, and (5) is tighten up with \( U^1 \).
\[
\max \text{ (min) } \sum_{k=1}^{n} \frac{1}{k} \sum_{i \in V} y^k_i \\
\text{s.t.} \sum_{k=1}^{n} y^k_i = p(i) \quad \forall \ i \in V, \\
\sum_{k=2}^{n} (k-1) \cdot y^k_i = \sum_{R \in \Omega} p_R \quad \forall \ i \in V \quad (12) \\
\sum_{j \in V \setminus \{i\}} y^k_j - (k-1) \cdot y^k_i \geq 0 \quad \forall \ i \in V, \text{ and } k = 1, \ldots, n. \\
y^k_i \geq 0 \quad \forall \ i \in V, \text{ and } k = 1, \ldots, n.
\]

Let us denote by \( IP_G \) the linear programming problem formed by (12) and by \( LB(IP_G) \) and \( UB(IP_G) \) the corresponding minimum and maximum values.

| \( n \) | \( UB(IP_G) \) Mean | Std | Max | \( UB(IP_G) \) Mean | Std | Max | \( LB(IP_G) \) Mean | Std | Max | \( LB(IP_G) \) Mean | Std | Max |

Table 1: Mean, standard deviation, and maximum value of the percentage relative error.

In Table 1 we compare the bounds. For upper bounds, we generate 100 instances for \( n \) from 7 to 15; for \( n \) from 16 to 18, we generate 50 instances. And, for lower bounds, we generate 100 instances for \( n \) from 7 to 13; for \( n \) from 14 to 18, we generate 20 instances. Let \( opt \) be the tightest possible bound, which can be achieved by solving (1). Then we calculate the percentage relative error by \( 100 \times | \text{ bound } - \text{ opt } | / \text{ opt } \). We can see that in many examples the addition of \( U^1 \) improves strictly both the lower and upper bounds.
5 The Aggregation by Yang et al.

In [28] a novel aggregation model was considered that in our terms and notation corresponds to the case of

\[ E^2 = \{ E_Q^k \mid Q \in \Omega_1 \cup \Omega^2, \; |Q| \leq k \leq n \}, \]

where

\[ E_Q^k = \{ S \subseteq V \mid Q \subseteq S, \; |S| = k \} \; \forall \; Q \in \Omega_1 \cup \Omega^2, \; |Q| \leq k \leq n. \]

In other words, they consider the aggregation, defined by the following mapping

\[ L_{E^2}(x) = y = (y_Q^k \mid Q \in \Omega^1 \cup \Omega^2, \; |Q| \leq k \leq n), \]

where

\[ y_Q^k = \sum_{S \in \Omega^k \subseteq S} x_S \; \forall \; Q \in \Omega^1 \cup \Omega^2, \; |Q| \leq k \leq n. \quad (13) \]

Note also that this notation is somewhat redundant, since we have the equalities

\[ y_{\{i\}}^k = \frac{1}{k-1} \sum_{Q \in \Omega^2, i \in Q} y_Q^k \quad (14) \]

for all \( i \in V \) and \( 2 \leq k \leq n \). Note finally that in general there are no other linear relations between these variables. Thus in fact, this aggregation is a linear mapping \( L_{E^2} \) into the space of dimension \( N = n + (n-1) \cdot \binom{n}{2} \).

It is easy to verify that with this aggregation the objective function and the left hand sides of the equality constraints in (2) can be represented as linear expressions, Namely we have

\[
\sum_{S \in \Omega} x_S = \sum_{Q \in \Omega^1} y_Q^1 + \sum_{k=2}^{n} \frac{1}{k-1} \sum_{Q \in \Omega^2} y_Q^k \quad \rightarrow \max \quad (E1)
\]

\[
\sum_{S \in \Omega \mid \ i \in S} x_S = y_{\{i\}}^1 + \sum_{k=2}^{n} \frac{1}{k-1} \sum_{Q \in \Omega^2, i \in Q} y_Q^k = p_{\{i\}} \; \forall \; i \in V \quad (E2)
\]

\[
\sum_{S \in \Omega \mid \ Q \subseteq S} x_S = \sum_{k=2}^{n} y_Q^k = p_Q \; \forall \; Q \in \Omega^2 \quad (E3)
\]

\[
y_{\{i\}}^k \geq 0 \; \forall \; i \in V, 1 \leq k \leq n \quad (E4)
\]

\[
y_Q^k \geq 0 \; \forall \; Q \in \Omega^2, 2 \leq k \leq n \quad (E5)
\]

leading to a quite tight polynomial size aggregation of our exponential sized original problem. Note that inequalities (E4) include redundant ones, according
to (14), but we keep this redundancy, since it will help us to realize a more
general structure to these inequalities.

The nonnegativity of the $y_{i}^1$, $i \in V$ and $y_Q^k$, $Q \in \Omega^2$ variables are implied
by their definition (13), since all $x_S$ variables are nonnegative. The authors
of this aggregation however noticed that in this case $L_{E^2}(\mathbb{R}_+^\Omega) \neq \mathbb{R}_+^N$. In fact,
several other nonnegative combination of the $x_S$ variables are linear functions
of $y$. For instance, we can note that for $i \in V$ and integers $2 \leq k \leq n$ we have

$$\sum_{S \in \Omega^k \atop R \cap S = \emptyset} x_S = \frac{1}{(k^2/2)} \sum_{Q \in \Omega^2} y_Q^k - \frac{1}{k-1} \sum_{Q \in \Omega^2 \atop |R \cap Q| = 1} y_Q^k \geq 0$$

Note that the nonnegativity of this expression is not a consequence of the non-
egativity of $y$. Thus the nonnegativity of this expression could be added to
the aggregation, tightening it up. In fact in (28) the authors came up with the
following additional nonnegative combinations of the $x$ variables that can be
expressed as a linear function of the $y$ variables when we use substitutions (13).

$$\sum_{S \in \Omega^k \atop R \cap S = \emptyset} x_S = \frac{1}{k-1} \left( \sum_{Q \in \Omega^2} y_Q^k - \frac{k-2}{k-1} \sum_{Q \in \Omega^2 \atop |R \cap Q| = 1} y_Q^k \right) \geq 0 \quad (E6)$$

for all $R \in \Omega^2$, and $2 \leq k \leq n$.

$$\sum_{S \in \Omega^k \atop R \cap S = \emptyset} x_S = \frac{1}{k-1} \left( \sum_{Q \in \Omega^2} y_Q^k - (k-2)y_R^k \right) \geq 0 \quad (E7)$$

for all $i \in V$, $i \in R \in \Omega^2$, and $2 \leq k \leq n$.

$$\sum_{S \in \Omega^k \atop (R \cap S) \in \{0,3\}} x_S = \frac{1}{(k^2/2)} \sum_{Q \in \Omega^2} y_Q^k - \frac{1}{k-1} \sum_{Q \in \Omega^2 \atop |R \cap Q| = 1} y_Q^k + \frac{k-3}{k-1} \sum_{Q \in \Omega^2 \atop Q \subseteq R} y_Q^k \geq 0 \quad (E8)$$

for all $R \in \Omega^3$ and $2 \leq k \leq n$.

$$\sum_{S \in \Omega^k \atop (R \cap S) \in \{1\}} x_S = \frac{1}{k-1} \sum_{Q \in \Omega^2} y_Q^k + y_R^k - \frac{k-2}{k-1} \sum_{Q \in \Omega^2 \atop Q \subseteq R} y_Q^k \geq 0 \quad (E9)$$

for all $i \in V$, $i \in R \in \Omega^3$, and $2 \leq k \leq n$. 

11
Let us remark that the polynomial sized linear programming aggregation (E1) - (E9) proposed by [28] provides a bound for our original problem that is not weaker than the one proposed by [27] in the previous subsection. This is because problem (E) and its strengthening by \( U_1 \) are both aggregations of problem (E1) - (E9). To see this, note that \( y^1_i, i \in V \) have identical definitions in both aggregations (see (4) and (13)), and for \( y^k_i, i \in V \) and \( k = 2, ..., n \) we have the equalities (14). Furthermore the inequalities defining \( U_1 \) are consequences of (E4) - (E7).

The question arise: do the inequalities (E4) - (E9) describe the cone \( L_{E2}(\mathbb{R}_+^\Omega) \)? The answer is no. In what follows we provide an exact polyhedral description of \( L_{E2}(\mathbb{R}_+^\Omega) \).

Let us start observing that the analogue of Lemma 2 can be shown for this case, too.

For real numbers \( \alpha_0, \alpha^k_Q, Q \in \Omega^1 \cup \Omega^2, k = 1, ..., n \) we call the inequality

\[
\alpha_0 + \sum_{k=1}^n \sum_{Q \in \Omega^1 \cup \Omega^2} \alpha^k_Q \cdot y^k_Q \geq 0 \tag{15}
\]

a valid inequality for \( L_{E2}(\mathbb{R}_+^\Omega) \) if it holds for all \( x \in \mathbb{R}_+^\Omega \) under the substitutions (13).

Lemma 5 If (15) is a tightest valid inequality for \( L_{E2}(\mathbb{R}_+^\Omega) \), then we must have \( \alpha_0 = 0 \), and there exists an integer \( 1 \leq k \leq n \) such that \( \alpha^k_Q = 0 \) for all \( Q \in \Omega^1 \cup \Omega^2 \) and \( \ell \neq k \).

Proof: Let us note first that for \( x = 0 \in \mathbb{R}_+^\Omega \) we have \( y^k_Q = 0 \) for all \( Q \in \Omega^1 \cup \Omega^2 \) and \( k = 1, ..., n \). Thus, \( \alpha_0 \geq 0 \) follows.

We claim next, that for an arbitrary value of \( k (1 \leq k \leq n) \) the inequality

\[
\sum_{k=1}^n \sum_{Q \in \Omega^1 \cup \Omega^2} \alpha^k_Q \cdot y^k_Q \geq 0
\]

is also a valid inequality for \( L_{E2}(\mathbb{R}_+^\Omega) \). For this let us denote the left hand side of the above inequality as \( F^k(x) \) for \( x \in \mathbb{R}_+^\Omega, k = 1, ..., n \), assuming the substitutions (13). Let us also note that this expression depends only on variables \( x_S \) with \( |S| = k \). Consequently we can assume that \( x_S = 0 \) for all \( S \in \Omega \) with \( |S| \neq k \). Assume then indirectly that the above inequality is not valid, that is that there exists a vector \( x \in \mathbb{R}_+^\Omega \) with \( x_S = 0 \) for all \( S \in \Omega \) with \( |S| \neq k \) such that \( F^k(x) < 0 \). For such a vector, and for any positive real \( \lambda > 0 \) we have that the left hand side of (15) is equal to

\[
\alpha_0 + F^k(\lambda \cdot x) = \alpha_0 + \lambda \cdot F^k(x)
\]

which for large \( \lambda \) values would turn negative, contradicting the validity of (15). This contradiction, when applied for all values of \( k \), and the nonnegativity of
\(\alpha_0\) implies that (15) is a linear consequence of the inequalities

\[
\sum_{k=1}^{n} \sum_{Q \in \Omega_1 \cup \Omega_2} \alpha_Q \cdot y_Q \geq 0 \quad \forall \ k = 1, \ldots, n.
\]

Thus we can focus on subsets of a certain size. Let us also note that for sets \(S \in \Omega^1\) we have \(x_S = y^S \geq 0\) by (14), thus we can focus on set sizes \(2 \leq k \leq n\). Note also that all inequalities (14)-(19) involve \(y_Q^k\) variables for a fixed value of \(k\).

For notational simplicity let us introduce \(\Omega_0 = \{\emptyset\}\), set \(\Sigma = \Omega_0 \cup \Omega^1 \cup \Omega^2\), and define for \(2 \leq k \leq n\)

\[
y_Q^k = \sum_{S \in \Omega^k} x_S = \frac{1}{2} \sum_{Q \in \Omega^2} y_Q^k,
\]

where the second equality follows by the definitions of the \(y^k\) variables, see (13) and (16).

Let us now fix a \(2 \leq k \leq n\) value, and introduce \(x^k = (x_S \mid S \in \Omega^k)\) and \(y^k = (y_Q^k \mid Q \in \Sigma)\). Recall that the \(y_Q^k\) variables are in fact (linear) functions of \(x^k\) according to (13) and (16). Thus, for a real vector \(\alpha \in \mathbb{R}^\Sigma\) we say that the inequality

\[
\sum_{Q \in \Sigma} \alpha_Q \cdot y_Q^k \geq 0
\]

is valid if it holds for all nonnegative \(x^k \in \mathbb{R}^{\Omega^k}\). We denote the left hand side of inequality (17) by \(L_{\alpha}(\ast)\), where \(\ast\) indicates the set of variables we want to use. Thus inequality (17), as it is written, is the expression \(L_{\alpha}(y^k) \geq 0\). We can also view the left hand side as a function of \(x^k\), and then we write \(L_{\alpha}(x^k)\). Due to the relations (13) and (16), we can also write \(L_{\alpha}(y_Q^k \mid Q \in \Omega^2)\). Note finally that the same \(\alpha\) vector can be used as coefficients for different \(k\) values, e.g., \(L_{\alpha}(y^\ell) = L_{\alpha}(x^\ell)\) for \(\ell \neq k\) are also well defined.

In what follows we characterize all valid inequalities (for all \(2 \leq k \leq n\)), and hence provide a complete description for \(L_{\alpha}(\mathbb{R}^{\Omega^k})\). To arrive to such a complete description, we consider a (perhaps surprising) mapping into the space of nonnegative quadratic pseudo-Boolean functions.

Introduce \(Z = (Z_i \mid i \in V) \in \{0,1\}^V\), and associate to inequality (17) the quadratic pseudo-Boolean function (or QPBF in short)

\[
F_{\alpha}(Z) = \sum_{Q \in \Sigma} \alpha_Q \cdot \prod_{i \in Q} Z_i,
\]

where we have \(\prod_{i \in \emptyset} Z_i = 1\) by definition. For a subset \(S \subseteq V\) we denote by \(\chi_S \in \{0,1\}^V\) its characteristic vector.
Lemma 6  Given a real vector \( \alpha \in \mathbb{R}^\Sigma \) and a subset \( \emptyset \neq S \subseteq V \), the real value \( F_\alpha(\chi_S) \) is the coefficient of \( x_S \) in \( L_\alpha(x^{|S|}) \).

Proof: Observe that \( x_S \) appears in \( y^k \) with coefficient 1 exactly when \( Q \subseteq S \), and we have
\[
F_\alpha(\chi_S) = \sum_{Q \subseteq S} \alpha_Q
\]
by (18).

\( \square \)

Corollary 1 If \( F_\alpha(Z) \geq 0 \) for all \( Z \in \{0, 1\}^V \), then \( L_\alpha(y^k) \geq 0 \) is a valid inequality for all \( k = 2, \ldots, n \).

Proof: By Lemma 6 the coefficients of the \( x_S, S \in \Omega \) variables are all nonnegative, since \( F_\alpha \) is a nonnegative function. Thus \( L_\alpha(y^k) \) is a nonnegative real for all \( x^k \in \mathbb{R}^\Sigma_+ \).

\( \square \)

Since linear combinations of QPBF-s is again a QPBF, the set of nonnegative QPBF-s form a convex cone (in the space of their coefficients, i.e., in dimension \( 1 + n + \binom{n}{2} \)). It is well-known that this cone is polyhedral, and its extremal rays are in a one-to-one correspondence with the facets of the cut polytope [12]. Let us denote by \( \mathcal{G} \) the finite set of extremal nonnegative QPBF-s, and thus \( \text{cone}(\mathcal{G}) \) is the set of nonnegative QPBF-s.

Let us now consider the polyhedral cone defined by the valid inequalities corresponding to nonnegative QPBFs.

\[
U^2 = \left\{ y \left| \begin{array}{l}
y^1_i \geq 0 \quad \forall \ i \in V, \\
\sum_{Q \subseteq \Sigma} \alpha_Q \cdot y^k_Q \geq 0 \quad \forall \ \alpha \in \mathbb{R}^\Sigma \text{ and } 2 \leq k \leq n \\
\text{such that } F_\alpha(Z) \in \mathcal{G}
\end{array} \right. \right\}
\] (19)

Since by Corollary 1 all these inequalities are valid for \( L_{\mathcal{E}^2(\mathbb{R}^\Sigma_+^\Omega)} \), we have the relation
\[
L_{\mathcal{E}^2(\mathbb{R}^\Sigma_+^\Omega)} \subseteq U^2
\]

In what follows we show that in fact we have equality here. The main difficulty in proving this claim stems from the fact that an inequality of the form (17) may correspond to multiple QPBF-s \( F_\alpha(Z) \). This is because of the linear dependencies, like equations (14) and (16), we have in the \( y^k \) space. In fact, to a given QPBF we have several corresponding inequalities of the form (17), with different \( k \) values. Some may be valid for \( L_{\mathcal{E}^2(\mathbb{R}^\Sigma_+^\Omega)} \) and some may not. More precisely, a real vector \( \alpha \) as coefficients in such an inequality may yield a valid one with variables \( y^k \), while if we replace \( y^k \) with \( y^\ell \) for some \( \ell \neq k \), then the same expression may not be a valid inequality. Thus we need a mechanism that can transform a QPBF into another one, without changing a corresponding inequality (for a particular value of \( k \)).

A very helpful observation is the following claim:
Lemma 7 Given an integer $2 \leq k \leq n$, let $\alpha \in \mathbb{R}^\Sigma$ be the coefficient vector of the QPBF

$$
\left( k - \sum_{i \in V} Z_i \right)^2 = k^2 - (2k - 1) \cdot \sum_{i \in V} Z_i + 2 \cdot \sum_{1 \leq i < j \leq n} Z_i Z_j.
$$

Then $L_\alpha(y^k_Q \mid Q \in \Omega^2)$ is the identically zero function.

Proof: Let us observe first that the equality in the above formula holds, because for binary variables we have $Z^2_i = Z_i$ for all $i \in V$. Thus we have

$$
L_\alpha(y^k) = k^2 \cdot y^k_0 - (2k - 1) \sum_{Q \in \Omega^1} y^k_Q + 2 \sum_{Q \in \Omega^2} y^k_Q.
$$

The claim now follows by elementary algebra, using the equalities (14) and (16).

$$
L_\alpha(y^k_Q \mid Q \in \Omega^2) = k^2 \left( \frac{1}{k} \sum_{Q \in \Omega^2} y^k_Q \right) - (2k - 1) \sum_{i \in V} \left( \frac{1}{k-1} \sum_{Q \in \Omega^2} y^k_Q \right)
+ 2 \sum_{Q \in \Omega^2} y^k_Q
$$

Thus, for an arbitrary $Q \in \Omega^2$ the coefficient of $y^k_Q$ in the above expression is

$$
k^2 \frac{1}{k} - (2k - 1) \frac{2}{k-1} + 2 = 0.
$$

Note that $L_\alpha(y^l_Q \mid Q \in \Omega^2)$ may not be identically zero if $l \neq k$.

Now, we are ready to claim our main result in this section.

Theorem 8

$$
L_{E^2}(\mathbb{R}^\Omega) = U^2
$$

Proof: For $k = 1$ we have $y^1_i = x_{\{i\}}$ for all $i \in V$, and clearly no other inequality of these variables can be minimally valid. For $k \geq 2$, the containment “$\subseteq$” is implied by Corollary 1. To see the reverse containment, let us assume that $\alpha^* \in \mathbb{R}^\Sigma$ is a real vector for which the inequality

$$
\sum_{Q \in \Sigma} \alpha^*_Q y^k_Q \geq 0
$$

is valid, and for which $F_{\alpha^*}(Z)$ is not a nonnegative QPBF. Let us introduce

$$
\gamma = \min_{Z \in \{0,1\}^V} F_{\alpha^*}(Z) < 0.
$$

15
Then,

\[ F_{\alpha}'(Z) = F_{\alpha}(Z) - \gamma \left( k - \sum_{i \in V} Z_i \right)^2 \]

is a nonnegative QPBF, and \( L_{\alpha}^*(y_Q^k \mid Q \in \Omega^2) \geq 0 \) is identical to \( L_{\alpha}^*(y_Q^k \mid Q \in \Omega^2) \geq 0 \) by Lemma 7.

Note that the inequalities introduced by [28] correspond to some known extremal nonnegative QPBFs, see [5] or see Proposition 18 in [6]. Namely, inequality (E4) corresponds to \( Z_i \geq 0 \). Inequality (E5) corresponds to \( Z_i Z_j \geq 0 \). Inequality (E7) corresponds to \( Z_i(1 - Z_j) \geq 0 \). Inequality (E6) corresponds to \( (1 - Z_i)(1 - Z_j) \geq 0 \). Inequality (E8) corresponds to \( Z_i Z_j Z_\ell + (1 - Z_i)(1 - Z_j)(1 - Z_\ell) = 1 - Z_i - Z_j - Z_\ell + Z_i Z_j + Z_i Z_\ell + Z_j Z_\ell \geq 0 \).

Finally, inequality (E9) corresponds to

\[ Z_i(1 - Z_j)(1 - Z_\ell) + (1 - Z_i)Z_j Z_\ell = Z_i - Z_i Z_j - Z_i Z_\ell + Z_j Z_\ell \geq 0 \]

These nonnegative quadratic functions are known to belong to \( \mathcal{G} \), see [4]. There are however many more members in \( \mathcal{G} \) that can be added to tighten up the formulation. In fact the set \( \mathcal{G} \) is partitioned \( \mathcal{G} = \mathcal{G}^2 \cup \mathcal{G}^3 \cup \cdots \cup \mathcal{G}^n \) into families of increasing complexity, and it is known that none of these is empty, and together they contain exponentially many functions [4].

By the above analysis and results, the model proposed by [28] utilizes exactly the members of \( \mathcal{G}^2 \cup \mathcal{G}^3 \). Let us denote by YAT their model and by \( LB(YAT) \) and \( UB(YAT) \) the corresponding minimum and maximum values.

\[
\begin{align*}
\text{max (min)} \quad & \sum_{Q \in \Omega^1} y_Q^1 + \sum_{k=2}^n \frac{1}{\binom{k}{2}} \sum_{Q \in \Omega^2} y_Q^k \\
\text{s.t.} \quad & y_{\{i\}} + \sum_{k=2}^n \frac{1}{k-1} \sum_{Q \in \Omega^2} y_Q^k = p_{\{i\}} \quad \forall i \in V \\
& \sum_{k=2}^n y_Q^k = p_Q \quad \forall Q \in \Omega^2 \\
& y_{\{i\}} \geq 0 \quad \forall i \in V \quad 1 \leq k \leq n \\
& \sum_{Q \in \Sigma} \alpha_Q \cdot y_Q^k \geq 0 \quad \forall 2 \leq k \leq n \quad \alpha \in \mathbb{R}^\Sigma \quad \text{and} \quad F_{\alpha}(Z) \in \mathcal{G}^2 \cup \mathcal{G}^3
\end{align*}
\]

The above theorem provides a surprising connection to the cone of nonnegative quadratic pseudo-Boolean functions, which is known to be equivalent with
the cut-polytope (see [12]). It was already known that the dual of problem (2) has strong connections to the cut-polytope [13, 14], but this connection to an aggregation of the primal problem is different.

Let us denote by $\text{QP B}$ the linear programming problem formed by the objective (E1), the equalities (E2) and (E3), and the linear inequalities (exponentially many) describing $L_{E^2}(R_+\Omega)$ as in Theorem 8, and denote by $\text{LB}(\text{QP B})$ and $\text{UB}(\text{QP B})$ the minimum and maximum values of it.

$$\max \ (\min) \ \sum_{Q\in\Omega^1} y_Q^1 + \sum_{k=2}^{n} \frac{1}{(2)} \sum_{Q\in\Omega^2} y_Q^k \ s.t.$$ $$y_{i(1)}^1 + \sum_{k=2}^{n} \frac{1}{(k-1)} \sum_{Q\in\Omega^2} y_Q^k = p(i) \ \forall \ i \in V$$ $$\sum_{k=2}^{n} y_Q^k = p_Q \ \forall \ Q \in \Omega^2$$ $$y_Q^k \geq 0 \ \forall \ i \in V \ \ 1 \leq k \leq n$$ $$\sum_{Q\in\Sigma} \alpha_Q \cdot y_Q^k \geq 0 \ \forall \ 2 \leq k \leq n \ \text{where} \ F_\alpha(Z) \in G$$ \hfill (21)

**Corollary 2** We have the equalities

$$\text{LB}(H) = \text{LB}(\text{QP B}) \quad \text{and} \quad \text{UB}(H) = \text{UB}(\text{QP B}).$$

**Proof:** By Theorem 8 for every feasible solution $y$ of problem $\text{QP B}$ there exists a corresponding feasible solution $x$ of problem (2) satisfying the equalities (13). \hfill □

In practice, we cannot use all inequalities described by Theorem 8. In this paper we suggest to use some of the functions in $G^4 \cup \cdots \cup G^n$ to tighten up the formulation (E1) - (E9).

For instance, we recall the following result from [3]: given a subset of the literals $W \subseteq \{Z_1, \ldots, Z_n\} \cup \{1 - Z_1, \ldots, 1 - Z_n\}$ of cardinality $|W| \geq 4$ and an integer $1 \leq \gamma \leq |W| - 2$, then the function defined by following binomial expression

$$G_{W,\gamma}(Z) = \left( \sum_{w\in W} w - \gamma \right) \choose 2$$

is a member of $G^{|W|}$. As an example, consider $W = \{Z_1, Z_2, 1 - Z_3, Z_4\}$ and $\gamma = 2$. Then we have
\[ G_{W,\gamma} (Z) = \left( Z_1 + Z_2 + (1 - Z_3) + Z_4 - 2 \right) \]
\[ \quad = \left( Z_1 + Z_2 - Z_3 + Z_4 - 1 \right) (Z_1 + Z_2 - Z_3 + Z_4 - 2) \]
\[ \quad = \frac{(Z_1 + Z_2 - Z_3 + Z_4)^2 - 3(Z_1 + Z_2 - Z_3 + Z_4) + 2}{2} \]
\[ \quad = 1 - Z_1 - Z_2 + Z_3 - Z_4 + Z_1 Z_2 - Z_1 Z_3 + Z_1 Z_4 - Z_2 Z_3 + Z_2 Z_4 - Z_3 Z_4 \]

Please recall that we have \( Z_i^2 = Z_i \) and \( (1 - Z_i)^2 = 1 - Z_i \) for all \( i \in V \), since these expressions take only binary values. Thus, from this small example we get the inequality

\[ y_k^1 - y_k^{(1)} - y_k^{(2)} + y_k^{(3)} - y_k^{(4)} + y_k^{(1,2)} - y_k^{(1,3)} + y_k^{(1,4)} - y_k^{(2,3)} + y_k^{(2,4)} - y_k^{(3,4)} \geq 0. \]

Let us introduce these inequalities with \( |W| = 4 \) and \( \gamma = 1, 2 \). Since we utilize some functions in \( G^4 \), we call this weaker model as problem \( QPB^- \) (and denote by \( LB(QPB^-) \) and \( UB(QPB^-) \) the corresponding minimum and maximum values). Note that \( QPB^- \) is still a polynomial sized formulation, and thus we can compute the corresponding lower and upper bounds in polynomial time.

**Corollary 3** We have the inequalities

\[
LB(H) = LB(QPB) \geq LB(QPB^-) \geq LB(YAT) \quad \text{and} \quad UB(H) = UB(QPB) \leq UB(QPB^-) \leq UB(YAT).
\]

\[\square\]

In fact, we do not generate all such inequalities, but add them one-by-one, as needed. The following table with numerical results demonstrates that already the addition of a few new inequalities provide strict improvements when compared to \( [20] \).

Table 2: Mean, standard deviation, and maximum value of the percentage relative error.
In Table 2 we compare the bounds provided by these models. For upper bounds, we generate 100 instances from n from 8 to 10; for n from 11 to 15, we generate 20 instances. For lower bounds, we generate 100 instances for n from 8 to 10; for n from 11 to 12, we generate 20 instances; for n from 13 to 15, we generate 10 instances. Note that in many cases we get a strict improvement by the addition of only a few members of $G^4$ of the above type.
