Abstract

Theoretical work has shed light on the phase behavior of idealized mixtures with random interactions. But many mixtures instead contain a large number of components that interact through a smaller number of features, leading to a structured interaction matrix. Here we consider such solutions with non-random interactions and derive mean-field conditions for thermodynamic stability and critical behavior. These conditions only depend on the distribution of components in the lower-dimensional space of features, and thereby strongly reduce the system’s complexity.

Main text

Determining the phase behavior of mixtures is an important goal of Statistical Physics, not least because of their prevalence in both nature and industrial applications. But while the thermodynamics of mixtures with few components is well understood theoretically [1], most functional mixtures like those observed in living cells [2] are made up from a large number of distinct components, and the principles underlying the phase and critical behavior of such multicomponent mixtures are less clear. Previous research on these systems has mostly focused on mixtures with random interactions and equimolar components [3–5] or on polydisperse systems with a continuous distribution of attributes [6,7]. For the latter, Sollich and others [6 –8] have shown analytically based on so-called moment methods that the cumulants of polydisperse attributes are important determinants for phase behavior. Similarly, pioneering work by Sear and Cuesta based on random matrix theory [3] and subsequent numerical and analytical studies [4,5] have clearly demonstrated that the variance in the intramolecular interaction strengths is an important indicator for phase behavior in random mixtures.

Different from these theoretical studies, in biological and physical examples interactions are likely neither continuous nor random but have structure governed by the physical details that underpin them. In lipid membranes, though there are thousands of chemical species, interactions are thought to be primarily driven by just a few features – the electrostatic and van-der-Waals interactions between headgroups, the degree of acyl-chain saturation, and the mismatch between hydrophobic height [9 –13]. In protein condensates interactions are likely mediated by a combination of specific motifs like repetitive binding domains, and less specific electrostatic and hydrophobic interactions [2, 14, 15]. In both cases the resulting interaction between pairs of components is plausibly determined by their respective features, leading to an effective pairwise interaction matrix which is non-random in a particular way: its rank, given by the number of independent features, is smaller than its dimension.

To systematically investigate the role of such interaction structures for phase behavior, in this work we present and analyze a family of models for mixtures with many components and a pairwise interaction matrix of variable rank. We derive analytic, mean-field conditions for the stability of phases and critical behavior and demonstrate how these results enable us to reduce the complexity of the multicomponent system to the generally lower-dimensional feature space.

Mean-field model. We specifically consider a family of multicomponent models with a pairwise interaction matrix of variable rank (see Fig. 1). The mixture is made up of \( N \) different component types, representing, for instance, different lipids and/or proteins. Component type \( i \) is characterized by a “feature vector” \( \vec{s}_i \) composed of \( R \) scalar features \( s_i^{(\alpha)} \in \mathbb{R}, \alpha=1, \ldots, R \). Each feature conveys an additive, Ising-like interaction with interaction strength \( J^{(\alpha)} \neq 0 \), and could be interpreted as arising from a particular protein domain, or from the lipid headgroup or tail. The corresponding lattice Hamiltonian reads \( \mathcal{H} = - \sum_{\alpha=1}^{R} J^{(\alpha)} \sum_{\langle xy \rangle} \sigma^{(\alpha)}(x) \sigma^{(\alpha)}(y) \) where \( \sum_{\langle xy \rangle} \) is the sum over all neighboring sites \( x,y \) on the lattice and \( \sigma^{(\alpha)}(x) = s_i^{(\alpha)} \) if site \( x \) is occupied by component type \( i \) (see [16] for a related model with a single feature).
The spinodal which is defined as the boundary of local thermodynamic stability, corresponds to the submanifold of compositions and temperature where the smallest eigenvalue of the Hessian matrix is zero. Since a matrix is invertible
if and only if all of its eigenvalues are non-zero, the spinodal is also the submanifold where the Hessian is singular but positive semi-definite – or, coming from all positive eigenvalues, the submanifold where the matrix becomes singular for the first time. Here we take advantage of the fact that $H_{ij}$ is the sum of a positive definite matrix $K_{ij}$ with inverse $K_{ij}^{-1} = \delta_{ij} \rho_i - \rho_i \rho_j$ and a lower rank contribution $UU^T$ arising from interactions. We use the Woodbury matrix identity \[^{19}\] on $K$ and $UU^T$ to invert $H$ and find that the Hessian is invertible if and only if $1 - UK^{-1}U^T = 1 - \text{Cov}$ is invertible; see Supplemental Material. Here, Cov is the covariance matrix between the (rescaled) features:

$$\text{Cov}_{\alpha \beta} = \left( \langle r^{(\alpha)}r^{(\beta)} \rangle_{\vec{\rho}} \right)^{(N)} - \left( \langle r^{(\alpha)} \rangle_{\vec{\rho}} \right)^{(N)} \left( \langle r^{(\beta)} \rangle_{\vec{\rho}} \right)^{(N)},$$

where the averages are taken with respect to the $N$-dimensional densities: $\langle X_{\alpha}^{(N)} \rangle = \sum_{i=1}^{N} \rho_i X_i$. The covariances among the features are thus measured with respect to the probability measure given by the mixture composition $\bar{\rho}_{\alpha}^{(N)}$. Cov is a true (positive definite) covariance matrix only if all $r^{(\alpha)} \in \mathbb{R}$ (or equivalently $J^{(\alpha)} > 0$). If some interaction strengths are negative, it is a pseudo-covariance matrix, amenable to a similar though more complex treatment (see Supplemental Material and discussion below). Furthermore, the rank of the covariance matrix $R_{\text{Cov}}$ corresponds to the maximal number of linearly independent feature vectors, $R_{\text{Cov}} \leq R$; see Supplemental Material.

**Thermodynamic stability** These results imply that the mixture becomes unstable when the largest eigenvalue of the covariance matrix $\lambda^{(1)} = 1$, i.e. when the variance along the first principal component (PC) of the (rescaled) feature distribution is 1. Importantly, this condition is independent of the number of different component types, including as limits the two-component mean-field Ising model and the infinite-component limit, as discussed in the context of polydisperse systems \[^{6}\].

**Direction of instability** If $1 - \text{Cov}$ is invertible, the inverse of the Hessian matrix $H^{-1}$ exists and is given by $H^{-1} = K^{-1} + K^{-1}U(1-\text{Cov})^{-1}U^TK^{-1}$. Using the eigendecomposition of the covariance matrix in terms of its (descending) eigenvalues $\lambda^{(\gamma)}, \gamma = 1, ..., R$ and the corresponding orthonormal eigenvectors $V^{(\gamma)}$ (whose dependency on $\vec{\rho}$ we drop for conciseness) $\text{Cov}_{\alpha \beta} = \sum_{\gamma=1}^{R} \lambda^{(\gamma)} V^{(\gamma)}_\alpha V^{(\gamma)}_\beta$, the inverse of the Hessian is $H_{ij}^{-1} = \delta_{ij} \rho_i - \rho_i \rho_j + \sum_{\gamma=1}^{R} \frac{1}{1-\lambda^{(\gamma)}} e_{i}^{(\gamma)} e_{j}^{(\gamma)}$, with

$$e_i^{(\gamma)} := \rho_i E_i^{(\gamma)} := \rho_i \sum_{\alpha=1}^{R} V^{(\gamma)}_\alpha \left( r_i^{(\alpha)} - \langle r^{(\alpha)} \rangle_{\vec{\rho}} \right)^{(N)}.$$

Close to the spinodal ($\lambda^{(1)} \approx 1$), the dominant term is $\frac{1}{1-\lambda^{(1)}} e_{i}^{(1)} (e_{i}^{(1)})^T$. Correspondingly, on the spinodal $e_{i}^{(1)}$ is the eigenvector of the Hessian with eigenvalue 0 and coincides with the direction of instability $He^{(1)} = 0$ \[^{[1]}\] (see also Ref. \[^{6}\] for polydisperse systems). Equation \[^{[4]}\] implies that, to lowest order, the relative enrichment $\delta \rho_i / \rho_i \sim e_{i}^{(1)} / \rho_i = E_i^{(1)}$ of component $i$ along the initial direction of phase separation at the spinodal (“partition coefficient”) is given by the deviations of the features from their mean, projected onto the first PC of the feature distribution; see Fig. \[^{2}\] for an illustration.

**Critical points** The spinodal marks the edge of local thermodynamic stability. Except at special points, the spinodal lies within the binodal, the region of global thermodynamic stability. Points where the spinodal and binodal make contact are critical points (cp). At a usual critical point $\vec{\rho}^{(\text{cp})}$, two phases become indistinguishable, corresponding to two minima and one maximum of the tilted Landau free energy $f \rightarrow f - \sum_i \rho_i \partial_i f_{|_{\text{cp}}}$ merging into one minimum. This merging occurs when the change in free energy along the direction of instability $\delta f = f(\rho^{(\text{cp})}) + \epsilon e^{(1)} - f(\rho^{(\text{cp})})$ is zero up to order $\leq 3$ in $\epsilon$. The first order term of the tilted free energy is zero by definition and $(\partial_i \partial_j f) e_i^{(1)} e_j^{(1)} \big|_{\text{cp}} = 0$ as $\vec{\rho}^{(\text{cp})}$ lies on the spinodal, yielding the following additional condition for the critical point:

$$\left. (\partial_i \partial_j \partial_k f) e_i^{(1)} e_j^{(1)} e_k^{(1)} \right|_{\text{cp}} = 0 \rightarrow \left. (E^{(1)})^3 \right|_{\text{cp}} = 0,$$

where the average is with respect to the density at the critical point $\vec{\rho}^{(\text{cp})}$; see Supplemental Material (compare also \[^{6}\]). Thus, the third cumulant of the partition coefficient needs to be zero at a critical point; see Fig. \[^{2}\]. Taken together, the conditions for the spinodal and critical manifold only depend on the distribution of components along the first principal component of the covariance matrix in the $R$-dimensional space of features.

\[^{1}\] Note that unless stated otherwise we assume that the covariance matrix has a non-degenerate maximal eigenvalue, $\lambda^{(2)} < 1$. 

3
rescaled feature 2
i
minimizing and setting the coefficients in front of a way that it minimizes the free energy change \( \delta f \) the system has to be stable against fluctuations in orthogonal directions. Thus, we determine the curve \( n \) term vanishes, should be of order 2 \( \delta f \) density space, parameterized by \( \epsilon \) do not necessarily lie on a straight line. Instead, the phases merge along a more general smooth curve \( \rho \) a high-dimensional density space, the phases that become indistinguishable when crossing the \( n \) parameter (density)

Higher-order critical points At an \( n \)-th order critical point \( \bar{\rho}^{(cp)} \), \( n \) phases become indistinguishable. For a single order parameter (density) \( \rho \), this condition corresponds to the merging of \( n \) minima and \( n-1 \) maxima into a single minimum of the tilted Landau free energy. The free energy expansion around the critical point is then of the order 2 \( \delta f \sim O(\delta \rho^{2n}) \). In a high-dimensional density space, the phases that become indistinguishable when crossing the \( n \)-th order critical point \( \bar{\rho}^{(cp)} \) do not necessarily lie on a straight line. Instead, the phases merge along a more general smooth curve \( \rho_i(\epsilon) = \rho_i^{(cp)} + \delta \rho_i(\epsilon) \) in density space, parameterized by \( \epsilon \); see also [6]:

\[
\delta \rho_i(\epsilon) = \sum_{m=1}^{\infty} \frac{\epsilon^m}{m!} \mathbf{Y}^{(m)}_i,
\]

for some vectors \( \mathbf{Y}^{(m)}_i, m \in \mathbb{Z} \), with \( \sum_k \mathbf{Y}^{(m)}_k = 0 \) to conserve the incompressibility constraint. The (tilted) free energy change \( \delta f(\epsilon) = f(\bar{\rho}_c + \delta \bar{\rho}(\epsilon)) - f(\bar{\rho}_c) \), whose first order term vanishes, should be of order 2\( n \) in \( \epsilon \):

\[
\delta f(\epsilon) = \sum_{k=2}^{\infty} \frac{1}{k!} \sum_{i_1, \ldots, i_k} \frac{\partial^k f}{\partial \rho_{i_1} \cdots \partial \rho_{i_k}} |_{\mathbf{c}_p} \delta \rho_{i_1} \cdots \delta \rho_{i_k} = O(\epsilon^{2n}).
\]

At the same time, the system has to be stable against fluctuations in orthogonal directions. Thus, we determine the curve \( \delta \bar{\rho} \) around \( \bar{\rho}^{(cp)} \) in a way that it minimizes the free energy change \( \delta f \) up to the respective order; see Supplemental Material. Systematically minimizing and setting the coefficients in front of \( \epsilon^m \) to zero, we find the following conditions for an \( n \)-th order critical
The extent to which the negative features influence the phase behavior depends on the relative correlations between all $q$-state Potts models; see Supplemental Material. We observe that this direction of instability again corresponds to (a combination of) feature

$$\frac{1}{2} \sum_{\alpha=1}^{R} \sum_{k=1}^{m-1} \left( \frac{m}{k} \right) \langle e^{\alpha} \Omega^{(k)} \rangle_{cp} \lambda_{\alpha}^{(1)} = \sum_{l=2}^{m} (-1)^{l}(l-2)! \left\langle B_{m,l} \Omega^{(1)}, \Omega^{(2)}, \ldots \right\rangle_{cp}, \quad 2 \leq m \leq 2n-1,$$

which only depend on the vectors $\gamma^{(m)} := \rho^{(cp)} \Omega^{(m)}, m = 1, \ldots, n-1$ determined recursively: $\Omega^{(1)} = E^{(1)}$ and

$$\Omega^{(m)} = \sum_{l=2}^{m} [\bar{B}_{m,l} - \langle \bar{B}_{m,l} \rangle_{cp} + \sum_{\alpha=2}^{R} \frac{E^{(\alpha)}}{1-\lambda^{(\alpha)}} \left\langle E^{(\alpha)} \bar{B}_{m,l} \right\rangle_{cp}],$$

where $\bar{B}_{m,l} := (-1)^{l}(l-1)!B_{m,l} \Omega^{(1)}, \ldots, \Omega^{(m-l+1)}$.

In the case of a single feature $R=1$, this recursion is solved by $\Omega^{(m)} = \partial_{\mu}^{(m)}(e^{cr}/\langle e^{cr} \rangle_{cp}) \Big|_{r=0}$ for $r = \sqrt{-C}s$, and the conditions for an $n$-th order critical point reduce to $\kappa^{(s)} = k_{B} T/(zJ)$ (spinodal) together with $\kappa^{(s)} = 0 \forall m = 3, \ldots, 2n-1$. Here $\kappa^{(s)}$ is the $m$-th cumulant of the spin $s$ with respect to $\rho^{(cp)}$. These conditions for the cumulants imply that the “closer” the distribution of spin values $s$ gets to a Gaussian random variable (wrt the densities), the more phases become indistinguishable and the higher the order of the critical point can be.

**Multiple directions of instability** A series of critical points distinct from the previously discussed higher-order critical points occurs when the largest eigenvalue $1$ of Cov is $D$-fold degenerate; see Supplemental Material. To ensure stability along any direction in the corresponding $D$-dimensional subspace of eigenvectors, the third cumulant of all vectors in the subspace then needs to equal $0$. For example, a system has a critical point with two unstable directions if it has two degenerate eigenvalues, $\lambda^{(1)} = \lambda^{(2)} = 1$, and if the four distinct third cumulants $\kappa^{(12)} := \langle E^{(1)} E^{(2)} \rangle_{cp}$ with $\alpha\beta\gamma = 111, 112, 122, 222$ are zero. In general, a $D+1$-th order critical point with $D$ degenerate unstable directions has codimension $D + \binom{D+2}{3}$ parameters: it requires tuning $D$ parameters for Cov to have its largest eigenvalues equal to $1$ and $\binom{D+2}{3}$ for the third cumulants; see Supplemental Material.

The emergent symmetry of these critical points is reminiscent of the order-parameter symmetry in $q$-state Potts models, with $q = D+1$. In two dimensions there are known to be critical transitions in the $q$-state Potts model for $q \leq 4$ [20], but in mean field these transitions are first order [21,22] except for the case of the Ising model, $q = 2$ [23,24]. Our results show that it is possible to have critical transitions in mean field in models that have the symmetry of $q$-state Potts models, but only in models with sufficient flexibility. An example of an $N=6$ component model with $R=2$ features is given explicitly in the SM; a model with $N=3$ is not enough to match all six conditions on the eigenvalues of Cov and the third cumulants: its parameter space is five dimensional (two ratios of densities and three interaction parameters).

**Model extensions** So far we have focused on a mean-field free energy whose interaction matrix has positive eigenvalues and whose components are of the same size. We now briefly discuss how the previous conditions generalize to the case of negative interaction strengths, and comment on components with different sizes as in the original Flory-Huggins theory [17,18] in the Supplemental Material. If the feature interaction strengths $J^{(\gamma)}$ are all positive, the pairwise interactions satisfy $2\chi_{ij} - (\chi_{ii} + \chi_{jj}) < 0 \forall i, j$, and interactions between alike components are always energetically preferred compared to unlike components. To resolve this limitation, we now consider the general case with $R^+$ “positive”, attractive features and $R^−R^+$ “negative”, repulsive ones: $J^{(\alpha)} > 0 \forall \alpha = 1, \ldots, R^+$ and $J^{(\alpha)} < 0 \forall \alpha = R^+ + 1, \ldots, R$. Performing a conceptually similar but more intricate analysis as before, the spinodal criterion is $\lambda^{(1)} = 1$. Here $\lambda^{(1)}$ is the largest eigenvalue of the real, symmetric matrix $\bar{C} = C^{(+)} - C^{(−)}(1 + C^{(−)})^{-1}C^{(−)}$, which is determined by the covariances among the subsets of positive ($+$) and negative ($-$) features; see Supplemental Material. $\bar{C}$ has dimensions $R^+ \times R^+$ and can be interpreted as representing a multicomponent system with $R^+$ positive features and effective, reduced interactions. The extent to which the negative features influence the phase behavior depends on the relative correlations between all features. If for each dominant positive feature, there is a highly correlated negative feature of similar strength, their effects will roughly cancel and the mixture will not phase separate. Conversely, if the dominant positive features driving phase separation correlate weakly with the negative features, thermodynamic stability is barely modified by the presence of the latter. At the spinodal, the direction of instability is $\bar{e}^{(1)} = \rho_1 \sum_{\alpha=1}^{R^+} \phi^{(1)}_{\alpha} \left[ \bar{\pi}^{(\alpha)}_{i} - \sum_{\beta,\gamma=1}^{R^+} C_{\alpha\beta}^{(−)}(1 + C^{(−)})_{\beta\gamma} \nu^{(\gamma)}_{i} \right]$ in terms of the first eigenvector $\phi^{(1)}$ of $\bar{C}$ and the deviations of positive ($\pi$) and negative ($\nu$) features from the mean; see Supplemental Material. We observe that this direction of instability again corresponds to a (combination of) feature

$$\bar{e}^{(i)} = \rho_1 \sum_{\alpha=1}^{R^+} \phi^{(i)}_{\alpha} \left[ \bar{\pi}^{(\alpha)}_{i} - \sum_{\beta,\gamma=1}^{R^+} C_{\alpha\beta}^{(−)}(1 + C^{(−)})_{\beta\gamma} \nu^{(\gamma)}_{i} \right], \quad 2 \leq i \leq 2n-1,$$
deviations from the mean, projected onto the first principal component \( \phi^{(1)} \) (now of the “effective covariance matrix” \( \tilde{C} \)). Roughly speaking, the relative sign of the contributions of the negative and positive features depends on whether they are correlated or anti-correlated (negative or positive sign). Finally, performing the same analysis as for the original model, we find an analogous condition for the ordinary critical point: \( \left\langle (\tilde{E}^{(1)})^3 \right\rangle_{cp} = 0 \), where \( \tilde{e}_i^{(1)} = \rho_i \tilde{E}_i^{(1)} \).

**Discussion**  
In this work, we consider a general mean-field model for multicomponent mixtures with an arbitrary pairwise interaction matrix \( \chi_{ij} \) of variable rank which we decompose in terms of different “features” mediating additive interactions between the components. The analytic conditions we derive for the spinodal and (higher-order) critical points only depend on the distribution of components in feature space. Specifically, the spinodal and submanifold of ordinary critical points are determined exclusively by the variance and third cumulant of the component distribution projected along the first principal component of the feature covariance matrix. Similarly, the initial direction of phase separation – the vector of relative enrichments of the components right at the spinodal – just depends on this projection of the feature vectors onto the first principal component (Fig. 2). If there are considerably fewer features than distinct components, the feature space is much lower-dimensional than the component space and this representation strongly reduces the complexity of the problem. This representation in feature space and the conditions for the spinodal and ordinary critical points are reminiscent of the dimensional reduction and conditions obtained for polydisperse systems whose excess free energy only depends on a few generalized moments of the attributes \([3,5]\). While the derivation of the “moment free energies” relies on either a division of density space into a subspace of moments and its “transverse” space or on combinatorial arguments \([6,8]\), here we take a different approach, which is particularly suited for mixtures with discrete component types: We reformulate the spinodal condition in terms of the inverse of the Hessian matrix and exploit that the latter only depends on the inverse of an \( R \)-dimensional matrix in feature space which originates from the interaction structure. The representation in feature space also suggests a principled method for finding coarse-grained binary mixtures with similar properties. By choosing the composition and interaction strength of the binary mixture so as to preserve the largest eigenvalue of the covariance matrix and its corresponding third cumulant, the coarse-grained binary mixture maintains the location of the multicomponent system with respect to the spinodal and critical manifold, and might therefore serve as a first approximation of the original solution; see Fig. 2 and Supplemental Material.

In addition, our analysis allows for a systematic identification of the co-dimension of different series of critical points in multicomponent systems; see also \([25,29]\). For instance, we find that, in the absence of symmetries, a tricritical point has codimension 4 in mean-field. Furthermore, higher-order critical points with symmetry reminiscent of the \( q \)-state Potts model require tuning of \( q-1+{q+3 \choose 3} \) parameters. For the \( q=3 \)-states Potts model, this counting suggests a codimension of 6 for the critical point, which is larger than the one accessible with just \( N=3 \) components but feasible for a mean-field model with \( N=6 \) components and \( R=2 \); see Supplemental Material.

Looking ahead, a realistic description of the pairwise interactions in functional multicomponent mixtures presumably includes both a highly structured part – due to a small number of (physical) features as considered here – and an additional random part which is due to microscopic differences between otherwise similar components; see recent work \([27]\). While we do not expect the random part to substantially influence our results in the case when the noise is small compared to the variance along the first principal component, interesting effects might arise in the cross-over regime. With regard to functional mixtures, our results might also offer an appealing perspective on intracellular liquid-liquid phase separation, which has been suggested as a pervasive mechanism for the spatial organization of components without membranes \([2]\), and on the critical phase behavior observed in cell-derived plasma membranes composed of many lipids and proteins \([28]\). For both types of systems, coarse-graining procedures based on the feature space representation might help to understand under what conditions the addition and/or removal of components qualitatively alters the phase behavior. To bridge the gap between our work and such biological systems, it will be important to check in what ways the mean-field conditions determined here differ from exact conditions for critical points in finite-dimensional systems like 2D cellular membranes or the 3D cytoplasm. Finally, our analytic theory only makes predictions about local thermodynamic properties but cannot now make statements about the global phase behavior, which would require knowledge of the full free energy landscape \([1,3,5,29,30]\). This is an interesting direction for future research.

References

In this Supplemental Material we present in detail the derivations of the conditions for the spinodal and critical points as outlined in the main text and explain how we generated the distribution of features in the multicomponent mixtures depicted in Fig. 2 of the main text. We first discuss the mean-field approximation of the lattice Hamiltonian in terms of a free energy of Flory-Huggins type. In this approximation, we then derive the condition for the spinodal and the initial direction of phase separation, the direction of instability. To find the conditions for (higher-order) critical points, we further systematically expand the mean-field free energy around the critical density. After deriving these conditions, we look at two extensions of our original model, systems with components of different sizes and mixtures with partially negative and partially positive interaction strengths, and derive the corresponding conditions for the spinodal and ordinary critical points. To show that our result do not depend on choosing the features linearly independently, we then comment on the case of linearly dependent features. While our focus is on the case where the largest eigenvalue of the covariance matrix is non-degenerate, we then dedicate one section to a small discussion of the case with several directions of instability. Based on this discussion, we further propose an effective mean-field model for the two-dimensional q=3-states Potts model which exhibits a critical point, in contrast to the regular mean-field theory of the Potts model. We then briefly discuss our idea how to coarse-grain multicomponent mixtures in terms of an effective binary mixture. Finally, we provide details about how we generated the multicomponent mixtures illustrated in Fig. 2 of the main text.

S1 Mean-field approximation of the lattice Hamiltonian

The Hamiltonian from the main text is

$$\mathcal{H} = - \sum_{\gamma=1}^{R} J^{(\gamma)} \sum_{\langle xy \rangle} \sigma^{(\gamma)}(x) \sigma^{(\gamma)}(y),$$  \hspace{1cm} (S1)

where $\gamma = 1, \ldots, R$ denotes the different features, $x$ and $y$ label the sites on the lattice and $\langle xy \rangle$ denotes the set of all nearest neighbors on the lattice. If component type $i \in \{1, \ldots, N\}$ occupies site $x$, $\sigma^{(\gamma)}(x) = s_{i}^{(\gamma)}$. Since we assume that each lattice site is occupied by exactly one component (particle), the overall number of lattice sites equals the number of particles.

In a mean-field approximation, we neglect correlations between the different sites on the lattice and the different sites are not distinguished anymore. The probability that component type $i$ occupies any site $x$ is $\rho_{i}$. Denoting by $z$ the coordination number of the lattice, there are $z/2$ pairs of nearest neighbors per particle. For each pair of nearest neighbors $\langle xy \rangle$ with component type $i$ on $x$ and $j$ on $y$, the energetic contribution is $\sum_{\gamma=1}^{R} J^{(\gamma)} s_{i}^{(\gamma)} s_{j}^{(\gamma)}$. The probability for this configuration is $\rho_{i} \rho_{j}$. Thus, the MF contribution per particle is $(z/2) \sum_{i,j=1}^{N} \rho_{i} \rho_{j} \sum_{\gamma=1}^{R} J^{(\gamma)} s_{i}^{(\gamma)} s_{j}^{(\gamma)}$. Overall, the energetic contribution per particle is

$$\frac{U_{MF}}{M} = - \frac{z}{2} \sum_{\gamma=1}^{R} J^{(\gamma)} \left( \sum_{i=1}^{N} \rho_{i} s_{i}^{(\gamma)} \right)^{2},$$  \hspace{1cm} (S2)

where $M$ denotes the total number of particles/lattice sites. Combining the energetic contribution with the entropic contribution, $k_{B} T \sum_{i=1}^{N} \rho_{i} \log \rho_{i}$, per particle, we find the following mean-field free energy per particle and $k_{B} T$

$$\tilde{f}_{N} := \frac{F_{N}}{M k_{B} T} = \sum_{i=1}^{N} \rho_{i} \log \rho_{i} - \sum_{\gamma=1}^{R} \left( \sum_{i=1}^{N} \rho_{i} \sqrt{C^{(\gamma)}} s_{i}^{(\gamma)} \right)^{2},$$  \hspace{1cm} (S3)

with

$$C^{(\gamma)} := \frac{z J^{(\gamma)}}{2k_{B} T}.$$  \hspace{1cm} (S4)

The subscript $N$ indicates that $\tilde{f}$ is a function of all $N$ densities $\tilde{\rho}^{(N)}$.

S1.1 Flory-Huggins interaction matrix

Comparing the energetic contribution from the pairwise interactions with a Flory-Huggins term, $-\sum_{i,j=1}^{N} \rho_{i} \chi_{ij} \rho_{j}$, we identify the interaction matrix as

$$\chi_{ij} = \sum_{\gamma=1}^{R} C^{(\gamma)} s_{i}^{(\gamma)} s_{j}^{(\gamma)}.$$  \hspace{1cm} (S5)

S1.2 Effective reduction to an $N-1$-component system

Due to the incompressibility constraint, not all the densities can be changed independently. Here, we directly impose this constraint by replacing

$$\rho_{N} \rightarrow 1 - \sum_{i=1}^{N-1} \rho_{i} =: 1 - P$$  \hspace{1cm} (S6)
in the free energy. Instead of \( \tilde{f}_N \), we consider the “restricted” free energy

\[
f_{N-1} = \tilde{f}_N(\rho_1, \ldots, \rho_{N-1}, 1 - P) = \\
= \sum_{i=1}^{N-1} \rho_i \log \rho_i + (1 - P) \log(1 - P) - \sum_{\gamma=1}^{R} C^{(\gamma)} \left( \sum_{i=1}^{N-1} \rho_i s_i^{(\gamma)} + (1 - P) s_N^{(\gamma)} \right)^2,
\]

which only depends on the first \( N - 1 \) densities \( \tilde{\rho}^{(N-1)} \). Note that as expected and as we will see explicitly below, the “physical results” do not depend on this choice of integrating out component \( N \) (instead of any other or a combination of them).

### S2 Derivatives of the free energy \( f_{N-1} \) and the Hessian matrix

Taking the derivative of the restricted free energy \( f_{N-1} \), Eq. [S7] with respect to the density \( \rho_i, i = 1, \ldots, N - 1 \) yields

\[
\partial_i f_{N-1} := \frac{\partial f_{N-1}}{\partial \rho_i} = 1 + \log \rho_i - \log(1 - P) - 2 \sum_{\gamma=1}^{R} C^{(\gamma)} \left( \sum_{j=1}^{N-1} \rho_j s_j^{(\gamma)} + (1 - P) s_N^{(\gamma)} \right) (s_i^{(\gamma)} - s_N^{(\gamma)}) = \\
= \log \rho_i - \log(1 - P) - 2 \sum_{\gamma=1}^{R} C^{(\gamma)} \left( s_N^{(\gamma)} + \sum_{j=1}^{N-1} \rho_j (s_j^{(\gamma)} - s_N^{(\gamma)}) \right) (s_i^{(\gamma)} - s_N^{(\gamma)}).
\]

For the Hessian matrix \( H_{ij}, i, j = 1, \ldots, N - 1 \), we find

\[
H_{ij} := \partial_i \partial_j f_{N-1} := \frac{\partial^2 f_{N-1}}{\partial \rho_i \partial \rho_j} = \delta_{ij} \frac{1}{\rho_i} + 1_{ij} \frac{1}{1 - P} - 2 \sum_{\gamma=1}^{R} C^{(\gamma)} (s_i^{(\gamma)} - s_N^{(\gamma)}) (s_j^{(\gamma)} - s_N^{(\gamma)}) =: \\
=: K_{ij} - \sum_{\gamma=1}^{R} r_i^{(\gamma)} r_j^{(\gamma)} =: A_{ij}^{(2)},
\]

where we define \( 1_{ij} := 1 \forall i, j \) in order to keep track of sums over repeated indices.

\[
K_{ij} := \delta_{ij} \frac{1}{\rho_i} + 1_{ij} \frac{1}{1 - P}
\]

corresponds to the Hessian of an incompressible \( N \)-component system without interactions. Furthermore,

\[
\tau_i^{(\gamma)} = \sqrt{2C^{(\gamma)}(s_i^{(\gamma)} - s_N^{(\gamma)})}
\]

denotes the rescaled and shifted features.

Similarly, the higher-order derivatives \( n \geq 3 \) are

\[
A_{i_1 i_2 \ldots i_n}^{(n)} := \partial_{i_1 i_2 \ldots i_n} f_{N-1} := \frac{\partial^n}{\partial \rho_{i_1} \ldots \partial \rho_{i_n}} f_{N-1} = (n - 2)! \left[ \delta_{i_1 i_2 \ldots i_n} (-1)^n \frac{1}{\rho_i^{n-1}} + 1_{i_1 i_2 \ldots i_n} \frac{1}{(1 - P)^{n-1}} \right],
\]

where \( \delta_{i_1 i_2 \ldots i_n} = \prod_{k=1}^{n-1} \delta_{i_k i_{k+1}} \) and \( 1_{i_1 i_2 \ldots i_n} = 1 \forall i_1, \ldots, i_n \).

### S3 Spinodal condition and direction of instability

For a non-interacting multicomponent mixture, which is entirely dominated by entropic effects and accordingly does not phase separate, the Hessian matrix equals \( K \). All eigenvalues of the Hessian are thus positive: For each vector \( w \in \mathbb{R}^{N-1}, \)
there is a vector \( v \in \mathbb{R}^{N-1} \) with \( w_i = \rho_i v_i \) (assuming all \( \rho_i > 0 \)). Thus,

\[
 w_i K_{ij} w_j = \rho_i v_i K_{ij} \rho_j v_j = \sum_{i=1}^{N-1} \rho_i v_i^2 + \frac{1}{1-P} \left( \sum_{i=1}^{N-1} \rho_i v_i \right)^2 = \left( \frac{1-P}{1-P} \right) \left( \sum_{i=1}^{N-1} \rho_i v_i \right)^2 = 0, \quad (S13)
\]

where in the last step, we used that the variance of \( v \) is the probability measure \( \bar{\rho}_i = \rho_i/(1-P), i = 1, \ldots, N-1 \) for the \( N-1 \)-component system is always larger or equal to 0. Note that \( w_i K_{ij} w_j = 0 \) only if \( \text{Var}_\rho(v) = \langle v \rangle_\rho = 0 \) and thus \( v_i = w_i = 0 \forall i \); the matrix \( K \) is positive definite.

Introducing (positive) interactions among the component types, the system becomes more and more prone to phase separate and the eigenvalues of the Hessian decrease. The system becomes marginally thermodynamically stable if the smallest eigenvalue of the Hessian crosses 0. Since a square matrix is invertible if and only if all eigenvalues are non-zero, marginal stability is equivalent to the Hessian matrix becoming singular for the first time.

### S3.1 Inverse of Hessian matrix

From Eq \([S9]\), we observe that the Hessian corresponds to a rank \( \leq R \) correction to the matrix \( K \). The existence of the inverse of such a rank correction to \( K \) and its explicit form has been determined by Woodbury \([19]\). A matrix \( K - UW \) with \( K : (N-1) \times (N-1) \), \( U : (N-1) \times R \), \( W : R \times (N-1) \) is invertible if and only if \( K \) and \( 1 - WK^{-1}U \) are both invertible (here \( 1 : R \times R \)). In this case, the inverse is given by

\[
 (K - UW)^{-1} = K^{-1} + K^{-1}U \left( 1 - WK^{-1}U \right)^{-1} WK^{-1}. \quad (S14)
\]

Identifying \( U_{ia} = r_{i}^{(\alpha)} \) and \( W = U^T \), we find that the Hessian matrix, Eq \([S9]\), is invertible if and only if \( K \) and \( 1 - UTK^{-1}U \) are invertible. As we will see next, \( K \) is always invertible and \( 1 - UTK^{-1}U \) is rewritten as \( 1 - \text{Cov} \), with the covariance matrix as defined in the main text: \( \text{Cov}_{\alpha \beta} = \langle r^{(\alpha)} r^{(\beta)} \rangle_\rho - \langle r^{(\alpha)} \rangle_\rho \langle r^{(\beta)} \rangle_\rho \).

**Inverse of \( K \)**

\( K \) itself is written as a rank-1 correction to a diagonal matrix \( M \):

\[
 K_{ij} = \delta_{ij} \frac{1}{\rho_i} + \frac{1}{1-P} \delta_{ij} =: M_{ij} + Q_i Q_j \quad \text{where} \quad Q_i = \frac{1}{\sqrt{1-P}} \forall i \quad (S15)
\]

Since \( M \) is always invertible with inverse \( (M^{-1})_{ij} = \delta_{ij} \rho_i \), the matrix \( K \) is invertible if and only if

\[
 1 + Q M^{-1} Q = 1 + Q_i \delta_{ij} \rho_i Q_j = 1 + \sum_{i=1}^{N-1} \rho_i \frac{1}{1-P} = \frac{1}{1-P} \neq 0. \quad (S16)
\]

Since \( P \leq 1 \), this condition is always satisfied and the inverse of \( K \) is

\[
 (K^{-1})_{ij} = (M^{-1})_{ij} - (M^{-1})_{ik} Q_k (1-P) M^{-1}_{ij} = \delta_{ij} \rho_i - \delta_{ik} \rho_i Q_k (1-P) Q_i = \delta_{ij} \rho_i - \rho_i \rho_j. \quad (S17)
\]

It is straightforward to test that indeed \( KK^{-1} = K^{-1}K = 1 \).

**Inverse of \( 1 - UTK^{-1}U \)**

Using the definition of \( U_{ia} = r_i^{(\alpha)} \) with \( r_N^{(\alpha)} = 0 \) and the previous result \( (K^{-1})_{ij} = \delta_{ij} \rho_i - \rho_i \rho_j \), we find

\[
 (1 - UT K^{-1} U)_{\alpha \beta} = \delta_{\alpha \beta} - \sum_{i,j=1}^{N-1} r_i^{(\alpha)} (\delta_{ij} \rho_i - \rho_i \rho_j) r_j^{(\beta)} = \delta_{\alpha \beta} - \sum_{i=1}^{N} \rho_i r_i^{(\alpha)} r_i^{(\beta)} + \sum_{i=1}^{N} \rho_i r_i^{(\alpha)} \sum_{j=1}^{N} r_j^{(\beta)} = \delta_{\alpha \beta} - \left( \langle r^{(\alpha)} r^{(\beta)} \rangle_\rho - \langle r^{(\alpha)} \rangle_\rho \langle r^{(\beta)} \rangle_\rho \right) = (1 - \text{Cov})_{\alpha \beta}. \]

14
Here and in the following averages $\langle \ldots \rangle_{\rho}^{(N)}$ are with respect to the densities of the $N$-component system (for simplicity, we will often omit the $N$ and the vector notation):

$$\langle X \rangle_{\rho}^{(N)} := \langle X \rangle := \sum_{i=1}^{N} \rho_{i} X_{i}.$$  

(S18)

Taken together, we find that the Hessian matrix is invertible if and only if $1 - \text{Cov}$ is invertible. Note that the Hessian matrix is an $(N-1) \times (N-1)$ matrix whereas $1 - \text{Cov}$ has dimensions $R \times R$.

For positive interaction strengths, Cov is a true covariance matrix, which is real, symmetric and positive semi-definite. The eigenvalues of $1 - \text{Cov}$ are thus all real and $\leq 1$. For high temperature or weak/no interactions, the rescaled features $r^{(\alpha)}_{\rho}$ are small and thus $1 - \text{Cov}$ has only positive eigenvalues. Decreasing the temperature or increasing the attractive interactions, the mixture becomes marginally stable when $1 - \text{Cov}$ becomes singular for the first time, i.e. when the largest eigenvalue of Cov is 1. Writing the covariance matrix in terms of its eigenvectors $\bar{V}^{(\gamma)}$ and eigenvalues $\lambda^{(\gamma)}$, $\gamma = 1, \ldots, R$:

$$\text{Cov} = \sum_{\gamma=1}^{R} \lambda^{(\gamma)} \bar{V}^{(\gamma)} (\bar{V}^{(\gamma)})^{T},$$

(S19)

with $\lambda^{(\alpha)} \geq \lambda^{(\beta)} \forall \alpha \leq \beta$, this condition for marginal stability (spinodal) is

$$\lambda^{(1)} = 1 \quad \text{(condition for the spinodal).}$$

(S20)

If $1 - \text{Cov}$ is invertible, $\lambda^{(\gamma)} \neq 1 \forall \gamma$, the inverse of the Hessian is given by

$$H^{-1} = (K - UU^{T})^{-1} = K^{-1} + K^{-1}U(1 - \text{Cov})^{-1}U^{T}K^{-1},$$

(S21)

or written in terms of the eigenvectors and eigenvalues of the covariance matrix,

$$(H^{-1})_{ij} = (K^{-1})_{ij} + \sum_{k,m=1}^{N-1} \sum_{\alpha,\beta=1}^{R} (K^{-1})_{ik} U_{k\alpha} \left( \sum_{\gamma=1}^{R} \frac{1}{1 - \lambda^{(\gamma)}} V^{(\gamma)}_{\alpha} V^{(\gamma)}_{\beta} \right) (U^{T})_{\beta m} (K^{-1})_{mj} =$$

$$= \delta_{ij} \rho_{i} \rho_{j} + \sum_{k,m=1}^{N-1} \sum_{\alpha,\beta=1}^{R} \delta_{ik} \rho_{i} - \rho_{i} \rho_{k} r^{(\alpha)}_{k} \left( \frac{1}{1 - \lambda^{(\gamma)}} V^{(\gamma)}_{\alpha} V^{(\gamma)}_{\beta} \right) r^{(\beta)}_{m} (\delta_{mj} \rho_{j} - \rho_{m} \rho_{j}) =$$

$$= \delta_{ij} \rho_{i} \rho_{j} + \sum_{\gamma=1}^{R} \frac{1}{1 - \lambda^{(\gamma)}} e^{(\gamma)}_{i} e^{(\gamma)}_{j},$$

(S22)

(S23)

where

$$e^{(\gamma)}_{i} := \rho_{i} E^{(\gamma)}_{i} := \rho_{i} \sum_{\alpha=1}^{R} V^{(\gamma)}_{\alpha} \left( r^{(\alpha)}_{i} - \langle r^{(\alpha)} \rangle_{\rho} \right).$$

(S25)

and we used that $\sum_{i=1}^{N} \rho_{i} r^{(\alpha)}_{i} = \sum_{i=1}^{N} \rho_{i} V^{(\alpha)}_{i} = \langle r^{(\alpha)} \rangle_{\rho}$.

Approaching the spinodal, the inverse of the Hessian is dominated by the term $\sim 1/(1 - \lambda^{(1)})$ suggesting that on the spinodal $e^{(1)}$ is the eigenvector of the Hessian to eigenvalue 0. Using that $r^{(\gamma)}_{N} = 0 \forall \gamma$ and $\sum_{\beta=1}^{R} V^{(\alpha)}_{\beta} \text{Cov}_{\beta \gamma} = \lambda^{(\alpha)} V^{(\alpha)}_{\gamma}$ by definition, and

$$\langle E^{(\alpha)} \rangle_{\rho} = 0 \quad \forall \alpha,$$

or the terms $\sim 1/(1 - \lambda^{(i)})$, $i = 1, \ldots, D$ if the zero eigenvalue of the Hessian is $D$-fold degenerate.
we indeed find that
\[
H_{ij} e_j^{(α)} = \left( δ_{ij} \frac{1}{ρ_i} + 1 - \frac{1}{P} \right) - \frac{1}{P} \sum_{γ=1}^{N-1} r_i^{(γ)} r_j^{(γ)} \right) \rho_j E_j^{(α)} = E_i^{(α)} + \frac{1}{P} \sum_{j=1}^{N-1} \frac{1}{ρ_j} E_j^{(α)} - \sum_{γ=1}^{N-1} r_i^{(γ)} \left( E^{(α)} r^{(γ)} \right)_ρ = E_i^{(α)} - E_N^{(α)} - \frac{1}{P} \sum_{γ=1}^{N-1} \sum_{β=1}^{D} V_β^{(α)} \left( \left( r^{(β)} r^{(γ)} \right)_ρ - \left( r^{(β)} \right)_ρ \left( r^{(γ)} \right)_ρ \right) = \sum_{β=1}^{D} V_β^{(α)} r_β^{(γ)} - \frac{1}{P} \sum_{γ=1}^{N-1} \sum_{β=1}^{D} V_β^{(α)} V_β^{(γ)} \operatorname{Cov}_{βγ} = (1 - λ^{(α)}) \sum_{γ=1}^{N-1} V_γ^{(α)} r_γ^{(γ)}. \quad (S26)
\]

In particular, \( H e^{(α)} = 0 \) if \( λ^{(α)} = 1 \). On the spinodal, where \( λ^{(1)} = 1, e^{(1)} \) thus corresponds to the eigenvector of the Hessian to eigenvalue 0:
\[
(e_1^{(1)}) = p_1 \sum_{α=1}^{R} V_α^{(1)} \left( r_α^{(γ)} - \left( r^{(γ)} \right)_ρ \right) = \text{direction of instability}. \quad (S27)
\]

### S3.2 Degenerate maximal eigenvalue of Cov: Dimensionality of the plane of instability

If Cov has a \( D \)-fold degenerate maximal eigenvalue of 1, the corresponding eigenvectors can be chosen orthonormal since Cov is real and symmetric. Therefore, they span a \( D \)-dimensional submanifold in feature space. One may wonder if also the corresponding plane in component space, spanned by the different directions of instability \( e^{(1)}, \ldots, e^{(D)} \), is \( D \)-dimensional, or if these directions of instability might be linearly dependent. Here we briefly show that the (generally non-orthogonal) vectors \( e^{(1)}, \ldots, e^{(D)} \) are indeed linearly independent:

Suppose \( \sum_{α=1}^{D} c_α e^{(α)} = 0 \) for all \( α \), then \( \sum_{i=1}^{N} E_i^{(β)} \sum_{α=1}^{D} c_α e^{(α)} = 0 \) for all \( β \). Furthermore, \( \sum_{i=1}^{N} E_i^{(β)} e^{(α)} = \sum_{γ,δ=1}^{N} V_γ^{(α)} V_δ^{(β)} \sum_{i=1}^{N} r_i^{(γ)} - \left( r^{(γ)} \right)_ρ \left( r^{(δ)} \right)_ρ = \sum_{γ,δ=1}^{N} V_γ^{(α)} V_δ^{(β)} \operatorname{Cov}_{γδ} = \sum_{γ=1}^{N} V_γ^{(α)} λ^{(β)} V_γ^{(β)} = λ^{(β)} δ_{αβ}, \) where we used the orthonormality of the eigenvectors \( V^{(α)} \) of the covariance matrix. As a result, \( \forall β = 1, \ldots, D, \) we find \( \sum_{α=1}^{D} c_α λ^{(β)} δ_{αβ} = c_β λ^{(β)} = c_β = 0 \).

Taken together, it follows from \( \sum_{α=1}^{D} c_α e^{(α)} = 0 \) that \( c_α = 0 \) \( \forall α = 1, \ldots, D \) and, correspondingly, the \( e^{(α)} \) are linearly independent, thus spanning a \( D \)-dimensional plane of instability in component space. This argument is indeed true for all sets of vectors \( \{ e^{(γ)} \} \), for which all corresponding eigenvalues \( λ^{(γ)} \neq 0 \). As we will see later, \( λ^{(γ)} = 0 \) only for linearly dependent features, and we conclude that the plane in component space spanned by \( \{ e^{(γ)} \} = 1, \ldots, R \) has dimension equal to the number of linearly independent features.

### S4 Systematic expansion of the free energy along a path in density space

The spinodal corresponds to the submanifold in phase space where a homogeneous phase becomes unstable with respect to local fluctuations and the system spontaneously phase separates into two (or more) phases. Critical points on the spinodal occur if these phases become indistinguishable. Here, we define an \( n \)-th order critical point as a point where \( n \) different phases become indistinguishable and merge into one phase. In a one-dimensional system, an \( n \)-th order critical point at densities \( ρ^{(cp)} \) manifests as a minimum of order \( 2n-1 \) in the tilted Landau free energy \( f_{N-1} \rightarrow f_{N-1} - \sum_{i=1}^{N-1} \partial_1 f_{N-1} ρ_i \).

There \( n \) minima and the \( n-1 \) maxima in between merge into one minimum. We generalize this idea to the multicomponent system by requiring that for an \( n \)-th order critical point, the free energy change \( Δf_{N-1} \) (with respect to \( ρ^{(cp)} \)) along the path of minimal change exhibits a minimum of order \( ≥ 2n-1 \):
\[
Δf_{N-1}(ε) := f_{N-1}(ρ(ε)) - f_{N-1}(ρ^{(cp)}) ≥ 0 \quad \text{to order } \mathcal{O}(ε^{2n}). \quad (S28)
\]

for all paths
\[
ρ_i(ε) := ρ_i^{(cp)} + δρ_i(ε) := ρ_i^{(cp)} \left( 1 + \sum_{m=1}^{∞} \frac{ε^m}{m!} \omega_i^{(m)} \right) \quad (S29)
\]

16
in density space, with equality
\[ f_{N-1}(\rho^{\text{opt}}(\epsilon)) - f_{N-1}(\rho^{(cp)}) = \mathcal{O}(\epsilon^2) \]  
along an “optimal” path in density space
\[ \rho_i^{\text{opt}}(\epsilon) := \rho_i^{(cp)} + \delta \rho_i^{\text{opt}}(\epsilon) := \rho_i^{(cp)} \left( 1 + \sum_{m=1}^{\infty} \frac{\epsilon^m}{m!} \Omega_i^{(m)} \right), \]  
for which \( \omega^{(m)} = \Omega^{(m)} \ \forall m \). Here, the density vectors (for which we omit the vector notation) are to be understood in the \( N - 1 \) dimensional space. The incompressibility constraint, \( \sum_{i=1}^{N} \rho_i = 1 \), is taken care of implicitly by extending density vectors to \( N \) dimensions via \( \rho_N(\epsilon) = 1 - \sum_{i=1}^{N-1} \rho_i(\epsilon) \). Similarly, the changes in density need to satisfy \( \sum_{i=1}^{N} \delta \rho_i(\epsilon) = 0 \ \forall \epsilon \) and, in particular,
\[ \sum_{i=1}^{N} \rho_i^{(cp)}(\omega^{(m)}) = (\omega)_{\rho^{(cp)}} = 0, \]  
if extended to \( N \) dimensions. Note that in Eq. S29 we have defined the “derivatives” \( \omega^{(m)} \) in a way that factors out the densities \( \rho_i^{(cp)} \). Furthermore, \( \omega^{(m)} \) generally depends on the density \( \rho^{(cp)} \). For simplicity, we omit this dependency in the following.

Since the first derivative of the tilted free energy is zero, expanding \( \Delta f_{N-1}(\epsilon) \) in terms of the (higher-order) derivatives of \( f_{N-1} \) yields
\[ \Delta f_{N-1}(\epsilon) = f_{N-1}(\rho(\epsilon)) - f_{N-1}(\rho^{(cp)}) = \sum_{l=2}^{\infty} \frac{1}{l!} \frac{\partial^l f_{N-1}}{\partial \rho_1 \cdots \partial \rho_l} \bigg|_{\rho^{(cp)}} \delta \rho_1(\epsilon) \cdots \delta \rho_l(\epsilon) = \sum_{l=2}^{\infty} \frac{1}{l!} A^{(l)}_{i_1 \ldots i_l} \delta \rho_1(\epsilon) \cdots \delta \rho_l(\epsilon), \]  
where we implicitly sum over repeated indices \( i_1, \ldots, i_l \) and implicitly assume that \( A^{(l)} \) is evaluated at the critical density \( \rho^{(cp)} \) here and in the following. Grouping these terms in orders of \( \epsilon \) gives
\[ \Delta f_{N-1}(\epsilon) = \sum_{n=2}^{\infty} \epsilon^n \sum_{l=2}^{n} \frac{1}{l!} A^{(l)}_{i_1 \ldots i_l} \rho_i^{(cp)} \cdots \rho_i^{(cp)} \sum_{\{m_1, \ldots, m_l\} \in \mathbb{N}_l, \sum_{k=1}^{l} m_k = n} \prod_{j=1}^{l} \frac{\omega_{i_j}^{(m_j)}}{m_j!}. \]  
Since \( A^{(l)}_{i_1 \ldots i_l} \) and \( \rho_i^{(cp)} \) are invariant with respect to permutations of the indices \( \{i_j\}_{j=1 \ldots l} \), we do not need to explicitly keep track of the indices in \( \omega^{(m_j)} \) and simplify the previous expression as
\[ \Delta f_{N-1}(\epsilon) = \sum_{n=2}^{\infty} \epsilon^n \sum_{l=2}^{n} \frac{1}{l!} A^{(l)} \sum_{\{m_1, \ldots, m_l\} \in \mathbb{N}_l, \sum_{k=1}^{l} m_k = n} \prod_{j=1}^{l} \frac{\omega^{(m_j)}}{m_j!}, \]  
where we defined the full contraction
\[ A^{(l)} \prod_{j=1}^{l} \alpha^{(j)} := A^{(l)}_{i_1 \ldots i_l} \prod_{j=1}^{l} \alpha^{(j)}_{i_j} \]  
and furthermore \( \omega^{(m)} := \rho^{(cp)} \omega^{(m)} \), or in index notation
\[ \omega_i^{(m)} = \rho_i^{(cp)} \omega_i^{(m)} \ \forall m. \]  
The last sum in Eq. S35 contains products with \( l \) factors of \( \psi^{(m_j)} \), whose superscripts \( m_j \) add up to \( n \), i.e. terms of the form \((\psi^{(1)})^{p_1} \cdots (\psi^{(n)})^{p_n}\) with \( p_1, \ldots, p_n \in \mathbb{N}_0 \), subject to the constraints \( \sum_{j=1}^{n} p_j = l \) and \( \sum_{j=1}^{n} j p_j = n \). The number of
combinatorial possibilities to get a term of the form \((v^{(1)})^{p_1} \cdots (v^{(n)})^{p_n}\) is \(l!/ (p_1! \cdots p_n!)\), corresponding to the number of distinct permutations with repeated elements. As a result, Eq. S35 is rewritten as

\[
\Delta f_{N-1}(\epsilon) = \sum_{n=2}^{\infty} \epsilon^n \sum_{l=2}^{n} \frac{1}{l!} A^{(l)} \sum_{\{p_1, \ldots, p_n\} \in \mathbb{N}_0^n \atop \sum_{k=1}^{n} p_k = l} \frac{l!}{p_1! \cdots p_n!} \prod_{j=1}^{n} \left( \frac{v^{(j)}}{j!} \right)^{p_j} = \sum_{n=2}^{\infty} \epsilon^n \frac{n!}{n!} \sum_{l=2}^{n} A^{(l)} \sum_{\{p_1, \ldots, p_n\} \in \mathbb{N}_0^n \atop \sum_{k=1}^{n} p_k = l} \frac{1}{p_1! \cdots p_n!} \prod_{j=1}^{n} \left[ \frac{1}{p_j!} \left( \frac{v^{(j)}}{j!} \right)^{p_j} \right].
\]

(S38)

(S39)

The last sum exactly corresponds to the partial exponential Bell polynomial \(B_{n,l}(v^{(1)}, v^{(2)}, \ldots)\) and we find

\[
\Delta f_{N-1}(\epsilon) = \sum_{n=2}^{\infty} \epsilon^n \sum_{l=2}^{n} A^{(l)} B_{n,l}(v^{(1)}, v^{(2)}, \ldots) = \sum_{n=2}^{\infty} \epsilon^n \sum_{l=2}^{n} A^{(l)} B_{n,l}(\rho^{(cp)}\omega^{(1)}, \rho^{(cp)}\omega^{(2)}, \ldots),
\]

(S40)

with the implicit contraction between \(A^{(l)}\) and the Bell polynomial \(B_{n,l}\).

To find conditions for the occurrence of (higher-order) critical points, we successively determine the optimal vectors \(\Omega^{(m)}\) by minimizing the coefficients in front of \(\epsilon^n\) (only necessary for even \(n\); see below) and setting them to zero one after the other (up to order \(2n - 1\) for an \(n\)-th order critical point as discussed before).

### S4.1 Critical point

For the usual critical point \(n = 2\), we have to second order

\[
\mathcal{O}(\epsilon^2) : \min_{\omega^{(1)}} \left( A^{(2)} B_{2,2}(\rho^{(cp)}\omega^{(1)}) \right) = \min_{\omega^{(1)}} \left( A^{(2)}_{ij} \rho_i^{(cp)} \omega_1^{(1)} \rho_j^{(cp)} \omega_2^{(1)} \right) = \min_{\omega^{(1)}} \left( \omega_1^{(1)} A_i^{(2)} \omega_i^{(1)} \right) = 0.
\]

(S41)

It follows that the Hessian \(H = A^{(2)}\) needs to be positive semi-definite and the system is metastable thermodynamically (each critical point lies on the spinodal). Correspondingly, the tangent to the optimal path \(\rho^{(cp)}\Omega^{(1)}\) coincides with the direction of the instability:

\[
\Upsilon^{(1)} := \rho^{(cp)}\Omega^{(1)} = e^{(1)} = \rho^{(cp)}E^{(1)} \quad \text{or} \quad \Omega^{(1)} = E^{(1)}.
\]

(S42)

Note that, in principle, there could be several directions of instability if the smallest, zero eigenvalue of the Hessian is degenerate. Here, we focus on the non-degenerate case with a unique direction of instability, but we will briefly comment on the degenerate case below in a separate section.

Using Eq. S42 with the optimal \(v^{(1)} = \Upsilon^{(1)}\), we find for the third order

\[
\mathcal{O}(\epsilon^3) : \min_{\omega^{(2)}} \left( A^{(2)} B_{3,2}(\Upsilon^{(1)}, \rho^{(cp)}\omega^{(2)}) + A^{(3)} B_{3,3}(\Upsilon^{(1)}) \right) = \min_{\omega^{(2)}} \left( 3A^{(2)}_{ij} \Upsilon_i^{(1)} \Upsilon_j^{(2)} + A^{(3)}_{ijk} \Upsilon_i^{(1)} \Upsilon_j^{(1)} \Upsilon_k^{(1)} \right) = \frac{1}{\rho^{(cp)}} \left( \Omega^{(1)} \right)^3 = 0,
\]

(S43)

where in the second step we used Eq. S42 and the definition of the direction of instability, \(A^{(2)}_{ij} \Upsilon_i^{(1)} = A^{(2)}_{ij} e_i^{(1)} = H_{ij} e_i^{(1)} = 0\), and in the third step Eq. S325.

Taken together, apart from critical points lying on the spinodal, the third cumulant (or moment) of the direction of instability needs to be zero at a critical point:

\[
\left\langle \left( \frac{1}{\rho^{(cp)}} (E^{(1)})^3 \right) \right\rangle = 0 \quad \text{critical point condition}.
\]

(S44)

Before discussing higher-order critical points, we observe that the third order coefficient, Eq. S43, is independent of any vector \(\omega^{(2)}\) not yet determined previously, and therefore does not provide a condition on the next higher vector \(\omega^{(2)}\).
Instead setting it to zero yields a further condition on \( \omega^{(1)} \) without the need for minimization. As we will see in the next subsection, this pattern that minimizing the coefficient in front of \( \epsilon^{2n} \) defines the vector \( \omega^{(n)} \) and that the coefficient of the next higher order \( \epsilon^{2n+1} \) only depends on the previously determined vectors \( \omega^{(m)} \), \( m \leq n \), is true for all values of \( n \). Correspondingly, increasing the order of the critical point by 1, \( n \rightarrow n+1 \), imposes two more conditions on the critical point and simultaneously defines one additional vector.

### S4.2 Higher-order critical points

More precisely, for an \( n \)-th order critical point we find the following recursive equation defining vectors \( \Upsilon^{(m)} \), \( m \leq n-1 \):

\[
\Upsilon^{(1)} = e^{(1)}
\]

\[
\Upsilon^{(m)} = -(A_{\text{pseudo}}^{(2)})^{-1} \sum_{l=3}^{m+1} A^{(l)} B_{m,l-1}(\Upsilon^{(1)}, \ldots, \Upsilon^{(m-1)}) = -(A_{\text{pseudo}}^{(2)})^{-1} b^{(m)} \quad \forall m = 2, \ldots, n-1. \tag{S45}
\]

Here, \((A_{\text{pseudo}}^{(2)})^{-1}\) is the pseudo-inverse of the Hessian \( H = A^{(2)} \) (which is singular on the spinodal where all critical points lie). Specifically, we define/choose it as

\[
(A_{\text{pseudo}}^{(2)})^{-1} := \delta_{ij} \rho_i - \rho_i \rho_j + \sum_{\gamma=2}^{R} \frac{1}{1 - \lambda^{(\gamma)}} e_i^{(\gamma)} e_j^{(\gamma)},
\]

where – as noted previously – we assume a non-degenerate maximal eigenvalue of 1 for the covariance matrix, i.e. that \( \lambda^{(\gamma)} < 1 \ \forall \gamma \geq 2 \). The vectors \( b^{(m)} \), \( m = 2, \ldots, n-1 \) satisfy the “orthogonality” relation

\[
\left\langle \Omega^{(1)} b^{(m)} \right\rangle_{cp} = 0. \tag{S47}
\]

The conditions of the \( n \)-th order critical point, Eqs. S30 and S40, can then be rewritten in terms of the vectors \( \Upsilon^{(m)} \) as

\[
\sum_{l=2}^{m} A^{(l)} B_{m,l}(\Upsilon^{(1)}, \Upsilon^{(2)}, \ldots) = A^{(2)} B_{m,2}(\Upsilon^{(1)}, \Upsilon^{(2)}, \ldots) + \sum_{l=3}^{m} (-1)^{l}(l-2)! \left\langle B_{m,l}(\Omega^{(1)}, \Omega^{(2)}, \ldots) \right\rangle_{\rho^{(cp)}} = 0 \quad \forall m = 2, \ldots, 2n-1, \tag{S48}
\]

where we used Eq. S25 to write the full contraction for \( l \geq 3 \) in terms of averages.

We will prove the recursion relation, Eq. S45 together with the orthogonality relation, Eq. S47 by induction.

**Base case** For an ordinary critical point \( (n = 2) \), we already know that \( \Upsilon^{(1)} = e^{(1)} \) and Eq. S45 is satisfied.

**Induction step** : \( n \rightarrow n+1 \) Suppose now that the recursion, Eq. S45 holds for a critical point of order \( n \). We will show that it then also holds for a critical point of order \( n+1 \). The argument will be done in three steps:

1. **Orthogonality** We show that if the recursion relation and the orthogonality condition hold for all \( m = 2, \ldots, n-1 \), then the orthogonality condition holds for \( n \) as well: \( \left\langle \Omega^{(1)} b^{(n)} \right\rangle_{\rho^{(cp)}} = 0 \).
2. **\( \epsilon^{2n} \)-term: Independence of higher-order vectors and minimization** next recursion step We demonstrate that the orthogonality condition implies that the coefficients in front of the \( \epsilon^{2n} \) term, which is the first additional one considered for a critical point of order \( n+1 \), does not depend on any vector \( \nu^{(i)} \) with \( i \geq n+1 \). By minimizing the coefficient for \( \epsilon^{2n} \) with respect to \( \nu^{(n)} \), we then recover the next step in the recursion, relating \( \Upsilon^{(n)} \) to the previously determined vectors \( \Upsilon^{(i)} \), \( i \leq n-1 \).
3. **\( \epsilon^{2n+1} \)-term: Independence of higher-order vectors** From the recursion relation for \( \Upsilon^{(n)} \) together with the orthogonality condition, it then follows that also the coefficient in front of the \( \epsilon^{2n+1} \) term is independent of any vector \( \nu^{(i)} \) with \( i \geq n+1 \).

We will go through them one-by-one.

Suppose that Eqs. S45 and S47 hold for a critical point of order \( n \).
1) Orthogonality  To begin with, we use the definition of \( b^{(n)} \) to write

\[
\langle \Omega^{(1)} b^{(n)} \rangle_{cp} = \left\langle \Omega^{(1)} \sum_{l=3}^{n+1} A^{(l)} B_{n,l-1} \left( \Upsilon^{(1)}, \Upsilon^{(2)}, \ldots \right) \right\rangle_{cp} = \sum_{l=3}^{n+1} (-1)^l(l-2)! \langle \Omega^{(1)} B_{n,l-1} \left( \Omega^{(1)}, \Omega^{(2)}, \ldots \right) \rangle_{cp},
\]

where we used Eq. S324 and \( \langle \Omega^{(1)} \rangle_{cp} = 0 \) to rewrite the partial contraction of \( A^{(l)} \) and \( B_{n,l-1} \). The partial Bell polynomials satisfy the recursion relation

\[
B_{n+1,l}(x^{(1)}, x^{(2)}, \ldots) = \sum_{i=1}^{n+2-l} \binom{n}{i-1} x^{(i)} B_{n+1-i,l-1}.
\]

Using this relation, we rewrite \( \langle \Omega^{(1)} b^{(n)} \rangle_{cp} \) as

\[
\langle \Omega^{(1)} b^{(n)} \rangle = \sum_{l=3}^{n+1} (-1)^l(l-2)! \left( \langle B_{n+1,l} \left( \Omega^{(1)}, \ldots \right) \rangle - \sum_{i=2}^{n+2-l} \binom{n}{i-1} \langle \Omega^{(i)} B_{n+1-i,l-1} \left( \Omega^{(1)}, \ldots \right) \rangle \right),
\]

where, for simplicity, we skip the index \( \text{cp} \) here and in the following. We have \( n \geq 2 \), or \( n+1 \leq 2n-1 \), and so

\[
\sum_{l=3}^{n+1} (-1)^l(l-2)! \langle B_{n+1,l} \left( \Omega^{(1)}, \ldots \right) \rangle = -\lambda^{(2)} B_{n+1,2}(\Upsilon^{(1)}, \Upsilon^{(2)}, \ldots),
\]

according to Eq. S48. Thus,

\[
\langle \Omega^{(1)} b^{(n)} \rangle = -\lambda^{(2)} B_{n+1,2}(\Upsilon^{(1)}, \Upsilon^{(2)}, \ldots) - \sum_{l=3}^{n+1} (-1)^l(l-2)! \sum_{i=2}^{n+2-l} \binom{n}{i-1} \langle \Omega^{(i)} B_{n+1-i,l-1} \left( \Omega^{(1)}, \ldots \right) \rangle = -\frac{1}{2} \sum_{k=2}^{n-1} \left( \binom{n+1}{k} A^{(2)} \rho^{(cp)} \Omega^{(k)} \right) \left[ \rho^{(cp)} \Omega^{(n+1-k)} \right] - \sum_{i=2}^{n-1} \left( \binom{n}{i-1} \langle \Omega^{(i)} b^{(n+1-i)} \rangle \right),
\]

where we used that \( A^{(2)} \Upsilon^{(1)} = 0 \) (spinodal condition) and the definition of

\[
b^{(n+1-i)} = \sum_{l=3}^{n+2-i} (-1)^l(l-2)! B_{n+1-i,l-1}(\Omega^{(1)}, \Omega^{(2)}, \ldots) - \sum_{l=3}^{n+2-i} (-1)^l(l-2)! B_{n+1-i,l-1}(\Omega^{(1)}_N, \Omega^{(2)}_N, \ldots)
\]

together with \( \langle \Omega^{(1)} \rangle = 0 \) for all \( i = 2, \ldots, n-1 \). Furthermore, \([xy]\) denotes a vector with indices \([xy]_i = x_i y_i\). For all \( k = 2, \ldots, n-1 \) the recursion relation \( \rho^{(cp)} \Omega^{(k)} = \Upsilon^{(k)} = -\lambda^{(2)} A^{(2)}_{\text{pseudo}} b^{(k)} \) holds by induction and we have

\[
\langle \Omega^{(1)} b^{(n)} \rangle = \frac{1}{2} \sum_{k=2}^{n-1} \left( \binom{n+1}{k} A^{(2)} \left[ A^{(2)}_{\text{pseudo}} b^{(k)} \right] \left[ \rho^{(cp)} \Omega^{(n+1-k)} \right] - \sum_{i=2}^{n-1} \left( \binom{n}{i-1} \langle \Omega^{(i)} b^{(n+1-i)} \rangle \right) \right).
\]

Employing Eq. S329 for the product of the Hessian \( A^{(2)} \) with its pseudo-inverse and using that \( b^{(k)}_N = 0 \) (Eq. S54), we find

\[
A^{(2)} \left[ A^{(2)}_{\text{pseudo}} b^{(k)} \right] = b^{(k)} - \langle \Omega^{(1)} b^{(k)} \rangle \sum_{\gamma=1}^{R} V^{(1)}_{\gamma} V^{(1)}_{\gamma} = b^{(k)},
\]

(56)
where we used that $\langle \Omega^{(1)} b^{(k)} \rangle = 0$ for $k = 2, \ldots, n - 1$ by induction. Thus,

$$\langle \Omega^{(1)} b^{(n)} \rangle = \frac{1}{2} \sum_{k=2}^{n-1} \left( \binom{n+1}{k} \langle \Omega^{(n+1-k)} b^{(k)} \rangle - 2 \binom{n}{k-1} \langle \Omega^{(k)} b^{(n+1-k)} \rangle \right).$$

(S57)

The recursion relation, Eq. S45 together with the definition of the pseudo-inverse, Eq. S46, implies that $\forall i, j = 2, \ldots, n - 1$

$$\langle \Omega^{(i)} b^{(j)} \rangle = b^{(j)} [\rho(\text{cp})]_{\Omega^{(i)}} = b^{(j)} \Upsilon^{(i)} = -b^{(j)} \left( A_{\text{pseudo}}^{(i)} \right)^{-1} b^{(i)} =$$

$$= -\langle b^{(i)} b^{(j)} \rangle + \langle b^{(i)} \rangle \langle b^{(j)} \rangle - \sum_{\gamma=2}^{n} \frac{1}{1 - \lambda(\gamma)} \langle b^{(i)} \rangle E^{(\gamma)} \langle b^{(j)} \rangle E^{(\gamma)} = \langle \Omega^{(j)} b^{(i)} \rangle,$$

(S58)

(S59)

where the last step is due to symmetry $i \leftrightarrow j$. As a result, we have

$$\langle \Omega^{(1)} b^{(n)} \rangle = \frac{1}{2} \sum_{k=2}^{n-1} \left( \binom{n+1}{k} \langle \Omega^{(n+1-k)} b^{(k)} \rangle - \binom{n}{k-1} \langle \Omega^{(k)} b^{(n+1-k)} \rangle \right) =$$

$$= \frac{1}{2} \sum_{k=2}^{n-1} \left( \binom{n+1}{k} \langle \Omega^{(n+1-k)} b^{(k)} \rangle - \binom{n}{n-k} \langle \Omega^{(n-k)} b^{(n-k)} \rangle - \langle \Omega^{(k)} \rangle \right) =$$

$$= \frac{1}{2} \sum_{k=2}^{n-1} \left( \binom{n+1}{k} - \binom{k}{n} - \binom{n}{k-1} \right) \langle b^{(k)} \rangle \Omega^{(n+1-k)}),$$

(S60)

In the second step, we used the variable transformation $k \rightarrow n + 1 - k$ on the second term. Overall, since $\binom{n+1}{k} - \binom{n}{k} - \binom{n}{n-k} = 0$ for $2 \leq k \leq n - 1$, we conclude that

$$\langle \Omega^{(1)} b^{(n)} \rangle = 0.$$ 

(S61)

2) $\epsilon^{2n}$-term: Independence of higher-order vectors and minimization: next recursion step

Consider now the coefficient in front of $\epsilon^{2n}$,

$$\frac{1}{(2n)!} \sum_{l=2}^{2n} A^{(l)} B_{2n,l}(v^{(1)}, v^{(2)}, \ldots) = \sum_{l=2}^{2n} A^{(l)} \sum_{\{p_1, \ldots, p_{2n}\} \in \mathbb{N}_0^{2n}} \prod_{j=1}^{2n} \left( \frac{1}{p_j!} \binom{v^{(j)}}{j} \right).$$

(S62)

Collecting all terms containing $v^{(n+1+s)}$ for $0 \leq s \leq n - 2$ ($B_{2n,l}$ only includes vectors $v^{(i)}$ with $i \leq 2n - l + 1$ since all its terms contain $l$ factors whose sum of superscripts needs to equal $2n$), we find

$$\tau_{n+1+s} := \sum_{l=2}^{2n} A^{(l)} \frac{v^{(n+1+s)}}{(n+1+s)!} \sum_{\{p_1, \ldots, p_{n+1+s}\} \in \mathbb{N}^{n+1-s}} \prod_{j=1}^{n+1-s} \left( \frac{1}{p_j!} \binom{v^{(j)}}{j} \right),$$

(S63)

where we used that any vector $v^{(n+1+s)}$ with $s \geq 0$ cannot be in a product together with any other vector $v^{(n-1-s+t)}$ with $t > 0$ (otherwise the sum of the superscripts exceeds $2n$). In particular $v^{(n+1+s)}$ with $s \geq 0$ cannot occur with a power $> 1$. Furthermore, since we factored out $v^{(n+1+s)}$ in the last sum the number of factors $l$ gets reduced by 1 and the sum of the superscripts by $n + 1 + s$ (effectively setting $p_{n+1+s} = 1$). We
observe that the last sum is exactly $B_{n-1-s,t-1/(n-1-s)!}$, giving

$$
\tau_{n+1+s} = \sum_{i=2}^{n-s} A^{(i)} B_{n-1,s,t-1}(v^{(i)}, v^{(2)}, \ldots) \frac{v^{(n+1+s)}}{(n+1+s)!(n-1-s)!} = \\
\left[ A^{(2)} B_{n-1,s,t-1}(v^{(1)}, v^{(2)}, \ldots) + \sum_{i=3}^{n-s} A^{(i)} B_{n-1,s,t-1}(v^{(1)}, v^{(2)}, \ldots) \right] \frac{v^{(n+1+s)}}{(n+1+s)!(n-1-s)!} = \\
\left[ A^{(2)} v^{(n-1-s)} + \sum_{i=3}^{n-s} A^{(i)} B_{n-1,s,t-1}(v^{(1)}, v^{(2)}, \ldots) \right] \frac{v^{(n+1+s)}}{(n+1+s)!(n-1-s)!},
$$

(S64)

where terms in brackets [ ] are to be interpreted as vectors with single index. Plugging in the optimal vectors as determined from the conditions for the $n$-th order critical point, $v^{(i)} = \Upsilon^{(i)} \forall i = 1, \ldots, n-1$, we have

$$
\tau_{n+1+s} = \left[ A^{(2)} \Upsilon^{(n-1-s)} + b^{(n-s-1)} \right] \frac{v^{(n+1+s)}}{(n+1+s)!(n-1-s)!},
$$

(S65)

Furthermore, the recursion relation for the $n$-th order critical point:

$$
\Upsilon^{(n-1-s)} = -\left( A^{(2)}_{pseudo} \right)^{-1} b^{(n-1-s)}
$$

(S66)

can be rewritten as

$$
A^{(2)} \Upsilon^{(n-1-s)} = -A^{(2)}(A^{(2)}_{pseudo})^{-1} b^{(n-1-s)} =
$$

(S67)

$$
= -b^{(n-1-s)} + \left( \sum_{\gamma=1}^{R} \Upsilon^{(1)} \gamma \right) \left( E^{(1)} b^{(n-1-s)} \right)_{\rho(cp)} =
$$

(S68)

$$
= -b^{(n-1-s)} + \left( \sum_{\gamma=1}^{R} \Upsilon^{(1)} \gamma \right) \left( \Omega^{(1)} b^{(n-1-s)} \right)_{\rho(cp)} = -b^{(n-1-s)}
$$

(S69)

using Eq. S329 and that $\left( \Omega^{(1)} b^{(n-1-s)} \right)_{\rho(cp)} = 0$ for all $0 \leq s \leq n-2$ due to the orthogonality relation for the $n$-th order critical point. Thus,

$$
\tau_{n+1+s} = 0
$$

(S70)

and the coefficient in front of $\epsilon^{2n}$ is independent of $v^{(n+1+s)}$ for $s \geq 0$. Correspondingly, the $\epsilon^{2n}$-coefficient is only a function of $v^{(n)}$ and the previously determined $\Upsilon^{(i)}, i = 1, \ldots, n-1$, and by minimizing it with respect to $v^{(n)}$, the optimal vector $\Upsilon^{(n)}$ can be determined.

Specifically, the coefficient in front of $\epsilon^{2n}$, $c_{2n}$ contains a quadratic term in $\Upsilon^{(n)}$, a linear term in $\Upsilon^{(n)}$ and a constant term:

$$
c_{2n} = \frac{1}{2(2n)!} \left( \frac{2n}{n} \right) A^{(2)} v^{(n)} v^{(n)} + \frac{2n}{n!} A^{(i)} v^{(n)} B_{n,t-1}(\Upsilon^{(1)}, \Upsilon^{(2)}, \ldots) + \text{const} =
$$

(S71)

$$
= \frac{1}{(n)!^2} \left( \frac{1}{2} A^{(2)} v^{(n)} v^{(n)} + \sum_{i=3}^{n+1} A^{(i)} B_{n,t-1}(\Upsilon^{(1)}, \Upsilon^{(2)}, \ldots) v^{(n)} \right) + \text{const} =
$$

(S72)

$$
= \frac{1}{(n)!^2} \left( \frac{1}{2} A^{(2)} v^{(n)} v^{(n)} + b^{(n)} v^{(n)} \right) + \text{const}.
$$

(S73)

Using the orthogonality condition for $b^{(n)}$ analogously as in Eq. S56 for $b^{(k)}, k = 2, \ldots, n-1$, $A^{(2)} \left[ (A^{(2)}_{pseudo})^{-1} b^{(n)} \right] = b^{(n)}$, we rewrite $c_{2n} := 2(n)!^2 (c_{2n} - \text{const})$ as

$$
c_{2n} = \left( v^{(n)} + (A^{(2)}_{pseudo})^{-1} b^{(n)} \right)^T A^{(2)} \left[ v^{(n)} + (A^{(2)}_{pseudo})^{-1} b^{(n)} \right] - \left[ b^{(n)} \right]^T (A^{(2)}_{pseudo})^{-1} b^{(n)},
$$

(S74)
where we used the normal matrix and vector \([\cdot]\) notation (\([\cdot]^T\) is the transpose).

Since the Hessian \(A^{(2)}\) is a positive semi-definite matrix, \(c^{(i)}\) (or, equivalently, \(c_{2n}\)) has a minimum for \(\upsilon^{(n)} = \Upsilon^{(n)}\) if

\[
\Upsilon^{(n)} = -(A^{(2)}_{\text{pseudo}})^{-1}b^{(n)} + \alpha e^{(1)}
\]

(S75)

for any \(\alpha \in \mathbb{R}\). Here, we choose \(\alpha = 0\) for simplicity. This choice, however, does not influence any of our conditions for critical points as it just corresponds to a rescaling of the path in density space (see below). We thus recover the next step of the recursion relation:

\[
\Upsilon^{(n)} = -(A^{(2)}_{\text{pseudo}})^{-1}b^{(n)}.
\]

(S76)

The minimized coefficient \(c_{2n}^{\text{min}}\) must then equal zero and we find the first additional condition when going from an \(n\)-th to and \(n+1\)-th order critical point:

\[
\sum_{l=2}^{2n} A^{(l)} B_{2n,l}(\Upsilon^{(1)}, \Upsilon^{(2)}, \ldots) = 0.
\]

(S77)

As discussed before, this expression is a function of \(\Upsilon^{(1)}, \ldots, \Upsilon^{(n)}\) only. All terms with higher-order vectors cancel each other. The same is true for the coefficient in front of the \(c^{2n+1}\) term, as we will show next. Therefore, for an \((n+1)\)-th order critical point, only the vectors \(\Upsilon^{(1)}, \ldots, \Upsilon^{(n)}\) need to be (or can uniquely be) specified.

3) \(c^{2n+1}\)-term: Independence of higher-order vectors Similarly, we rewrite the coefficient in front of \(c^{2n+1}\):

\[
\frac{1}{(2n+1)!} \sum_{l=2}^{2n+1} A^{(l)} B_{2n+1,l}(\upsilon^{(1)}, \upsilon^{(2)}, \ldots) = \sum_{l=2}^{2n+1} A^{(l)} \sum_{\{p_1, \ldots, p_{2n+1}\} \in \mathbb{N}^{2n+1}} \prod_{j=1}^{2n+1} \left( \frac{1}{p_j!} \binom{\upsilon(j)}{p_j} \right).
\]

(S78)

The terms linear in \(\upsilon^{(n+s)}\) for \(0 \leq s \leq n - 2\) are

\[
\tilde{\tau}_{n+1+s} := \sum_{l=2}^{2n+1} A^{(l)} \frac{\upsilon^{(n+s)}}{(n+1+s)!} \sum_{\{p_1, \ldots, p_{2n+1}\} \in \mathbb{N}^{n-s}} \prod_{j=1}^{n-s} \left( \frac{1}{p_j!} \binom{\upsilon(j)}{p_j} \right) = \sum_{l=2}^{2n+1} A^{(l)} B_{n-s,l-1}(\upsilon^{(1)}, \upsilon^{(2)}, \ldots) \frac{\upsilon^{(n+s)}}{(n+1+s)! (n-s)!} = A^{(2)} \upsilon^{(n-s)} + \sum_{l=3}^{n-s+1} A^{(l)} B_{n-s,l-1}(\upsilon^{(1)}, \upsilon^{(2)}, \ldots) \frac{\upsilon^{(n+s)}}{(n+1+s)! (n-s)!}.
\]

(S80)

(S81)

Evaluated at \(\upsilon^{(i)} = \Upsilon^{(i)}\) \(\forall i = 1, \ldots, n-1\), this expression yields

\[
\tilde{\tau}_{n+1+s} = [A^{(2)} \Upsilon^{(n-s)} + b^{(n-s)}] \frac{\upsilon^{(n+s)}}{(n+1+s)! (n-s)!} = 0,
\]

(S82)

where we used the recursion relation for \(\Upsilon^{(i)}\) together with the orthogonality condition \(\langle \Omega^{(1)} b^{(i)} \rangle_{\rho^{(c)}} = 0\) for all \(1, \ldots, n\) (with the ones for \(i = n\) as determined by induction in the first and second step, respectively). Furthermore, the term linear in \(\upsilon^{(2n)}\) is \(\tilde{\tau}_{2n} = A^{(2)} \Upsilon^{(2n)} \frac{\upsilon^{(2n)}}{(2n)!} = 0\).

The coefficient \(c_{2n+1}\) in front of \(c^{2n+1}\) is thus fully determined by the vectors \(\Upsilon^{(i)}, i = 1, \ldots, n\) and cannot be minimized by a specific choice of higher-order vectors - in contrast to \(c_{2n}\).
Taken together, we find the following to additional conditions for an $n + 1$-th order critical point as compared to an $n$-th order critical point:

$$\sum_{l=2}^{2n} A^{(l)} B_{2n,l}(\Upsilon^{(1)}, \Upsilon^{(2)}, \ldots) = 0$$  \hspace{1cm} (S83)

$$\sum_{l=2}^{2n+1} A^{(l)} B_{2n+1,l}(\Upsilon^{(1)}, \Upsilon^{(2)}, \ldots) = 0,$$  \hspace{1cm} (S84)

which both only depend on the vectors $\Upsilon^{(i)}, i = 1, \ldots, n$ given by the recursion relation

$$\Upsilon^{(1)} = e^{(1)}$$

$$\Upsilon^{(i)} = -(A_{\text{pseudo}}^{-1})^{i-1} \sum_{l=3}^{i+1} A^{(l)} B_{i,l-1}(\Upsilon^{(1)}, \ldots, \Upsilon^{(i-1)}), \quad i \geq 2.$$  \hspace{1cm} (S85)

It follows that

$$\Omega^{(1)} = E^{(1)}$$  \hspace{1cm} (S86)

and for $i = 2, \ldots, n$

$$\rho^{(cp)} \Omega^{(i)} = -(A_{\text{pseudo}}^{-1})^{i-1} \sum_{l=3}^{i+1} (-1)^{l-2} \left[ B_{i,l-1}(\Omega^{(1)}, \Omega^{(2)}, \ldots) - B_{i,l-1}(\Omega^{(1)}, \ldots, \Omega^{(i-2)}, \Omega^{(i)}, \ldots) \right] =$$

$$= -\rho^{(cp)} \sum_{l=3}^{i+1} (-1)^{l-2} \left[ B_{i,l-1}(\Omega) - \langle B_{i,l-1}(\Omega) \rangle_{cp} + \sum_{\gamma=2}^{R} \frac{1}{1 - \lambda(\gamma)} E^{(\gamma)} \langle E^{(\gamma)} B_{i,l-1}(\Omega) \rangle_{cp} \right] =$$

$$= \rho^{(cp)} \sum_{l=2}^{i} (-1)^{l} \left[ B_{i,l}(\Omega) - \langle B_{i,l}(\Omega) \rangle_{cp} + \sum_{\gamma=2}^{R} \frac{1}{1 - \lambda(\gamma)} E^{(\gamma)} \langle E^{(\gamma)} B_{i,l}(\Omega) \rangle_{cp} \right],$$  \hspace{1cm} (S87)

where we used Eqs. S324, S326 and abbreviated $B_{i,l}(\Omega) := B_{i,l}(\Omega^{(1)}, \Omega^{(2)}, \ldots)$. Thus, we find the following vectors for an $n$-th order critical point:

$$\Omega^{(1)} = E^{(1)}$$  \hspace{1cm} (S90)

$$\Omega^{(i)} = \sum_{l=2}^{i} \left[ \tilde{B}_{i,l}(\Omega) - \langle \tilde{B}_{i,l}(\Omega) \rangle_{cp} + \sum_{\gamma=2}^{R} \frac{1}{1 - \lambda(\gamma)} E^{(\gamma)} \langle E^{(\gamma)} \tilde{B}_{i,l}(\Omega) \rangle_{cp} \right] \quad \forall i = 2, \ldots, n - 1,$$  \hspace{1cm} (S91)

with $\tilde{B}_{i,l}(\Omega) := (-1)^{i-1} B_{i,l}(\Omega)$, as given in the main text.

The conditions for the $n$-th order critical point are then

$$0 = \sum_{l=2}^{m} A^{(l)} B_{m,l}(\Omega) =$$

$$= \sum_{l=2}^{m} \sum_{k=1}^{m-1} R \left[ \langle r(\gamma) \Omega^{(k)} \rangle_{cp} \langle r(\gamma) \Omega^{(m-k)} \rangle_{cp} \right] \sum_{\gamma=2}^{R} \frac{1}{1 - \lambda(\gamma)} E^{(\gamma)} \langle E^{(\gamma)} B_{m,l}(\Omega) \rangle_{cp} \quad \forall m = 2, \ldots, 2n - 1,$$  \hspace{1cm} (S93)

where we used Eqs. S320, S325 and that $B_{m,2}(\Omega) = \frac{1}{2} \sum_{k=1}^{m-1} \binom{m}{k} \Omega^{(k)} \Omega^{(m-k)}$.

Note that choosing a different pseudo-inverse by adding a term like $\beta e_i^{(1)} e_j^{(1)}$ to our specific choice of the pseudo-inverse, Eq. S46, does not influence our results: $\Omega^{(1)}$ is orthogonal to $b^n$ for any choice of $\beta$. 

24
S4.3 Recursion relation in terms of derivatives of an “Hamiltonian”-like function

Instead of expressing the recursion relation in terms of the partial exponential Bell polynomials, they can also be rewritten in terms of derivatives of a “Hamiltonian”-like function. To see this equivalence, we define the analytic function $G(\epsilon)$ with $G(0) \equiv 1$ (for convenience, see below) via its derivatives at $\epsilon = 0$:

$$G^{(m)}(\epsilon) \bigg|_{\epsilon=0} := \frac{d^m G(\epsilon)}{d\epsilon^m} \bigg|_{\epsilon=0} = \Omega^{(m)} \quad \forall m \geq 1,$$

which needs to fulfill $\Omega^{(0)}(0) = 1$. The function $G$ needs to fulfil

$$0 = \left( \Omega^{(m)} \right)_{cp} = \frac{d^m \left< G \right>_{cp}}{d\epsilon^m} \bigg|_{\epsilon=0} \quad \forall m \geq 1,$$

or equivalently,

$$\left< G \right>_{cp} = \text{const} = \left< G(0) \right>_{cp} = 1.$$  

Note that since $\Omega^{(m)}$ is a vector, $G^{(m)}$ is also a vector: $G^{(m)}(\epsilon) \bigg|_{\epsilon=0} = \Omega^{(m)}$. The recursion relation for an $n$-th order critical point, Eq. S45, is then rewritten as

$$\Upsilon^{(m)} = -(A_{\text{pseudo}}^{(2)})^{-1} \sum_{l=1}^{m} A^{(l+1)} B_{m,l} (\rho^{(cp)} G^{(1)}(\epsilon), \rho^{(cp)} G^{(2)}(\epsilon), \ldots) \bigg|_{\epsilon=0} =$$

$$= -(A_{\text{pseudo}}^{(2)})^{-1} \sum_{l=2}^{m} (-1)^{l+1} (l-1)! \left[ B_{m,l} (G^{(1)}(\epsilon), G^{(2)}(\epsilon), \ldots) - B_{m,l} (G^{(1)}_{N}(\epsilon), G^{(2)}_{N}(\epsilon), \ldots) \right] \bigg|_{\epsilon=0} \quad \forall m = 2, \ldots, n - 1,$$

using Eq. S324. Importantly, the partial Bell polynomials satisfy Faà di Bruno’s formula:

$$\frac{d^n}{d\epsilon^n} F(G(\epsilon)) = \sum_{k=1}^{n} F^{(k)}(G(\epsilon)) B_{n,k}(G^{(1)}(\epsilon), G^{(2)}(\epsilon), \ldots).$$

We use this formula for the function $F(x) = 1 - x + \log x$, whose derivatives fulfil $F^{(k)}(G(\epsilon)) \big|_{\epsilon=0} = F^{(k)}(1) = (-1)^{k+1}(k-1)! \forall k \geq 2$ and $F^{(k)}(G(\epsilon)) \big|_{\epsilon=0} = 0$ otherwise. This allows us to express $\Upsilon^{(m)}$ as follows:

$$\Upsilon^{(m)} = -(A_{\text{pseudo}}^{(2)})^{-1} \frac{d^m}{d\epsilon^m} \left[ F(G(\epsilon)) - F(G_{N}(\epsilon)) \right] \bigg|_{\epsilon=0} = (A_{\text{pseudo}}^{(2)})^{-1} \frac{d^m}{d\epsilon^m} \left[ G - \log G - G_{N} + \log G_{N} \right] \bigg|_{\epsilon=0} =$$

$$= \rho \frac{d^m}{d\epsilon^m} \left[ G - \log G - \left< G \right>_{cp} + \left< \log G \right>_{cp} + \sum_{\gamma=2}^{R} \frac{1}{1 - \lambda(\gamma)} E^{(\gamma)} \left< E^{(\gamma)} (G - \log G) \right>_{cp} \right] \bigg|_{\epsilon=0} \quad \forall m = 2, \ldots, n - 1,$$

where in the last step we used Eq. S326. Thus,

$$\frac{d^m}{d\epsilon^m} G \bigg|_{\epsilon=0} = \frac{d^m}{d\epsilon^m} \left[ G - \log G - \left< G \right>_{cp} + \left< \log G \right>_{cp} + \sum_{\gamma=2}^{R} \frac{1}{1 - \lambda(\gamma)} E^{(\gamma)} \left< E^{(\gamma)} (G - \log G) \right>_{cp} \right] \bigg|_{\epsilon=0} \quad \forall m = 2, \ldots, n - 1.$$
While for general number of features, we did not manage to find an explicit solution to these equations, we did solve them. We now express

\[ G = \frac{e^h}{\langle e^h \rangle_{cp}} \quad \text{or} \quad \log G = h - \log \langle e^h \rangle_{cp} \]  

(S104)

in terms of a Hamiltonian-like function \( h \) with \( h(0) = 0 \). This specific form satisfies \( G(0) = 1 \) and \( \langle G \rangle_{cp} = 1 \) as desired. Eq. [S103] then requires that the Hamiltonian fulfils

\[ \frac{d^m}{d\epsilon^m} \left[ -h + \langle h \rangle_{cp} + \sum_{\gamma=2}^{R} \frac{1}{1 - \lambda(\gamma)} E^{(\gamma)} \left( E^{(\gamma)} \left( \frac{e^h}{\langle e^h \rangle_{cp}} - h \right) \right) \right] \bigg|_{\epsilon=0} \forall m = 2, ..., n - 1. \]  

(S105)

since \( \langle E^{(\gamma)} \log \langle e^h \rangle_{cp} \rangle_{cp} = 0 \). Assuming that \( h \) is analytic, we thus find

\[ h - \langle h \rangle_{cp} - \sum_{\gamma=2}^{R} \frac{1}{1 - \lambda(\gamma)} E^{(\gamma)} \left( E^{(\gamma)} \left( \frac{e^h}{\langle e^h \rangle_{cp}} - h \right) \right)_{cp} = c_0 + c_1 \epsilon + \mathcal{O}(\epsilon^n). \]  

(S106)

Evaluating this expression and its derivative at \( \epsilon = 0 \) determines the constants of integration:

\[ c_0 = 0 \]  

(S107)

\[ c_1 = \Omega^{(1)}, \]  

(S108)

where we used that \( \Omega^{(1)} = G^{(1)}(\epsilon = 0) = h^{(1)}(\epsilon) - \langle h^{(1)}(\epsilon) \rangle_{cp} \bigg|_{\epsilon=0} \). Taken together,

\[ h - \langle h \rangle_{cp} - \sum_{\gamma=2}^{R} \frac{1}{1 - \lambda(\gamma)} E^{(\gamma)} \left( E^{(\gamma)} \left( \frac{e^h}{\langle e^h \rangle_{cp}} - h \right) \right)_{cp} = \epsilon \Omega^{(1)} + \mathcal{O}(\epsilon^n). \]  

(S109)

This form of the recursion relation has to be combined with the conditions for the critical points, Eqs. [S48] which are rewritten as

\[ \frac{d^k}{d\epsilon^k} \left[ \frac{\langle e^h \rangle_{cp} - \log \langle e^h \rangle_{cp}}{\langle e^h \rangle_{cp}^2} - \frac{1}{2} \sum_{\gamma=1}^{R} \frac{\langle r^{(\gamma)} \rangle_{cp} \langle e^h \rangle_{cp} - 2 \langle e^h \rangle_{cp} \langle r^{(\gamma)} \rangle_{cp}}{\langle e^h \rangle_{cp}^2} \right] \bigg|_{\epsilon=0} = 0 \quad \forall k = 2, ..., 2n - 1 \]  

(S110)

in terms of the Hamiltonian \( h \), using Faà di Bruno’s formula with \( F(x) = -x + x \log x + 1 \).

While for general number of features, we did not manage to find an explicit solution to these equations, we did solve them for \( R = 1 \). We discuss this solution in the next subsection.

### S4.4 Single feature \( R = 1 \): Solution of the recursion relation and explicit conditions for higher-order critical points

For a single feature \( R = 1 \), the recursion relation for the Hamiltonian \( h \), Eq. [S109] reduces to

\[ h - \langle h \rangle_{cp} = \epsilon \Omega^{(1)} + \mathcal{O}(\epsilon^n) = \epsilon \left( r - \langle r \rangle_{cp} \right) + \mathcal{O}(\epsilon^n), \]  

(S111)

where we abbreviated \( r^{(1)} = r \) and have used that \( \Omega^{(1)} = E^{(1)} = \sum_{\gamma=1}^{1} V_{\gamma}^{(1)} \langle r^{(\gamma)} \rangle_{cp} - \langle r^{(\gamma)} \rangle_{cp} \rangle_{cp} = r - \langle r \rangle_{cp} \). This recursion – indeed for all orders \( n \) – is solved by

\[ h = \epsilon r + c = cr, \]  

(S112)
where \( c \) is a constant in terms of the vector, i.e. independent of the vector index. Without loss of generality, we choose \( c = 0 \) (any constant cancels in \( G = e^{h+c}/\langle e^{h+c} \rangle_{cp} = e^{h}/\langle e^{h} \rangle_{cp} \)) and we find
\[
G = \frac{e^{cr}}{\langle e^{cr} \rangle_{cp}}.
\] (S113)

In terms of \( G \) (or the Hamiltonian \( h = cr \)), the optimal path is given by
\[
\rho_{i}^{\text{opt}}(\epsilon) = \rho_{i}^{(cp)} \left( 1 + \sum_{m=1}^{\infty} \frac{\epsilon^{m}}{m!} \Omega_{i}^{(m)} \right) = \rho_{i}^{(cp)} \sum_{m=0}^{\infty} \frac{\epsilon^{m}}{m!} G_{i}^{(m)}(0) = \rho_{i}^{(cp)} G(\epsilon) = \rho_{i}^{(cp)} \frac{e^{cr}}{\langle e^{cr} \rangle_{cp}}.
\] (S114)

Here, it becomes apparent why we chose \( G(0) = 1 \): This choice allows to directly express the optimal path as Taylor series of \( G \) in \( \epsilon \).

This explicit representation of the optimal path (vectors) in terms of \( G \) also enables us to derive explicit conditions for critical points of arbitrary order \( n \). To that end, we rewrite the conditions for higher-order critical points, Eq. S48, in terms of \( G \):
\[
0 = \sum_{l=2}^{m} A^{(l)} B_{m,l}(Y^{(1)}, Y^{(2)}, \ldots) = \frac{1}{2} \sum_{k=1}^{m-1} \binom{m}{k} \left[ r \Omega^{(k)} \right]_{cp} \langle r \Omega^{(m-k)} \rangle_{cp} + \sum_{l=2}^{m} (-1)^{l} (l-2)! \langle B_{m,l}(\Omega^{(1)}, \Omega^{(2)}, \ldots) \rangle_{cp} \quad \forall m = 2, \ldots, 2n-1,
\] (S115)

where we used Eq. [S320] and that \( B_{m,2}(x^{(1)}, x^{(2)}, \ldots) = \frac{1}{2} \sum_{k=1}^{m-1} \binom{m}{k} x^{(k)} x^{(m-k)} \). Defining \( \bar{F}(x) := 1 - x + x \log x \), whose derivatives are \( \bar{F}^{(k)}(G(0)) = \bar{F}^{(k)}(1) = (-1)^{k} (k-2)! \forall k \geq 2 \) and \( \bar{F}^{(k)}(G(0)) = 0 \) otherwise, we use Faà di Bruno’s formula again and find
\[
0 = \left[ -\frac{1}{2} \sum_{k=1}^{m-1} \binom{m}{k} \left[ r \frac{\partial}{\partial \epsilon} \langle r G^{(k)} \rangle_{cp} \right] + \sum_{l=2}^{m} (-1)^{l} (l-2)! \langle B_{m,l}(\langle r G^{(1)} \rangle_{cp}, \langle G^{(2)} \rangle_{cp}, \ldots) \rangle_{cp} \right] \bigg|_{\epsilon=0} = \frac{d}{d\epsilon} \langle r G \rangle_{cp}
\] (S116)
\[
0 = \left[ -\frac{1}{2} \sum_{k=1}^{m-1} \binom{m}{k} \left[ \frac{d}{d\epsilon} \langle r G \rangle_{cp} \right] + \frac{d}{d\epsilon} \langle r G \rangle_{cp} \right] \bigg|_{\epsilon=0} = \frac{d}{d\epsilon} \langle G \log G \rangle_{cp}
\] (S117)
\[
0 = \left[ -\frac{1}{2} \sum_{k=1}^{m-1} \binom{m}{k} \left[ \frac{d}{d\epsilon} \langle r G \rangle_{cp} \right] + \frac{d}{d\epsilon} \langle G \log G \rangle_{cp} \right] \bigg|_{\epsilon=0} = \frac{d}{d\epsilon} \langle G \log G \rangle_{cp}
\] (S118)

since \( \frac{d^{m}}{d\epsilon^{m}} (1 - G)_{cp} = -\langle \Omega^{(m)} \rangle_{cp} = 0 \) for \( m \geq 2 \). Importantly, both \( \langle r G \rangle_{cp} \) and \( \langle G \log G \rangle_{cp} \) can be written in terms of the cumulant-generating function
\[
K_{r}(\epsilon) = \log \langle e^{cr} \rangle_{cp}
\] (S119)
of \( r \):
\[
\langle r G \rangle_{cp} = \frac{\langle re^{cr} \rangle_{cp}}{\langle e^{cr} \rangle_{cp}} = \frac{d}{d\epsilon} \log \langle e^{cr} \rangle_{cp} = \frac{d}{d\epsilon} K_{r}(\epsilon)
\] (S120)
\[
\langle G \log G \rangle_{cp} = \frac{\langle e^{cr} \left( r - \log \langle e^{cr} \rangle_{cp} \right) \rangle_{cp}}{\langle e^{cr} \rangle_{cp}} = \frac{d}{d\epsilon} \log \langle e^{cr} \rangle_{cp} - \log \langle e^{cr} \rangle_{cp} = \frac{d}{d\epsilon} K_{r}(\epsilon) - K_{r}(\epsilon).
\] (S121)

Using that
\[
\frac{d^{m}}{d\epsilon^{m}} \left( \epsilon \frac{d}{d\epsilon} K_{r}(\epsilon) - K_{r}(\epsilon) \right) = (m-1) \frac{d^{m} K_{r}}{d\epsilon^{m}} + \epsilon \frac{d^{m+1} K_{r}}{d\epsilon^{m+1}} \quad \forall m \geq 1,
\] (S122)
which can be shown by induction, the conditions for an $n$-th order critical point, Eq. S118, are given in terms of the cumulants of $r$:

\[
0 = \left[ -\frac{1}{2} \sum_{k=1}^{m-1} \binom{m}{k} \left( \frac{d^{k+1}}{de^{k+1}} K_r(e) \right) \left( \frac{d^{m-k-1}}{de^{m-k-1}} K_r(e) \right) + (m-1) \frac{d^m}{de^m} K_r(e) \right]_{e=0} = (S123)
\]

\[
= -\frac{1}{2} \sum_{k=1}^{m-1} \binom{m}{k} \kappa_{k+1, m-k+1} + (m-1) \kappa_m \quad \forall m = 2, \ldots, 2n-1. \tag{S124}
\]

Here, $\kappa_i$ is the $i$-th cumulant of $r$. Solving these equations recursively yields:

\[
\kappa_2 = 1 \tag{S125}
\]

\[
\kappa_i = 0 \quad \forall i = 3, \ldots, 2n-1, \tag{S126}
\]

which we briefly demonstrate by induction:

**Base case** $n = 2$ Eq. S124 gives:

\[
m = 2 : \quad 0 = -\frac{1}{2} \sum_{k=1}^{2} \binom{2}{k} \kappa_{k+1, 2-k} + \kappa_2 = \kappa_2(1 - \kappa_2) \tag{S127}
\]

\[
m = 3 : \quad 0 = -\frac{1}{2} \sum_{k=1}^{2} \binom{3}{k} \kappa_{k+1, 3-k} + 2\kappa_3 = -3\kappa_2\kappa_3 + 2\kappa_3. \tag{S128}
\]

Since $\kappa_2$ corresponds to the variance of $r = \sqrt{2Cs}$ and since $\kappa_2 = 0$ can be excluded as this case would correspond to all component types being equal, we conclude that $\kappa_2 = 1$ and $\kappa_3 = 0$.

**Induction step** $n \rightarrow n + 1$ Assuming that $\kappa_2 = 1$ and $\kappa_i = 0 \quad \forall i = 3, \ldots, 2n-1$, Eq. S124 yields

\[
m = 2n : \quad 0 = -\frac{1}{2} \sum_{k=1}^{2n-1} \binom{2n}{k} \kappa_{k+1, 2n-k+1} + (2n-1)\kappa_{2n} = \tag{S129}
\]

\[
= -\frac{1}{2} \sum_{k=2}^{2n-2} \binom{2n}{k} \kappa_{k+1, 2n-k+1} - 2n\kappa_2\kappa_2 + (2n-1)\kappa_{2n} = \tag{S130}
\]

\[
= -\frac{1}{2} \sum_{k=2}^{2n-2} \binom{2n}{k} \kappa_{k+1, 2n-k+1} - \kappa_{2n} \quad \text{and} \tag{S131}
\]

\[
m = 2n + 1 : \quad 0 = -\frac{1}{2} \sum_{k=1}^{2n} \binom{2n+1}{k} \kappa_{k+1, 2n+2-k} + 2n\kappa_{2n+1} = \tag{S132}
\]

\[
= -\frac{1}{2} \sum_{k=2}^{2n-1} \binom{2n+1}{k} \kappa_{k+1, 2n+2-k} - (2n+1)\kappa_2\kappa_{2n+1} + 2n\kappa_{2n+1} = \tag{S133}
\]

\[
= -\frac{1}{2} \sum_{k=2}^{2n-1} \binom{2n+1}{k} \kappa_{k+1, 2n+2-k} - \kappa_{2n+1}. \tag{S134}
\]

By induction, we know that $\kappa_i = 0 \quad \forall i = 3, \ldots, 2n-1$, and we conclude that $\kappa_{2n} = \kappa_{2n+1} = 0$.

Overall, we thus find the following conditions for an $n$-th order critical point:

\[
\kappa_2 = 1 \tag{S135}
\]

\[
\kappa_m = 0 \quad \forall m = 3, \ldots, 2n-1, \tag{S136}
\]

28
The partial exponential Bell polynomials can be defined via the following series expansion:

\[ \kappa_2^{(s)} = \frac{1}{2C} = \frac{kT}{zJ} \]  
\[ \kappa_m^{(s)} = 0 \quad \forall m = 3, \ldots, 2n - 1. \]  

In the limit \( n \to \infty \), the spins \( s_i \) need to be distributed according to a Gaussian with variance \( 1/(2C) \), implicitly requiring an infinite number of component types \( N \to \infty \).

### S4.5 Choice of \( \alpha \) in the recursion relation

In Eq. S75, we have seen that in principle there are several solutions for the recursion relation, namely all recursions of the form

\[ Y^{(1)} = \alpha^{(1)} e^{(1)} \]  
\[ Y^{(n)} = -(A^{(2)}_{\text{pseudo}})^{-1} b^{(n)}(Y^{(1)}, Y^{(2)}, \ldots) + \alpha^{(n)} e^{(1)}, \]  

where \( \alpha^{(n)} \) is a constant and \( \alpha^{(1)} \neq 0 \) (otherwise, all \( Y^{(n)} = 0 \)). So far, we have chosen \( \alpha^{(n)} = \delta_{n1} \), and one may wonder whether other choices lead to the same conditions for the spinodal and critical points.

In this section, we show that the choice of \( \alpha^{(n)} \) (with \( \alpha^{(1)} \neq 0 \)) does not change our results. Instead it just corresponds to an effective rescaling of \( \epsilon \). To see this, we perform the following steps:

1. We show that if \( Z^{(i)} = \sum_{j=1}^{i} Y^{(j)} B_{i,j}(\alpha^{(1)}, \alpha^{(2)}, \ldots) \) for all \( i = 1, \ldots, n - 1 \), then
   \[ B_{k,m}(Z^{(1)}, Z^{(2)}, \ldots) = \sum_{j=m}^{k} B_{k,j}(\alpha^{(1)}, \alpha^{(2)}, \ldots) B_{j,m}(Y^{(1)}, Y^{(2)}, \ldots) \quad \forall k = 2, \ldots, n \quad \forall m = 2, \ldots, k. \]

2. Using the previous equation, we then demonstrate that if \( Y \) solves the recursion relation
   \[ Y^{(1)} = e^{(1)} \]  
\[ Y^{(m)} = -(A^{(2)}_{\text{pseudo}})^{-1} b^{(m)}(Y^{(1)}, \ldots) \quad \forall m = 2, \ldots, n - 1 \]

and \( Z \) solves

\[ Z^{(1)} = \alpha^{(1)} e^{(1)} \]  
\[ Z^{(m)} = -(A^{(2)}_{\text{pseudo}})^{-1} b^{(m)}(Z^{(1)}, \ldots) + \alpha^{(m)} e^{(1)} \quad \forall m = 2, \ldots, n - 1, \]

then

\[ Z^{(i)} = \sum_{j=1}^{i} Y^{(j)} B_{i,j}(\alpha^{(1)}, \alpha^{(2)}, \ldots) \quad \forall i = 1, \ldots, n - 1. \]

3. We show that the conditions for a critical point of order \( n \) determined previously, \( \sum_{i=2}^{m} A^{(i)} B_{m,i} = 0 \forall m = 2, \ldots, 2n - 1 \), are equivalent for \( Y^{(n)} \) and \( Z^{(n)} \): If \( \sum_{i=2}^{m} A^{(i)} B_{m,i}(Y^{(1)}, Y^{(2)}, \ldots) = 0 \forall m = 2, \ldots, 2n - 1 \) then \( \sum_{i=2}^{m} A^{(i)} B_{m,i}(Z^{(1)}, Z^{(2)}, \ldots) = 0 \forall m = 2, \ldots, 2n - 1 \) and vice versa.

The partial exponential Bell polynomials can be defined via the following series expansion:

\[ \sum_{n=k}^{\infty} B_{n,k}(x^{(1)}, x^{(2)}, \ldots) \frac{t^n}{n!} = \frac{1}{k!} \left( \sum_{j=1}^{\infty} x^{(j)} \frac{t^j}{j!} \right)^k. \]
Thus, $B_{n,k}(x^{(1)}, x^{(2)}, \ldots)$ is given by

$$B_{n,k}(x^{(1)}, x^{(2)}, \ldots) = \frac{1}{k!} \frac{\partial^n}{\partial t^n} \left. \left( \sum_{m=1}^{\infty} x^{(m)} \frac{t^m}{m!} \right)^k \right|_{t=0}. \quad (S148)$$

Using this expression and abbreviating $B_{n,k}(x^{(1)}, x^{(2)}, \ldots) =: B_{n,k}(x)$, we rewrite

$$\sum_{j=m}^{k} B_{k,j}(\alpha) B_{j,m}(Y) = \sum_{j=m}^{k} \frac{1}{j! m!} \frac{\partial^k}{\partial t^k} \left. \left( \sum_{r=1}^{\infty} \alpha^{(r)} \frac{t^r}{r!} \right)^j \right|_{t=0} \frac{\partial^j}{\partial s^j} \left. \left( \sum_{n=1}^{\infty} Y^{(n)} \frac{s^n}{n!} \right)^m \right|_{s=0} = \quad (S149)$$

$$= \frac{1}{m!} \frac{\partial^k}{\partial t^k} \left[ \sum_{j=m}^{k} \frac{1}{j!} \left( \sum_{r=1}^{\infty} \alpha^{(r)} \frac{t^r}{r!} \right)^j \frac{\partial^j}{\partial s^j} \left( \sum_{n=1}^{\infty} Y^{(n)} \frac{s^n}{n!} \right)^m \right]_{t,s=0}. \quad (S150)$$

As a next step, we observe that the boundaries for $j$ can be extended to 0 and $\infty$, respectively. For $j \geq k + 1$, the term $(\sum_{r=1}^{\infty} \alpha^{(r)} \frac{t^r}{r!})^j$ is of order $O(t^{k+1})$ since $r \geq 1$, and yields a zero contribution when the $k$-th derivative $\partial^k / \partial t^k$ is evaluated at $t = 0$. Similarly, for $j \leq m - 1$, the term $(\sum_{n=1}^{\infty} Y^{(n)} \frac{s^n}{n!})^m$ is of order $O(s^{j+1})$ and is zero when the derivative $\partial^j / \partial s^j$ is evaluated at $s = 0$. We thus find

$$\sum_{j=m}^{k} B_{k,j}(\alpha) B_{j,m}(Y) = \frac{1}{m!} \frac{\partial^k}{\partial t^k} \left[ \sum_{j=m}^{\infty} \frac{1}{j!} \left( \sum_{r=1}^{\infty} \alpha^{(r)} \frac{t^r}{r!} \right)^j \frac{\partial^j}{\partial s^j} \left( \sum_{n=1}^{\infty} Y^{(n)} \frac{s^n}{n!} \right)^m \right]_{t=0} = \quad (S151)$$

$$= \frac{1}{m!} \frac{\partial^k}{\partial t^k} \left[ \left( \sum_{n=1}^{\infty} Y^{(n)} \frac{1}{n!} \left( \sum_{r=1}^{\infty} \alpha^{(r)} \frac{t^r}{r!} \right)^n \right)^m \right]_{t=0}. \quad (S152)$$

Finally, we express $\sum_{n=1}^{\infty} Y^{(n)} \frac{1}{n!} \left( \sum_{r=1}^{\infty} \alpha^{(r)} \frac{t^r}{r!} \right)^n$ in terms of Bell polynomials:

$$\sum_{n=1}^{\infty} Y^{(n)} \frac{1}{n!} \left( \sum_{r=1}^{\infty} \alpha^{(r)} \frac{t^r}{r!} \right)^n = \sum_{n=1}^{\infty} Y^{(n)} \frac{1}{n!} \sum_{s=1}^{\infty} t^s \sum_{\{p_1, \ldots, p_s\} \in \mathbb{N}_0^s} \prod_{j=1}^{s} \frac{\alpha^{(p_j)}}{p_j!} = \quad (S153)$$

$$= \sum_{n=1}^{\infty} Y^{(n)} \frac{1}{n!} \sum_{s=1}^{\infty} t^s \sum_{\{q_1, \ldots, q_s\} \in \mathbb{N}_0^s} \prod_{r=1}^{s} \frac{n!}{q_1! \ldots q_s!} \prod_{k=1}^{s} \frac{\alpha^{(q_k)}}{q_k!} = \quad (S154)$$

$$= \sum_{n=1}^{\infty} Y^{(n)} \frac{1}{n!} \sum_{s=1}^{\infty} t^s n! \sum_{s=1}^{\infty} t^s Y^{(s)} B_{s,n}(\alpha) = \sum_{s=1}^{\infty} t^s \sum_{n=1}^{s} Y^{(n)} B_{s,n}(\alpha). \quad (S155)$$

Taken together,

$$\sum_{j=m}^{k} B_{k,j}(\alpha) B_{j,m}(Y) = \frac{1}{m!} \frac{\partial^k}{\partial t^k} \left[ \left( \sum_{s=1}^{\infty} \frac{t^s}{s!} \sum_{n=1}^{s} Y^{(n)} B_{s,n}(\alpha) \right)^m \right]_{t=0} = \frac{1}{m!} \frac{\partial^k}{\partial t^k} \left[ \left( \sum_{s=1}^{k-1} \frac{t^s}{s!} \sum_{n=1}^{s} Y^{(n)} B_{s,n}(\alpha) \right)^m \right]_{t=0} = \quad (S156)$$

$$= \frac{1}{m!} \frac{\partial^k}{\partial t^k} \left[ \left( \sum_{s=1}^{k-1} \frac{t^s}{s!} Z^{(s)} \right)^m \right]_{t=0} = B_{k,m}(Z) \quad \forall k = 2, \ldots, n \forall m = 2, \ldots, k, \quad (S157)$$

where we used the definition of $Z^{(i)}$ for $i = 1, \ldots, n - 1$ and that, since $m \geq 2$, if $s \geq k$ in one factor, the terms are of order $O(t^{k+1})$ and yield zero after taking the derivative and setting $t = 0$, thus concluding part 1.

Suppose $Y$ and $Z$ satisfy the recursion relations, Eqs. S143 S145 respectively. We will show by induction that then $Z^{(i)} = \sum_{j=1}^{i} Y^{(j)} B_{i,j}(\alpha) \forall i = 1, \ldots, n - 1$. 

30
As a last step, we show that

\[ Z^{(1)} = \alpha^{(1)}e^{(1)} = \alpha^{(1)}Y^{(1)} = \sum_{j=1}^{1} Y^{(j)}B_{1,j}(\alpha). \]  

(S158)

**Induction step:** \( n \to n + 1 \) Suppose \( Z^{(l)} = \sum_{j=1}^{l} Y^{(j)}B_{i,j}(\alpha) \) \( \forall i = 1, \ldots, n - 1 \), then since \( Z \) satisfies recursion (S145)

\[ Z^{(n)} - \alpha^{(n)}Y^{(1)} = -(A^{(2)}_{\text{pseudo}})^{-1} \sum_{l=3}^{n+1} A^{(l)}B_{n,l-1}(Z) = -(A^{(2)}_{\text{pseudo}})^{-1} \sum_{l=3}^{n+1} A^{(l)} \sum_{j=l-1}^{n} B_{n,j}(\alpha)B_{j,l-1}(Y) = \]  

\[ = -(A^{(2)}_{\text{pseudo}})^{-1} \sum_{j=2}^{n} B_{n,j}(\alpha) \sum_{l=3}^{j+1} A^{(l)}B_{j,l-1}(Y) = \sum_{j=2}^{n} B_{n,j}(\alpha) \left( -(A^{(2)}_{\text{pseudo}})^{-1} \sum_{l=3}^{j+1} A^{(l)}B_{j,l-1}(Y) \right) = \]  

\[ = \sum_{j=2}^{n} B_{n,j}(\alpha)Y^{(j)}, \]  

(S160)

or, equivalently, since \( B_{n,1}(\alpha) = \alpha^{(n)} \),

\[ Z^{(n)}Y^{(1)} = \alpha^{(n)}Y^{(1)} + \sum_{j=2}^{n} B_{n,j}(\alpha)Y^{(j)} = \sum_{j=1}^{n} B_{n,j}(\alpha)Y^{(j)}, \]  

(S162)

concluding our proof by induction and thereby part 2.

As a last step, we show that \( Y \) and \( Z \) yield the same conditions for critical points and the spinodal. Suppose that

\[ \sum_{l=2}^{m} A^{(l)}B_{m,l}(Z) = 0 \quad \forall m = 2, \ldots, n. \]  

(S163)

Then

\[ \sum_{l=2}^{m} A^{(l)}B_{m,l}(Y) = 0 \quad \forall m = 2, \ldots, n, \]  

(S164)

which is proven by a simple induction.

**Base case** \( n = 2 \) If \( A^{(2)}B_{2,2}(Z) = 0 \), then \( 0 = A^{(2)}(Z^{(1)})^2 = (\alpha^{(1)})^2A^{(2)}(Y^{(1)})^2 \) and since \( \alpha^{(1)} \neq 0 \), we conclude that \( A^{(2)}(Y^{(1)})^2 = A^{(2)}B_{2,2}(Y) = 0 \).

**Induction step** \( n \to n + 1 \) If \( \sum_{l=2}^{m} A^{(l)}B_{m,l}(Z) = 0 \) \( \forall m = 2, \ldots, n + 1 \) and suppose that \( \sum_{l=2}^{m} A^{(l)}B_{m,l}(Y) = 0 \) \( \forall m = 2, \ldots, n \), then

\[ 0 = \sum_{l=2}^{n+1} A^{(l)}B_{n+1,l}(Z) = \sum_{l=2}^{n+1} A^{(l)} \sum_{j=l}^{n+1} B_{n+1,j}(\alpha)B_{j,l}(Y) = \sum_{j=2}^{n+1} B_{n+1,j}(\alpha) \sum_{l=2}^{j} A^{(l)}B_{j,l}(Y) = \]  

\[ = B_{n+1,1}(\alpha) \sum_{l=2}^{n+1} A^{(l)}B_{n+1,l}(Y) = (\alpha^{(1)})^{n+1} \sum_{l=2}^{n+1} A^{(l)}B_{n+1,l}(Y). \]  

(S165)

(S166)

Since \( \alpha^{(1)} \neq 0 \), we conclude that \( \sum_{l=2}^{n+1} A^{(l)}B_{n+1,l}(Y) = 0 \), thus concluding our proof.

Conversely, if

\[ \sum_{l=2}^{m} A^{(l)}B_{m,l}(Y) = 0 \quad \forall m = 2, \ldots, n. \]  

(S167)
Then
\[ \sum_{l=2}^{m} A^{(l)} B_{m,l}(Z) = \sum_{i=2}^{m} A^{(i)} \sum_{j=1}^{m} B_{m,j}(\alpha) B_{j,l}(Y) = \sum_{j=2}^{m} B_{m,j}(\alpha) \sum_{l=2}^{j} A^{(l)} B_{j,l}(Y) = 0. \] (S168)

Overall, we thus find that irrespective of the choice of \( \alpha^{(n)} \) (\( \alpha^{(1)} \neq 0 \)) in the recursion relation, our analysis yields the same conditions. Without loss of generality, we can thus set \( \alpha^{(n)} = \delta_{n,1} \).

Note that in Eq. S165 we implicitly used that the conditions only depend on the vectors \( Y^{(i)} \) or \( Z^{(i)} \) determined up to this point: \( i \leq m - 1 \) for an \( m \)-th order critical point.

In terms of the optimal path in component space, the choice of \( \alpha^{(n)} \) just corresponds to a certain parameterization of the curve:
\[ \sum_{m=1}^{\infty} \frac{e_{m}}{m!} Z^{(m)} = \sum_{m=1}^{\infty} \frac{e_{m}}{m!} \sum_{j=1}^{m} Y^{(j)} B_{m,j}(\alpha) = \sum_{j=1}^{\infty} Y^{(j)} \sum_{m=j}^{\infty} \frac{e_{m}}{m!} B_{m,j}(\alpha) = \quad (S169) \]
\[ = \sum_{j=1}^{\infty} Y^{(j)} \sum_{m=j}^{\infty} \frac{e_{m}}{m!} \frac{\partial^{m}}{\partial m^{m}} \left[ \frac{1}{j!} \left( \sum_{p=1}^{\infty} \alpha^{(p)} \frac{t^{p}}{p!} \right) \right]_{t=0} = \quad (S170) \]
\[ = \sum_{j=1}^{\infty} Y^{(j)} \frac{1}{j!} \left( \sum_{p=1}^{\infty} \alpha^{(p)} \frac{t^{p}}{p!} \right) = : \sum_{j=1}^{\infty} \frac{\epsilon_{j}}{j!} Y^{(j)}. \quad (S172) \]

Thus, going from \( Y \) to \( Z \) leads to a reparameterization of \( \epsilon \) as
\[ \sum_{p=1}^{\infty} \alpha^{(p)} \frac{t^{p}}{p!}. \] (S173)

S5 Components of different sizes

In Eq. S7, the densities \( \rho_{i} \) can be interpreted as either the volume or the number fraction of component \( i \) in the mixture. These are equivalent if all components have the same size and occupy the same number of lattice sites. In realistic mixtures of lipids, proteins and DNA, this assumption might not be satisfied. So how does the size of components modify the phase and critical behavior of the mixture? Addressing this question requires modifying Eq. S7 to include the sizes/lengths \( l_{i} \) of components \( i \). Here we do this in a purely mean-field way that neglects correlations between lattice sites arising due to the finite length of the components, as done in Flory’s and Huggins’ pioneering work for two-component systems 17][18:

\[ \hat{f}^{(l)} = \sum_{i=1}^{N} \frac{\rho_{i}}{l_{i}} \log \rho_{i} - \sum_{i,j=1}^{N} \rho_{i} \chi_{ij} \rho_{j}, \] (S174)

where \( \rho_{i} \) is now the volume fraction of component \( i \). The number fraction is given by \( (\rho_{i}/l_{i})/\sum_{j} (\rho_{j}/l_{j}) \).

Expressing the free energy in terms of the volume fractions \( \rho_{i}, i = 1, \ldots, N - 1 \) (using that \( \rho_{N} = 1 - \sum_{i=1}^{N-1} \rho_{i} \) due to the incompressibility) and differentiating the free energy twice yields the Hessian
\[ \tilde{H}_{ij} = \tilde{A}^{(2)}_{ij} = \partial_{i} \partial_{j} \hat{f}^{(l)} = \frac{\delta_{ij}}{\rho_{i} l_{i}} + \frac{1}{l_{N}(1 - P)} - \sum_{\gamma=1}^{R} r^{(\gamma)}_{i} r^{(\gamma)}_{j} = : L_{ij} - \sum_{\gamma=1}^{R} r^{(\gamma)}_{i} r^{(\gamma)}_{j} \quad i, j = 1, \ldots, N - 1. \] (S175)
Using Woodbury’s matrix identity \[17\] on \(L\), we find for its inverse:

\[(L^{-1})_{ij} = \delta_{ij} \rho_i \bar{l} - \frac{1}{\bar{l}} \rho_i \rho_j \bar{l},\]  

(S176)

where \(\bar{l} = \sum_{i=1}^{N} \rho_i l_i\) is the average length. Using similar arguments as before, the Hessian is invertible if and only if \(1 - U^T L^{-1} U\) is invertible. This matrix can be rewritten as

\[
\delta_{\alpha\beta} - U_{\alpha \alpha} (L^{-1})_{\alpha \beta} = \delta_{\alpha\beta} - \nu r^{\alpha} \nu r^{\beta} - \frac{1}{\bar{l}} \sum_{i=1}^{N} \rho_i l_i \nu r^{\alpha} r^{\beta} = 
\]

(S177)

\[
\sum_{i=1}^{N} \rho_i l_i \nu r^{\alpha} r^{\beta} + \frac{1}{\bar{l}} \sum_{i=1}^{N} \rho_i l_i \nu r^{\alpha} r^{\beta}.
\]

(S178)

Due to the factors of \(l\) appearing here, the second part is not as straightforwardly written as a covariance matrix, at least not with respect to \(\rho\). However, we can define a new probability measure \(\bar{\phi}\) by

\[
\phi_m = \frac{\rho_m l_m}{\bar{l}},
\]

(S179)

which satisfies \(\phi_m \geq 0\) and \(\sum_m \phi_m = (\sum_{m=1}^{N} \rho_m l_m) / \bar{l} = 1\), as desired. In terms of \(\bar{\phi}\), the matrix \(1 - U^T L^{-1} U\) is

\[
\delta_{\alpha\beta} - U_{\alpha \alpha} (L^{-1})_{\alpha \beta} = \delta_{\alpha\beta} - \bar{l} \nu r^{\alpha} \nu r^{\beta} + \bar{l} (\nu r^{\alpha} \nu r^{\beta}).
\]

(S180)

and so

\[
1 - U^T L^{-1} U = 1 - \bar{l} \text{Cov}^{(\bar{\phi})},
\]

(S181)

where \(\text{Cov}^{(\bar{\phi})}\) is the covariance matrix of the rescaled and shifted features \(r^{(\gamma)}\) with respect to the new probability measure \(\bar{\phi}\):

\[
\text{Cov}^{(\bar{\phi})}_{\alpha\beta} = \langle r^{(\alpha)} r^{(\beta)} \rangle_{\bar{\phi}} - \langle r^{(\alpha)} \rangle_{\bar{\phi}} \langle r^{(\beta)} \rangle_{\bar{\phi}}.
\]

(S182)

Here, all averages are taken with respect to the weighted volume fractions of the different components: \(\langle X \rangle_{\phi} := \sum_{i=1}^{N} \phi_i X_i = \sum_{i}^{N} \rho_i l_i / \bar{l}\).

Overall, we find that the Hessian matrix is invertible if and only if \(1 - \bar{l} \text{Cov}^{(\bar{\phi})}\) is invertible. By analogous arguments as before we thus conclude that the condition for the spinodal is

\[
\bar{\lambda}(1) = \frac{1}{\bar{l}}.
\]

(S183)

where \(\bar{\lambda}(1)\) is the variance of the first principal component of \(\text{Cov}^{(\bar{\phi})}\).

The direction of instability is determined by looking at the inverse of the Hessian matrix \(H^{-1} = L^{-1} + L^{-1} U (1 - \bar{l} \text{Cov}^{(\bar{\phi})})^{-1} U^T L^{-1}\). We rewrite its components as

\[
(H^{-1})_{ij} = \delta_{ij} \rho_i \bar{l} - \frac{1}{\bar{l}} \rho_i \rho_j \bar{l} + (\delta_{im} \rho_i \bar{l} - \frac{1}{\bar{l}} \rho_i \rho_m \bar{l}) r^{(\alpha)}_m (1 - \bar{l} \text{Cov}^{(\bar{\phi})})^{-1}_{\alpha \beta} r^{(\beta)}_k (\delta_{kj} \rho_j \bar{l} - \frac{1}{\bar{l}} \rho_k \rho_j \bar{l}) =
\]

(S184)

\[
= \delta_{ij} \rho_i \bar{l} - \frac{1}{\bar{l}} \rho_i \rho_j \bar{l} + \rho_i \rho_j \bar{l} \left( \langle r^{(\alpha)} \rangle_{\bar{\phi}} - \langle r^{(\alpha)} \rangle_{\bar{\phi}} \right) \langle r^{(\beta)} \rangle_{\bar{\phi}} - \langle r^{(\beta)} \rangle_{\bar{\phi}}.
\]

(S185)

The covariance matrix \(\text{Cov}^{(\bar{\phi})}\) is a real and symmetric matrix and therefore can be decomposed into an orthonormal set of eigenvectors \(\bar{\mathbf{V}}^{(\gamma)}\) corresponding to the descending eigenvalues \(\bar{\lambda}(\gamma)\):

\[
\text{Cov}^{(\bar{\phi})}_{\alpha\beta} = \sum_{\gamma=1}^{R} \bar{\lambda}(\gamma) \bar{\mathbf{V}}^{(\gamma)}_{\alpha} \bar{\mathbf{V}}^{(\gamma)}_{\beta}.
\]

(S186)
Using this decomposition the inverse of the Hessian is

\[
(H^{-1})_{ij} = \delta_{ij} \rho_i l_i - \frac{1}{l} \rho_i \rho_j l_j + \rho_i \rho_j l_j \sum_{\gamma=1}^{R} \frac{1}{1 - \lambda(\gamma)} \bar{V}_\alpha^{(\gamma)}(r_i^{(\alpha)} - \langle r^{(\alpha)} \rangle_\phi)\bar{V}_\beta^{(\gamma)}(r_j^{(\beta)} - \langle r^{(\beta)} \rangle_\phi) =: \\
= \delta_{ij} \rho_i l_i - \frac{1}{l} \rho_i \rho_j l_j + \rho_i \rho_j l_j \sum_{\gamma=1}^{R} \frac{1}{1 - \lambda(\gamma)} \tilde{E}_i^{(\gamma)} \tilde{E}_j^{(\gamma)},
\]

where

\[
\tilde{E}_i^{(\gamma)} = \sum_{\alpha=1}^{R} \bar{V}_\alpha^{(\gamma)}(r_i^{(\alpha)} - \langle r^{(\alpha)} \rangle_\phi).
\]

On the spinodal, where \(\tilde{\lambda}(\gamma) = 1/\tilde{l}\), the inverse of the Hessian is dominated by the term \(\frac{1}{1 - \tilde{\lambda}(\gamma)}(\rho_i l_i \tilde{E}_i^{(1)})(\rho_j l_j \tilde{E}_j^{(1)})\), suggesting that the direction of instability is given by

\[
\epsilon_i^{(1)} := \phi_i \tilde{E}_i^{(1)} \sim \rho_i l_i \tilde{E}_i^{(1)}.
\]

This can also be verified by explicitly calculating

\[
H_{ij} \epsilon_j^{(1)} = \sum_{\gamma=1}^{R} \tilde{V}_\alpha^{(\gamma)} l_i^{(\alpha)} (1 - \tilde{\lambda}(1)),
\]

which is zero on the spinodal, where \(\tilde{\lambda}(1) = 1/\tilde{l}\).

Looking at the (tilted) free energy change along a path \(\rho(\epsilon) = \rho^{(cp)} + \delta \rho(\epsilon) = \rho^{(cp)} + \sum_{n=1}^{\infty} \epsilon^n \tilde{\gamma}^{(n)}\) centered on a point \(\rho^{(cp)}\) on the spinodal, we find up to second order in \(\epsilon\)

\[
\tilde{f}(\rho(\epsilon)) - \tilde{f}(\rho^{(cp)}) = \left(\epsilon^2 \frac{1}{2} \tilde{A}_{i,j}^{(2)} \tilde{Y}_i^{(1)} \tilde{Y}_j^{(1)} + \epsilon^3 \left[ \frac{1}{2} \tilde{A}_{i,j}^{(2)} \tilde{Y}_i^{(1)} \tilde{Y}_j^{(1)} + \frac{1}{3!} \tilde{A}_{i,j,k}^{(3)} \tilde{Y}_i^{(1)} \tilde{Y}_j^{(1)} \tilde{Y}_k^{(1)} \right] + O(\epsilon^4) \right)|_{cp},
\]

where

\[
\tilde{A}_{i,j,k}^{(3)} = \tilde{\partial}_i \tilde{\partial}_j \tilde{\partial}_k \tilde{f}^{(l)} = - \delta_{ijk} + \frac{1}{l_i l_j l_k} + \frac{1}{l_i (1 - P)^2}
\]

and all terms are evaluated at \(\rho^{(cp)}\).

Analogously to before, if we require that two minima and one maximum merge along the path, we identify \(\tilde{Y}^{(1)} = \epsilon^{(1)}\). To determine the condition for the critical point, we then set the third order term in \(\epsilon\) to zero, giving

\[
0 = \tilde{A}_{i,j,k}^{(3)} \tilde{Y}_i^{(1)} \tilde{Y}_j^{(1)} \tilde{Y}_k^{(1)}|_{cp} = \left( \sum_{i=1}^{N-1} \frac{\tilde{Y}_i^{(1)} \tilde{Y}_j^{(1)} \tilde{Y}_k^{(1)}}{l_i l_j l_k} + \frac{\sum_{i=1}^{N-1} \tilde{Y}_i^{(1)} \tilde{Y}_j^{(1)} \tilde{Y}_k^{(1)}}{l_N (1 - P)^2} \right)|_{cp} = - \sum_{i=1}^{N} \frac{\tilde{Y}_i^{(1)} \tilde{Y}_j^{(1)} \tilde{Y}_k^{(1)}}{l_i l_j l_k}|_{cp},
\]

where we used that \(\sum_{i=1}^{N} \tilde{Y}_i^{(1)} = \sum_{i=1}^{N} \tilde{\epsilon}^{(1)} = \sum_{i=1}^{N} \tilde{\phi}_i \sum_{\alpha=1}^{R} \bar{V}_\alpha^{(1)} (r_i^{(\alpha)} - \langle r^{(\alpha)} \rangle_\phi) = 0\). Using \(\tilde{Y}_i^{(1)} = \phi_i \tilde{E}_i^{(1)}\) together with \(l_i l_j l_k = \tilde{l}^2 \tilde{\phi}_i^2 / l_i\) we thus find

\[
0 = \tilde{l}^2 \sum_{i=1}^{N} \frac{\tilde{Y}_i^{(1)} \tilde{Y}_j^{(1)} \tilde{Y}_k^{(1)}}{l_i l_j l_k}|_{cp} = \tilde{l}^2 \sum_{i=1}^{N} \frac{\phi_i^2 \tilde{E}_i^{(1)} \tilde{E}_j^{(1)} \tilde{E}_k^{(1)}}{l_i^3 \phi_i^3}|_{cp} = \sum_{i=1}^{N} \frac{\phi_i \tilde{E}_i^{(1)} \tilde{E}_j^{(1)} \tilde{E}_k^{(1)}}{l_i^3 \phi_i^3}|_{cp} = \langle l \tilde{E}_i^{(1)} \rangle_\phi^3|_{cp},
\]

as condition for the critical point.
S6  Negative interaction strengths

So far, we have implicitly assumed that the rescaled features \( r^{(\gamma)} \) are all real and that Cov is a true covariance matrix, which is symmetric and positive semi-definite and has an orthonormal set of eigenvectors. However, these assumptions are only true if the interaction strengths \( J^{(\gamma)} \) between the features are all positive. Our previous analysis is thus restricted to the case where all eigenvalues of the interaction matrix \( \chi \) are positive and where the pairwise interactions satisfy \( 2\chi_{ij} - (\chi_{ii} + \chi_{jj}) = -\sum_{\gamma=1}^{R} C^{(\gamma)} [s_i^{(\gamma)} - s_j^{(\gamma)}]^2 < 0 \forall \ i, j \); interactions between alike components are always energetically preferred as compared to interactions between dislike components.

To resolve this limitation, we now discuss the general case with a combination of positive and negative interaction strengths. Without loss of generality, we assume that the first \( R^+ \) “positive” features are attractive and the remaining \( R^- = R - R^+ \) “negative” ones are repulsive:

\[
J^{(\gamma)} > 0 \forall \gamma = 1, \ldots, R^+ \quad \& \quad J^{(\gamma)} < 0 \forall \gamma = R^+ + 1, \ldots, R.
\] (S196)

The rescaled and shifted features can thus be written in terms of real numbers \( \tilde{r}^{(\gamma)} \in \mathbb{R} \forall \gamma = 1, \ldots, R \) as

\[
\tilde{r}^{(\gamma)} =: \tilde{r}^{(\gamma)} \forall \gamma = 1, \ldots, R^+
\]

\[
\tilde{r}^{(\gamma)} =: i\tilde{r}^{(\gamma)} \forall \gamma = R^+ + 1, \ldots, R,
\] (S197)

and the “covariance” matrix Cov as

\[
\text{Cov} = \begin{pmatrix}
C^{(++)} & iC^{(+-)} \\
iC^{(+-)} & -C^{(-)}
\end{pmatrix},
\] (S198)

with the real matrices

\[
C^{(++)}_{\alpha\beta} = \text{Cov}^{(r)}_{\alpha\beta} \quad \forall \alpha, \beta = 1, \ldots, R^+
\]

\[
C^{(+-)}_{\alpha\beta} = \text{Cov}^{(r)}_{\alpha,\beta+R^+} \quad \forall \alpha = 1, \ldots, R^+, \quad \beta = 1, \ldots, R^-
\]

\[
C^{(+-)}_{\alpha\beta} = \text{Cov}^{(r)}_{\alpha+R^+,\beta} = C^{(+-)}_{\beta\alpha} \quad \forall \alpha = 1, \ldots, R^-, \quad \beta = 1, \ldots, R^+
\]

\[
C^{(-)}_{\alpha\beta} = \text{Cov}^{(r)}_{\alpha+R^+,\beta+R^+} \quad \forall \alpha, \beta = 1, \ldots, R^-. \tag{S199}
\]

These matrices quantify the covariances between the subsets of positive (+) and negative (-) features, respectively: \( \text{Cov}^{(r)}_{\alpha\beta} = \langle \tilde{r}^{(\alpha)} \tilde{r}^{(\beta)} \rangle_{\rho} - \langle \tilde{r}^{(\alpha)} \rangle_{\rho} \langle \tilde{r}^{(\beta)} \rangle_{\rho} \). In particular, \( C^{(++)} \) and \( C^{(+-)} \) are true covariance matrices restricted to \( \tilde{r}^{(\gamma)} \) for \( \gamma = 1, \ldots, R^+ \) and \( R^+ + 1, \ldots, R \), respectively, and are positive semi-definite: \( C^{(++)}, C^{(+-)} \succeq 0 \). The matrix \( 1 - \text{Cov} \) occurring in the condition for the Hessian to be invertible is thus a \( 2 \times 2 \) block matrix whose lower diagonal element is \( 1 + C^{(+-)} \succeq 1 \) and hence invertible. Therefore, \( 1 - \text{Cov} \) is invertible if its Schur complement with respect to \( 1 + C^{(+-)} \), denoted by \( (1 - \text{Cov})/(1 + C^{(+-)}) =: 1 - \bar{C} \), is invertible and has no zero eigenvalue. Here \( \bar{C} \) is given by

\[
\bar{C} = C^{(++)} - C^{(+-)} (1 + C^{(+-)})^{-1} C^{(+-)},
\] (S200)

which is a real and symmetric matrix since \( C^{(++)} \) and \( C^{(+-)} \) are symmetric and \( (C^{(+-)})^T = C^{(+-)} \).

**Spinodal**

For small absolute values of the interaction strengths, for which the system should not phase separate, the matrices \( C^{(\pm\pm/\pm\mp)} \) are small and, consequently, \( 1 - \bar{C} \) is close to \( 1 \) and has only positive eigenvalues. The condition for the spinodal is thus that the smallest eigenvalue of \( 1 - \bar{C} \) is 0, or, equivalently, that the largest eigenvalue of \( \bar{C} \) is 1:

\[
\lambda^{(1)}_{\bar{C}} = 1 \quad \text{(spinodal criterion)}, \tag{S201}
\]

where \( \{\lambda^{(\alpha)}_{\bar{C}}\}_\alpha \) denote the eigenvalues of \( \bar{C} \) in descending order. Note that the matrix dimension of the Schur complement, \( 1 - \bar{C} \), Eq. [S200] is \( R^+ \times R^+ \). This illustrates that phase separation relies on features with positive interaction strengths (positive eigenvalues of the interaction matrix). Then again, features with negative interaction strengths modify the
propensity to phase separate. More specifically, since \((C^{(++)})^T = C^{(--)}\) and \(1 + C^{(--)}\) (or, equivalently, \((1 + C^{(--)})^{-1}\)) are positive semi-definite, \(C^{(++)}(1 + C^{(--)})^{-1} C^{(--)}\) is positive semi-definite: \(v^T C^{(++)}(1 + C^{(--)})^{-1} C^{(--)} v = (C^{(--)} v)^T (1 + C^{(--)} C^{(--)})^{-1} (C^{(--)} v) \geq 0\) for any real vector \(v\). For two real, symmetric, positive semi-definite matrices \(A\) and \(B\), the largest eigenvalue of \(A - B\) is smaller than the largest eigenvalue of \(A\): Let \(v\) be the orthonormal eigenvector corresponding to the largest eigenvalue \(\lambda^{(A-B)}_{\max}\) of \(A - B\). Then \(\lambda^{(A-B)}_{\max} = v^T (A - B) v = v^T A v - v^T B v \leq \lambda^{(A)}_{\max} \). Thus, the negative features always tend to lower the eigenvalue of \(\tilde{C}\) and thereby prevent phase separation. The extent to which they influence the phase behavior depends on the relative correlations between all features: Suppose \(v^{(++)}\) is the orthonormal eigenvector of \(C^{(++)}\) corresponding to the largest eigenvalue. Or, in other words, assume that the dominant combination of positive features that drives phase separation is \(R^{(++)} := \sum_{\alpha=1}^{R^{++}} v^{(++)}_\alpha r^{(\alpha)}\). Then we find 
\[
C^{(++)} v^{(++)}_\alpha = \left(\tilde{\rho}(\beta+R^{++}) r^{(\alpha)}\right)_\rho - \left(\tilde{\rho}(\beta+R^{++}) r^{(\alpha)}\right)_\rho v^{(++)}_\alpha = \left(\tilde{\rho}(\beta+R^{++}) R^{(++)}\right)_\rho - \left(\tilde{\rho}(\beta+R^{++}) R^{(++)}\right)_\rho .
\] 
As a result, if the dominant combinations of positive features driving phase separation correlate only weakly with the negative features, \(\left(\tilde{\rho}(\beta+R^{++}) R^{(++)}\right)_\rho - \left(\tilde{\rho}(\beta+R^{++}) R^{(++)}\right)_\rho \approx 0\) \(\forall \beta\), the thermodynamic stability is barely modified by the presence of the latter: \(\tilde{C} v^{(++)} = C^{(++)} v^{(++)} - C^{(--)}(1 + C^{(--)})^{-1} C^{(--)} v^{(++)} \approx C^{(++)} v^{(++)}\). Conversely, if for each dominant combination of positive features, there is a highly correlated negative feature, the two effects counteract each other and, depending on the relative strengths and correlations, the effective interactions between the components may be small – the mixture will not phase separate. In a similar spirit, depending on the correlation structure, the addition of repulsive features may shift the relevance of the different attractive features with respect to their role for phase separation. Taken together, \(\tilde{C}\) can be interpreted as representing a multicomponent system with \(R^{++}\) positive features with effective, reduced interactions integrating the interplay of the positive and negative features in the original system.

**Direction of instability** If the Schur complement \(1 - \tilde{C}\) of \(1 - \text{Cov}\) with respect to \(1 + C^{(--)}\) is invertible, the inverse of \(1 - \text{Cov}\) exists and is given by
\[
(1 - \text{Cov})^{-1} = \begin{pmatrix} (1 - \tilde{C})^{-1} & i (1 - \tilde{C})^{-1} (1 + C^{(--)})^{-1} (1 - \tilde{C})^{-1} \\ i (1 + C^{(--)})^{-1} (1 - \tilde{C})^{-1} & (1 - \tilde{C})^{-1} (1 + C^{(--)})^{-1} (1 - \tilde{C})^{-1} \end{pmatrix}.
\] 
For our purposes, this expression is conveniently rewritten as
\[
(1 - \text{Cov})^{-1} = \begin{pmatrix} 0 & 0 \\ 0 & (1 + C^{(--)})^{-1} \end{pmatrix} + \begin{pmatrix} 1_{R^+ \times R^+} & 0 \\ 0 & i (1 + C^{(--)})^{-1} C^{(--)} \end{pmatrix} \begin{pmatrix} (1 - \tilde{C})^{-1} & (1 - \tilde{C})^{-1} \\ (1 - \tilde{C})^{-1} & (1 - \tilde{C})^{-1} \end{pmatrix} \begin{pmatrix} 1_{R^+ \times R^+} & 0 \\ 0 & i C^{(--)} \end{pmatrix}.
\] 
The inverse of the Hessian matrix then exists and is given by \(H^{-1} = K^{-1} + K^{-1} U (1 - \text{Cov})^{-1} U^T K^{-1}\) or
\[
(H^{-1})_{ij} = \delta_{ij} \rho_i - \rho_i \rho_j + (\delta_{ik} \rho_i - \rho_i \rho_k) r^{(\alpha)}_k (1 - \text{Cov})_{\alpha \beta} r^{(\beta)}_m (\delta mj \rho_j - \rho_m \rho_j) = \delta_{ij} \rho_i - \rho_i \rho_j + \rho_i \rho_j \left( -\tilde{v}_i^T (1 + C^{(--)})^{-1} \tilde{v}_j + \tilde{z}_i^T (1 - \tilde{C})^{-1} \tilde{z}_j \right),
\] 
where for all \(i, j = 1, \ldots, N - 1\) we have defined the deviations of the rescaled features from the mean and their weighted sum
\[
\pi_i := \begin{pmatrix} \tilde{\rho}^{(1)}_i - \langle \tilde{\rho}^{(1)} \rangle_\rho \\ \vdots \\ \tilde{\rho}^{(R^+)}_i - \langle \tilde{\rho}^{(R^+)} \rangle_\rho \end{pmatrix}, \quad \bar{v}_i := \begin{pmatrix} \tilde{\rho}^{(R^++)}_i - \langle \tilde{\rho}^{(R^++)} \rangle_\rho \\ \vdots \\ \tilde{\rho}^{(R^-)}_i - \langle \tilde{\rho}^{(R^-)} \rangle_\rho \end{pmatrix} = \begin{pmatrix} \nu^{(1)}_i \\ \vdots \\ \nu^{(R^-)}_i \end{pmatrix}, \quad \bar{z}_i := \pi_i - C^{(--)} (1 + C^{(--)})^{-1} \bar{v}_i.
\]
Since \( C^{(++)} \) and \( C^{(--)} \) are symmetric, \( C^{(+-)} = (C^{(-+)})^T \) and all matrices are real, \( \bar{C} \) is real and symmetric and thus has an orthonormal set of \( R^+ \) eigenvectors \( \bar{\phi}^{(\gamma)} \) corresponding to the descending eigenvalues \( \bar{\lambda}^{(\gamma)} \):

\[
\bar{C}_{\alpha\beta} = \sum_{\gamma=1}^{R^+} \bar{\lambda}^{(\gamma)} \phi^{(\gamma)}_\alpha \phi^{(\gamma)}_\beta. \tag{S207}
\]

If \( \bar{\lambda}^{(\gamma)} \neq 1 \forall \gamma = 1, \ldots, R^+ \), then \( (1 - \bar{C})_{\alpha\beta}^{-1} = \sum_{\gamma=1}^{R^+} (1 - \bar{\lambda}^{(\gamma)})^{-1} \phi^{(\gamma)}_\alpha \phi^{(\gamma)}_\beta \) and we find

\[
(H^{-1})_{ij} = \delta_{ij} \rho_i - \rho_i \rho_j - \rho_i \bar{v}^T_i \left( 1 + C^{(--)} \right)^{-1} \rho_j \bar{v}_j + \sum_{\gamma=1}^{R^+} \frac{1}{1 - \bar{\lambda}^{(\gamma)}} \bar{e}^{(\gamma)}_i \bar{e}^{(\gamma)}_j, \tag{S208}
\]

where

\[
\bar{e}^{(\gamma)}_i = \rho_i \bar{z}^T_i \bar{\phi}^{(\gamma)} = \rho_i \sum_{\alpha=1}^{R^+} \phi^{(\gamma)}_\alpha \left[ \sum_{\beta, \delta=1}^{R^-} C_{\alpha\beta}^{(++)} \left( (1 + C^{(--)})^{-1} \right)_{\beta\delta} \nu^{(\delta)}_i \right]. \tag{S209}
\]

Close to the spinodal, the inverse of the Hessian is dominated by the term \( \frac{1}{1 - \bar{\lambda}^{(1)}} \bar{e}^{(1)}_i \bar{e}^{(1)}_j \). Similarly to before, we thus identify \( \bar{e}^{(1)} \) with the eigenvector of the Hessian to eigenvalue 0 at the spinodal:

\[
H \bar{e}^{(1)} \bigg|_{\text{spinodal}} = 0 \quad \text{(direction of instability).} \tag{S210}
\]

**Critical point** Expanding the free energy along a path \( \rho(\epsilon) \) up to third order in \( \epsilon \), we find an analogous condition for the critical point as for the original model:

\[
\left\langle \left( \tilde{E}^{(1)} \right)^3 \right\rangle_{cp} = 0 \quad \text{(condition critical point),} \tag{S211}
\]

where \( \tilde{e}^{(1)}_i = \rho_i \tilde{E}^{(1)}_i \).

### S7 Linearly dependent features

In this section, we show that adding linearly dependent features does not change the results of our analysis. We restrict our discussion to the case of only positive interaction strengths and find that there is an additional zero eigenvalue \( \lambda^{(T)} = 0 \) (all others remain the same) but the corresponding additional eigenvector \( V^{(T)} \) leads to a zero vector \( E^{(T)} = 0 \), thus not changing our predictions.

To simplify notation, we assume without loss of generality that \( 2C^{(\gamma)} = 1 \) (absorbing the interaction strengths into the spin values) and that \( s_{N}^{(\gamma)} = 0 \) (shifting the spin values). Thus, \( r^{(\gamma)} = s^{(\gamma)} \).

Suppose now that the \( R \)-th feature can be written as a linear combination of the other features:

\[
s^{(R)} = \sum_{\alpha=1}^{R-1} \nu_{\alpha} s^{(\alpha)}. \tag{S212}
\]

with \( \nu \in \mathbb{R}^{R-1} \) and \( s^{(\gamma)} = (s_{1}^{(\gamma)}, \ldots, s_{N}^{(\gamma)}) \). Then we can rewrite the interaction matrix \( \chi \) as

\[
\chi_{ij} = \sum_{\gamma=1}^{R} s_{i}^{(\gamma)} s_{j}^{(\gamma)} = \sum_{\gamma=1}^{R-1} s_{i}^{(\gamma)} s_{j}^{(\gamma)} + \sum_{\alpha, \beta=1}^{R-1} \nu_{\alpha} \nu_{\beta} s_{i}^{(\alpha)} s_{j}^{(\beta)} = \sum_{\alpha, \beta=1}^{R-1} (\delta_{\alpha\beta} + \nu_{\alpha} \nu_{\beta}) s_{i}^{(\alpha)} s_{j}^{(\beta)} = (\bar{S}^{T} M \bar{S})_{ij}, \tag{S213}
\]
where we defined the matrices $\tilde{S}_{\alpha i} = s_i^{(\alpha)}$ for $i = 1, \ldots, N$, $\alpha = 1, \ldots, R - 1$ and $M_{\alpha \beta} = \delta_{\alpha \beta} + \nu_\alpha \nu_\beta$ for $\alpha, \beta = 1, \ldots, R - 1$. The latter matrix is real and symmetric and can thus be written in terms of a diagonal matrix $D$ and an orthogonal matrix $Q$:

$$M = QDQ^T \quad \text{with} \quad QQ^T = Q^TQ = 1. \quad (S214)$$

Further, since $M$ is a rank-1 correction of the identity matrix, the eigenvalues of $M$ are $1 + ||\nu||^2$ and $1$ ($R - 2$ times degenerate):

$$M_{\alpha \beta} \nu_\beta = \nu_\alpha (1 + ||\nu||^2) \quad \text{and} \quad M_{\alpha \beta} w_\beta = w_\alpha + \nu_\alpha (\nu \cdot w) = w_\alpha \quad \forall \nu \perp \nu. \quad (S215)$$

The corresponding normalized eigenvectors are thus $\nu/||\nu|| =: w^{(1)}$ and a set of $R - 2$ normal vectors $w^{(\gamma)}, \gamma = 2, \ldots, R - 1$ with $w^{(\gamma)} \perp w^{(\delta)}$ for all $\gamma \neq \delta$. In terms of these, the matrices are

$$D = \begin{pmatrix} 1 + ||\nu||^2 & \cdots & 1 \\ \vdots & \ddots & \vdots \\ 1 & \cdots & 1 \end{pmatrix} \quad \text{and} \quad Q = (w^{(1)}, \ldots, w^{(R - 1)}). \quad (S216)$$

Moreover, we can express the interaction matrix as

$$\chi_{ij} = (\tilde{S}^TQDQ^T\tilde{S})_{ij} = (P^TP), \quad (S217)$$

where

$$P = \sqrt{D}Q^T\tilde{S} \quad (S218)$$

and the square of the diagonal matrix is

$$\sqrt{D} = \begin{pmatrix} \sqrt{1 + ||\nu||^2} & \cdots & 1 \\ \vdots & \ddots & \vdots \\ 1 & \cdots & 1 \end{pmatrix}. \quad (S219)$$

We thus have two representations of $\chi$, one in terms of $R$ linearly dependent features and the other one where we have integrated out the last feature:

$$\sum_{\gamma = 1}^{R} s_i^{(\gamma)} s_j^{(\gamma)} = (S^TS)_{ij} = \chi_{ij} = (P^TP) = \sum_{\delta = 1}^{R - 1} p_i^{(\delta)} p_j^{(\delta)}, \quad (S220)$$

where $S_{ij} = s_i^{(\gamma)}$ has dimensions $R \times N$ and $P_{\delta i} := p_i^{(\delta)}$ has $(R - 1) \times N$. Do these two representations yield the same conditions for the spinodal and the critical points?

To answer these questions, we consider the respective covariance matrices $\text{Cov}^{(s)}$ and $\text{Cov}^{(p)}$ and their eigenvalues and eigenvectors next.

$$\text{Cov}^{(p)}_{\alpha \beta} = \left< p^{(\alpha)} p^{(\beta)} \right> - \left< p^{(\alpha)} \right> \left< p^{(\beta)} \right> = \sum_{i=1}^{N} \rho_i p_i^{(\alpha)} p_i^{(\beta)} - \sum_{i,j=1}^{N} \rho_i p_i^{(\alpha)} p_j^{(\beta)} = \sum_{i=1}^{N} \rho_i P_{\alpha i} P_{\beta i} - \sum_{i,j=1}^{N} \rho_i P_{\alpha i} \rho_j P_{\beta j} =$$

$$= \sum_{\gamma, \delta, \epsilon=1}^{R-1} \sum_{i=1}^{N} \rho_i \sqrt{D}_{\alpha \gamma} Q_{\gamma \delta}^T S_{\delta i} \sqrt{D}_{\beta \epsilon} Q_{\epsilon \phi}^T S_{\phi i} - \sum_{\gamma, \delta, \epsilon=1}^{R-1} \sum_{i,j=1}^{N} \rho_i \rho_j \sqrt{D}_{\alpha \gamma} Q_{\gamma \delta}^T S_{\delta i} \sqrt{D}_{\beta \epsilon} Q_{\epsilon \phi}^T S_{\phi j} = \quad (S221)$$

$$= \sum_{\gamma, \delta, \epsilon=1}^{R-1} \sqrt{D}_{\alpha \gamma} Q_{\gamma \delta}^T \text{Cov}^{(s)}_{\delta \phi} Q_{\epsilon \phi} \sqrt{D}_{\epsilon \beta}, \quad (S222)$$

38
where we used that
\[ \sum_{i=1}^N \rho_i s_{\delta i} s_{\phi i} - \sum_{i,j=1}^N \rho_i \rho_j s_{\delta i} s_{\phi j} = \sum_{i=1}^N \rho_i s_1^{(\delta)} s_i^{(\phi)} - \sum_{i,j=1}^N \rho_i \rho_j s_1^{(\delta)} s_j^{(\phi)} = \text{Cov}_{\delta \phi}, \] (S223)

Thus,
\[ \text{Cov}^{(p)} = \sqrt{D} Q^T \text{Cov}^{(s|R-1)} Q \sqrt{D}, \] (S224)

where \( \text{Cov}^{(s|R-1)} \) is the covariance matrix \( \text{Cov}^{(s)} \) restricted to the first \( R - 1 \) features/dimensions. More specifically, since
\[ \text{Cov}^{(s)} = \begin{pmatrix} \text{Cov}^{(s|R-1)} & \text{Cov}^{(s|R-1)} \nu \\ \nu^T \text{Cov}^{(s|R-1)} & \nu^T \text{Cov}^{(s|R-1)} \nu \end{pmatrix} = \begin{pmatrix} 1_{R-1} & \nu \\ \nu^T & \nu^T \end{pmatrix} \text{Cov}^{(s|R-1)} \begin{pmatrix} 1_{R-1} \\ \nu \end{pmatrix}, \] (S227)

where \( 1_{R-1} \) is the identity matrix of dimensions \( (R - 1) \times (R - 1) \) and \( \nu = (\nu_1, \ldots, \nu_{R-1})^T \). This representation demonstrates that
\[ V^{(R)} := \begin{pmatrix} \nu \\ -1 \end{pmatrix} \] (S228)
is an eigenvector of \( \text{Cov}^{(s)} \) to eigenvalues \( \lambda^{(R)} = 0 \). The corresponding vector \( E^{(R)} \) is
\[ E^{(R)} = \sum_{\alpha=1}^R V^{(R)}_\alpha \left( s^{(\alpha)} - \left< s^{(\alpha)} \right> \right) = \begin{pmatrix} \sum_{\alpha=1}^{R-1} \nu_\alpha \left( s^{(\alpha)} - \left< s^{(\alpha)} \right> \right) \end{pmatrix} - \begin{pmatrix} s^{(R)} - \left< s^{(R)} \right> \end{pmatrix} = 0, \] (S229)

and hence does not add any contribution to e.g. the pseudoinverse of the Hessian.

Since \( D \) is diagonal and \( Q \) orthogonal, the relation Eq. [S224] between \( \text{Cov}^{(p)} \) and \( \text{Cov}^{(s|R-1)} \) is easily inverted as
\[ \text{Cov}^{(s|R-1)} = Q \sqrt{D}^{-1} \text{Cov}^{(p)} \sqrt{D}^{-1} Q^T. \] (S230)

As a result,
\[ \text{Cov}^{(s)} = \begin{pmatrix} 1_{R-1} \\ \nu^T \end{pmatrix} Q \sqrt{D}^{-1} \text{Cov}^{(p)} \sqrt{D}^{-1} Q^T \begin{pmatrix} 1_{R-1} \\ \nu \end{pmatrix} =: \hat{Q} \text{Cov}^{(p)} \hat{Q}^T. \] (S231)

The explicit expression of \( \hat{Q}^T \) is calculated as
\[ \hat{Q}^T = \sqrt{D}^{-1} Q^T \begin{pmatrix} 1_{R-1} \\ \nu \end{pmatrix} = \begin{pmatrix} \frac{1}{\sqrt{1 + ||\nu||^2}} (w^{(1)})^T \\ \frac{||\nu||}{1 + ||\nu||^2} (w^{(2)})^T \\ 0 \\ \vdots \\ 0 \end{pmatrix}, \] (S232)
where we used that \( (w^{(α)})^T \nu = (w^{(α)})^T w^{(1)} ||\nu|| = \delta_{α1} ||\nu|| \). Importantly,

\[
\tilde{Q}^T \hat{Q} = \begin{pmatrix}
\frac{1}{\sqrt{1+||\nu||^2}} (w^{(1)})^T & \frac{||\nu||}{\sqrt{1+||\nu||^2}} \\
\vdots & \ddots & \ddots \\
\frac{1}{\sqrt{1+||\nu||^2}} (w^{(R-1)})^T & 0
\end{pmatrix}
\begin{pmatrix}
\frac{1}{\sqrt{1+||\nu||^2}} w^{(1)} & w^{(2)} & \ldots & w^{(R-1)} \\
\vdots & \ddots & \ddots & \vdots \\
\frac{1}{\sqrt{1+||\nu||^2}} & 0 & \ldots & 0
\end{pmatrix}
= (S233)
\]

allowing Eq. (S231) to be rewritten as

\[
\tilde{Q}^T \text{Cov}(s) = \text{Cov}(p) \tilde{Q}^T.
\] (S235)

Thus, if \( \text{Cov}(s) \) has eigenvectors \( V^{(α)}, α = 1, \ldots, R \) corresponding to eigenvalues \( λ^{(α)} \),

\[
\text{Cov}(s) V^{(α)} = λ^{(α)} V^{(α)},
\] (S236)

then

\[
\text{Cov}(p) (\tilde{Q}^T V^{(α)}) = \tilde{Q}^T \text{Cov}(s) V^{(α)} = λ^{(α)} (\tilde{Q}^T V^{(α)}) = λ^{(α)} \tilde{v}^{(α)}.
\] (S237)

Note, however, that

\[
\tilde{v}^{(R)} = \tilde{Q}^T V^{(R)} = 0,
\] (S238)

and so we conclude that \( \text{Cov}(p) \) has the same eigenvalues \( λ^{(α)}, α = 1, \ldots, R \) as \( \text{Cov}(s) \), except for \( λ^{(R)} = 0 \). The corresponding eigenvectors are \( \tilde{V}^{(α)} = \tilde{Q}^T V^{(α)}, α = 1, \ldots, R - 1 \).

To conclude, we will check that these different sets of eigenvectors give the same vectors \( E^{(γ)} \) in the space of components. To this end, we observe that for \( γ = 1, \ldots, R - 1 \)

\[
\tilde{E}^{(γ)} := \sum_{α=1}^{R-1} \tilde{V}^{(γ)} \langle p^{(α)} - \langle p^{(α)} \rangle \rangle = \sum_{α=1}^{R-1} \sum_{β=1}^{R} \tilde{Q}^T V^{(β)} (p^{(α)} - \langle p^{(α)} \rangle) = \sum_{β=1}^{R} V^{(β)} \sum_{α=1}^{R-1} \tilde{Q}_{βα} (p^{(α)} - \langle p^{(α)} \rangle).
\] (S239)

Using the definitions of \( \tilde{Q} \) and \( P \) and that \( Q \) is an orthogonal matrix, we find

\[
\sum_{α=1}^{R-1} \tilde{Q}_{βα} p^{(α)} = (\tilde{Q} P)_{βi} = \left( \begin{pmatrix} 1 \\ \nu^T \end{pmatrix} \text{Q} \sqrt{D}^{-1} \sqrt{D} Q^T \tilde{S} \right)_{βi} = \left( \begin{pmatrix} 1 \\ \nu^T \end{pmatrix} \text{Q} \sqrt{D}^{-1} \sqrt{D} Q^T \tilde{S} \right)_{βi} = \left( \begin{pmatrix} 1 \\ \nu^T \end{pmatrix} \text{Q} \sqrt{D}^{-1} \sqrt{D} Q^T \tilde{S} \right)_{βi}.
\] (S240)

For \( β = 1, \ldots, R - 1 \), this expression simplifies to \( \sum_{α=1}^{R-1} \tilde{Q}_{βα} p^{(α)} = s^{(β)}_i \) and, similarly, for \( β = R \), we have \( \sum_{α=1}^{R-1} \tilde{Q}_{βα} p^{(α)} = (\nu^T \tilde{S})_i = \sum_{δ=1}^{R-1} ν_δ s^{(δ)}_i = s^{(R)}_i \). Overall, we conclude that

\[
\sum_{α=1}^{R-1} \tilde{Q}_{βα} p^{(α)} = s^{(β)}_i \quad ∀ β = 1, \ldots, R.
\] (S241)

Combining this with Eq. (S239), we find

\[
\tilde{E}^{(γ)} = \sum_{β=1}^{R} V^{(β)} \left( s^{(β)} - \langle s^{(β)} \rangle \right) = E^{(γ)},
\] (S242)
showing that indeed both representations lead to the same vectors in the space of components.

Taken together, we find that the addition of linearly dependent features does not change the eigenvalues of the covariance matrix, nor the resulting vectors in component space. Our results for the spinodal and the critical points thus do not depend on whether or not the features are chosen as linearly independent.

Finally, we observe that if the covariance matrix has a zero eigenvalue \( \lambda(R) = 0 \), then the corresponding vector \( E(R) = 0 \).

Furthermore, either one features is deterministic, \( r(\gamma) = r(\gamma) \forall i \), and therefore does not lead to any effective interaction between the components, or the features are linearly dependent. To see this, we note that since the covariance matrix is real and symmetric, we can write it as

\[
\text{Cov} = T \Delta T^T, \tag{S243}
\]

where \( T \) is orthogonal \( TT^T = T^T T = 1 \) with \( T_{\alpha \beta} = V^{(\delta)}_{\alpha} \) and \( \Delta \) is a diagonal matrix with \( \Delta_{RR} = \lambda(R) = 0 \). As a result,

\[
0 = \Delta_{RR} = (T^T \text{Cov} T)_{RR} = \sum_{\gamma, \delta=1}^{R} T_{\gamma R} \text{Cov}_{\gamma \delta} T_{\delta R} = \sum_{\gamma=1}^{R} \sum_{\delta=1}^{R} T_{\gamma R} R_{\gamma R} (\gamma R)^{\gamma (\delta)} = 0.
\]

where

\[
\sum_{\gamma=1}^{R} T_{\gamma R} R_{\gamma R} (\gamma R)^{\gamma (\delta)} = \sum_{\gamma=1}^{R} V^{(R)}_{\gamma R} (\gamma R)^{\gamma (\delta)}. \tag{S246}
\]

Since the variance of \( z \) can only be zero if \( z \) is deterministic/constant, we have

\[
z_i = c \quad \forall i. \tag{S247}
\]

For the vector \( E(R) \) we then find

\[
E(R) = \sum_{\gamma=1}^{R} V^{(R)}_{\gamma R} \left( r^{(\gamma)} - \langle r^{(\gamma)} \rangle_{\rho} \right) = z - \langle z \rangle_{\rho} = 0. \tag{S248}
\]

Finally, since \( V^{(R)} \) is an eigenvector of \( \text{Cov} \), it is not equal to the zero vector and, unless \( r^{(\delta)} - \langle r^{(\delta)} \rangle_{\rho} = 0 \) for some \( \delta \), we conclude that the (shifted) features \( \{ r^{(\gamma)} - \langle r^{(\gamma)} \rangle_{\rho} \}_{\gamma=1, \ldots, R} \) are linearly dependent.

**S8 Several directions of instability**

In this section, we briefly comment on a second series of higher-order critical points, arising from several directions of instability, i.e. in the case when on the spinodal the largest eigenvalue of the covariance matrix is degenerate.

**S8.1 Codimension of the critical submanifold**

Suppose that the covariance matrix has a degenerate maximal eigenvalue of 1:

\[
\lambda(\gamma) = 1 \quad \forall \gamma = 1, \ldots, D \tag{S249}
\]

\[
\lambda(\gamma) < 1 \quad \forall \gamma > D. \tag{S250}
\]

Then, according to Eq. \[S26\], we have

\[
H_{ij} e^{(\gamma)}_{j} = 0 \quad \forall \gamma = 1, \ldots, D, \tag{S251}
\]
with the directions of instability \( e^{(\gamma)} = \rho \sum_{\delta=1}^{R} V^{(\gamma)}_{\delta} \left( \langle r^{(\delta)} \rangle - \langle r^{(\delta)} \rangle_{\rho} \right) \) as defined previously in terms of the orthonormal set of eigenvectors \( V^{(\gamma)} \) of the covariance matrix. Note that since the covariance matrix is real and symmetric, eigenvectors corresponding to degenerate eigenvalue can still be chosen orthogonal, which we assume in the following.

The Hessian is a linear operator and so we have

\[
H_{ij}(\sum_{\gamma=1}^{D} \mu_{\gamma} e^{(\gamma)}) = 0
\]

(S252)

for any linear combination \( \sum_{\gamma=1}^{D} \mu_{\gamma} e^{(\gamma)} \), \( \mu_{\gamma} \in \mathbb{R} \), of the directions of instability. Furthermore, the directions of instability are linearly independent: Suppose that

\[
\sum_{\gamma=1}^{D} \mu_{\gamma} e^{(\gamma)} = 0 \quad \forall i.
\]

(S253)

Multiplying by \( E^{(\beta)}_{i} \) for \( \beta = 1, \ldots, D \) and summing over all \( i = 1, \ldots, N \) yields

\[
0 = \left( E^{(\beta)} \sum_{\gamma=1}^{D} \mu_{\gamma} E^{(\gamma)} \right)_{\rho} = \sum_{\gamma=1}^{D} \mu_{\gamma} \sum_{\delta,\epsilon=1}^{R} V^{(\beta)}_{\delta} V^{(\gamma)}_{\epsilon} \text{Cov}_{\delta \epsilon} = \sum_{\gamma=1}^{D} \mu_{\gamma} \delta_{\beta \gamma} \lambda^{(\gamma)} = \mu_{\beta},
\]

de demonstrating that the directions of instability are linearly independent. They thus span a \( D \)-dimensional subspace of the component density space along which the second derivative of the free energy is zero.

What are the conditions that \( m \leq D + 1 \) local minima of the free energy merge along this \( D \)-dimensional subspace? One possibility is that simultaneously along each of \( m - 1 \) linearly independent directions of instability, two minima merge, i.e. that a usual critical point arises simultaneously along \( m - 1 \) linearly independent linear combinations \( \sum_{\gamma=1}^{D} \mu_{\gamma} e^{(\gamma)}, i = 1, \ldots, m - 1 \) of the directions of instability. In analogy to our previous analysis, where we considered the optimal path in the density space, this requires that the third cumulant of these linear combinations has to be zero:

\[
\left\langle \left( \sum_{\gamma=1}^{D} \mu_{\gamma}^{(i)} E^{(\gamma)} \right)^{3} \right\rangle_{E_{cp}} = 0 \quad \forall i = 1, \ldots, m - 1.
\]

(S255)

However, since it should not be possible to minimize the free energy along any other direction (in the \( D \)-dimensional subspace where the Hessian is zero), the third cumulant needs to be zero for all linear combinations of the \( D \) directions of instability:

\[
\left\langle \left( \sum_{\gamma=1}^{D} \mu_{\gamma} E^{(\gamma)} \right)^{3} \right\rangle_{E_{cp}} = 0 \quad \forall \mu \in \mathbb{R}^{D},
\]

(S256)

and therefore there will be simultaneous ordinary (or higher-order) critical points along all \( D \) directions of instability, thus making the critical point order \( D + 1 \) (or higher). The above conditions are only fulfilled if

\[
\left\langle E^{(\gamma_{1})} E^{(\gamma_{2})} E^{(\gamma_{3})} \right\rangle_{E_{cp}} = 0
\]

(S257)

for all possible combinations of \( \gamma_{1}, \gamma_{2}, \gamma_{3} = 1, \ldots, D \). Since the distinct combinations correspond to drawing a number in \( 1, \ldots, D \) three times without considering the ordering, there are another \( \binom{3+D-1}{3} \) conditions that need to be satisfied. Taken together, for this series of \( D + 1 \)-th order critical points, we find \( D + \binom{3+D-1}{3} \) conditions (\( D \) from the \( D \) largest eigenvalues being 1 and \( \binom{D+2}{3} \) from the third cumulants being 0). Note that for \( D \) directions of instability (at least) \( D + 1 \) phases will become indistinguishable at a critical point: either all third cumulants in the \( D \)-dimensional subspace of directions of instability are zero (and at least \( D + 1 \) phases merge) or there is a direction along which the free energy can be lowered and the point is not thermodynamically stable.
S8.2 A mean-field version of the q=3-states Potts model

The regular mean-field version of the Potts model can be expressed in terms of our framework by a \( N = 3 \)-component system with the following \( R = 3 \) features:

\[
\hat{s}_{i}^{(\gamma)} = a \delta_{i \gamma},
\]

where \( i, \gamma = 1, 2, 3 \). Here and in the following, we directly incorporate the interaction strengths \( J^{(\gamma)} \) (and other constant factors) into the spin values and only keep the dependency on the temperature \( T \), effectively setting \( z J^{(\gamma)} / k_B = 1 \). Then, the covariance matrix is given by

\[
\operatorname{Cov}_{\alpha \beta} = \frac{1}{T} \left( \left( \langle s^{(\alpha)} s^{(\beta)} \rangle_{\rho} - \langle s^{(\alpha)} \rangle_{\rho} \langle s^{(\beta)} \rangle_{\rho} \right) \right). \tag{S259}
\]

At the symmetry point \( \rho_1 = \rho_2 = \rho_3 = 1/3 \), we have

\[
\operatorname{Cov} = \frac{a^2}{9T} \begin{pmatrix}
2 & -1 & -1 \\
-1 & 2 & -1 \\
-1 & -1 & 2
\end{pmatrix}, \tag{S260}
\]

with eigenvalues \( \lambda^{(1)} = \lambda^{(2)} = a^2/3/T \) and \( \lambda^{(3)} = 0 \). The spinodal is thus located at \( a^2 = 3T \) and the system exhibits two directions of instability with corresponding (orthonormal) eigenvectors of \( \operatorname{Cov} \):

\[
V^{(1)} = \frac{1}{\sqrt{2}} \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix} \quad \text{and} \quad V^{(2)} = \frac{1}{\sqrt{6}} \begin{pmatrix} -1 \\ 2 \\ -1 \end{pmatrix}. \tag{S261}
\]

Importantly, not all combinations of third cumulants of these directions of instability are zero. While two are indeed zero, the other two are equal to \( \pm a^3/3\sqrt{6} \), thus leading to thermodynamic instability along certain directions in the 2-dimensional subspace of directions of instability. Hence, as noted previously \cite{21,22}, the symmetric state does not exhibit critical behavior, in contrast to the two-dimensional q=3-states Potts model \cite{20}. Ultimately, this lack of a continuous transition is due to the fact that for \( D = 2 \), 6 conditions need tuning while any \( N = 3 \), \( R = 3 \) model only exhibits 5 degrees of freedom, 2 ratios of densities and 3 interaction parameters: The 3 feature vectors necessarily lie in a plane, thus making the effective number of features =2 (a rotation of the feature vectors onto e.g. the x-y-plane does not change the system) and the number of parameters =6. However, each feature is invariant under constant shifts and the system is invariant under rotations of the features, thus reducing the number of degrees of freedom to 6−2−1 = 3.

While this regular mean-field version of the q=3-states Potts model does not exhibit a critical point, here, we propose a slightly more complex version with \( N = 6 \) and \( R = 2 \), which preserves the S\(_3\) symmetry group of the q=3-states Potts model but represents each “lattice component type” by two “effective component types”.

More specifically, we consider a mixture with the following feature vectors:

\[
\vec{s}_1 = a \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad \vec{s}_2 = a \begin{pmatrix} -1/2 \\ \sqrt{3}/2 \end{pmatrix} \quad \vec{s}_3 = a \begin{pmatrix} -1/2 \\ -\sqrt{3}/2 \end{pmatrix} \quad \vec{s}_4 = b \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad \vec{s}_5 = b \begin{pmatrix} -1/2 \\ \sqrt{3}/2 \end{pmatrix} \quad \vec{s}_6 = b \begin{pmatrix} -1/2 \\ -\sqrt{3}/2 \end{pmatrix}, \tag{S262}
\]

corresponding to two equilateral triangles centered around the origin (see Fig. S\(_1\)). For simplicity, we absorb all the interaction strengths and constants into the spin values, and assume that \( 2C^{(3)} = 2C^{(1)} = 1/T \), retaining only the...
Figure S1: Possible choice of feature vectors for the mean-field Potts model; here $a = 1$ and $b = -1.5$. The component types preserve the permutation symmetry and their feature vectors lie on two equilateral triangles, centered at the origin. We focus on the symmetric state where the component types belonging to the same triangle are present with equal densities: $\rho_1 = \rho_2 = \rho_3 = \frac{x}{3}$ and $\rho_4 = \rho_5 = \rho_6 = \frac{1-x}{3}$.

dependency on temperature. Furthermore, we focus on the symmetric state where all component types belonging to the same equilateral triangle have the same densities:

$$\rho_1 = \rho_2 = \rho_3 = \frac{x}{3} \quad \text{and} \quad \rho_4 = \rho_5 = \rho_6 = \frac{1-x}{3}.$$  

(S263)

For this symmetric case, the average of all spins vanishes, $\langle s^{(1)} \rangle = \langle s^{(2)} \rangle = 0$, and the covariance matrix is given by

$$\text{Cov} = \frac{1}{2T} \left( xa^2 + (1-x)b^2 \right) \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$  

(S264)

The eigenvalues can be read off as

$$\lambda^{(1)} = \lambda^{(2)} = \frac{1}{2T} \left( xa^2 + (1-x)b^2 \right),$$  

(S265)

with corresponding eigenvectors

$$\mathbf{v}^{(1)} = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad \text{and} \quad \mathbf{v}^{(2)} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$  

(S266)

The largest eigenvalue is thus two-fold degenerate and on the spinodal,

$$xa^2 + (1-x)b^2 = 2T,$$  

(S267)

there are two directions of instability. According to our previous analysis, we thus need the third cumulant of any linear
This quadratic form exhibits a minimal value although to be zero in order for the system to be at its critical point (where then the 3 symmetric phases merge into a single phase):
\[
\left\langle \left( \alpha_1 E^{(1)} + \alpha_2 E^{(2)} \right) \right\rangle^3 = \frac{1}{4} \alpha_1 \left( \alpha_1^2 - 3\alpha_2^2 \right) \left( x a^3 + (1 - x) b^3 \right) = 0 \quad \forall \alpha_1, \alpha_2.
\] (S270)

In addition to the condition for the spinodal, we thus find that
\[
x a^3 + (1 - x) b^3 = 0 \quad \text{or} \quad x = \frac{b^3}{b^3 - a^3}
\] (S271)

at the critical point. Since \(x\) and \(1 - x\) denote the combined densities of component types 1, 2, 3 and 4, 5, 6, respectively, (and since we have seen previously that a three component system is not enough,) we need \(x \in (0, 1)\), yielding the additional constraint
\[
ab < 0.
\] (S273)

Choosing the density as in Eq. S272, the spinodal condition is
\[
a^2 b^2 (b - a) = b^3 \left( \frac{1 - r}{1 - r^3} \right)^2 = 2 T,
\] (S274)

where \(r = a/b\) is the ratio between the linear dimensions of the two “feature triangles”.

In principle, equality S274 is satisfied by a one-dimensional submanifold of \((b, r)\)-space. We do, however, need to ensure that the symmetry state is thermodynamically stable (at least to local fluctuations) and that up to the next order in the free energy expansion (the fourth order), the free energy change is positive for all possible paths in density space. The fourth order term in the free energy expansion is (see Eq. S40)
\[
F := A^{(4)} B_{4,4} \left( \rho(\alpha_1 E^{(1)} + \alpha_2 E^{(2)}), \rho \omega^{(2)} \right) + A^{(3)} B_{4,3} \left( \rho(\alpha_1 E^{(1)} + \alpha_2 E^{(2)}), \rho \omega^{(2)} \right) + A^{(2)} B_{4,2} \left( \rho(\alpha_1 E^{(1)} + \alpha_2 E^{(2)}), \rho \omega^{(2)} \right).
\] (S275)

Here, we have used that the paths of minimal change in free energy have a tangent within the plane of instabilities: \(\Omega^{(1)} = \alpha_1 E^{(1)} + \alpha_2 E^{(2)} := E\). Thus \(A^{(2)}(\rho E) = 0\) and the fourth order term is rewritten as
\[
F = 6 \left( \frac{1}{2} A^{(2)}(\rho \omega^{(2)})^2 + (\rho \omega^{(2)}) \left[ \frac{A^{(3)} (\rho E)^2}{\rho E} + \frac{1}{6} A^{(4)} (\rho E)^4 \right] \right).
\] (S276)

This quadratic form exhibits a minimal value although \(A^{(2)}\) is only positive semi-definite: Analogously to the case with a single direction of instability we can define the pseudoinverse of \(A^{(2)}\) by
\[
(A^{(2)}_{\text{pseudo}})^{-1} = \delta_{ij} \rho_i - \rho_i \rho_j.
\] (S277)

It satisfies
\[
\left( A^{(2)}(A^{(2)}_{\text{pseudo}})^{-1} \right)_{ik} = \left( \delta_{ij} \frac{1}{\rho_i} + \frac{1}{1 - F} - r^{(1)} r^{(1)} - r^{(2)} r^{(2)} \right) \delta_{ik} - \sum_{\gamma=1}^{2} r^{(\gamma)} r^{(\gamma)} \delta_{ik} \rho_j - \rho_j \rho_k = \delta_{ik} - \sum_{\gamma=1}^{2} r^{(\gamma)} r^{(\gamma)} \left( \delta_{ij} \rho_j - \rho_j \rho_k \right) =
\]
\[
= \sum_{\gamma=1}^{2} \sum_{\alpha=1}^{2} \sum_{\delta=1}^{4} \sum_{\gamma=1}^{4} \sum_{\alpha=1}^{4} \sum_{\delta=1}^{4} \delta_{\alpha \gamma} \left[ r^{(\alpha)} - \rho \omega^{(2)} \right] \left[ r^{(\gamma)} - \rho \omega^{(2)} \right] = \delta_{ik} - \rho_k \left[ r^{(\gamma)} - \rho \omega^{(2)} \right] \left[ r^{(\gamma)} - \rho \omega^{(2)} \right].
\] (S278)

(3)
In particular,
\[
(A^{(2)}(A^{(2)}_{\text{pseudo}})^{-1}) b = b - \frac{1}{2} \left( \sum_{\gamma=1}^{2} V_{\gamma}^{(2)} r^{(\gamma)} \right) A^{(3)}(\rho E)^2(\rho E)^{(3)} = b + \frac{1}{6} \left( \sum_{\gamma=1}^{2} V_{\gamma}^{(2)} r^{(\gamma)} \right) \langle E^2 E^{(3)} \rangle = b,
\]
(S280)
where we used Eq. S325 and that the third cumulants \( \langle (E^2)^2 E^{(3)} \rangle = 0 \ \forall \delta \). As a result, \( F \) has a minimum, which is given by
\[
F_{\text{min}} = 6 \left( \frac{1}{2} b^T (A^{(2)}_{\text{pseudo}})^{-1} b + \frac{1}{6} A^{(4)}(\rho E)^4 \right) = 6 \left( -\frac{1}{2} b_i (\delta_{ij} \rho_i - \rho_j) b_j + \frac{1}{6} 2 \langle E^4 \rangle \right) = 3 \langle b^2 \rangle - 3 \langle b^2 \rangle + 2 \langle E^4 \rangle = 3 \langle E^2 \rangle^2 - 3 \langle E^4 \rangle + 2 \langle E^4 \rangle = -\left( \langle E^4 \rangle - 3 \langle E^2 \rangle^2 \right) = -\kappa_4^{(E)}.
\]
(S281)
(S282)
Here \( \kappa_4^{(E)} \) is the fourth cumulant of \( E \) and we used Eq. S325 together with S324. Overall, we thus find that the fourth order term is positive for all optimal paths only if \( \kappa_4^{(E)} < 0 \).

Rewriting the fourth cumulant gives
\[
\kappa_4^{(E)} = \langle E^4 \rangle - 3 \langle E^2 \rangle^2 = \left( \langle \alpha_1 E^{(1)} + \alpha_2 E^{(2)} \rangle^4 \right) - 3 \left( \langle \alpha_1 E^{(1)} + \alpha_2 E^{(2)} \rangle^2 \right)^2 =
\]
\[
= \frac{3}{8} (\alpha_1^2 + \alpha_2^2) 2a^3b^2(a^2 + 3ab + b^2)
\]
\[
(\langle E^2 \rangle)^2.
\]
(S283)
(S284)
Since \( ab < 0 \), this expression is negative only if
\[
a^2 + 3ab + b^2 = b^2(r^2 + 3r + 1) > 0.
\]
(S285)
We thus find the following condition for the ratio \( r \) between \( a \) and \( b \):
\[
r \in \left( \frac{-3 - \sqrt{5}}{2}, \frac{-3 + \sqrt{5}}{2} \right) \approx (-2.62, -0.38).
\]
(S286)
We note that this range is invariant under \( r \rightarrow 1/r \), as expected from relabelling \( a \leftrightarrow b \).

Taken together, this \( N=6/R=2 \) model with threefold symmetry exhibits a critical point where three phases merge if \( b \) and \( r = a/b \) are chosen as
\[
2T = b^2 \frac{(1 - r)r^2}{1 - r^3} \quad \text{for some} \quad r \in \left( \frac{1}{2}(-3 - \sqrt{5}, -3 + \sqrt{5}) \right).
\]
We suggest that any such model might therefore be a candidate for a mean-field version of the two-dimensional \( q=3 \)-states Potts model which retains a continuous phase transition.

Interestingly, we first tried a version with \( R = 3 \) features and \( N = 6 \) component types whose spin vectors don’t lie in one plane but instead in two parallel planes:
\[
\vec{s}_1 = a \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \quad \vec{s}_2 = a \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \quad \vec{s}_3 = a \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \quad \vec{s}_4 = b \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \quad \vec{s}_5 = b \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \quad \vec{s}_6 = b \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}.
\]
(S288)

In this case, it is not possible to simultaneously satisfy the spinodal and third cumulants condition and to have a positive fourth order term for all possible paths. Ultimately, this is due to the fact that in this case where the features space is three- instead of two-dimensional, the free energy can be lowered by choosing a vector of second derivatives \( \omega^{(2)} \) that leaves the plane of instability.

Looking ahead, it will be interesting to see whether a related model with \( R = 3 \) and three directions of instability could serve as a mean-field version of the two-dimensional \( q=4 \)-Potts model, which also exhibits a continuous transition in two dimensions but not in regular mean-field theory. One possibility might be to consider feature vectors spanning a regular tetrahedron and rotations thereof. Furthermore, it would be enlightening to understand whether such types of models are not possible for \( D > 4 \) (for the two-dimensional \( q>4 \)-states Potts models, the transitions are indeed discontinuous).
Coarse-graining a multicomponent mixtures as a binary mixture

In this section, we discuss one idea how to coarse-grain a multicomponent mixture as a binary mixture of two components with effective features, while conserving two local thermodynamic properties, the spinodal line and the line of ordinary critical points. As we have seen before, the conditions for the spinodal and ordinary critical points only depend on the first principal component of the covariance matrix (note that we restrict our discussion to the case of a non-degenerate maximal eigenvalue of the covariance matrix). Hence, if only those two characteristics are to be preserved, only the distribution of features along the first principal component is of relevance and it might be enough to consider a binary system with the same first principal component. We therefore suggest to coarse-grain the multicomponent mixture (denoted by regular symbols) as a binary mixture (denoted by tildes) whose components \( i = 1, 2 \) exhibit feature vectors along the 1st principal component of the original system:

\[
\sqrt{2C(\gamma)} \tilde{\xi}_i^{(\gamma)} = x_i V^{(1)}_\gamma \tag{S289}
\]

where \( x_i \) is the distance of component \( i \) along the 1st principal component and \( \gamma = 1, \ldots, R \) denotes the different features (note that it would equally be possible to do this coarse-graining procedure with a single feature, corresponding to a rotation of this feature vector onto the first axis). This binary mixture has a covariance matrix

\[
\tilde{\text{Cov}}_{\alpha \beta} = \frac{1}{2} \left( \tilde{\rho}_{\alpha} \tilde{\rho}_{\beta} \right)_{\varphi} - \frac{1}{2} \left( \tilde{\rho}_{\alpha} \tilde{\rho}_{\beta} \right)_{\varphi} = 2\sqrt{C(\alpha)C(\beta)} \left( \frac{1}{2} \left( \tilde{\xi}_{\alpha} \tilde{\xi}_{\beta} \right)_{\varphi} - \frac{1}{2} \left( \tilde{\xi}_{\alpha} \tilde{\xi}_{\beta} \right)_{\varphi} \right) = \varphi_1 x_1^2 V_{\alpha_{1}}^{(1)} V_{\beta_{1}}^{(1)} + \varphi_2 x_2^2 V_{\alpha_{2}}^{(1)} V_{\beta_{2}}^{(1)} - \left( \varphi_1 x_1 V_{\alpha_{1}}^{(1)} + \varphi_2 x_2 V_{\alpha_{2}}^{(1)} \right) \left( \varphi_1 x_1 V_{\beta_{1}}^{(1)} + \varphi_2 x_2 V_{\beta_{2}}^{(1)} \right) = \ldots = V_{\alpha_{1}}^{(1)} V_{\beta_{1}}^{(1)} \varphi_1 \left( 1 - \varphi_1 \right) (x_1 - x_2)^2, \tag{S290}
\]

where \( \varphi_1 \) is the density of component type \( i = 1, 2 \) of the binary mixture: \( \varphi_2 = 1 - \varphi_1 \). We observe that \( \tilde{\text{Cov}} \) is a rank-1 matrix and, as desired, the first principal component of the original multicomponent mixture, \( V^{(1)} \), is also an eigenvector of \( \text{Cov} \) (corresponding to the only non-zero eigenvalue, \( \varphi_1 (1 - \varphi_1) (x_1 - x_2)^2 \)).

Similarly, for the third cumulant of the direction in component space corresponding to this eigenvector we find

\[
\left\langle \left( \sum_{\alpha=1}^{R} V_{\alpha}^{(1)} \left( \tilde{\rho}_{\alpha} - \left( \tilde{\rho}_{\alpha} \right)_{\varphi} \right) \right)^3 \right\rangle_{\varphi} = \left\langle \left( \sum_{\alpha=1}^{R} V_{\alpha}^{(1)} \left( \sqrt{2C(\alpha)} \tilde{\xi}^{(\alpha)} - \sqrt{2C(\alpha)} \tilde{\xi}^{(\alpha)} \right) \right)^3 \right\rangle_{\varphi} = \left\langle \left( x - \langle x \rangle_{\varphi} \right)^3 \right\rangle_{\varphi} + \frac{1}{2} \left( \sum_{\alpha=1}^{R} \left( V_{\alpha}^{(1)} \right)^2 \right)^3 = \left\langle \left( x - \langle x \rangle_{\varphi} \right)^3 \right\rangle_{\varphi}, \tag{S293}
\]

where we used that \( \tilde{\rho}_{i}^{(\alpha)} = \sqrt{2C(\alpha)} \tilde{\xi}^{(\alpha)}_{i} - \sqrt{2C(\alpha)} \tilde{\xi}^{(\alpha)}_{2} = (x_i - x_2) V_{\alpha}^{(1)} \) and so

\[
\left\langle \left( \tilde{\rho}_{\alpha} - \left( \tilde{\rho}_{\alpha} \right)_{\varphi} \right) \left( \tilde{\rho}_{\beta} - \left( \tilde{\rho}_{\beta} \right)_{\varphi} \right) \left( \tilde{\rho}_{\gamma} - \left( \tilde{\rho}_{\gamma} \right)_{\varphi} \right) \right\rangle_{\varphi} = V_{\alpha}^{(1)} V_{\beta}^{(1)} V_{\gamma}^{(1)} \left\langle \left( x - \langle x \rangle_{\varphi} \right)^3 \right\rangle_{\varphi}. \tag{S295}
\]

Using that \( \langle x \rangle_{\varphi} = \varphi_1 x_1 + \varphi_2 x_2 = x_2 + \varphi_1 (x_1 - x_2) \), the third cumulant of \( x \) (and thus of the potential direction of instability) is rewritten as

\[
\left\langle \left( \sum_{\alpha=1}^{R} V_{\alpha}^{(1)} \left( \tilde{\rho}_{\alpha} - \left( \tilde{\rho}_{\alpha} \right)_{\varphi} \right) \right)^3 \right\rangle_{\varphi} = \varphi_1 ((1 - \varphi_1) (x_1 - x_2))^3 - (1 - \varphi_1) (\varphi_1 (x_1 - x_2))^3 = \varphi_1 (1 - \varphi_1) (1 - 2\varphi_1) (x_1 - x_2)^3. \tag{S296}
\]

\[
\text{One possibility to maintain the location of the spinodal and critical line while coarse-graining is to preserve the second and third moment along the first principal component, i.e. to require that}
\]

\[
\varphi_1 (1 - \varphi_1) (x_1 - x_2)^2 = \lambda^{(1)} = \left\langle \left( E^{(1)} \right)^2 \right\rangle_{\rho} = : \mu_2
\]

\[
\varphi_1 (1 - \varphi_1) (1 - 2\varphi_1) (x_1 - x_2)^3 = \left\langle \left( E^{(1)} \right)^3 \right\rangle_{\rho} = : \mu_3, \tag{S299}
\]
where $\langle \ldots \rangle_p$ denotes the average in the original space of densities of the multicomponent mixture. As a result,
\[
\frac{(\mu_2)^3}{(\mu_3)^2} = \frac{\varphi_1^3}{\varphi_1^2} \frac{(1 - \varphi_1)^3}{(1 - 2\varphi_1)^2} \frac{(x_1 - x_2)^6}{(1 - 2\varphi_1)^2} = \varphi_1 (1 - \varphi_1),
\]
(S300)
which is solved by
\[
\varphi_1 = \frac{1}{2} \left( 1 \pm \sqrt{\frac{(\mu_3)^2}{(\mu_3)^2 + 4(\mu_2)^3}} \right) = \frac{1}{2} \left( 1 \pm \sqrt{\frac{1}{1 + \tau}} \right).
\]
(S301)
with
\[
\tau = \frac{4(\mu_2)^3}{(\mu_3)^2}.
\]
(S302)
For $x_1 - x_2$ we then find
\[
(x_1 - x_2)^2 = \frac{\mu_2}{\frac{1}{4} \left( 1 + \sqrt{1 + \tau} \right) \left( 1 - \sqrt{1 + \tau} \right)} = 4\mu_2 \left( 1 + \frac{1}{\tau} \right).
\]
(S303)
Taken together, we find the following mapping
\[
\varphi_1 \equiv \frac{1}{2} \left( 1 + \frac{1}{\sqrt{1 + \tau}} \right)
\]
(S304)
\[
|x_1 - x_2| \equiv 2\sqrt{\mu_2 \left( 1 + \frac{1}{\tau} \right)}.
\]
(S305)
For the density we chose the positive sign without loss of generality.
To proceed we note that $x_1 - x_2$ is related to the Flory-Huggins interaction strength $\bar{\chi}$:
\[
\bar{\chi} := \tilde{\chi}_{11} + \tilde{\chi}_{22} - 2\tilde{\chi}_{12} = \sum_{\gamma=1}^R \hat{\rho}(\gamma) \left( \tilde{s}_1^{(\gamma)} - \tilde{s}_2^{(\gamma)} \right)^2 = \frac{1}{2} \sum_{\gamma=1}^R (x_1 - x_2)^2 \left( V_1^{(1)} \right)^2 = \frac{1}{2} (x_1 - x_2)^2,
\]
which leads to the following conditions for the composition $\varphi := \varphi_1$ and the interaction strength:
\[
\varphi = \frac{1}{2} \left( 1 + \frac{1}{\sqrt{1 + \tau}} \right),
\]
(S307)
\[
\bar{\chi} = 2\mu_2 \left( 1 + \frac{1}{\tau} \right).
\]
(S308)
At the critical point, where $\mu_3 = 0$ and so $\tau \to \infty$, we have
\[
\varphi_c = \frac{1}{2}
\]
(S309)
\[
\bar{\chi}_c = 2\mu_2.
\]
(S310)
We hence find for the distance of the interaction strength from its critical value
\[
\Delta \bar{\chi} := \bar{\chi} - \bar{\chi}_c = \frac{1}{\tau},
\]
(S311)
and for density difference $\Delta \varphi := \varphi_1 - \varphi_2 = 2\varphi - 1$
\[
\Delta \varphi = \sqrt{\frac{1}{1 + \tau}} = \sqrt{\frac{\frac{1}{2}}{1 + \frac{1}{\tau}}} = \sqrt{\frac{\Delta \bar{\chi}}{1 + \Delta \bar{\chi}}} \approx \sqrt{\Delta \bar{\chi}} = \sqrt{\frac{1}{1 + \tau}},
\]
(S312)
where the approximation is valid close to the critical point.
Taken together, coarse-graining procedures based on such (or similar) arguments can conserve local properties of the free energy like the spinodal and critical points. Whether (and in what cases) the same can be said for global characteristics like the binodal is, however, not clear a priori and is an interesting question for future research.
S10 Generation of the multicomponent mixtures illustrated in Fig. 2 of the main text

To illustrate the role of the skewness of the distribution of the relative enrichments $\delta \rho_i / \rho_i$ for the occurrence of critical behavior, we generated the multicomponent mixtures as displayed in Fig. 2 of the main text from random distributions with zero and non-zero skewness, respectively. More specifically, we followed the procedure as outline next (for simplicity, we assume $2C(\gamma) = 1 \forall \gamma$).

S10.1 Mixture 1: zero skewness

We first drew $N=1000$ two-dimensional feature vectors (component types) from a multivariate Gaussian distribution with zero mean and covariance matrix

$$\begin{pmatrix} \sigma_1^2 & 0 \\ 0 & \sigma_2^2 \end{pmatrix}$$

with $\sigma_1 = 1, \sigma_2 = 0.3$. We then randomly generated the corresponding densities of the component types by drawing $N=1000$ exponentially distributed random variables (with rate $\lambda = 100$) and by normalizing the vector so that its sums (1-norm) equals 1. In order to enforce a variance of 1 along the first principal component and to illustrate the case when the first principal component is not aligned with a feature axis, we proceeded as follows:

1. We rotated all feature vectors in a way that the first principal component aligns with the $x$-axis (by multiplying them by the matrix of eigenvectors of the covariance matrix).
2. We rescaled the first component of the feature vectors by $\sigma_1 / \sigma_{PC1}$ and the second one by $\sigma_2 / \sigma_{PC2}$. Here $\sigma_{PC1/2}^2$ is the variance of the features along the first and second principal component, corresponding to the variance along the $x$- and $y$-axis after step 1. (Steps 1 and 2 together thus (re)align the first and second principal component with the $x$- and $y$-axis and fix the variances as $\sigma_{PC1/2} = \sigma_{1/2}$, respectively.)
3. We rotated all feature vectors (and thereby the first and second principal component) counterclockwise by an angle $\vartheta = \pi/6$, thus aligning the first principal component $V^{(1)}$ with $\begin{pmatrix} \cos(\vartheta) \\ \sin(\vartheta) \end{pmatrix}$.

The relative enrichment $\delta \rho_i / \rho_i$ of component type $i$ was then determined by taking the scalar product of the difference of the respective feature vector from the mean of the feature vectors (weighted by the densities) with $\begin{pmatrix} \cos(\vartheta) \\ \sin(\vartheta) \end{pmatrix}$. In mixture 1 displayed in Fig. 2 of the main text, the skewness is $\mu_3 \approx 0.022$, thus very close to zero (it is non-zero due to the finite size of the sample). Note that for the discussion there, we treat it as being equal to zero.

S10.2 Mixture 2: non-zero skewness

For mixture 2, the densities of the component types were generated as for mixture 1 from an exponential distribution with rate $\lambda = 100$ and proper normalization. In order to achieve a non-zero skewness for mixture 2, we randomly generated the feature vectors as follows:

1. Feature 1 (the first component of the feature vectors) was generated as a sum of two independent random variables, a Poisson distribution with variance $\sigma_{Poisson} = 1.5$ and a Gaussian distribution with zero mean and variance $\sigma_{Gaussian1} = 0.1$.
2. Feature 2 was generated independently of feature 1 from a Gaussian distribution with zero mean and variance $\sigma_{Gaussian2} = 0.03$.
3. To ensure a variance of 1 along the first principal component $V^{(1)}$ and to align it with the $x$-axis, we then rotated and rescaled them as described for mixture 1: We multiplied them by the matrix of eigenvectors of the covariance matrix (obtained after steps 1 and 2) and then rescaled the first and second components of the feature vectors by $\sigma_1 / \sigma_{PC1}$ and $\sigma_2 / \sigma_{PC2}$, respectively (again $\sigma_1 = 1$ and $\sigma_2 = 0.3$).
The relative enrichment $\delta \rho_i / \rho_i$ of component type $i$ was then determined analogously to mixture 1 by taking the scalar product of the difference of the respective feature vector from the mean of the feature vectors (weighted by the densities) with $\begin{pmatrix} \cos(\vartheta) \\ \sin(\vartheta) \end{pmatrix}$, where $\vartheta = 0$ for mixture 2. Mixture 2 displayed in Fig. 2 of the main text exhibits a skewness of $\mu_3 \approx 0.99$.

### S10.3 Invariance under constant shifts and rotations

Note that all the physical results are invariant under constant shifts or rotations of the set of feature vectors. We tried to illustrate this invariance by choosing a principal component not aligned with any feature axis for mixture 1 and by generating a mixture with non-zero (weighted) mean for the feature vectors for mixture 2.

### S10.4 Binary system

The binary systems for both mixtures were determined as described in the previous section with $\mu_2 = 1$ and $\mu_3$ as determined from the empirical distributions of the relative enrichments (weighted by the densities of the component types). In particular, we chose the feature vectors as

\[
\tilde{r}_1^{(\gamma)} = \left( \sqrt{\mu_2(1 + \frac{1}{\tau})} + \mu_1 \right) V_1^{(1)},
\]

\[
\tilde{r}_2^{(\gamma)} = \left( -\sqrt{\mu_2(1 + \frac{1}{\tau})} + \mu_1 \right) V_1^{(1)},
\]

where $\tau = 4(\mu_2)^3/(\mu_3)^2$. Furthermore, $\mu_1$ is the (weighted) mean of the projections of the feature vectors of the original $N=1000$ mixture along the first principal component; $\mu_1$ is non-zero for mixture 2. Note that, as noted previously, the constant shift by $\mu_1 V_1^{(1)}$ leaves the physical characteristics of the binary system invariant. Finally, the densities were chosen as

\[
\phi_1 = \frac{1}{2} \left( 1 + \frac{1}{\sqrt{1 + \tau}} \right),
\]

\[
\phi_2 = \frac{1}{2} \left( 1 - \frac{1}{\sqrt{1 + \tau}} \right).
\]

### S10.5 Histograms

For both histograms, we chose a bin width of 0.1.
S11 Useful formula

S11.1 Properties of the Hessian

Hessian acting on a vector For the Hessian $A^{(2)}$, Eq. S9, and a vector $Z$ with $\langle Z^{(N)} \rangle = 0$ we find

$$ (A^{(2)})_{ij} \rho_j Z_j = Z_i - Z_N - \sum_{\gamma=1}^{R} \sum_{j=1}^{N-1} r_{i}^{(\gamma)} \langle r^{(\gamma)} Z \rangle_{\rho}^{(N)}. $$  (S317)

Proof:

$$ (A^{(2)})_{ij} \rho_j Z_j = \left( \frac{\delta_{ij} + \frac{1}{1 - P} - \sum_{\gamma=1}^{R} r_{i}^{(\gamma)} r_{j}^{(\gamma)}}{\rho_i} \right) \rho_j Z_j = Z_i + \frac{1}{1 - P} \sum_{\gamma=1}^{R} \sum_{j=1}^{N-1} r_{i}^{(\gamma)} \sum_{j=1}^{N-1} r_{j}^{(\gamma)} Z_j $$  (S318)

$$ = Z_i + \frac{1}{1 - P} \left( \langle Z \rangle_{\rho} - (1 - P) Z_N \right) - \sum_{\gamma=1}^{R} r_{i}^{(\gamma)} \sum_{j=1}^{N-1} r_{j}^{(\gamma)} Z_j = Z_i - Z_N - \sum_{\gamma=1}^{R} r_{i}^{(\gamma)} \langle r^{(\gamma)} Z \rangle_{\rho}, $$  (S319)

since $r_{N}^{(\gamma)} = 0$.

Full contraction of the Hessian If $\langle v \rangle_{\rho}^{(N)} = \langle w \rangle_{\rho}^{(N)} = 0$, then

$$ A^{(2)}_{ij} \rho_i v_i \rho_j w_j = \langle vw \rangle_{\rho}^{(N)} - \sum_{\gamma=1}^{R} \langle vr^{(\gamma)} \rangle_{\rho}^{(N)} \langle wr^{(\gamma)} \rangle_{\rho}^{(N)} $$  (S320)

implicitly summing over all repeated indices on the left-hand side.

Proof: Using Eq. S317 we have

$$ A^{(2)}_{ij} \rho_i v_i \rho_j w_j = \rho_i v_i (w_i - w_N) - \sum_{\gamma=1}^{R} r_{i}^{(\gamma)} \langle r^{(\gamma)} w \rangle_{\rho} = $$  (S321)

$$ = \langle vw \rangle_{\rho} - (1 - P) v_N w_N - \langle v \rangle_{\rho} (1 - P) v_N w_N - \sum_{\gamma=1}^{R} \langle r^{(\gamma)} v \rangle_{\rho} \langle r^{(\gamma)} w \rangle_{\rho} = $$  (S322)

$$ = \langle vw \rangle_{\rho} - \sum_{\gamma=1}^{R} \langle r^{(\gamma)} v \rangle_{\rho} \langle r^{(\gamma)} w \rangle_{\rho}. $$  (S323)

S11.2 (Partial) Contraction of higher-order derivatives of the free energy

Partial contraction If $n \geq 3$ and $\langle Z^{(k)} \rangle_{\rho}^{(N)} = 0$ $\forall k = 1, \ldots, n - 1$, then

$$ A^{(n)}_{i_1 i_2 \ldots i_{n-1} j} \prod_{k=1}^{n-1} \left( \rho_{i_k} Z_{i_k}^{(k)} \right) = (-1)^n (n - 2)! \left[ \prod_{k=1}^{n-1} Z_{j_k}^{(k)} - \prod_{k=1}^{n-1} Z_{N_k}^{(k)} \right], $$  (S324)

implicitly summing over all repeated indices on the left-hand side.
\[
A_{i_1 i_2 \ldots i_{n-1} j}^{(n)} \prod_{k=1}^{n-1} (\rho_{i_k} Z_{i_k}^{(k)}) = (n - 2)! \left[ \delta_{i_1 \ldots i_{n-1} j} (-1)^n \frac{1}{\rho_{i_1}} + 1_{i_1 \ldots i_{n-1} j} \left( \frac{1}{(1 - P)^{n-1}} \prod_{k=1}^{n-1} (\rho_{i_k} Z_{i_k}^{(k)}) \right) \right]
\]

\[
= (n - 2)! \left[ (-1)^n \prod_{k=1}^{n-1} Z_j^{(k)} + \frac{1}{(1 - P)^{n-1}} \prod_{k=1}^{n-1} \sum_{i_k=1}^{N-1} \rho_{i_k} Z_{i_k}^{(k)} \right]
\]

\[
= (n - 2)! (-1)^n \left[ \prod_{k=1}^{n-1} Z_j^{(k)} - \prod_{k=1}^{n-1} Z_N^{(k)} \right],
\]

where we used the partial contraction, Eq. (S324), in the first equality, and that \(\rho_N = 1 - P\) and \(\langle Z^{(k)} \rangle_{/\rho} = 0\).

**Full contraction** If \(n \geq 3\) and \(\langle Z^{(k)} \rangle_{/\rho} = 0\) \(\forall k = 1, \ldots, n\), then

\[
A_{i_1 i_2 \ldots i_n}^{(n)} \prod_{k=1}^{n} (\rho_{i_k} Z_{i_k}^{(k)}) = (-1)^n (n - 2)! \left\langle \prod_{k=1}^{n} Z^{(k)} \right\rangle_{/\rho}^{(N)},
\]

implicitly summing over all repeated indices on the left-hand side.

**Proof:**

\[
A_{i_1 i_2 \ldots i_n}^{(n)} \prod_{k=1}^{n} (\rho_{i_k} Z_{i_k}^{(k)}) = (n - 2)! (-1)^n \left[ \prod_{k=1}^{n-1} Z_j^{(k)} - \prod_{k=1}^{n-1} Z_N^{(k)} \right] \rho_{i_n} Z_{i_n}^{(n)} =
\]

\[
= (n - 2)! (-1)^n \left[ \sum_{l=1}^{N-1} \rho_l \prod_{k=1}^{n} Z_l^{(k)} - \left( \sum_{l=1}^{N-1} \rho_l Z_l^{(n)} \right) \prod_{k=1}^{n-1} Z_N^{(k)} \right] =
\]

\[
= (n - 2)! (-1)^n \left\langle \prod_{k=1}^{n} Z^{(k)} \right\rangle_{/\rho}^{(N)},
\]

where we used the partial contraction, Eq. (S324) in the first equality, and that \(\langle Z^{(n)} \rangle_{/\rho} = 0\).

**S11.3 Pseudoinverse of the Hessian matrix**

**Pseudo-inverse** \((A_{\text{pseudo}}^{(2)})^{-1}\) acting on a vector For the pseudo-inverse of the Hessian \((A_{\text{pseudo}}^{(2)})^{-1}\), Eq. (S46), and a vector \(Z\) with \(Z_N = 0\) we find

\[
\left( (A_{\text{pseudo}}^{(2)})^{-1} \right)_{ij} Z_j = \rho_i \left( Z_i - \langle Z \rangle_{/\rho} + \sum_{\gamma=2}^{R} \frac{1}{1 - \lambda(\gamma)} E_i^{(\gamma)} \langle E^{(\gamma)} Z \rangle_{/\rho}^{(N)} \right).
\]

(S326)
Proof:

\[
\left( (A_{\text{pseudo}}^{(2)})^{-1} \right)_{ij} Z_j = \left( \delta_{ij} \rho_j - \rho_i \rho_j + \sum_{\delta=2}^R \frac{1}{1 - \lambda(\delta)} r^{(\delta)}_i r^{(\delta)}_j \right) Z_j = \\
= \rho_i Z_i - \rho_i (Z_i)^{(N)}_{\beta} + \rho_i \sum_{\delta=2}^R \frac{1}{1 - \lambda(\delta)} r^{(\delta)}_i \left( E^{(\delta)} Z \right)^{(N)}_{\beta} .
\]

(S328)

Product of the Hessian \( A^{(2)} \) and its pseudo-inverse \( (A_{\text{pseudo}}^{(2)})^{-1} \) For the Hessian \( A^{(2)} = H \), Eq. S9 and its pseudo-inverse \( (A_{\text{pseudo}}^{(2)})^{-1} \) we find

\[
\left( (A^{(2)} (A_{\text{pseudo}}^{(2)})^{-1}) \right)_{ij} = \delta_{ij} - \rho_j E_j^{(1)} \sum_{\gamma=1}^R V^{(1)}_{\gamma} r^{(\gamma)}_i = \left( (A_{\text{pseudo}}^{(2)})^{-1} A^{(2)} \right)_{ji} .
\]

(S329)

Proof:

\[
\left( (A^{(2)} (A_{\text{pseudo}}^{(2)})^{-1}) \right)_{ij} = \left( \delta_{ik} \frac{1}{\rho_k} + 1_{ik} \frac{1}{1 - P} - \sum_{\gamma=1}^R r^{(\gamma)}_i r^{(\gamma)}_k \right) \left( \delta_{ej} \rho_j - \rho_j \rho_k + \sum_{\delta=2}^R \frac{1}{1 - \lambda(\delta)} e^{(\delta)}_j e^{(\delta)}_k \right) = \\
= \delta_{ij} + \sum_{\delta=2}^R \frac{1}{1 - \lambda(\delta)} \left[ E^{(\delta)}_i - E^{(\delta)}_N \right] e^{(\delta)}_j - \rho_j \sum_{\gamma=1}^R r^{(\gamma)}_i \left[ r^{(\gamma)}_j - \left( r^{(\gamma)}_\rho \right) \right] - \sum_{\delta=2}^R \lambda(\delta) e^{(\delta)}_j \sum_{\gamma=1}^R V^{(\delta)}_\gamma r^{(\gamma)}_i ,
\]

where we used that \( \left< E^{(\delta)} \right>_\rho = 0 = r^{(\gamma)}_N \) and

\[
\sum_{k=1}^{N-1} r^{(\gamma)}_k e^{(\delta)}_k = \left< r^{(\gamma)} E^{(\delta)} \right>_\rho = \sum_{\alpha=1}^R V^{(\delta)}_\alpha \left< r^{(\gamma)} \left( r^{(\alpha)} - \left< r^{(\alpha)} \right> \right)_\rho \right> = \sum_{\alpha=1}^R V^{(\delta)}_\alpha \text{Cov}_{\gamma \alpha} = \lambda^{(\delta)} V^{(\delta)}_\gamma .
\]

(S332)

Using that \( E^{(\delta)}_i - E^{(\delta)}_N = \sum_{\alpha=1}^R V^{(\delta)}_\alpha r^{(\alpha)}_i \), we simplify Eq. S331 to

\[
\left( (A^{(2)} (A_{\text{pseudo}}^{(2)})^{-1}) \right)_{ij} = \delta_{ij} + \sum_{\delta=2}^R e^{(\delta)}_j \sum_{\gamma=1}^R V^{(\delta)}_\gamma r^{(\gamma)}_i - \rho_j \sum_{\gamma=1}^R r^{(\gamma)}_i \left[ r^{(\gamma)}_j - \left< r^{(\gamma)} \right> \right]_\rho .
\]

(S333)

As a next step, we rewrite

\[
\sum_{\delta=2}^R V^{(\delta)}_\gamma E_j^{(1)} = \sum_{\delta=2}^R V^{(\delta)}_\gamma V^{(\delta)}_\alpha \left( r^{(\alpha)}_j - \left< r^{(\alpha)} \right> \right)_\rho = \sum_{\alpha=1}^R \left( r^{(\alpha)}_j - \left< r^{(\alpha)} \right> \right)_\rho \sum_{\delta=2}^R V^{(\delta)}_\gamma V^{(\delta)}_\alpha = \\
= \sum_{\alpha=1}^R \left( r^{(\alpha)}_j - \left< r^{(\alpha)} \right> \right)_\rho \left( \delta_{\alpha \gamma} - V^{(1)}_\gamma V^{(1)}_\alpha \right) = \\
= r^{(\gamma)}_j - \left< r^{(\gamma)} \right> - \sum_{\alpha=1}^R \left( r^{(\alpha)}_j - \left< r^{(\alpha)} \right> \right)_\rho V^{(1)}_\gamma V^{(1)}_\alpha .
\]

(S334)

(S335)

(S336)

Substituting this into Eq. S333 yields

\[
\left( (A^{(2)} (A_{\text{pseudo}}^{(2)})^{-1}) \right)_{ij} = \delta_{ij} - \rho_j E_j^{(1)} \sum_{\gamma=1}^R V^{(1)}_\gamma r^{(\gamma)}_i .
\]

(S337)

Since both \( A^{(2)} \) and \( (A_{\text{pseudo}}^{(2)})^{-1} \) are symmetric, we have \( (A^{(2)} (A_{\text{pseudo}}^{(2)})^{-1})_{ij} = \left( (A_{\text{pseudo}}^{(2)})^{-1} A^{(2)} \right)_{ji} . \)

53
Projection properties of \((A_{\text{pseudo}}^{(2)})^{-1}A^{(2)}\) The product satisfies a few projection-operator like properties:

1. Applying it to the (non-orthogonal) basis \(\{e^{(\gamma)}\}_{\gamma=1,...,R}\) maps to zero or leaves the vector invariant: \(\left((A_{\text{pseudo}}^{(2)})^{-1}A^{(2)}\right)_{ij}e^{(\gamma)}_j = \begin{cases} 0 & \gamma = 1 \\ e^{(\gamma)}_i & \gamma \neq 1 \end{cases}\).

2. Applying it several times, yields the same result: \(\left((A_{\text{pseudo}}^{(2)})^{-1}A^{(2)}\right)^2 = (A_{\text{pseudo}}^{(2)})^{-1}A^{(2)}\).

Thus, \((A_{\text{pseudo}}^{(2)})^{-1}A^{(2)}\) can be interpreted as a projection operator along \(e^{(1)}\) with respect to the (non-orthogonal) basis \(\{e^{(\gamma)}\}_{\gamma=1,...,R}\).

Proof:

1. Using Eqs. S337 and S332 we have

\[
\left((A_{\text{pseudo}}^{(2)})^{-1}A^{(2)}\right)_{ij}e^{(\delta)}_j = \left(\delta_{ij} - \rho_i E_i^{(1)} \sum_{\gamma=1}^R V_{\gamma}^{(1)} r_{\gamma}^{(\gamma)}\right) e^{(\delta)}_j = e^{(\delta)}_i - e^{(1)}_i \sum_{\gamma=1}^R V_{\gamma}^{(1)} \sum_{j=1}^{N-1} r_{\gamma}^{(\gamma)} e^{(\delta)}_j = (S338)
\]

\[
= e^{(\delta)}_i - e^{(1)}_i \sum_{\gamma=1}^R V_{\gamma}^{(1)} \lambda^{(\delta)} V_{\gamma}^{(\delta)} = e^{(\delta)}_i - e^{(1)}_i \delta_{i\delta}.
\]

(S339)

2. According to Eq. S329 \((A_{\text{pseudo}}^{(2)})^{-1}A^{(2)} = 1 - C\) is equal to the identity matrix minus a matrix \(C\), so the square is \((1 - C)^2 = 1 - 2C + C^2\). Furthermore, using Eq. S332

\[
C_{ij}C_{jk} = \left(\rho_i E_i^{(1)} \sum_{\gamma=1}^R V_{\gamma}^{(1)} r_{\gamma}^{(\gamma)}\right) \left(\rho_j E_j^{(1)} \sum_{\delta=1}^R V_{\delta}^{(1)} r_{\delta}^{(\delta)}\right) = (S340)
\]

\[
= \rho_i E_i^{(1)} \sum_{\delta=1}^R V_{\delta}^{(1)} r_{\delta}^{(\delta)} \sum_{\gamma=1}^R V_{\gamma}^{(1)} \left(r^{(\gamma)} E^{(1)}\right)_\rho C_{ik} \sum_{\gamma=1}^R V_{\gamma}^{(1)} r_{\gamma}^{(1)} = C_{ik}.
\]

(S341)

Thus, \(\left((A_{\text{pseudo}}^{(2)})^{-1}A^{(2)}\right)^2 = (A_{\text{pseudo}}^{(2)})^{-1}A^{(2)}\). (S342)
