Automorphisms of Zappa-Szép Product

Ratan Lal and Vipul Kakkar

October 25, 2021

Abstract

In this paper, we have found the automorphism group of the Zappa-Szép product of two groups. Also, we have computed the automorphism group of the Zappa-Szép product of a cyclic group of order \( m \) and a cyclic group of order \( p^2 \), where \( p \) is a prime.

Keywords: Zappa-Szép Product, Automorphism Group.

1 Introduction

A group \( G \) is called the internal Zappa-Szép product of its two subgroups \( H \) and \( K \) if \( G = HK \) and \( H \cap K = \{1\} \). The Zappa-Szép product is a natural generalization of the semidirect product of two groups in which neither of the factor is required to be normal. If \( G \) is the internal Zappa-Szép product of \( H \) and \( K \), then \( K \) appears as a right transversal to \( H \) in \( G \). Let \( h \in H \) and \( k \in K \). Then \( kh = \sigma(x, h)\theta(x, h) \), where \( \sigma(x, h) \in H \) and \( \theta(x, h) \in K \). This determines the maps \( \sigma : K \times H \to H \) and \( \theta : K \times H \to K \). These maps are called the matched pair of groups. We denote \( \sigma(k, h) = k \cdot h \) and \( \theta(k, h) = k^h \). These maps satisfy the following conditions (See [3])

\begin{align*}
(C1) \ 1 \cdot h &= h \text{ and } k^1 = k, \\
(C2) \ k \cdot 1 &= 1 = 1^h, \\
(C3) \ kk' \cdot h &= k \cdot (k' \cdot h), \\
(C4) \ (kk')^h &= k^{k'}k^h, \\
(C5) \ k \cdot (hh') &= (k \cdot h)(k^h \cdot h'), \\
(C6) \ k^{hh'} &= (k^h)^{h'},
\end{align*}
for all \( h, h' \in H \) and \( k, k' \in K \).

On the other hand, let \( H \) and \( K \) are two groups. Let \( \sigma : K \times H \to H \) and \( \theta : K \times H \to K \) be two maps defined by \( \sigma(k, h) = k \cdot h \) and \( \theta(k, h) = k^h \) which satisfy the above conditions. Then, the external Zappa-Szép product \( G = H \bowtie K \) of \( H \) and \( K \) is the group defined on the set \( H \times K \) with the binary operation defined by

\[
(h, k)(h', k') = (h(k \cdot h'), k^h k')
\]

The internal Zappa-Szép product is isomorphic to the external Zappa-Szép product (see [3, Proposition 2.4, p. 4]). We will identify the external Zappa-Szép product with the internal Zappa-Szép product.

The Zappa-Szép product of two groups was introduced by G. Zappa in [13]. J. Szép in the series of papers (few of them are [9, 7, 8, 10]) studied such type of products. From the QR decomposition of matrices, one concludes that the general linear group \( GL(n, \mathbb{C}) \) is a Zappa-Szép product of the unitary group and the group of upper triangular matrices. Z. Arad and E. Fisman in [11] studied the finite simple groups as a Zappa-Szép product of two groups \( H \) and \( K \) with the order of \( H \) and \( K \) coprime. In the same paper, they studied the finite simple groups as a Zappa-Szép product of two groups \( H \) and \( K \) with one of \( H \) or \( K \) is \( p \)-group, where \( p \) is a prime. From the main result of [4], one observes that a finite group \( G \) is solvable if and only if \( G \) is a Zappa-Szép product of a Sylow \( p \)-subgroup and a Sylow \( p \)-complement.

Note that, if either of the actions \( k \cdot h \) or \( k^h \) is a group homomorphism, then the Zappa-Szép product reduces to the semidirect product of groups. M. J. Curran [2] and N. C. Hsu [5] studied the automorphisms of the semidirect product of two groups as the \( 2 \times 2 \) matrices of maps satisfying some certain conditions. In this paper (with the same terminology as in [2] and [5]), we have found the automorphism group of the Zappa-Szép product of two groups as the \( 2 \times 2 \) matrices of maps satisfying some certain conditions. As an application, we have found the automorphism group of the Zappa-Szép product of two cyclic groups in which one is of order \( p^2 \) and other is of order \( m \). Throughout the paper, \( \mathbb{Z}_n \) denotes the cyclic group of order \( n \) and \( U(n) \) denotes the group of units of \( n \). Also, \( Aut(G) \) denotes the group of all automorphisms of a group \( G \). Let \( U \) and \( V \) be groups. Then \( CrossHom(U, V) \) denotes the group of all crossed homomorphisms from \( U \) to \( V \). Also, if \( U \) acts on \( V \), then \( Stab_U(V) \) denotes the stabilizer of \( V \) in \( U \).
2 Structure of Automorphism Group

Let $G = H \bowtie K$ be the Zappa-Szép product of two groups $H$ and $K$. Let $U, V$ and $W$ be any groups. $Map(U, V)$ denotes the set of all maps between the groups $U$ and $V$. If $\phi, \psi \in Map(U, V)$ and $\eta \in Map(V, W)$, then $\phi + \psi \in Map(U, V)$ is defined by $(\phi + \psi)(u) = \phi(u)\psi(u)$, $\eta \phi \in Map(U, W)$ is defined by $\eta \phi(u) = \eta(\phi(u))$, $\phi \cdot \psi \in Map(U, V)$ is defined by $(\phi \cdot \psi)(u) = \phi(u) \cdot \psi(u)$ and $\phi^\psi \in Map(U, V)$ is defined by $\phi^\psi(u) = \phi(u)^{\psi(u)}$, for all $u \in U$.

Now, consider the set,

$$\mathcal{A} = \left\{ \left( \begin{array}{ccc} \alpha & \beta \\ \gamma & \delta \end{array} \right) \mid \alpha \in Map(H, H), \quad \beta \in Map(K, H), \quad \gamma \in Map(H, K), \quad \delta \in Map(K, K) \right\},$$

where $\alpha, \beta, \gamma$ and $\delta$ satisfy the following conditions,

(A1) $\alpha(hh') = \alpha(h)(\gamma(h) \cdot \alpha(h'))$,

(A2) $\gamma(hh') = \gamma(h)^{\alpha(h')}\gamma(h')$,

(A3) $\beta(kk') = \beta(k)(\delta(k) \cdot \beta(k'))$,

(A4) $\delta(kk') = \delta(k)^{\beta(k')}\delta(k')$,

(A5) $\beta(k)(\delta(k) \cdot \alpha(h)) = \alpha(k \cdot h)(\gamma(k \cdot h) \cdot \beta(kh))$,

(A6) $\delta(k)^{\alpha(h)}\gamma(h) = \gamma(h)^{\beta(k)}\delta(kh)$,

(A7) For any $h'k' \in G$, there exists a unique $h \in H$ and $k \in K$ such that $h' = \alpha(h)(\gamma(h) \cdot \beta(k))$ and $k' = \gamma(h)^{\beta(k)}\delta(k)$.

Then, the set $\mathcal{A}$ forms a group with the binary operation defined by

$$\left( \begin{array}{ccc} \alpha' & \beta' \\ \gamma' & \delta' \end{array} \right) \cdot \left( \begin{array}{ccc} \alpha & \beta \\ \gamma & \delta \end{array} \right) = \left( \begin{array}{ccc} \alpha'\alpha + \gamma'\alpha \cdot \beta'\gamma & \alpha'\beta + \gamma'\beta \cdot \beta'\delta \\ \gamma'\alpha^\beta + \delta'\gamma^\beta & \gamma'\beta + \delta'\beta^\delta \end{array} \right).$$

Proposition 2.1. Let $\left( \begin{array}{ccc} \alpha &=& \beta \\ \gamma &=& \delta \end{array} \right) \in \mathcal{A}$. Then $\alpha(1) = 1 = \beta(1) = \gamma(1) = \delta(1)$.

Proof. Let $h \in H$ be any element. Then, using (A1), $\alpha(h) = \alpha(h1) = \alpha(h)(\gamma(h) \cdot \alpha(1))$ which implies that $\gamma(h) \cdot \alpha(1) = 1 = \gamma(h) \cdot 1$ by (C2). Thus $\gamma(h)^{-1} \cdot (\gamma(h) \cdot \alpha(1)) = \gamma(h)^{-1} \cdot (\gamma(h) \cdot 1)$. Hence, using (C1), $\alpha(1) = 1$.

Using (A2), $\gamma(h) = \gamma(h1) = \gamma(h)^{\alpha(1)}\gamma(1)$. Using (C1), $\gamma(1) = 1$. Using the similar argument, we get $\beta(1) = 1$ and $\delta(1) = 1$. □
Let us define the kernel of the map $\alpha \in \text{Map}(H, H)$ as usual, that is, $\ker(\alpha) = \{ h \in H \mid \alpha(h) = 1 \}$. Here, we should remember that the map $\alpha$ need not to be a homomorphism. $\ker(\beta), \ker(\gamma) \text{ and } \ker(\delta)$ are defined in the same sense.

**Lemma 2.1.**

1. $\ker(\alpha) \leq H$,
2. $\ker(\beta) \leq K$,
3. $\ker(\gamma) \leq H$,
4. $\ker(\delta) \leq K$,
5. $\ker(\alpha) \cap \ker(\gamma) = \{1\}$,
6. $\ker(\beta) \cap \ker(\delta) = \{1\}$.

**Proof.**

(i) Let $h, h' \in \ker(\alpha)$. Then using (A1) and (C2), $\alpha(hh') = \alpha(h)(\gamma(h) \cdot \alpha(h')) = \gamma(h) \cdot 1 = 1$. Also, $1 = \alpha(1) = \alpha(h^{-1}h) = \alpha(h^{-1})(\gamma(h^{-1}) \cdot 1)$. Thus, $\alpha(h^{-1}) = 1$. Hence, $hh', h^{-1} \in \ker(\alpha)$ and so $\ker(\alpha) \leq H$.

(ii) One can easily prove it using the similar argument as in the part (i).

(iii) Let $h, h' \in \ker(\gamma)$. Then using (A2) and (C2), $\gamma(hh') = \gamma(h(\alpha(h') \gamma(h')) = 1^{\alpha(h')} = 1$. Also, $1 = \gamma(1) = \gamma(h(h^{-1}) = \gamma(h^o(h^{-1}) \gamma(h^{-1})$. Then, $\gamma(h^{-1}) = 1$ and so, $hh', h^{-1} \in \ker(H)$. Hence, $\ker(\gamma) \leq H$.

(iv) One can easily prove it using the similar argument as in the part (iii).

(v) Let $h \in \ker(\alpha) \cap \ker(\gamma)$. Then $\alpha(h) = 1 = \gamma(h)$. Therefore, $\theta(h) = 1$. Since $\theta \in \text{Aut}(G)$, $h = 1$. Hence, (v) holds.

(vi) One can easily prove it using the similar argument as in the part (v).

**Theorem 2.1.** Let $G = H \bowtie K$ be the Zappa-Szép product of two groups $H$ and $K$, and $A$ be as above. Then there is an isomorphism of groups between $\text{Aut}(G)$ and $A$ given by $\theta \leftrightarrow \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}$, where $\theta(h) = \alpha(h)\gamma(h)$ and $\theta(k) = \beta(k)\delta(k)$, for all $h \in H$ and $k \in K$.

**Proof.** Let $\theta \in \text{Aut}(G)$ be defined by $\theta(h) = \alpha(h)\gamma(h)$ and $\theta(k) = \beta(k)\delta(k)$, for all $h \in H$ and $k \in K$. Now, for all $h, h' \in H$, $\theta(hh') = \theta(h)\theta(h') = \alpha(h)\gamma(h)\alpha(h')\gamma(h') = \alpha(h)(\gamma(h) \cdot \alpha(h'))\gamma(h)^o(h')$. Thus, $\alpha(hh')\gamma(hh') = (\alpha(h)(\gamma(h) \cdot \alpha(h')))(\gamma(h)^o(h') \gamma(h'))$. Therefore, by uniqueness of representation, we have (A1) and (A2). By the similar argument, we get (A3) and (A4).

Now, $\theta(kh) = \theta((k \cdot h)(kh)) = \theta(k \cdot h)\theta(kh) = \alpha(k \cdot h)\gamma(k \cdot h)\beta(kh)\delta(kh) = \alpha(k \cdot h)(\gamma(k \cdot h) \cdot \beta(kh))\gamma(k \cdot h)^o(h)\delta(kh)$. Also, $\theta(kh) = \theta(k)\theta(h) = \beta(k)\delta(k)\alpha(h)\gamma(h) = \beta(k)(\delta(k) \cdot \alpha(h))\delta(k)^o(h)\gamma(h)$. Therefore, by the uniqueness of
representation, $\beta(k)(\delta(k)\cdot\alpha(h)) = \alpha(k\cdot h)(\gamma(k\cdot h)\cdot\beta(k^h))$ and $\delta(k)\alpha(h)\gamma(h) = \gamma(k\cdot h)\beta(k^h)\delta(k^h)$, which proves (A5) and (A6). Finally, (A7) holds because $\theta$ is onto. Thus, to every $\theta \in \text{Aut}(G)$ we can associate the matrix $\begin{pmatrix} \alpha^\theta & \beta^\theta \\ \gamma^\theta & \delta^\theta \end{pmatrix} \in \mathcal{A}$.

This defines a map $T : \text{Aut}(G) \to \mathcal{A}$ given by $\theta \mapsto \begin{pmatrix} \alpha^\theta & \beta^\theta \\ \gamma^\theta & \delta^\theta \end{pmatrix}$.

Now, if $\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \in \mathcal{A}$ satisfying the conditions (A1) – (A7), then we associate to it, the map $\theta : G \to G$ defined by $\theta(h) = \alpha(h)\gamma(h)$ and $\theta(k) = \beta(k)\delta(k)$, for all $h \in H$ and $k \in K$. Using (A1) – (A6), one can check that $\theta$ is an endomorphism of $G$. Also, by (A7), the map $\theta$ is onto. Now, let $hk \in \ker(\theta)$. Then $\theta(hk) = 1$. Therefore, $\alpha(h)(\gamma(h)\cdot\beta(k))\gamma(h)\beta(k)\delta(k) = 1$ and so, by the uniqueness of representation $\alpha(h)(\gamma(h)\cdot\beta(k)) = 1$ and $\gamma(h)\beta(k)\delta(k) = 1$. Again, by the uniqueness of representation and using (C1), (C2), (C3) and (C6), we get $\alpha(h) = 1 = \gamma(h)$ and $\beta(k) = 1 = \delta(k)$. Therefore, by the Lemma 2.1. (v), $h = 1 = k$ and so, $\ker(\theta) = \{1\}$. Thus, $\theta$ is one-one and hence, $\theta \in \text{Aut}(G)$. Thus, $T$ is a bijection. Let $\alpha, \beta, \gamma$ and $\delta$ be the maps associated with $\theta$ and $\alpha', \beta', \gamma'$ and $\delta'$ be the maps associated with $\theta'$. Now, for all $h \in H$ and $k \in K$, we have

$$
\theta'(\theta(h)) = \theta'(\alpha(h)\gamma(h)) \\
= \alpha'(\alpha(h))\gamma'(\alpha(h))\beta'(\gamma(h))\delta'(\gamma(h)) \\
= \alpha'(\alpha(h))(\gamma'(\alpha(h))\cdot\beta'(\gamma(h)))\gamma'(\alpha(h))\beta'(\gamma(h))\delta'(\gamma(h)) \\
= (\alpha'\alpha + (\gamma'\alpha\cdot\beta')\gamma')(\gamma'\alpha\beta + \delta'\gamma)\delta'(\gamma(h))
$$

Therefore, if we write $hk$ as $\begin{pmatrix} h \\ k \end{pmatrix}$, then $\theta'(\theta(h)) = \begin{pmatrix} \alpha'\alpha + (\gamma'\alpha\cdot\beta')\gamma' \\ (\gamma'\alpha\beta + \delta'\gamma) \end{pmatrix} \begin{pmatrix} h \\ 1 \end{pmatrix}$.

By the similar argument, $\theta'(\theta(k)) = \begin{pmatrix} \alpha'\beta + (\gamma'\beta\cdot\delta') \gamma' \\ (\gamma'\beta\gamma + \delta'\beta) \delta' \end{pmatrix} \begin{pmatrix} 1 \\ k \end{pmatrix}$. Thus,

$$
\theta'(\theta(hk)) = \begin{pmatrix} \alpha'\alpha + (\gamma'\alpha\cdot\beta')\gamma' \\ (\gamma'\alpha\beta + \delta'\gamma) \end{pmatrix} \begin{pmatrix} \alpha'\beta + (\gamma'\beta\cdot\delta') \\ (\gamma'\beta\gamma + \delta'\beta) \end{pmatrix} \begin{pmatrix} h \\ k \end{pmatrix}
$$

Therefore, $T(\theta') = \begin{pmatrix} \alpha'\alpha + (\gamma'\alpha\cdot\beta')\gamma' \\ (\gamma'\beta\gamma + \delta'\gamma) \end{pmatrix} \begin{pmatrix} \alpha'\beta + (\gamma'\beta\cdot\delta') \\ (\gamma'\beta\gamma + \delta'\beta) \end{pmatrix} = T(\theta)T(\theta')$. Hence, $T$ is an isomorphism of groups.

From here on, we will identify the automorphisms of $G$ with the matrices in
Let $P = \{ \alpha \in \text{Aut}(H) \mid k \cdot \alpha(h) = \alpha(k \cdot h) \text{ and } k^{\alpha(h)} = k^h \}$,
$Q = \{ \beta \in \text{Map}(K, H) \mid \beta(kk') = \beta(k)(k \cdot \beta(k')) \text{, } k = k^{\beta(k')} \},$
$R = \{ \gamma \in \text{Map}(H, K) \mid \gamma(hk') = \gamma(h)^{\gamma(k)} \gamma(h') \text{, } h' = \gamma(h) \cdot h' \},$
$S = \{ \delta \in \text{Aut}(K) \mid \delta(k) \cdot h = k \cdot h \text{, } \delta(k)^h = \delta(k^h) \}$,
$X = \{ (\alpha, \gamma, \delta) \in \text{Map}(H, H) \times \text{Map}(H, K) \times \text{Aut}(K) \mid \alpha(hk') = \alpha(h)(\gamma(h) \cdot \alpha(h')) \},$
$Y = \{ (\alpha, \beta, \delta) \in \text{Aut}(H) \times \text{Map}(K, H) \times \text{Map}(K, K) \mid \beta(kk') = \beta(k)(\delta(k) \cdot \beta(k')) \},$
$Z = \{ (\alpha, \delta) \in \text{Aut}(H) \times \text{Aut}(K) \mid \delta(k) \cdot \alpha(h) = \alpha(k \cdot h) \},$

Then one can easily check that $P$, $S$, $X$, $Y$ and $Z$ are all subgroups of the group $\text{Aut}(G)$. But $Q$ and $R$ need not be subgroup of the group $\text{Aut}(G)$. However, if $H$ and $K$ are abelian groups, then $Q$ and $R$ are subgroups of $\text{Aut}(G)$. Let

\[ A = \left\{ \begin{pmatrix} \alpha & 0 \\ 0 & 1 \end{pmatrix} \mid \alpha \in P \right\}, \quad B = \left\{ \begin{pmatrix} 1 & \beta \\ 0 & 1 \end{pmatrix} \mid \beta \in Q \right\}, \]
\[ C = \left\{ \begin{pmatrix} 1 & 0 \\ \gamma & 1 \end{pmatrix} \mid \gamma \in R \right\}, \quad D = \left\{ \begin{pmatrix} 1 & 0 \\ 0 & \delta \end{pmatrix} \mid \delta \in S \right\}, \]
\[ E = \left\{ \begin{pmatrix} \alpha & 0 \\ \gamma & \delta \end{pmatrix} \mid (\alpha, \gamma, \delta) \in X \right\}, \quad F = \left\{ \begin{pmatrix} \alpha & \beta \\ 0 & \delta \end{pmatrix} \mid (\alpha, \beta, \delta) \in Y \right\}, \]
\[ M = \left\{ \begin{pmatrix} \alpha & 0 \\ 0 & \delta \end{pmatrix} \mid (\alpha, \delta) \in Z \right\}. \]

be the corresponding subsets of $A$. Then one can easily check that $A$, $D$, $E$, $F$ and $M$ are subgroups of $A$, and if $H$ and $K$ are abelian groups, then $B$ and $C$ are also subgroups of $A$.

**Theorem 2.2.** Let $G = H \rtimes K$ be the Zappa-Szép product of two abelian groups $H$ and $K$ and $A, B, C,$ and $D$ be defined as above. Then $ABCD \subseteq A$. Further, if $1 - \beta \gamma \in P$, then $ABCD = A$. Therefore, $\text{Aut}(G) \simeq ABCD$.

**Proof.** Note that $A$ and $D$ normalizes $B$ and $C$. Then $ABCD$ is a subgroup of $\text{Aut}(G)$. Clearly, $ABCD \subseteq A$. Let $\alpha \in P$, $\beta \in Q$, $\gamma \in R$ and $\delta \in S$. Then note that, $\alpha \beta \delta \in Q$ and $\begin{pmatrix} \beta \\ \gamma \end{pmatrix} \in A$. Further, let us assume that $1 - \beta \gamma \in P$. Now, if $\hat{\beta} = \alpha^{-1} \beta \delta^{-1}$, then

\[ \begin{pmatrix} \hat{\beta} \\ \gamma \end{pmatrix} = \begin{pmatrix} 1 - \beta \gamma & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 - \beta \gamma^{-1} \hat{\beta} \\ 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \gamma \\ 1 \end{pmatrix} \in ABC. \]
Thus, if \(\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}\) \(\in \mathcal{A}\), then
\[
\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} = \begin{pmatrix} \alpha & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & \beta \\ \gamma & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & \delta \end{pmatrix} \in A(ABC)D = ABCD.
\]
Therefore, \(\mathcal{A} \subseteq ABCD\). Hence, \(ABCD = \mathcal{A}\) and so, \(\text{Aut}(G) \simeq \mathcal{A}\).  

3 Automorphisms of Zappa-Szép product of groups \(\mathbb{Z}_4\) and \(\mathbb{Z}_m\)

In [11], Yacoub classified the groups which are Zappa-Szép product of cyclic groups of order 4 and order \(m\). He found that these are of the following type (see [11, Conclusion, p. 126])

\[
L_1 = \langle a, b \mid a^m = 1 = b^4, ab = ba^r, r^4 \equiv 1 \pmod{m} \rangle,
\]
\[
L_2 = \langle a, b \mid a^m = 1 = b^4, ab = b^3 a^{2t+1}, a^2 b = ba^{2s} \rangle,
\]
where in \(L_2\), \(m\) is even. These are not non-isomorphic classes. The group \(L_1\) may be isomorphic to the group \(L_2\) depending on the values of \(m, r\) and \(t\) (see [11, Theorem 5, p. 126]). Clearly, \(L_1\) is a semidirect product. Throughout this section \(G\) will denote the group \(L_2\) and we will be only concerned about groups \(L_2\) which are Zappa-Szép product but not the semidirect product. Note that \(G = H \rtimes K\), where \(H = \langle b \rangle\) and \(K = \langle a \rangle\). For the group \(G\), the mutual actions of \(H\) and \(K\) are defined by \(a \cdot b = b^3, a^b = a^{2t+1}\) along with \(a^2 \cdot b = b\) and \((a^2)^b = a^{2s}\), where \(t\) and \(s\) are the integers satisfying the conditions

\[(G1)\ 2s^2 \equiv 2 \pmod{m},\]
\[(G2)\ 4t(s + 1) \equiv 0 \pmod{m},\]
\[(G3)\ 2(t + 1)(s - 1) \equiv 0 \pmod{m},\]
\[(G4)\ \gcd(s, \frac{m}{2}) = 1.\]

Lemma 3.1.
\[
(a^l)^b = \begin{cases} a^{2t+1+(l-1)s}, & \text{if } l \text{ is odd} \\ a^{ls}, & \text{if } l \text{ is even} \end{cases}.
\]

Lemma 3.2. Let \(\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}\) \(\in \mathcal{A}\). Then
Proof. 
(i) If possible, let $\delta(a) = a^r$, where $r$ is odd. Then, using (A3) and $a^2 \cdot b^l = b^l \cdot b^2$, $\beta$ is a homomorphism. Also, using $(a^2)^b = a^{2s}$, (C4) and (A4), if $\beta(a) = 1$ or $b^2$, then $\delta$ is defined by $\delta(a^l) = a^{rl}$, for all $l$. Similarly, if $\beta(a) = b$ or $b^3$, then $\delta$ is defined by

$$\delta(a^l) = \begin{cases} a^{\frac{4}{r} \nu + \frac{r}{s} r}, & \text{if } l \text{ is odd} \\ a^{\frac{2}{r}s(s+1)}, & \text{if } l \text{ is even} \end{cases}$$

One can easily observe that $\delta$ is neither one-one nor onto. But this is a contradiction by (A7). Hence, $\text{Im}(\delta) \subseteq \langle a^r \rangle$, where $r$ is odd.

(ii) Using (C3), and $a \cdot b = b^{-1}$, we have if $\nu$ is odd, then $a^\nu \cdot b^l = b^{-l}$, for all $l$. Thus using (A3), (C2) and part (i), $\beta(a^2) = \beta(a)(\delta(a) \cdot \beta(a)) = \beta(a)(\beta(a))^{-1} = 1$ and $\beta(a^3) = \beta(a)(\delta(a) \cdot \beta(a^2)) = \beta(a)(\beta(a) \cdot 1) = \beta(a)$. Inductively, we get the required result.

(iii) Suppose that $\gamma(b) = a^\lambda$, where $\lambda$ is odd. Then using (A1), $\alpha(b) = b^i = a^{i\lambda}$ and $\alpha(b^2) = 1 = \alpha(1)$, where $0 \leq i \leq 3$. Thus the map $\alpha$ is neither one-one nor onto, but by (A7), the map $\alpha$ is a bijection. This is a contradiction. Thus, $\lambda$ is even. Now, using (A2), for different choices of $\alpha(b)$ we find that $\gamma(b^2) \in \{a^{2\lambda}, a^{2\lambda+1}\}$. Since, $\lambda$ is even, $\gamma(b^2) \in \langle a^2 \rangle$. Similarly, $\gamma(b^3) \in \{a^{3\lambda}, a^{3\lambda+2}\}$ and so, $\gamma(b^3) \in \langle a^2 \rangle$. Hence, (iii) holds.

(iv) Using (iii) and (A1), one observes that $\alpha$ is an endomorphism of $H$. Also, by (A7), $\alpha$ is a bijection. Thus, $\alpha$ is an automorphism of $H$. Hence, (iv) holds.

(v) Using the parts (ii) and (iii), $\beta \gamma(h) = 1$, for all $h \in H$. Thus, $\beta \gamma = 0$. 

8
(vi) Using the relation \( a^2 \cdot b = b \) and the part (iii), (vi) holds.

(vii) Using (C4) and (G1), we get

\[
(a^{2t})^{b^j} = \begin{cases} 
a^{2ts}, & \text{if } j \text{ is odd} \\
a^2t, & \text{if } j \text{ is even} \end{cases}.
\]

Thus, if either \( s = 1 \) or \( \text{Im}(\beta) \subseteq \langle b^2 \rangle \), then using the part (iii) and the Equation (1), (vii) holds.

By 3.2 (ii), observe that, \( \beta(k^h) = \beta(k) \), for all \( k \in K \) and \( h \in H \).

**Lemma 3.3.** Let \( \beta \in Q \). Then \( \beta \in \text{Hom}(K, H) \) and \( \text{Im}(\beta) \subseteq \langle b^2 \rangle \). Also, \( \text{Im}(\beta) = \langle b^2 \rangle \) if and only if \( 2t(1 + s) \equiv 0 \pmod{m} \), where \( \gcd(s + 1, \frac{m}{2}) \neq 1 \).

**Proof.** Let \( \beta(a) = b^j \). Then using the Lemma 3.2 (ii), we have, \( \beta(a^{2j}) = 1 \) and \( \beta(a^{2j+1}) = b^j \), for all \( j \). So, it is sufficient to study only the \( \beta(a) \) in the following,

\[
a = a^{\beta(a)} = a^{b^j}.
\]

Clearly, the Equation (2) holds trivially for \( i = 0 \). If \( i = 1 \), then by the Equation (2), \( a = a^{2t+1} \) which implies that \( 2t \equiv 0 \pmod{m} \). Therefore, in the defining relations of the group \( G, ab = b^a \) which shows that \( G \) is a semidirect product of the groups \( H \) and \( K \). For \( i = 3 \), \( a = a^{b^j} = a^{4t+2ts+1} \), which gives that \( 4t+2ts \equiv 0 \pmod{m} \). So, using (G2) and (G4), \( 2ts \equiv 0 \pmod{m} \) which gives that \( t \equiv 0 \pmod{\frac{m}{2}} \). Thus, \( G \) is again the semidirect product of \( H \) and \( K \). Now, For \( i = 2 \), using (C6) and the Lemma 3.1, \( a^{b^2} = (a^{2t+1})^b = a^{2t+1+2ts} \). Then, \( a^{b^2} = a \) if and only if \( 2t(1 + s) \equiv 0 \pmod{m} \).

Now, if \( \gcd(s + 1, \frac{m}{2}) = 1 \), then \( t \equiv 0 \pmod{\frac{m}{2}} \) and so, \( G \) is a semidirect product of the groups \( H \) and \( K \). On the other hand, if \( \gcd(s + 1, \frac{m}{2}) \neq 1 \), then \( t \neq 0 \pmod{\frac{m}{2}} \). Thus, \( G \) is a Zappa-Szép product of \( H \) and \( K \). Thus, \( \text{Im}(\beta) = \langle b^2 \rangle \) if and only if \( 2t(1 + s) \equiv 0 \pmod{m} \) and \( \gcd(s + 1, \frac{m}{2}) \neq 1 \). Since \( \text{Im}(\beta) \subseteq \langle b^2 \rangle \), using the Lemma 3.2 (ii), one can easily observe that \( \beta \in \text{Hom}(K, H) \). Hence, the result holds.

Now, one can easily observe that for the given group \( G, k \cdot \alpha(h) = \alpha(k \cdot h) \), \( \beta(k) = \beta(k^h), k' = \gamma(h) \cdot h', \delta(k) \cdot h = k \cdot h, \delta(k) \cdot \alpha(h) = \alpha(k \cdot h) \) and \( \beta(k)(\delta(k) \cdot \alpha(h)) = \alpha(k \cdot h)\beta(k^h) \) always holds for all \( \alpha \in P, \beta \in Q, \gamma \in R, \delta \in S, (\alpha, \gamma, \delta) \in X, (\alpha, \delta) \in Z \) and \( (\alpha, \beta, \delta) \in Y \) respectively. Thus the
subgroups $P$, $Q$, $R$, $S$, $X$, $Y$ and $Z$. Reduces to the following,

$$P = \{ \alpha \in \text{Aut}(H) \mid k^\alpha(h) = k^h \},$$

$$Q = \{ \beta \in \text{Hom}(K, H) \mid k = k^{\beta(k')} \} = \text{Hom}(K, \text{Stab}_H(K)),$$

$$R = \{ \gamma \in \text{CrossHom}(H, \text{Stab}_K(H)) \mid \gamma(k \cdot h) = \gamma(h) \}$$

$$S = \{ \delta \in \text{Aut}(K) \mid \delta(k^h) = \delta(k^h) \},$$

$$X = \{ (\alpha, \gamma, \delta) \in \text{Aut}(H) \times \text{Map}(H, K) \times \text{Aut}(K) \mid \gamma(hh') = (\gamma(h))^{\alpha(h)} \gamma(h') \}$$

$$\delta(k)^{\alpha(h)} \gamma(h) = (k \cdot h) \delta(k^h),$$

$$Y = \{ (\alpha, \beta, \delta) \in \text{Aut}(H) \times \text{Map}(K, H) \times \text{Map}(K, K) \mid \beta(kk') = \beta(k)(\delta(k) \cdot \beta(k')), \}$$

$$\delta(kk') = \delta(k)^{\beta(k')} \delta(k'), \delta(k)^{\alpha(h)} = \delta(k^h),$$

$$Z = \{ (\alpha, \delta) \in \text{Aut}(H) \times \text{Aut}(K) \mid \delta(k)^{\alpha(h)} = \delta(k^h) \}. $$

**Theorem 3.1.** Let $A, B, C,$ and $D$ be defined as above. Then $\text{Aut}(G) = ABCD$.

**Proof.** Using the Lemma 3.2 (v), we have that $\beta \gamma = 0$ and so, $1 - \beta \gamma \in P$. Therefore, by the Theorem 2.2 we have, $\text{Aut}(G) = ABCD$. \qed

**Theorem 3.2.** Let \( \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \in A \). Then, if $\beta \in Q$ and $(\alpha, \gamma, \delta) \in X$, then $\text{Aut}(G) \cong E \times B \cong (C \rtimes M) \times B$.

**Proof.** Let $\beta \in Q$. Then using the Lemma 3.3 $\text{Im}(\beta) \leq \langle b^2 \rangle$. Let $k, k' \in K$ such that $\beta(k) = b^{2i}$ and $\beta(k') = b^{2j}$, for all $i, j$. Then

$$\gamma \beta(kk') = \gamma(\beta(k)(k \cdot \beta(k'))))$$

$$= \gamma(\beta(k))^{\alpha(k \cdot \beta(k'))} \gamma(k \cdot \beta(k'))$$

$$= \gamma(b^{2i})^{\alpha(b^{2j})} \gamma(b^{2j})$$

$$= (a^{i\lambda(s+1)})^{\alpha(b^{2j})} \gamma(b^{2j})$$

$$= (a^{i\lambda(s+1)})^{b^{2j}} \gamma(\beta(k'))$$

$$= a^{i\lambda(s+1)} \gamma(\beta(k'))$$

$$= a^{i\lambda(s+1)} \gamma(\beta(k'))$$

$$= \gamma(b^{2i}) \gamma(\beta(k'))$$

$$= \gamma(b^{2i}) \gamma(\beta(k')).$$

Thus $\gamma \beta \in \text{Hom}(K, K)$ and so, $\gamma \beta + \delta \in \text{Hom}(K, K)$. Now, let $\beta(a) = b^{2j}$ and $\delta(a) = a^r$, where $j \in \{0, 1\}$ and $r \in U(m)$. Then, using the Lemma 3.2...
we have
\[(\gamma \beta + \delta)(a^l) = \begin{cases} a^l, & \text{if } l \text{ is even} \\ a^{\lambda^j(s+1)+l}, & \text{if } l \text{ is odd} \end{cases}\]

One can easily observe that \(\gamma \beta + \delta\) defined as above is a bijection. Thus \(\gamma \beta + \delta \in Aut(K)\).

Now, using (C3) and (C4) and the Lemma 3.2 (iii), \((\gamma \beta + \delta)(a) \cdot \alpha(b) = \gamma \beta(a)\delta(a) \cdot \alpha(b) = \gamma \beta(a) \cdot (\delta(a) \cdot \alpha(b)) = \gamma \beta(a) \cdot \alpha(a \cdot b) = \alpha(a \cdot b) \cdot \gamma \beta(a) \cdot \delta(a)\) and \((\gamma \beta + \delta)(a^b)\gamma(b) = (\gamma \beta(a)\delta(a))\alpha(b)\gamma(b) = (\delta(a)\gamma \beta(a))\alpha(b)\gamma(b) = (\gamma \beta(a))\alpha(b)\gamma(b) = \gamma \beta(a)\gamma(b)\). Using the Lemma 3.2 (ii), we have
\[
\begin{pmatrix} 1 & \beta \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \alpha & 0 \\ \gamma & \delta \end{pmatrix} \begin{pmatrix} 1 & \beta \\ 0 & 1 \end{pmatrix}^{-1} = \begin{pmatrix} \alpha & \alpha + \beta \gamma (-\beta) + \beta \delta \\ \gamma & \gamma + \beta \delta \end{pmatrix} \in E.
\]

Now, using the Lemma 3.2 (ii), we have, \((\alpha + \beta \gamma)(-\beta) + \beta \delta) = (\alpha + \beta \gamma)(b^{-2j}b(\alpha^r) = \alpha(b^{2j})\beta(\gamma(b^{2j}))b^{2j}) = b^{2j}b^{2j} = b^{2j(i+1)} = 1\). Thus, \((\alpha + \beta \gamma)(-\beta) + \beta \delta = 0\). Therefore, by the Equation (3),
\[
\begin{pmatrix} 1 & \beta \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \alpha & 0 \\ \gamma & \delta \end{pmatrix} \begin{pmatrix} 1 & \beta \\ 0 & 1 \end{pmatrix}^{-1} = \begin{pmatrix} \alpha & 0 \\ \gamma & \gamma + \beta \delta \end{pmatrix} \in E.
\]

So, \(E \triangleleft A\). Now, if \(\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \in A\), then
\[
\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} = \begin{pmatrix} \alpha & 0 \\ \gamma & -\alpha^{-1} \beta + \delta \end{pmatrix} \begin{pmatrix} 1 & \alpha^{-1} \beta \\ 0 & 1 \end{pmatrix} \in EB.
\]

Clearly, \(E \cap B = \{1\}\). Thus, \(A = E \rtimes B\). Hence, \(Aut(G) \simeq E \rtimes B\).

Let \(\begin{pmatrix} \alpha & 0 \\ \gamma & \delta \end{pmatrix} \in E\). Then
\[
\begin{pmatrix} \alpha & 0 \\ \gamma & \delta \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ \delta^{-1} \gamma & 1 \end{pmatrix} \in MC.
\]

Clearly, \(M \cap C = \{1\}\). Since \(A \rtimes D\) normalizes \(C\), \(C \triangleleft E\). Thus, \(E = C \rtimes M\). Hence, \(X \simeq C \rtimes M\) and so, \(Aut(H) \simeq (C \rtimes M) \rtimes B\).
Now, we will find the structure and the order of the automorphism group $\text{Aut}(G)$. For this, we will proceed by first taking $t$ to be such that $\gcd(t, m) = 1$ and then by taking $t$ such that $\gcd(t, m) = d$, where $d > 1$.

**Theorem 3.3.** Let $4$ divides $m$ and $t$ be odd such that $\gcd(t, m) = 1$. Then

$$\text{Aut}(G) \simeq \begin{cases} (\mathbb{Z}_m \times (\mathbb{Z}_2 \times U(m))) \times \mathbb{Z}_2, & \text{if } s \in \left\{ \frac{m}{4} - 1, m - 1 \right\} \\ \mathbb{Z}_m \times (\mathbb{Z}_2 \times U(m)), & \text{if } s \in \left\{ \frac{m}{4} - 1, \frac{3m}{4} - 1 \right\} \end{cases}.$$  

**Proof.** Let $\gcd(t, m) = 1$. Then, using (G2), we get, $s \equiv -1 \pmod{\frac{m}{4}}$ which implies that $s \in \left\{ \frac{m}{4} - 1, \frac{m}{4} - 1, \frac{3m}{4} - 1, m - 1 \right\}$. Now, using (G3), we get $t \equiv -1 \pmod{\frac{m}{4}}$. Then $t \in \left\{ \frac{m}{4} - 1, \frac{m}{4} - 1, \frac{3m}{4} - 1, m - 1 \right\}$.

Let $(\alpha, \gamma, \delta) \in X$ be such that $\alpha(b) = b'$, $\gamma(b) = a^\lambda$ and $\delta(a) = a^r$, where $i \in \{1, 3\}$, $\lambda$ is even, $0 \leq \lambda \leq m - 1$, and $r \in U(m)$. Using $\gamma(hh') = \gamma(h)\alpha(h')\gamma(h')$, we get $\gamma(b^2) = a^\lambda(b^{2})$, $\gamma(b^3) = a^\lambda(s+2)$ and $\gamma(b^4) = 1$. We consider two cases based on the image of the map $\alpha$.

**Case (i):** Let $\alpha(b) = b$. Then, using $\gamma(a\cdot b)\delta(a^b) = \delta(a)\gamma(b)$, $a^{\lambda(s+2)+(2t+1)r} = \gamma(a \cdot b)\delta(a^b) = \delta(a)^\lambda\gamma(b) = (a^r)^\lambda a^\lambda = a^{2t+1+(r-1)s+s\lambda}$ which implies that

$$\lambda(s + 1) \equiv (r - 1)(s - 2t - 1) \pmod{m}. \quad (4)$$

If $s \in \left\{ \frac{m}{4} - 1, m - 1 \right\}$, then the Equation (4) holds for all values of $t$, $\lambda$ and $r$. Now, if $(s, t) \in \left\{ \left( \frac{m}{4} - 1, \frac{m}{4} - 1 \right), \left( \frac{m}{4} - 1, m - 1 \right) \right\}$, then by the Equation (4), $r \equiv 1 + \lambda \pmod{4}$. Since $\lambda$ is even, $r \equiv 1$ or $3 \pmod{4}$. Again, if $(s, t) \in \left\{ \left( \frac{m}{4} - 1, \frac{m}{4} - 1 \right), \left( \frac{m}{4} - 1, \frac{3m}{4} - 1 \right) \right\}$, then by the Equation (4), $r \equiv 3 - \lambda \pmod{4}$. Since $\lambda$ is even, $r \equiv 1$ or $3 \pmod{4}$. By the similar argument, we get the same results for $s = \frac{3m}{4} - 1$. Thus, in this case, the choices for the maps $\gamma$ and $\delta$ are, $\gamma(b) = a^\lambda$ and $\delta(a) = a^r$, for all $0 \leq \lambda \leq m - 1$, $\lambda$ is even, and $r \in U(m)$.

**Case (ii):** Let $\alpha(b) = b^3$. Then, $a^{\lambda(s+2)+(2t+1)r} = \gamma(a \cdot b)\delta(a^b) = \delta(a)^\lambda\gamma(b) = (a^r)^{b^3}a^\lambda = a^{4t+2st+1+(r-1)s+s\lambda}$ which implies that

$$\lambda(s + 1) \equiv 2t(s + 1) + (r - 1)(s - 2t - 1) \pmod{m}. \quad (5)$$

If $s \in \left\{ \frac{m}{4} - 1, m - 1 \right\}$, then the Equation (5) holds for all values of $t$, $\lambda$ and $r$. Now, if $(s, t) \in \left\{ \left( \frac{m}{4} - 1, \frac{m}{4} - 1 \right), \left( \frac{m}{4} - 1, m - 1 \right) \right\}$, then by the Equation (5), $r \equiv 3 + \lambda \pmod{4}$. Since $\lambda$ is even, $r \equiv 1$ or $3 \pmod{4}$. Again, if $(s, t) \in \left\{ \left( \frac{m}{4} - 1, \frac{m}{4} - 1 \right), \left( \frac{m}{4} - 1, \frac{3m}{4} - 1 \right) \right\}$, then by the Equation (5), $r \equiv 1 + \lambda \pmod{4}$. Since $\lambda$ is even, $r \equiv 1$ or $3 \pmod{4}$. By the similar argument, we get the same results for $s = \frac{3m}{4} - 1$. Thus, in this case, the choices for the maps $\gamma$ and $\delta$ are, $\gamma(b) = a^\lambda$ and $\delta(a) = a^r$, for all $0 \leq \lambda \leq m - 1$, $\lambda$ is even, and $r \in U(m)$.
Thus combining both the cases (i) and (ii), we get, for all $\alpha \in Aut(H)$, the choices for the maps $\gamma$ and $\delta$ are, $\gamma_{\lambda}(b) = a^{\lambda}$ and $\delta_{\nu}(a) = a^{\nu}$, where $0 \leq \lambda \leq m - 1$, $\lambda$ is even, and $r \in U(m)$. So, using the Theorem 3.2

$X \simeq \mathbb{Z}_2 \rtimes (\mathbb{Z}_2 \times U(m))$. Now, if $s \in \left\{ \frac{m}{2} - 1, m - 1 \right\}$, then $2t(s + 1) \equiv 0 \pmod{m}$. Therefore, using the Lemma 3.3, $Im(\beta) = \{b^2\}$ and so, $B \simeq \mathbb{Z}_2$. If $s \in \left\{ \frac{m}{2} - 1, \frac{3m}{4} - 1 \right\}$, then $2t(s + 1) \not\equiv 0 \pmod{m}$. Therefore, using the Lemma 3.3, $Im(\beta) = \{1\}$ and so, $B$ is a trivial group. Hence, by the Theorem 3.2

$$Aut(G) \simeq E \rtimes B \simeq \left\{ \begin{array}{ll}
(Z_2 \rtimes (Z_2 \times U(m))) \rtimes Z_2, & \text{if } s \in \left\{ \frac{m}{2} - 1, m - 1 \right\} \\
Z_2 \rtimes (Z_2 \times U(m)), & \text{if } s \in \left\{ \frac{m}{4} - 1, \frac{3m}{4} - 1 \right\}.
\end{array} \right.$$ 

\[ \square \]

**Theorem 3.4.** Let $m = 2q$, where $q > 1$ is odd and $gcd(t,m) = 1$. Then, $Aut(G) \simeq (Z_2 \rtimes (Z_2 \times U(m))) \rtimes \mathbb{Z}_2$.

*Proof.* Using (G1), (G2), and (G3), we get $s,t \in \left\{ \frac{m}{2} - 1, m - 1 \right\}$. Then, the result follows on the lines of the proof of the Theorem 3.3. \[ \square \]

**Theorem 3.5.** Let $m = 2^n$, $n \geq 3$. Then

(i) if $t$ is even, then $Aut(G) \simeq (Z_4 \rtimes (Z_2 \times (Z_2 \times Z_{2^{n-2}}))) \rtimes Z_2$,

(ii) if $t$ is odd, then

$$Aut(G) \simeq \left\{ \begin{array}{ll}
(Z_{2^{n-1}} \rtimes (Z_2 \times (Z_2 \times Z_{2^{n-2}}))) \rtimes Z_2, & \text{if } s \in \left\{ \frac{m}{4} - 1, m - 1 \right\} \\
Z_{2^{n-1}} \rtimes (Z_2 \times (Z_2 \times Z_{2^{n-2}})), & \text{if } s \in \left\{ \frac{m}{4} - 1, \frac{3m}{4} - 1 \right\}.
\end{array} \right.$$ 

*Proof.* We will find the automorphism group $Aut(G)$ in two cases namely, when $t$ is even and when $t$ is odd.

Case(i). Let $t$ be even. Then $2(t + 1)(s - 1) \equiv 0 \pmod{2^n}$ implies that $s \equiv 1 \pmod{2^{n-1}}$. Therefore, $s = 1,2^{n-1} + 1$. Now, $4t(s + 1) \equiv 0 \pmod{2^n}$ implies that $t \equiv 0 \pmod{2^{n-3}}$. Therefore, $t \in \{2^{n-3}, 2^{n-2}, 3 \cdot 2^{n-3}, 2^{n-1}, 5 \cdot 2^{n-3}, 3 \cdot 2^{n-2}, 7 \cdot 2^{n-3}, 2^n\}$. Note that, for $t = 2^{n-1}$ and $t = 2^n$, $G$ is the semidirect product of $H$ and $K$. So, we consider the other values of $t$.

Let $\gamma \in R$ be such that $\gamma(b) = a^{\lambda}$, where $0 \leq \lambda \leq m - 1$ and $\lambda$ is even. Then, since, $s = 1$ and $\lambda$ is even, by (A2), $\gamma \in Hom(H,K)$. Now, $1 = \gamma(b^t) = a^{4\lambda}$ which implies that $\lambda \equiv 0 \pmod{2^{n-2}}$. Therefore, $\lambda \in \{2^{n-2}, 2^{n-1}, 3 \cdot 2^{n-2}, 2^n\}$. Using $\gamma(a \cdot b) = \gamma(b)$, $a^{4\lambda} = \gamma(a \cdot b) = \gamma(b) = a^{\lambda}$ implies that $\lambda \equiv 0 \pmod{2^{n-1}}$. Thus, $\lambda \in \{0, 2^{n-1}\}$ and so, $C \simeq \mathbb{Z}_2$.

Now, let $(\alpha, \beta, \delta) \in Y$ be such that $\alpha(b) = b^{r}, \beta(a) = b^j$, and $\delta(a) = a^{r}$, where $i \in \{1,3\}$, $0 \leq j \leq 3$ and $0 \leq r \leq 2^n - 1$ and $r$ is odd. Using the
Lemma 3.2 (ii), \( \beta(kk') = \beta(k)(\delta(k) \cdot \beta(k')) \) holds, for all \( k, k' \in K \). Now, using \( \delta(kk') = \delta(k)\beta(k') \delta(k') \), we get
\[
\delta(a^l) = \begin{cases} 
a^{l-l(1)(j+1)}r, & \text{if } l \text{ is odd} \\
a^{l-1(j+1)}r, & \text{if } l \text{ is even} \end{cases}.
\]

Finally, using \( \delta(k^h) = \delta(k)^\alpha(h), a^{2l+r}= \delta(a)^\alpha(b) = \delta^2 = \delta(a^{2l+1}) = a^{2l+1} \). Thus, \( 2t(jt + r - i) \equiv 0 \mod 2^n \) which implies that
\[
\begin{align*}
r &\equiv i \pmod 4, &\text{if } t \in \{2^{n-3}, 3 \cdot 2^{n-3}, 5 \cdot 2^{n-3}, 7 \cdot 2^{n-3}\} \\
r &\equiv i + 2j \pmod 4, &\text{if } t \in \{2^{n-3}, 3 \cdot 2^{n-3}, 5 \cdot 2^{n-3}, 7 \cdot 2^{n-3}\} \text{ and } n \geq 5 \\
r &\equiv i \pmod 2, &\text{if } t \in \{2^{n-2}, 3 \cdot 2^{n-2}\}
\end{align*}
\]

Now, if \( j \in \{0, 2\} \), then \( r \equiv i \pmod 4 \) and if \( j \in \{1, 3\} \), then \( r \equiv i \) or \( i + 2 \pmod 4 \). Thus, for all \( \beta \in CrossHom(K, H) \), the choices for the maps \( \alpha \) and \( \delta \) are, \( \alpha_t(b) = b^t \) and \( \delta_t(a) = a^t \), where \( i \in \{1, 3\} \) and \( r \in U(m) \). Note that, if \( \left( \begin{array}{cc} \alpha & \beta \\ 0 & \delta \end{array} \right) \in F \), then
\[
\left( \begin{array}{cc} \alpha & \beta \\ 0 & \delta \end{array} \right) = \left( \begin{array}{cc} 1 & 0 \\ \gamma & 1 \end{array} \right) \left( \begin{array}{cc} \alpha & \beta \\ 0 & \delta \end{array} \right) \left( \begin{array}{cc} 1 & 0 \\ \gamma & 1 \end{array} \right)^{-1} = \left( \begin{array}{cc} \alpha & \beta \\ 0 & \delta \end{array} \right). \quad (6)
\]

Clearly, \( M \cap B = \{1\} \) and \( M \) normalizes \( B \). So, \( B \triangleleft F \) and \( F = B \rtimes M \). Therefore, \( Y \approx B \times M \approx \mathbb{Z}_4 \times (\mathbb{Z}_2 \times U(m)) \). Using the Lemma 3.2 (v) – (vii),
\[
\left( \begin{array}{cc} 1 & 0 \\ \gamma & 1 \end{array} \right) \left( \begin{array}{cc} \alpha & \beta \\ 0 & \delta \end{array} \right) \left( \begin{array}{cc} 1 & 0 \\ \gamma & 1 \end{array} \right)^{-1} = \left( \begin{array}{cc} \alpha & \beta \\ 0 & \delta \end{array} \right) \left( \begin{array}{cc} 1 & 0 \\ \gamma & 1 \end{array} \right). \quad (6)
\]

Now, \( (\gamma \alpha + (\gamma \beta + \delta)(-\gamma))(b) = \gamma \alpha(b)(\gamma \beta + \delta)(-\gamma)(b) = \gamma(b)(\gamma \beta + \delta)(a^{-\lambda}) = a^{\lambda \gamma}(\beta(a^{-\lambda}))\delta(a^{-\lambda}) = a^{\lambda \gamma}(1)a^{-\lambda(jt+r)} = a^{\lambda(jt-r)} = 1 \). Thus, \( (\gamma \beta + \delta)(-\gamma) = 0 \). Also, one can easily observe that \( (\alpha, \beta, \gamma \beta + \delta) \in Y \). Therefore, by the Equation (6),
\[
\left( \begin{array}{cc} 1 & 0 \\ \gamma & 1 \end{array} \right) \left( \begin{array}{cc} \alpha & \beta \\ 0 & \delta \end{array} \right) \left( \begin{array}{cc} 1 & 0 \\ \gamma & 1 \end{array} \right)^{-1} = \left( \begin{array}{cc} \alpha & \beta \\ 0 & \delta \end{array} \right) \left( \begin{array}{cc} 1 & 0 \\ \gamma & 1 \end{array} \right) \in F.
\]

So, \( F \triangleleft A \). Clearly, \( F \cap C = \{1\} \). Also, if \( \left( \begin{array}{cc} \alpha & \beta \\ \gamma & \delta \end{array} \right) \in A \), then
\[
\left( \begin{array}{cc} \alpha & \beta \\ \gamma & \delta \end{array} \right) = \left( \begin{array}{cc} \alpha & \beta \\ 0 & \delta \end{array} \right) \left( \begin{array}{cc} 1 & 0 \\ \delta^{-1} \gamma & 1 \end{array} \right) \in FC.
\]

Hence, \( A = F \rtimes C \) and so, \( Aut(G) \approx F \rtimes C \approx (\mathbb{Z}_4 \rtimes (\mathbb{Z}_2 \times (\mathbb{Z}_2 \times \mathbb{Z}_{2^n-2}))) \rtimes \mathbb{Z}_2 \).

**Case (ii).** Let \( t \) be odd. Then \( \gcd(t, m) = 1 \). Hence, the result follows from the Theorem 3.3 .
Now, we will discuss the structure of the automorphism group $Aut(G)$ in the case when $\gcd(t,m) > 1$.

**Theorem 3.6.** Let $m = 4q$, where $q > 1$ is odd and $\gcd(t,m) = 2^d$, where $i \in \{0, 1, 2\}$, and $d$ divides $q$. Then $Aut(G) \simeq (\mathbb{Z}_{2^i} \rtimes (\mathbb{Z}_2 \times U(m))) \rtimes \mathbb{Z}_2$.

**Proof.** Let $q = du$, for some integer $u$. Then, using (G2), $s \equiv -1 \pmod{u}$ which implies that $s = lu - 1$, where $1 \leq l \leq 4d$. Since, $\gcd(s, \frac{m}{2}) = 1$, $s$ is odd and so, $l$ is even. Using (G1) and (G3), we get $l(u\frac{t}{2} - 1) \equiv 0 \pmod{d}$ and $t + 1 \equiv u\frac{t}{2} \pmod{q}$. Now, one can easily observe that $\gcd(l, d) = 1$ which implies that $u\frac{t}{2} - 1 \equiv 0 \pmod{d}$. Thus, $2t(s + 1) \equiv 2ltu \equiv 0 \pmod{m}$ and $\gcd(s + 1, \frac{m}{2}) \neq 1$. Therefore, using the Lemma 3.3, $B \simeq \mathbb{Z}_2$.

Let $(\alpha, \gamma, \delta) \in X$ be such that $\alpha(b) = b^t$, $\gamma(b) = a^\lambda$ and $\delta(a) = a^r$, where $i \in \{1, 3\}$, $0 \leq \lambda \leq m - 1$, $\lambda$ is even, and $r \in U(m)$. Then, using $\gamma(hh') = \gamma(h)\gamma(h')\gamma(h')$, we have $\gamma(b^2) = a^{\lambda(s+1)}$, $\gamma(b^3) = a^{\lambda(s+2)}$, and $\gamma(b^4) = 1$. Now, using $\delta(a)\alpha(b)\gamma(b) = (a\cdot b)\delta(a^r)$ and the fact that $2t(s + 1) \equiv 0 \pmod{m}$, $a^{\lambda(s+2)+(2t+1)r} = \gamma(b^2)\delta(a^{2t+1}) = \gamma(a\cdot b)\delta(a^b) = \delta(a^\lambda)\gamma(b) = (a^r)^b\lambda = a^{2t+1+r-1}+r+\frac{1}{2}l(s+1) = a^{2t+1+r-1+s+\lambda}$. Thus
\[
\lambda(s+1) \equiv (r-1)(s-2t-1) \pmod{m}.
\] (7)

Since $2t(s + 1) \equiv 0 \pmod{m}$, using (G3), we get $2(s - 2t - 1) \equiv 0 \pmod{m}$. Therefore, by the Equation (7), $\lambda u \equiv 0 \pmod{m}$. Using the Lemma 3.2(iii), we get $\lambda \equiv 0 \pmod{2d}$. Thus, using the Theorem 3.2 $X \simeq \mathbb{Z}_{2^i} \rtimes (\mathbb{Z}_2 \times U(m))$. Hence, $Aut(G) \simeq E \rtimes B \simeq (\mathbb{Z}_{2^i} \rtimes (\mathbb{Z}_2 \times U(m))) \rtimes \mathbb{Z}_2$. □

**Theorem 3.7.** Let $m = 2q$, where $q > 1$ is odd and $\gcd(t,m) = 2^d$, where $i \in \{0, 1\}$, and $d$ divides $q$. Then $Aut(G) \simeq (\mathbb{Z}_{2^i} \rtimes (\mathbb{Z}_2 \times U(m))) \rtimes \mathbb{Z}_2$.

**Proof.** Follows on the lines of the proof of the Theorem 3.6. □

**Theorem 3.8.** Let $m = 2^n q$, $t$ be even and $\gcd(m,t) = 2^d$, where $1 \leq i \leq n$, $n \geq 3$, $q > 1$ and $d$ divides $q$. Then
\[
Aut(G) \simeq \begin{cases} 
(\mathbb{Z}_4 \rtimes (\mathbb{Z}_2 \times U(m))) \rtimes \mathbb{Z}_2, & \text{if } d = q \\
\mathbb{Z}_2 \times (\mathbb{Z}_{2^n} \rtimes (\mathbb{Z}_2 \times U(m))), & \text{if } d \neq q \text{ and } n - 2 \leq i \leq n \\
\mathbb{Z}_{2^n} \rtimes (\mathbb{Z}_2 \times U(m)), & \text{if } d \neq q \text{ and } i = n - 3 
\end{cases}.
\]

**Proof.** We consider the following four cases to find the structure of $Aut(G)$.

Case(i): Let $d = q$ and $\gcd(t+1,m) = u$. Since, $t+1$ is odd, $u$ is odd and $u$ divides $q$. Thus, $u$ divides $t$ and so, $u = 1$. Therefore, using (G2) and (G3), $s \equiv 1 \pmod{\frac{m}{2}}$ and $t \equiv 0 \pmod{\frac{m}{2}}$. By the similar argument used in the proof of the Theorem 3.2(i), we get, $Aut(G) \simeq F \rtimes C \simeq (\mathbb{Z}_4 \rtimes (\mathbb{Z}_2 \times U(m))) \rtimes \mathbb{Z}_2$. □
Case(ii): Let $n-2 \leq i \leq n$ and $q = du$, for some odd integer $u$. Then using (G2), $s \equiv -1 \pmod u$ and so, $s = lu - 1$, where $0 \leq l \leq 2^n d$. Since, \( \gcd(s, \frac{q}{2}) = 1 \), $s$ is odd and so, $l$ is even. Now, using (G1), \( \frac{1}{2}(\frac{1}{2}u - 1) \equiv 0 \pmod{2^{n-3}d} \) and by (G3), \( t \equiv \frac{1}{2}u - 1 \pmod{2^{n-2}q} \). Since, $t$ is even, \( \frac{1}{2} \) is odd and \( \gcd(\frac{1}{2}, d) = 1 \). Thus, \( \frac{1}{2}u \equiv 1 \pmod{2^{n-3}d} \) and $t \equiv 2d \pmod{2^{n-2}q}$. One can easily observe that $2t(s + 1) \equiv 0 \pmod{m}$. Therefore, using the similar argument as in the proof of the Theorem 3.3, we get, \( \text{Aut}(G) \simeq E \rtimes B \simeq (\mathbb{Z}_{2^2} \times (\mathbb{Z}_2 \times U(m))) \rtimes \mathbb{Z}_2 \).

Case(iii): Let $i = n - 3$, $d \neq q$ and $q = du$, for some odd integer $u$. Then using (G2), $s \equiv -1 \pmod{2u}$, that is, $s = 2lu - 1$, where $1 \leq l \leq 2^{n-1}d$. Now, using (G1) and (G3), \( l(lu - 1) \equiv 0 \pmod{2^{n-3}d} \) and \( (t + 1)(lu - 1) \equiv 0 \pmod{2^{n-2}q} \). \( i \) is even, then \( t \equiv lu - 1 \pmod{2^{n-2}q} \) gives that $t$ is odd, which is a contradiction. Therefore, $i$ is odd. Using \( (t + 1)(lu - 1) \equiv 0 \pmod{2^{n-2}q} \), one can easily observe that \( \gcd(l, d) = 1 \). Then, \( lu - 1 = 2^{n-3}dl' \) and \( s = 2^{n-2}dl' + 1 \), where $1 \leq l' \leq 8u$. Clearly, \( \gcd(l', u) = 1 \). Thus, \( (t + 1)l' \equiv 0 \pmod{2u} \). \( l' \) is odd, then \( (t + 1) \equiv 0 \pmod{2u} \) which implies that $t$ is odd. So, \( l' \) is even and so, \( t = uq' - 1, 1 \leq q' < 2^{n-1}d, q' \) is odd as $t$ is even. Note that \( s - 2t - 1 = 2^{n-2}dl' - 2t = 2^{n-2}d(l' - \frac{l}{2^{n-3}d}) = 2^{n-2}d \left( \frac{lu - 1}{2^{n-3}d} - \frac{uq' - 1}{2^{n-3}d} \right) \).

Let $(\alpha, \gamma, \delta) \in X$ be such that $\alpha(b) = b^i, \gamma(b) = a^\lambda$ and $\delta(a) = a^r$, where $i \in \{1, 3\}, 0 \leq \lambda \leq m - 1, \lambda$ is even and $r \in U(m)$. We consider two sub-cases based on the image of the map $\alpha$.

Sub-case(i): Let $\alpha(b) = b$. Then using $\delta(a)^{\alpha(b)} \gamma(b) = \gamma(a \cdot b) \delta(a^b)$, $a^{\lambda(s+2)+(2t+1)r} = \gamma(a \cdot b) \delta(a^b) = \delta(a^b) \gamma(b) = (a^r)^b a^\lambda = a^{2^t + 2s + 1 + (r - 1)s + \lambda}$ which implies that

$$\lambda(s + 1) \equiv (r - 1)(s - 2t - 1) \pmod{m}.$$ 

Therefore, \( \lambda(2lu) \equiv 2^{n-2}du(r - 1) \left( \frac{\frac{l}{2^n - 3d} - \frac{r}{2^n - 3d}}{2^n - 3d} \right) \pmod{2^n q} \) which implies that \( \lambda l \equiv 2^{n-3}d(r - 1) \left( \frac{\frac{l}{2^n - 3d} - \frac{r}{2^n - 3d}}{2^n - 3d} \right) \pmod{2^{n-1}d} \). Now, if $\lambda \equiv 0 \pmod{2^{n-2}d}$, then $r \equiv 1$ or $3 \pmod{4}$ and vice-versa. Thus, in this sub-case, the choices for the maps $\gamma$ and $\delta$ are, $\gamma_\alpha(b) = a^\lambda$ and $\delta_\gamma(a) = a^r$, where $\lambda$ is even and $\lambda \equiv 0 \pmod{2^{n-2}d}$, and $r \in U(m)$.

Sub-case(ii): Let $\alpha(b) = b^3$. Then using $\delta(a)^{\alpha(b)} \gamma(b) = \gamma(a \cdot b) \delta(a^b)$, $a^{\lambda(s+2)+(2t+1)r} = \gamma(a \cdot b) \delta(a^b) = \delta(a^b) \gamma(b) = (a^r)^b a^\lambda = a^{4t + 2ts + 1 + (r - 1)s + \lambda}$ which implies that

$$\lambda - 2t(s + 1) \equiv (r - 1)(s - 2t - 1) \pmod{m}.$$ 

Therefore, \( 2lu(\lambda - 2t) \equiv 2^{n-2}du(r - 1) \left( \frac{\frac{l}{2^n - 3d} - \frac{r}{2^n - 3d}}{2^n - 3d} \right) \pmod{2^n q} \) which implies that
If \( G \) contradicts. Now, if \( G \) using (3.2), one can easily observe that \( \gcd(l, d)\) is odd. Then \( \gamma \) is even and \( \lambda \equiv 0 \pmod{2^{n-2}d} \), and \( r \in U(m) \).

Thus combining both the sub-cases (i) and (ii), we get, for all \( \alpha \in \operatorname{Aut}(H) \), the choices for the maps \( \gamma \) and \( \delta \) are, \( \gamma \lambda(b) = b^\lambda \) and \( \delta_r(a) = a^r \), where \( \lambda \) is even and \( \lambda \equiv 0 \pmod{2^{n-2}d} \), and \( r \in U(m) \). Therefore, using the Theorem 3.2, \( X \simeq \mathbb{Z}_{4^k} \rtimes (\mathbb{Z}_2 \times U(m)) \). At last, since, \( l \) is odd, \( 2t(s + 1) \equiv 0 \pmod{m} \).

Proof. Let \( q = du \), for some odd integer \( u \). Then using (G2), \( s \equiv -1 \pmod{2^{n-i-2}u} \), that is, \( s = 2^{n-i-2}lu - 1 \), where \( 1 \leq l \leq 2^{n-2}d \). Now, using (G1) and (G3), \( l(2^{n-i-3}lu - 1) \equiv 0 \pmod{2^d} \) and \( (t+1)(lu2^{n-i-3}lu - 1) \equiv 0 \pmod{2^nq} \). Since, \( n-i-3 > 0 \), \( lu2^{n-i-3}lu - 1\) is odd.

If \( l \) is even, then \( t \equiv lu2^{n-i-3}lu - 1 \pmod{2^nq} \) gives that \( t \) is odd, which is a contradiction. Now, if \( l \) is odd, then Using \( (t+1)(lu - 1) \equiv 0 \pmod{2^nq} \), one can easily observe that \( \gcd(l, d) = 1 \). Thus, \( 2^{n-i-3}lu - 1 \equiv 0 \pmod{2^d} \), which is absurd. Hence, there is no such \( l \) exist and so, no such \( t \) and \( s \) exist and hence no group \( G \) exists as the Zappa-Szép product of \( H \) and \( K \).

Case (iv): Let \( 1 \leq i \leq n-4 \) and \( q = du \), for some odd integer \( u \). Then using (G2), we have \( s \equiv -1 \pmod{2^{n-2}u} \) which implies that \( s = 2^{n-2}lu - 1 \), where \( 1 \leq l \leq 4d \).

Now, using (G1), \( l(2^{n-3}lu - 1) \equiv 0 \pmod{d} \). Using (G3), we get
\[
(t+1)(lu2^{n-3} - 1) \equiv 0 \pmod{2^nq}. \tag{8}
\]

Case (i): If \( l \) is even, then by the Equation (8), \( t \equiv lu2^{n-3} - 1 \pmod{2^{n-2}q} \). Note that, \( 2t(s + 1) \equiv 0 \pmod{m} \) and \( \lambda(s + 1) = \lambda(2^{n-2}) \). Thus \( \lambda(s + 1) \equiv 0 \pmod{m} \) if and only if \( \lambda \equiv 0 \pmod{4d} \), which is true for all \( \lambda \equiv 0 \pmod{2d} \). Using the similar argument as in the proof of the Theorem 3.3, we get \( X \simeq \mathbb{Z}_{2^k} \rtimes (\mathbb{Z}_2 \times U(m)) \) and \( B \simeq \mathbb{Z}_2 \). Hence, \( \operatorname{Aut}(G) \simeq E \rtimes B \simeq (\mathbb{Z}_{2^k} \rtimes (\mathbb{Z}_2 \times U(m))) \rtimes \mathbb{Z}_2 \).

Case (ii): If \( l \) is odd, then using the Equation (8), one can easily observe that \( \gcd(l, d) = 1 \) which means that \( 2^{n-3}lu - 1 = dl' \), where \( l' \) is odd, \( \gcd(l', u) = 1 \)
and $1 \leq l' \leq 2^n u$. Thus, using the Equation $\square$, $(t + 1)dd' \equiv 0 \pmod{2^{n-2}q}$.

Since, $\gcd(l', u) = 1$, $t = 2^{n-2}uq' - 1$, where $1 \leq q' \leq 4d$. Now, $s - 2t - 1 = 2dl' - 2t = 2d(l' - \frac{l}{d}) = 2d(\frac{2^n - 2uq'}{d}) = 2^{n-2}du' \frac{2q'}{d}$.

Let $(\alpha, \gamma, \delta) \in X$ be such that $\alpha(b) = b^i$, $\gamma(b) = a^\lambda$ and $\delta(a) = a^r$, where $i \in \{1, 3\}$, $0 \leq \lambda \leq m - 1$, $\lambda$ is even and $r \in U(m)$. We consider two sub-cases based on the image of the map $\alpha$.

Sub-case (i): Let $\alpha(b) = b$. Then using $\delta(a)^{\alpha(b)}\gamma(b) = \gamma(a \cdot b)\delta(a^b)$, we get $a^{\lambda(s+2) + (2t+1)r} = \gamma(a \cdot b)\delta(a^b) = \delta(a)^b\gamma(b) = (a^r)^b a^\lambda = a^{2t + 1 + (r-1)s + \lambda}$ which implies that

$$\lambda(s + 1) \equiv (r - 1)(s - 2t - 1) \pmod{m}.$$ 

Therefore, $\lambda(lu2^{n-2}) \equiv 2^{n-2}q(r - 1)(\frac{2q'}{d}) \pmod{2^n q}$ which implies that $\lambda \equiv d(r - 1)(\frac{2q'}{d}) \pmod{4d}$. Now, if $\lambda \equiv 0 \pmod{2d}$, then $r \equiv 3 \pmod{4}$. Again, if $\lambda \equiv 0 \pmod{4d}$, then $r \equiv 1 \pmod{4}$. Thus, in this sub-case, the choices for the maps $\gamma$ and $\delta$ are, $\gamma(a) = a^\lambda$ and $\delta_r(a) = a^r$, where $\lambda$ is even and $\lambda \equiv 0 \pmod{2d}$, and $r \in U(m)$.

Sub-case (ii): Let $\alpha(b) = b^3$. Then using $\delta(a)^{\alpha(b)}\gamma(b) = \gamma(a \cdot b)\delta(a^b)$, $a^{\lambda(s+2) + (2t+1)r} = \gamma(a \cdot b)\delta(a^b) = \delta(a)^b\gamma(b) = (a^r)^b a^\lambda = a^{4t + 2ts + 1 + (r-1)s + \lambda}$ which implies that

$$(\lambda - 2t)(s + 1) \equiv (r - 1)(s - 2t - 1) \pmod{m}.$$ 

Therefore, $lu2^{n-2}(\lambda - 2t) \equiv 2^{n-2}q(r - 1)(\frac{2q'}{d}) \pmod{2^n q}$ which implies that $l(\lambda - 2t) \equiv d(r - 1)(\frac{2q'}{d}) \pmod{4d}$. Now, if $\lambda \equiv 0 \pmod{2d}$, then $r \equiv 3 \pmod{4}$. Thus, in this sub-case, the choices for the maps $\gamma$ and $\delta$ are, $\gamma(a) = a^\lambda$ and $\delta_r(a) = a^r$, where $\lambda$ is even and $\lambda \equiv 0 \pmod{2d}$, and $r \in U(m)$.

Thus combining both the sub-cases (i) and (ii), we get, for all $\alpha \in Aut(H)$, the choices for the maps $\gamma$ and $\delta$ are, $\gamma(a) = a^\lambda$ and $\delta_r(a) = a^r$, where $\lambda$ is even and $\lambda \equiv 0 \pmod{2d}$, and $r \in U(m)$. Therefore, using the Theorem $\square$ $E \simeq \mathbb{Z}_{2^n} \times (\mathbb{Z}_2 \times U(m))$. Also, since, $2t(s + 1) \neq 0 \pmod{m}$, using the Lemma $\square$ $Im(\beta) = \{1\}$. Thus, $B$ is a trivial group. Hence, using the Theorem $\square$ $Aut(G) \simeq E \rtimes B \simeq \mathbb{Z}_{2^n} \rtimes (\mathbb{Z}_2 \times U(m))$. 

\textbf{Theorem 3.10.} Let $m = 8q$, $t$ is odd, and $\gcd(t, m) = d$, where $q > 1$ is odd. Then

$$Aut(G) \simeq \begin{cases} \mathbb{Z}_{2^n} \rtimes (\mathbb{Z}_2 \times U(m)) \times \mathbb{Z}_2, & \text{if } 2t(s + 1) \equiv 0 \pmod{m} \\ \mathbb{Z}_{2^n} \rtimes (\mathbb{Z}_2 \times U(m)), & \text{if } 2t(s + 1) \not\equiv 0 \pmod{m} \end{cases}$$
Proof. Let \( q = du \), for some odd integer \( u \). Then using \((G2)\), \( s \equiv -1 \pmod{2u} \) which implies that \( s = 2lu - 1 \), where \( 1 \leq l \leq 4d \). Now, using \((G1)\), \( l(lu - 1) \equiv 0 \pmod{d} \). Using \((G3)\), we get

\[
(t + 1)(lu - 1) \equiv 0 \pmod{2q}.
\] (9)

**Case(i):** If \( l \) is even, then by the Equation \((9)\), \( t \equiv lu - 1 \pmod{2q} \). Note that, \( 2t(s + 1) \equiv 2t(2lu) \equiv 0 \pmod{m} \) and \( \lambda(s + 1) = \lambda(2lu) \). Thus \( \lambda(s + 1) \equiv 0 \pmod{m} \) if and only if \( \lambda l \equiv 0 \pmod{4d} \) which is true for all \( \lambda \equiv 0 \pmod{2d} \). Therefore, using the similar argument as in the proof of the Theorem 3.3, we get \( E \simeq \mathbb{Z}_{2^s} \times (\mathbb{Z}_2 \times U(m)) \) and \( B \simeq \mathbb{Z}_2 \). Hence, by the Theorem 3.2, \( \text{Aut}(G) \simeq E \rtimes B \simeq (\mathbb{Z}_{2^s} \times (\mathbb{Z}_2 \times U(m))) \rtimes \mathbb{Z}_2 \).

**Case(ii):** If \( l \) is odd, then using the Equation \((9)\), one can easily observe that \( \gcd(l, d) = 1 \) which means that \( lu - 1 = dl' \), where \( 1 \leq l' \leq 8u \) and \( \gcd(l', u) = 1 \). Since \( l - 1 \) is even, \( l' \) is even. Thus using the Equation \((9)\), \( (t + 1)dl' \equiv 0 \pmod{2q} \). Since, \( \gcd(l', u) = 1 \), \( t = uq' - 1 \), where \( 1 \leq q' \leq 8d \) and \( q' \) is even, as \( t \) is odd. Now, \( s - 2t - 1 = 2dl' - 2t = 2d(l' - \frac{t}{2}) = 2d(\frac{l - u}{d}) = 2du \frac{l - u}{d} \).

Let \((\alpha, \gamma, \delta) \in X\) be such that \( \alpha(b) = b^i \), \( \gamma(b) = a^\lambda \) and \( \delta(a) = a^r \), where \( i \in \{1, 3\} \), \( 0 \leq \lambda \leq m - 1 \), \( \lambda \) is even and \( r \in U(m) \). We consider two sub-cases based on the image of the map \( \alpha \).

**Sub-case(i):** Let \( \alpha(b) = b \). Then, \( a^{\lambda(s + 2) + (2t + 1)r} = \gamma(a \cdot b)\delta(a^\lambda) = \delta(a)^{\lambda}\gamma(b) = (a^r)^{\lambda}a^\lambda = a^{2\lambda + 1 + (r - 1)s + \lambda} \) which implies that

\[
\lambda(s + 1) \equiv (r - 1)(s - 2t - 1) \pmod{m}.
\]

Therefore, \( (2lu)(l - 2t) \equiv 2du(r - 1)(\frac{l - u}{d}) \pmod{8q} \) which implies that \( \lambda(l) \equiv d(r - 1)(\frac{l - u}{d}) \pmod{4d} \). Now, if \( \lambda \equiv 0 \pmod{2d} \), then \( r \equiv 3 \pmod{4} \). Again, if \( \lambda \equiv 0 \pmod{4d} \), then \( r \equiv 1 \pmod{4} \). Thus, in this sub-case, the choices for the maps \( \gamma \) and \( \delta \) are, \( \gamma(b) = a^\lambda \) and \( \delta_r(a) = a^r \), where \( \lambda \) is even and \( \lambda \equiv 0 \pmod{2d} \), and \( r \in U(m) \).

**Sub-case(ii):** Let \( \alpha(b) = b^3 \). Then, \( a^{\lambda(s + 2) + (2t + 1)r} = \gamma(a \cdot b)\delta(a^\lambda) = \delta(a)^{\lambda}\gamma(b) = (a^r)^{\lambda}a^\lambda = a^{3 + 2t + 1 + (r - 1)s + \lambda} \) which implies that

\[
(\lambda - 2t)(s + 1) \equiv (r - 1)(s - 2t - 1) \pmod{m}.
\]

Therefore, \( 2lu(\lambda - 2t) \equiv 2du(r - 1)(\frac{l - u}{d}) \pmod{8q} \) which implies that \( l(\lambda - 2t) \equiv d(r - 1)(\frac{l - u}{d}) \pmod{4d} \). Now, if \( \lambda \equiv 0 \pmod{2d} \), then \( r \equiv 1 \pmod{4} \). Again, if \( \lambda \equiv 0 \pmod{4d} \), then \( r \equiv 3 \pmod{4} \). Thus, in this sub-case, the choices for the maps \( \gamma \) and \( \delta \) are, \( \gamma(b) = a^\lambda \) and \( \delta_r(a) = a^r \), where \( \lambda \) is even and \( \lambda \equiv 0 \pmod{2d} \), and \( r \in U(m) \).

19
Thus combining both the sub-cases (i) and (ii), we get, for all \( \alpha \in Aut(H) \), the choices for the maps \( \gamma \) and \( \delta \) are, \( \gamma_\lambda(b) = a^\lambda \) and \( \delta_r(a) = a^r \), where \( \lambda \) is even and \( \lambda \equiv 0 \pmod{2d} \), and \( r \in U(m) \). Therefore, using the Theorem 3.2, \( X \simeq \mathbb{Z}_{m^2} \rtimes (\mathbb{Z}_2 \times U(m)) \). Also, since, \( 2t(s+1) \not\equiv 0 \pmod{m} \), using the Lemma 3.3, \( \text{Im}(\beta) = \{1\} \). Thus, \( B \) is a trivial group. Hence, by the Theorem 3.2, \( Aut(G) \simeq E \rtimes B \simeq \mathbb{Z}_{m^2} \rtimes (\mathbb{Z}_2 \times U(m)) \). □

4 Automorphisms of Zappa-Szép product of groups \( \mathbb{Z}_{p^2} \) and \( \mathbb{Z}_m \), \( p \) is odd prime

In [12], Yacoub classified the groups which are Zappa-Szép product of cyclic groups of order \( p^2 \) and order \( m \). He found that these are of the following type (see [12, Conclusion, p. 38])

\[
M_1 = \langle a, b \mid a^m = 1 = b^{p^2}, ab = ba^u, u^{p^2} \equiv 1 \pmod{m} \rangle,
\]
\[
M_2 = \langle a, b \mid a^m = 1 = b^{p^2}, ab = b'a, t^m \equiv 1 \pmod{p^2} \rangle,
\]
\[
M_3 = \langle a, b \mid a^m = 1 = b^{p^2}, ab = b'a^{pr+1}, a^pb = ba^{p(pr+1)} \rangle,
\]

where \( p \) is an odd prime and in \( M_3 \), \( p \) divides \( m \). These are not non-isomorphic classes. The groups \( M_1 \) and \( M_2 \) may be isomorphic to the group \( M_3 \) depending on the values of \( m, r \), and \( t \). Clearly, \( M_1 \) and \( M_2 \) are semidirect products. Throughout this section \( G \) will denote the group \( M_3 \) and we will be only concerned about groups \( M_3 \) which are Zappa-Szép product but not the semidirect product. Note that \( G = H \bowtie K \), where \( H = \langle b \rangle \) and \( K = \langle a \rangle \). For the group \( G \), the mutual actions of \( H \) and \( K \) are defined by \( a \cdot b = b' \), \( a^b = a^{pr+1} \) along with \( a^p \cdot b = b \) and \( (a^p)^b = a^{p(pr+1)} \), where \( t \) and \( r \) are integers satisfying the conditions

(G1) \( \gcd(t-1, p^2) = p \), that is, \( t = 1 + \lambda p \), where \( \gcd(\lambda, p) = 1 \),

(G2) \( \gcd(r, p) = 1 \),

(G3) \( p(pr + 1)^p \equiv p \pmod{m} \).

Lemma 4.1. \( a^{(pr+1)p^\lambda} = a^{i((pr+1)p^\lambda-1)+1} \), for all \( i \).

Proof. One can easily prove the result using (G3). □

Lemma 4.2. (i) \( a \cdot b^j = b^{jt} \), for all \( j \),
(ii) \(a^l \cdot b = b^{1 + lp^λ}, \) for all \(l,\)

(iii) \(a^{(j)} = a^{(pr + 1)^j}, \) for all \(j,\)

(iv) \((a^l)^b = a^{\frac{(l-1)!}{2}}(pr+1)^{l(p^λ-1)+l(pr+1)}, \) for all \(l,\)

(v) \(a^l \cdot b^l = b^{lt}, \) for all \(j \) and \(l,\)

(vi) \((a^l)^b = a^{\frac{(l-1)!}{2}}(pr+1)^{l(p^λ-1)+l(pr+1)^j}, \) for all \(j \) and \(l.\)

Proof. (i) Using (C3) and (C5), \(a \cdot b^2 = (a \cdot b)(a^2 \cdot b) = b^l(a^{pr+1} \cdot b) = b^l(a \cdot (a^{pr} \cdot b)) = b^l(a \cdot b) = b^2.\) Similarly, \(a \cdot b^3 = (a \cdot b)(a^2 \cdot b^2) = b^l(a \cdot (a^{pr} \cdot b^2)) = b^l(a \cdot b^2) = b^3.\) Inductively, we get \(a \cdot b^l = b^l, \) for all \(j.\)

(ii) Using (C3) and part (i), \(a^2 \cdot b = a \cdot (a \cdot b) = a \cdot b^l = b^l = b^{1+2p^λ}.\) Similarly, \(a^2 \cdot b = a \cdot (a^2 \cdot b) = b^3 = b^{1+3p^λ}.\) Inductively, we get, \(a^l \cdot b = b^{1+lp^λ}, \) for all \(l.\)

(iii) First, note that, using (C4), we have \((a^p)^b = a^{p^2(pr+1)}.\) Now, using (C4) and (C6), \((a^{b^2}) = (a^b)^b = (a^{pr+1})b = a^{(a^pr \cdot b)}a^{b} = a^{a^{pr}b}, \) Similarly, \((a^{b^3}) = (a^b)^b = (a^{pr+1})b^2 = a^{(a^pr \cdot b^2)}a^{b^2} = a^{b^3} \) \(= ((a^pr)^b)^2 = (a^{pr+1})b^3 = a^{a^{pr}b^2}a^{b^3} = a^{a^{pr+1}}b^3.\) Inductively, we get, \(a^{(b)} = a^{(pr+1)^j}, \) for all \(j.\)

(iv) Using (C4), (G3) and the part (iii), \((a^2)^b = a^{(a^b)}a^b = a^{(b)}a^{pr+1} = a^{(pr+1)^2(p^λ)}, a^{pr+1} = a^{(pr+1)^2(p^λ)}, a^{pr+1} = a^{(pr+1)^2(p^λ)}, a^{pr+1} = a^{(pr+1)^2(p^λ)}+1, \) By the similar argument, we get,

\[
(a^3)^b = (a^2)^{a-b}a^b = (a^2)^{b}a^{pr+1} = (a^{b^2})a^{pr+1} = (a^{2b})a^{pr+1} = (a^{b^1})a^{b^{pr+1}} = (a^{b})a^{b^{pr+1}} = a^{(b^1+2p^λ)}a^{(b^1+3p^λ)}a^{pr+1} = a^{(pr+1)^1+2p^λ+(pr+1)^3+p^λ+pr+1} = a^{2^((pr+1)^2(p^λ)-1)+1+pr+(pr+1)^3+p^λ+pr+1} = a^{3((pr+1)^3-1)+1+pr+(pr+1)^3+p^λ+pr+1}, \text{ (using the Lemma 4.1)}
\]

Inductively, we get, (iv).

(v) Follows inductively, using the parts (i) and (ii).
Lemma 4.3. If for all \( l \neq 0, (pr + 1)^l \not\equiv 1 \pmod{m} \), then

(i) \( \text{Im}(\gamma) \subseteq \langle a^p \rangle \),

(ii) \( \alpha \in \text{Aut}(H) \).

Proof. (i) Let \( \alpha(b) = b^i \) and \( \gamma(b) = a^\mu \). Then using \((A1)\) and the Lemma 4.2 \((v)\), \( \alpha(b^2) = \alpha(b) \alpha(b) = b^{i\mu} \cdot b^{i} = b^{i(1+\mu)} \). Inductively, we get,

\[
\alpha(b^u) = b^{i(1+\mu+t\mu+\cdots+t^{(u-1)}\mu)} = b^{i(1+p\mu\lambda+(1+2p\mu\lambda)+\cdots+(1+(u-1)p\mu\lambda))}
\]

for all \( 0 \leq u \leq p^2 - 1 \). Now, using \((A2)\) and the Lemma 4.2 \((vi)\), \( \gamma(b^u) = \gamma(b)^{\alpha(b^u)} = (a^\mu)^u \cdot a^\mu = a^{\mu((u-1)(pr+1)^{p\lambda}-1)+\mu(pr+1)^{p\lambda}} \). Inductively, we get,

\[
\gamma(b^u) = a^{i\frac{u(u-1)(mu-1)}{2}+u^2\frac{u(u-1)(u-2)}{6}(pr+1)^{p\lambda}-1} + \mu \sum_{\nu=0}^{u-1} (pr+1)^\nu
\]

for all \( 0 \leq u \leq p^2 - 1 \). Now, using \((G3)\), \( 1 = \gamma(p^2) = a^\mu \sum_{\nu=0}^{p^2-1} (pr+1)^\nu = a^\mu \left( \frac{pr+1)^{p^2-1}}{(pr+1)^{p^2-1}} \right) \) which implies that

\[
\mu \left( \frac{(pr+1)^{p^2}-1}{(pr+1)^{p^2}-1} \right) \equiv 0 \pmod{m}. \quad (10)
\]

If for all \( l \neq 0, (pr + 1)^l \equiv 1 \pmod{m} \), then by the Equation \((10)\), \( \mu \) can be anything. On the other hand, if for all \( l \neq 0, (pr + 1)^l \not\equiv 1 \pmod{m} \), then by the Equation \((10)\) and \((G3)\), \( \mu \equiv 0 \pmod{p} \). Also, note that, in both the cases, namely \( (pr + 1)^l \equiv 1 \pmod{m} \) and \( (pr + 1)^l \not\equiv 1 \pmod{m} \), we have that \( \gamma(b^u) = a^\mu \sum_{\nu=0}^{u-1} (pr+1)^\nu \). Hence, if \( (pr + 1)^l \not\equiv 1 \pmod{m} \), then \( \gamma(b^u) = a^\mu \sum_{\nu=0}^{u-1} (pr+1)^\nu \in \langle a^p \rangle \).

(ii) Follows immediately using the part (i).

Lemma 4.4. Let \( \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \in A \). Then, if \( \beta \in Q \), then
Proof. Let \( \beta \in \text{Hom}(K, H) \) and \( \text{Im}(\beta) \leq \langle b^p \rangle \),

(ii) \( l(pr+1)^j \equiv l \text{ (mod } m) \), for all \( l \),

(iii) \( \gamma(h) \cdot \beta(k) = \beta(k) \) and \( \gamma(h)^{\beta(k)} = \gamma(h) \), for all \( h \in H \) and \( k \in K \),

(iv) \( \gamma \beta = 0 \), where 0 is the trivial homomorphism in \( \text{Hom}(K, K) \),

(v) \( \gamma \beta + \delta \in \text{Aut}(K) \) and \( \gamma \beta + \delta \in S \),

(vi) \( \beta \gamma \in \text{Hom}(H, H) \),

(vii) \( \alpha + \beta \gamma \in \text{Aut}(H) \) and \( \alpha + \beta \gamma \in P \).

Let \( \beta(a) = b^j \). Then using (A3), \( \beta(a^2) = \beta(a) \cdot \beta(a) = b^j(a \cdot b^j) = b^{j+p} \cdot b^j \). Inductively, we get,

\[
\beta(a^l) = b^{j(1+1+2+\cdots+l-1)} = b^{j(1+(1+2+\cdots+l-1))} = b^{j(l+\frac{l(l-1)}{2})}.
\]

(i) Since \( \beta \in Q \), \( \beta(k^h) = \beta(k) \). Therefore, \( b^j = \beta(a) = \beta(a^h) = \beta(a^{pr+1}) = b^{j(pr+1)} \) which implies that \( jpr + j \equiv j \text{ (mod } p^2) \). Since \( \gcd(r, p) = 1 \), \( j \equiv 0 \text{ (mod } p) \). Thus, \( \beta(a^l) = b^{jl} \in \langle b^p \rangle \), for all \( l \). Hence, One can easily observe that \( \beta \) is a group homomorphism and \( \text{Im}(\beta) \leq \langle b^p \rangle \).

(ii) Since \( \beta \in Q \), \( k^{\beta(h^l)} = k \). Therefore, using the Lemma \( \text{(iv)} \), \( a^l = (a^j)^{\beta(a)} = (a^j)^{b^p} = a^{\frac{(pr+1)^l - 1}{p-1} + l(pr+1)^j} \). Now, using the part (i) and (G3), we get, \( l(pr+1)^j \equiv l \text{ (mod } m) \), for all \( l \).

(iii) First, note that \( a^l \cdot b^p = b^p \) and using the part (ii), \( (a^l)^{b^p} = a^l \), for all \( l \).

Hence, the result follows using the part (i).

(iv) Using the Lemma \( \text{(i)} \), we have, \( \gamma(b^u) = a^u \sum_{\nu=0}^{u-1} (pr+1)^\nu \), for all \( u \).

Then, using the part (ii), for all \( l \), we get,

\[
\gamma(\beta(a^l)) = \gamma(b^{lj}) = a^{u \sum_{\nu=0}^{l-1} (pr+1)^\nu} = a^{(\frac{(pr+1)^{lj} - 1}{(pr+1)^j - 1})} = 1.
\]

Thus, \( \gamma \beta = 0 \).

(v) Follows directly using the part (iv).

(vi) Using \( \beta(k^h) = \beta(k) \) and the part (i), \( \beta(\gamma(h^l)) = \beta(\gamma(h)^{\alpha(h^l)}) \gamma(h^l)) = \beta(\gamma(h)^{\alpha(h^l)}) \beta(\gamma(h^l)) = \beta(\gamma(h)) \beta(\gamma(h^l)). \) Hence, \( \beta \gamma \in \text{Hom}(K, K) \).
Therefore, by the Theorem 2.2, we have,

$$\text{Proof.}$$

Using the Lemma 4.4 (ABCD Theorem 4.1).

Now, using (i), we have, $\beta \gamma (b^u) = b^\alpha \mu$, for all $u$. Therefore,

$$(\alpha + \beta \gamma)(b^u) = b^{(i+j\mu+p\mu\lambda \frac{n_1}{g-1})}.$$  

Now, one can easily observe that $\alpha + \beta \gamma$ is a bijection. Hence, using the part (vi), $\alpha + \beta \gamma \in \text{Aut}(H)$.

Now, using the part (i), (C5) and (C6), $k \cdot (\alpha + \beta \gamma)(h) = k \cdot \alpha(h) \beta \gamma(h) = (k \cdot \alpha(h))(k^{\alpha(h)} \cdot \beta \gamma(h)) = \alpha(k \cdot h) \beta \gamma(k \cdot h) = (\alpha + \beta \gamma)(k \cdot h)$ and $k^{(\alpha + \beta \gamma)(h)} = k^{\alpha(h) \beta \gamma(h)} = k^{\alpha(h)} = k^h$. Hence, $\alpha + \beta \gamma \in P$.

Note that, using the Lemma 4.4 (iii), multiplication in the group $A$ reduces to the usual multiplication of matrices.

**Theorem 4.1.** Let $A, B, C,$ and $D$ be defined as above. Then $\text{Aut}(G) = ABCD$.

**Proof.** Using the Lemma 4.4 (vii), $\alpha + \beta \gamma \in P$. In particular, $1 - \beta \gamma \in P$. Therefore, by the Theorem 2.2, we have, $\text{Aut}(G) = ABCD$.

**Theorem 4.2.** Let $G$ be as above. Then

$$|\text{Aut}(G)| = \begin{cases} \frac{2m}{p \phi(m)} & \text{if } (pr + 1)^p \equiv 1 \pmod{m} \\ \frac{m}{p \phi(m)} & \text{if } (pr + 1)^p \not\equiv 1 \pmod{m} \end{cases}.$$  

**Proof.** Let $\beta \in Q$. Then using the Lemma 4.4 (i), we have that $\beta(a^i) = b^j$, where $j \equiv 0 \pmod{p}$. Thus, $B \simeq \mathbb{Z}_p$. Now, let $(\alpha, \gamma, \delta) \in X$ be such that $\alpha(b) = b^i$, $\gamma(b) = a^\mu$ and $\delta(a) = a^s$, where $i \in \mathbb{Z}_{p^2}$, $\gcd(i, p^2) = 1$, $0 \leq \mu \leq m - 1$, and $s \in U(m)$. Then using $\alpha(hh') = \alpha(h)(\gamma(h) \cdot \alpha(h'))$, $\gamma(hh') = \gamma(h)^{\alpha(h')} \gamma(h')$ and the Lemma 4.3 (i), we have

$$\alpha(b^u) = b^{(u + \frac{a(u+1)p\mu}{2})} \text{ and } \gamma(b^u) = a^\mu \sum_{i=0}^{u-1} (pr+1)^i.$$  

Now, using $(\alpha, \gamma, \delta) \in X$, $\delta(k) \cdot \alpha(h) = \alpha(k \cdot h)$, $b^j = \alpha(b^j) = \alpha(a \cdot b) = \delta(a) \cdot \alpha(b) = a^s \cdot b^i = b^i$. Thus, $i^s \equiv it \pmod{p^2}$ which implies that $1 + p\lambda^s \equiv 1 \pmod{p^2}$. Therefore, $s \equiv 1 \pmod{p}$. Using $(\alpha, \gamma, \delta) \in X$, $\delta(k)^{\alpha(h)} = \gamma(k \cdot h)\delta(k^h)$, (G3) and the fact that $s \equiv 1 \pmod{p}$, we get,

$$a^\mu \sum_{i=0}^{u-1} (pr+1)^i + s(pr+1) = \gamma(b^u) \delta(a^{pr+1}) = \gamma(a \cdot b) \delta(a^b) = \delta(a) \alpha(b) \gamma(b) = (a^s)^b \alpha^u.$$  

24
\[ a^{\frac{i(i+1)}{2}} ((pr+1)^{i+1}) \equiv 1 \mod p \]  
\[ \alpha, \beta, \gamma, \delta \in U(p^2), \alpha \equiv 1 \mod p \]  
Thus we have \( \alpha \beta \equiv \beta \alpha \mod p \).  
Using the Lemma 4.4 \((i)\) and \((iv)\), we get,  
\[ \left( \begin{array}{cc} 1 & \beta \\ 0 & 1 \end{array} \right) \left( \begin{array}{cc} \alpha & 0 \\ \gamma & \delta \end{array} \right) \left( \begin{array}{cc} 1 & \beta \\ 0 & 1 \end{array} \right)^{-1} = \left( \begin{array}{cc} \alpha + \beta \gamma & (\alpha + \beta \gamma)(-\beta) + \beta \delta \\ \gamma & \delta \end{array} \right) . \]  
(12)  
Using the Lemma 4.4 \((i)\) and \((ii)\), we have  
\[ ((\alpha + \beta \gamma)(-\beta) + \beta \delta)(a) = \alpha \beta (\gamma \beta)(-\beta)(a) = (\alpha + \beta \gamma)(b^{-j}) \beta(a^s) = \alpha(b^{-j}) \beta(\gamma)(b^{-j}) \beta(a^s) = b^{-ij} \beta(a^{\mu \sum_{j=0}^{i-1} i}) b^{sij} = b^{sij} \beta \left( a^{\mu \left( \frac{(pr+1)^{i+1} - 1}{(pr+1)^{i+1}} \right)} \right) = (pr+1) \beta(a^s) \]  
Thus \( \beta(1) = 1 \).  

Since, \( A \times D \) normalizes \( C \), \( M \) normalizes \( C \). So, clearly, \( C \triangleleft E \) and \( M \cap C = \{1\} \). Now, if \( \left( \begin{array}{cc} \alpha & 0 \\ \gamma & \delta \end{array} \right) \in E \), then  
\[ \left( \begin{array}{cc} \alpha & 0 \\ \gamma & \delta \end{array} \right) = \left( \begin{array}{cc} \alpha & 0 \\ 0 & \delta \end{array} \right) \left( \begin{array}{cc} 1 & 0 \\ \delta^{-1} & 1 \end{array} \right) \in MC \]  
Thus \( E = C \times M \). Now, using the Lemma 4.4 \((iii)\) and \((iv)\), we get,  
\[ \left( \begin{array}{cc} 1 & \beta \\ 0 & 1 \end{array} \right) \left( \begin{array}{cc} \alpha & 0 \\ \gamma & \delta \end{array} \right) \left( \begin{array}{cc} 1 & \beta \\ 0 & 1 \end{array} \right)^{-1} = \left( \begin{array}{cc} \alpha + \beta \gamma & (\alpha + \beta \gamma)(-\beta) + \beta \delta \\ \gamma & \delta \end{array} \right) . \]  
(12)  
Using the Lemma 4.4 \((i)\) and \((ii)\), we have  
\[ ((\alpha + \beta \gamma)(-\beta) + \beta \delta)(a) = \alpha \beta (\gamma \beta)(-\beta)(a) = (\alpha + \beta \gamma)(b^{-j}) \beta(a^s) = \alpha(b^{-j}) \beta(\gamma)(b^{-j}) \beta(a^s) = b^{-ij} \beta(a^{\mu \sum_{j=0}^{i-1} i}) b^{sij} = b^{sij} \beta \left( a^{\mu \left( \frac{(pr+1)^{i+1} - 1}{(pr+1)^{i+1}} \right)} \right) = (pr+1) \beta(a^s) \]  
Thus \( \beta(1) = 1 \).  

25
Thus, \((\alpha + \beta \gamma)(-\beta) + \beta \delta = 0\). Also, using the Lemma 4.4 (vii), one can easily observe that \((\alpha + \beta \gamma, \gamma, \delta) \in X\). Therefore, by the Equation (11),

\[
\begin{pmatrix}
1 & \beta \\
0 & 1
\end{pmatrix}
\begin{pmatrix}
\alpha & 0 \\
\gamma & \delta
\end{pmatrix}
\begin{pmatrix}
1 & \beta \\
0 & 1
\end{pmatrix}^{-1}
= \begin{pmatrix}
\alpha + \beta \gamma & 0 \\
\gamma & \delta
\end{pmatrix} \in E.
\]

Thus \(E \triangleleft A\). Clearly, \(E \cap B = \{1\}\). Now, if \(\begin{pmatrix}
\alpha & \beta \\
\gamma & \delta
\end{pmatrix} \in A\), then using \(\gamma \alpha \beta = 0\), we get

\[
\begin{pmatrix}
\alpha & \beta \\
\gamma & \delta
\end{pmatrix} = \begin{pmatrix}
\alpha & 0 \\
\gamma & \delta
\end{pmatrix} \begin{pmatrix}
1 & \alpha^{-1} \beta \\
0 & 1
\end{pmatrix} \in EB
\]

Hence, \(A = E \ltimes B\) and so, \(Aut(G) \simeq E \ltimes B \simeq (C \ltimes (A \ltimes D)) \ltimes B\).

Thus, \(|X| = p \times m \times \frac{\phi(m)}{p-1} = pm \frac{\phi(m)}{p-1}\) and \(|Aut(G)| = |X||B| = pm \frac{\phi(m)}{p-1} \times p = p^2 m \frac{\phi(m)}{p-1}\) in the case (i), and \(|X| = p \times m \times \frac{\phi(m)}{p-1} = m \frac{\phi(m)}{p-1}, |Aut(G)| = |X||B| = m \frac{\phi(m)}{p-1} \times p = pm \frac{\phi(m)}{p-1}\) in the case (ii).

Note that, in the Theorem 4.2 we have \(B \simeq \mathbb{Z}_p, \langle \alpha \rangle \simeq \mathbb{Z}_p, \langle \gamma \rangle \simeq \mathbb{Z}_m\) or \(\langle \gamma \rangle \simeq \mathbb{Z}_m^\phi\).

References
