ENDOSCOPIC RELATIVE ORBITAL INTEGRALS ON $U_3$

CHUNG-RU LEE

Abstract. Let $F$ be a nonarchimedean local field and consider the action of $SO_3$ on the spherical variety $(U_3/O_3)(F)$. We compute the nontrivial $\kappa$-orbital integrals of the basic function in this situation. This is the first time that such a computation has appeared in the literature for a spherical variety with type $N$-spherical roots.

1. Introduction

Let $G$ be a connected reductive group over a number field $K$, and let $G_0 \leq G$ be a reductive subgroup. Denote by $\mathbb{A}_K$ the ring of adeles of $K$. We say that a cuspidal automorphic representation $\pi$ of $G(\mathbb{A}_K)$ is distinguished by $G_0$ if the period integral

$$P(\varphi) = \int_{G_0(K) \backslash G_0(\mathbb{A}_K)} \varphi(g)dg$$

is nonzero for some $\varphi$ in the $\pi$-isotypic subspace of automorphic forms on $G(\mathbb{A}_K)$.

Characterization of distinguished representation is crucial for the study of automorphic representations. The celebrated conjectures of Sakellaridis and Venkatesh provide such a characterization in many cases. They provide a thorough conjectural description of the representations of $G$ that are distinguished by $G_0$ when the groups $G$ and $G_0$ are split and $G/G_0$ is spherical — that is, $G/G_0$ admits an open orbit under a Borel subgroup of $G$ [SV12].

2010 Mathematics Subject Classification. Primary 11F70; Secondary 11F66.
When $G = \text{GL}_n$, many cases of the conjecture are known due to work of Jacquet and his school [Jac05]. However, for classical groups much less is understood. Apart from its intrinsic interest, the distinction problem in classical groups holds additional value due to its connection to algebraic cycles on Shimura varieties (See Remark 1).

Jacquet’s strategy for studying distinction problems on classical groups is to use the comparisons of relative trace formulae. This strategy has been used to fantastic effect in proving the unitary case of the Gan-Gross-Prasad conjecture [BPCZ20]. The author remarks that the theory of endoscopy, which considerably complicates comparisons of trace formulae, is absent in this example.

Work of Getz and Wambach [GW14] treated a different comparison where endoscopy comes into play. Their work also suggested a rough informal procedure for reducing distinction problems on classical groups to distinction problems on the general linear group.

Let us describe the framework to their work. Let $E/F$ be a quadratic extension of local fields. Let $H$ be either $\text{GL}_n$ or $\text{Res}_{E/F}\text{GL}_n$ and let $G$ be a classical group, realized as the fixed points of an involution $\tau$ on $H$ (or the neutral component of the fixed points). Moreover, let $\sigma$ be an involution on $H$ that commutes with $\tau$. It then restricts to an involution on $G$. Lastly, consider a third involution $\theta = \sigma \circ \tau$.

Let $H^\sigma < H$, $H^\theta < H$, $G^\sigma < G$ be the subgroups fixed under $\sigma$ and $\theta$ accordingly. The idea is to relate suitable orbital integrals on the pair of quotients

$$H^\sigma \backslash H/ H^\theta \quad \text{and} \quad G^\sigma \backslash G/ G^\sigma$$

and thereby prove (roughly) that a representation of $G(\mathbb{A}_F)$ is $G^\sigma$-distinguished if and only if its transfer to $H(\mathbb{A}_F)$ with respect to a suitable $L$-map $^LG \rightarrow ^LH$ is distinguished by $H^\sigma$ and $H^\tau$. Note that the statement here is merely a guiding principle and must be modified according to the situation at hand. After [GW14], the next case where a suitable modification of this strategy has been implemented appears in the forthcoming work of Xiao and Zhang. More specifically, Xiao and Zhang consider a setting where $G$ is a form of a unitary group in $2n$ variables and $G^\sigma$ is a product of two copies of a unitary group in $n$ variables. We refer to this as the unitary Friedberg-Jacquet case.

In order to execute this comparison of trace formulae, one needs to stabilize the relative trace formula that parametrizes automorphic representations of $H(\mathbb{A}_F)$ distinguished by $H^\sigma$. This has been largely accomplished by Leslie in the unitary Friedberg-Jacquet case [Les19, Les20]. However, his methods do not obviously generalize to the setting considered we consider. In particular, there are many mysteries in the case where the spherical variety $G/G^\sigma$ has type $N$-spherical roots in the sense of [SV12]. When $G/G^\sigma$ has $N$-spherical roots, the generic stabilizer of a point in $G/G^\sigma$ under the left action of $G$ can be disconnected, or even finite.
In this paper we step into this unknown territory by computing endoscopic orbital integrals in a setting where there are type $N$-spherical roots and the generic stabilizer is finite.

Specifically, let $E/F$ be an unramified quadratic extension of nonarchimedean local fields and let $\text{Gal}(E/F) = \langle \theta \rangle$. We assume the residual characteristic is not 2. Let $\overline{F}$ be an algebraic closure of $F$ containing $E$.

The Galois automorphism $\theta$ defines an automorphism of $\text{Res}_{E/F} \text{GL}_n$ in a canonical way. We will also denote this automorphism by a bar above for notational simplicity. Let $J_n$ be defined inductively by $J_1 = (1)$ and

$$J_n = (j_{n-1}^{-1}).$$

Consider the quasi-split unitary group in $n$-variables, whose points in an $F$-algebra $R$ are given by

$$G(R) := U_n(R) := \{ g \in \text{Res}_{E/F} \text{GL}_n(R) : J_n g^{-t} J_n^{-1} = g \}.$$

The group $G$ admits an involution given on points by

$$\sigma(g) = J_n g^{-t} J_n^{-1}$$

and

$$G^\sigma(R) := \{ g \in \text{GL}_n(R) : \sigma(g) = g \} = O_n(R).$$

Thus $G^\sigma$ is a quasi-split orthogonal group.

Instead of working directly with $G^\sigma \setminus G$, it is convenient to work with the subscheme $S \subset G$ whose points in an $F$-algebra $R$ are given by

$$S(R) := \{ g \in G(R) : g = \sigma(g)^{-1} \}.$$

Then there is a natural action of $O_n$ on $S$ given by

$$S(R) \times G(R) \to S(R)$$

$$(\gamma, g) \mapsto g^{-1} \gamma g.$$

Our goal is to study orbital integrals for this action.

We henceforth assume $n = 3$. In this case, $G^\sigma = \{ \pm 1 \} \times \text{SO}_3$ and $\{ \pm 1 \}$ acts trivially on all of $S$. Thus we integrate over the $F$-points of

$$G_1 := \text{SO}_3,$$

instead of $G^\sigma$.

We say that two elements of $S(F)$ are in the same rational orbit if they are in the same $G_1(F)$-orbit, and in the same stable orbit if they are in the same $G_1(\overline{F})$-orbit.
For regular elements $\gamma \in \mathcal{S}(F)$ we study the orbital integrals
\[ O_\gamma(f) := \int_{G_1(F) \setminus G_1(F)} f(g^{-1}\gamma g)dg \] (1.2)
and the $\kappa$-orbital integrals
\[ SO_\gamma^\kappa(f) := \sum_{\gamma' \sim \gamma} \kappa(\gamma')O_{\gamma'}(f). \] (1.3)
Here the sum is over (a set of representatives for) the rational orbits in the stable orbit of $\gamma$ and $\kappa$ is a character of $\mathcal{D}(F, G_{1\gamma}, G_1)$ (see §2 for details).

It turns out that these groups are nontrivial only for a particular family of stable orbits $[\gamma]_{st}$. In fact, if $\mathcal{D}(F, G_{1\gamma}, G_1)$ is nontrivial then $\gamma$ is in the $G_1(F)$-orbit of an element of $\mathcal{S}(F)$ of the form
\[ \left( \begin{array}{ccc} x & y & z \\ ny & z & x \end{array} \right) \] (1.4)
with $x, y, z \in E$ and $\nu \in \{1, \xi^2, \varpi, \xi^2\varpi\}$, where $\varpi$ is a uniformizer of $F$ and $\xi \in O_E^\times$ satisfies $\text{tr}_{E/F}(\xi) = 0$ (Lemma 2.8). Thus it suffices to consider the $\kappa$-orbital integrals for $\gamma$ of such form.

Let $\gamma$ be of the form above. There is a canonical isomorphism between $\mathcal{D}(F, G_{1\gamma}, G_1)$ and
\[ \begin{cases} F^\times/N_{E/F}(E^\times) = \{1, \varpi\} & \text{if } \nu = \xi^2 \\ F^\times/(F^\times)^2 = \{1, \xi^2, \varpi, \xi^2\varpi\} & \text{if } \nu = \varpi \text{ or } \xi^2\varpi, \end{cases} \] (Lemma 2.10). We write elements in $\mathcal{D}(F, G_{1\gamma}, G_1)$ using this isomorphism.

To define an endoscopic orbital integral, one needs a character on $\mathcal{D}(F, G_{1\gamma}, G_1)$. When $\nu = \xi^2$, let $\kappa_1$ be the unique nontrivial character of $\mathcal{D}(F, G_{1\gamma}, G_1)$. When $\nu \neq \xi^2$, for $s \neq 1 \in \mathcal{D}(F, G_{1\gamma}, G_1)$, let $\kappa_s$ be the unique nontrivial character of $\mathcal{D}(F, G_{1\gamma}, G_1)$ such that $\kappa(s) = 1$.

The eigenvalues of $\gamma$, written in terms of the coordinates, will be labelled as
\[ \lambda_1 := x + \nu^{1/2}y, \quad \lambda_2 := z, \quad \lambda_3 := x - \nu^{1/2}y. \] (1.5)

We let
\[ M_{ij} := v(\lambda_i - \lambda_j), \]
\[ N_{ij} := v(\lambda_i + \lambda_j), \]
\[ z_y := \frac{(\lambda_2 + \lambda_3)(\lambda_2 - \lambda_1)}{2yz} + \nu. \] (1.6)

All of these are invariants of the $G_1(\overline{F})$-orbit of $\gamma$. Note that $v(y) = M_{13} - \frac{1}{2}v(\nu)$. 
**Theorem 1.1.** Let $\mathbb{1}_{S(O_F)}$ be the characteristic function of $S(O_F) = S(F) \cap G(O_F)$. Let $\gamma$ and $\kappa_s$ be as above. Then the $\kappa_s$-orbital integrals

$$SO_{\gamma_s}^\kappa(\mathbb{1}_{S(O_F)}) = 0$$

for $M_{ij}$ or $N_{ij} < 0$.

When $M_{ij}$ and $N_{ij}$ are non-negative, $SO_{\gamma_s}^\kappa(\mathbb{1}_{S(O_F)})$ are computed as in the following tables:

*If $\nu = \xi^2$,*

<table>
<thead>
<tr>
<th>$M_{13}$</th>
<th>$\kappa = \kappa_1$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$M_{13} = 0$</td>
<td>$\frac{1}{2}(-1)^{M_{13}}$</td>
</tr>
<tr>
<td>$M_{13} &gt; M_{12} = 0$</td>
<td>$\frac{1}{2}(-1)^{M_{13}}$</td>
</tr>
<tr>
<td>$M_{13} &gt; M_{12} &gt; 0$</td>
<td>$(-1)^{M_{12}-M_{13}-1}g^{[M_{12}/2]-1}q^1 - \frac{1}{2}(-1)^{M_{13}}$</td>
</tr>
<tr>
<td>$M_{12} = M_{13} = M_{23} &gt; 0$</td>
<td>$\frac{1}{2}(1 + \left(\frac{z^2 - \xi^2}{F}\right))g^{[M_{12}/2]-1}q^1 + \frac{1}{2}(-1)^{M_{12}}$</td>
</tr>
</tbody>
</table>

*If $\nu = 1$,* there are two choices for $\kappa = \kappa_s$:

<table>
<thead>
<tr>

Lastly, if $\nu = \omega$ or $\xi^2\omega$,
and one has 0 for all the other characters.

Here \((\bar{x}) = 1\) if \(x \in F\) is a square and is \(-1\) if \(x \notin F\) or \(x\) is not a square in \(F\). This main result is the combination of Corollaries 4.3, 5.2, and 6.2.

The expectation is that these \(\kappa\)-orbital integrals are related, by a transfer factor, to stable orbital integrals on a smaller symmetric space. Establishing this connection is the subject of the author’s current research. We point out that this paper does the majority of the work in this direction, as orbital integrals on symmetric spaces smaller than \(S\) are extremely simple in structure. We also compute orbital integrals for every \(\gamma'\) that is in the stable orbit of an element of the form of the form (1.4) above (see Corollary 2.11). We invite the reader to compare the formulae above with the individual formulae for \(O_{\gamma'}(\mathbb{1}_S(O_F))\) given in Theorems 4.2, 5.1, and 6.1.

Remark 1. The distinction problem we are addressing in this paper is of geometric interest due to its connection to algebraic cycles on Shimura varieties. Now we elaborate on this point.

For the moment, we change notation and let \(K = \mathbb{Q}\) and let \(L/\mathbb{Q}\) be an imaginary quadratic extension. One can choose reductive algebraic groups \(G\) and \(H\) over \(K\) such that

\[
\text{Lie } G^{\text{der}} = \text{Lie } U(2, n) \quad \text{and} \quad \text{Lie } H^{\text{der}} = \text{Lie } O(2, n),
\]

and Shimura data \((H, X_H)\) and \((G, X_G)\) so that there exists a map \(H \hookrightarrow G\) that sends \(X_H\) to \(X_G\).

The dimension of the Shimura variety \(\text{Sh}(H, X_H)\) is \(n\) and the dimension of \(\text{Sh}(G, X_G)\) is \(2n\) (see [Hel01, Page 518, Table V] for details). Thus \(\text{Sh}(H, X_H)\) defines a special cycle on \(\text{Sh}(G, X_G)\) in middle degree. This is an interesting cycle to study from the point of view of the Tate conjecture [GH19, §15.6, 15.8].

It is a natural approach to try understanding it using a comparison of relative trace formulae, as suggested earlier in the introduction. Studying the \(\kappa\)-orbital integrals computed in this paper and their higher rank analogues is a necessary first step in this process.

We close the introduction by outlining the sections of this paper. We classify the stable orbits with a nonzero endoscopic group in §2, where we also parametrize the rational orbits in those stable orbits explicitly. The Iwasawa decomposition is used in §3 to reduce the
computation of the orbital integrals to computing an infinite series of congruences. These series are then computed in §4, §5 and §6.

Acknowledgments

The author would like to thank his advisor Jayce R. Getz for suggesting this problem and for his guidance and countless supports. The author also thanks Spencer Leslie for several illuminating conversation throughout these years.

2. Classification of regular orbits in the symmetric space

To set up, let $F$ be a local field. We write $\mathcal{O}_F$ for its valuation ring, $\varpi_F$ for the uniformizer of $\mathcal{O}_F$, $k_F$ for its residue field $\mathcal{O}_F/\varpi_F\mathcal{O}_F$. Let $q_F = |k_F|$, and we normalize the norm on $F$ so that $|\varpi_F|_F = q_F^{-1}$. We will write $\text{Gal}_F$ to denote $\text{Gal}(\overline{F}/F)$.

Let $E/F$ be an unramified quadratic extension of local fields of characteristic 0 with Galois group $\text{Gal}(E/F) = \langle \theta \rangle$. Since $E/F$ is unramified, we may take $\varpi_E = \varpi_F$. We will simply denote this element by $\varpi$ from now on. We will write $q = q_F = q_E^{1/2}$.

Fix a generator $\xi$ for $E = F[\xi]$ satisfying $\text{tr}_{E/F} \xi = 0$ and $\xi \in \mathcal{O}_E^\times$. We denote $N(x) = x\theta(x)$ for any $x \in E$. Also, for any $x \in E$, let $v(x)$ be its valuation.

For any local field $K$ and $x \in K$, the leading coefficient of $x$ refers to the image of $\varpi_K^{-v(x)} x$ under the quotient map by $\varpi_K \mathcal{O}_K$ (which will be regarded as an element in the residue field of $K$). We write

$$g^\ast = g^{-\sigma}.$$ 

In this section, we study regular stable orbits in $\mathcal{S}$ under the action of $G_1$ and parametrize the rational orbits inside such stable orbits.

**Lemma 2.1.** The natural map

$$G_1 \backslash \mathcal{S} \rightarrow G \backslash G$$

induced by the inclusion $\mathcal{S} \rightarrow G$ is an isomorphism. Here the quotients are the geometric invariant theory quotients with respect to the conjugation action.

For the proof and later, we recall that a $\sigma$-split torus in $\mathcal{S}$ is a torus $T \subset \mathcal{S}$ such that for all $F$-algebras $R$ and $\gamma \in T(R)$ one has $\gamma = \gamma^\ast$. A $\sigma$-split torus is maximal if it is maximal among $\sigma$-split tori in $\mathcal{S}$.

Maximal $\sigma$-split tori always exist [Ric82, §2]. Be aware that in his paper Richardson calls $\sigma$-split tori $\sigma$-anisotropic.

**Proof.** It suffices to verify that the map is an isomorphism over $\overline{F}$. We have an isomorphism

$$G_{\overline{F}} \rightarrow \text{GL}_{3\overline{F}}.$$
intertwining $\sigma$ with the involution $\sigma'(g) := g^{-1}$. In $GL_3$, the maximal torus $T$ of diagonal matrices is both a maximal torus and a $\sigma'$-split maximal torus. Temporarily write $SO_3$ for the neutral component of the fixed points of $\sigma'$ acting on $GL_3$.

Let $W(T, SO_3) := N_{SO_3}(T)/C_{SO_3}(T)$ and $W(T, GL_3) := N_{GL_3}(T)/C_{GL_3}(T)$. These are constant étale group schemes over $\mathcal{F}$.

By Chevalley Restriction Theorem and its generalization due to Richardson [Ric82, Corollary 11.5], we have a commutative diagram

$$
\begin{array}{ccc}
W(T, SO_3) \downarrow & \longrightarrow & W(T, GL_3) \downarrow \\
\downarrow \quad \quad & \quad \quad & \downarrow \\
SO_3 \downarrow \quad & \quad \quad & GL_3 \downarrow \\
\end{array}
$$

Since we can take a set of representatives for $W(T, GL_3)(\mathcal{F})$ in $SO_3(\mathcal{F})$, we see that the groups $W(T, SO_3)$ and $W(T, GL_3)$ are isomorphic. Thus, the isomorphism in (2.1) follows from the diagram above.

For any $\gamma \in G(F)$, we let

$$
G_\gamma(R) := \{g \in G(R) : g^{-1}\gamma g = \gamma\}
$$

$$
G_1(\gamma)(R) := \{g \in G_1(R) : g^{-1}\gamma g = \gamma\}
$$

be the stabilizer for the adjoint action. Assume $\gamma$ is a regular semisimple element in $G(F)$. Then by definition $G_\gamma^0$ is a maximal torus in $G$. For any $\gamma \in S(F)$, we say that $\gamma$ is regular (resp. semisimple) if it is regular (resp. semisimple) as an element of $G(F)$. We denote by $[\gamma]_{st}$ the stable class of $\gamma$. Thus when $\gamma \in S(F)$, $[\gamma]_{st}$ is the set of all elements of $S(\mathcal{F})$ that are in the $G_1(\mathcal{F})$-orbit of $\gamma$.

The inclusion $G_1(\gamma) \hookrightarrow G_1$ induces a map of Galois cohomology pointed sets

$$
H^1(F, G_1(\gamma)) \longrightarrow H^1(F, G_1).
$$

**Definition 2.2.** We define the set

$$
\mathcal{D}(F, G_1(\gamma), G_1) := \ker[H^1(F, G_1(\gamma)) \rightarrow H^1(F, G_1)]
$$

(2.2)

to be classes in $H^1(F, G_1(\gamma))$ mapping to the neutral element of $H^1(F, G_1)$.

Recall the following well-known lemma [Rog90, §3.1]:

**Lemma 2.3.** $\mathcal{D}(F, G_1(\gamma), G_1)$ parametrizes the rational orbits inside $[\gamma]_{st}$. Explicitly, the inverse image of the coboundary $\sigma \mapsto g\sigma(g^{-1})$ for $g \in G_1(\mathcal{F})$ is $g^{-1}\gamma g$.

**Lemma 2.4.** $\mathcal{D}(F, G_1(\gamma), G_1)$ is an abelian subgroup of $H^1(F, G_1(\gamma))$. 
**Proof.** We have a commutative diagram

\[
\begin{array}{ccc}
H^1(F, G_{1,\gamma}) & \longrightarrow & H^1(F, G_1) \\
\downarrow & & \downarrow \\
H^1_{ab}(F, G_{1,\gamma}) & \longrightarrow & H^1_{ab}(F, G_1).
\end{array}
\] (2.3)

Here the vertical arrows are the abelianization maps, which are bijective since \( F \) is nonarchimedean [Bor98, Corollary 5.4.1]. Moreover the vertical arrow on the left is a group isomorphism when \( G_{1,\gamma} \) is abelian. The lemma then follows. \( \square \)

Let \( \gamma \in S(F) \) be regular semisimple. Let \( O_{3,\gamma} \) be the intersection of the stabilizer \( G_\gamma \) of \( \gamma \) in \( G \) with \( O_3 \). Then by passage to the algebraic closure we know that

\[ G_\gamma[2] = O_{3,\gamma}, \]

where the \([2]\) notation after a group denotes the 2-torsion. We deduce that

\[ G_\gamma[2] = \{ \pm 1_3 \} \times G_{1,\gamma}. \]

We have an exact sequence of algebraic \( F \)-groups

\[ 1 \longrightarrow G_\gamma[2] \longrightarrow G_\gamma \xrightarrow{[2]} G_\gamma \longrightarrow 1, \]

where the second nontrivial map is the squaring map. Taking Galois cohomology, this gives rise to an exact sequence

\[ 1 \longrightarrow G_\gamma(F)/G_\gamma(F)^2 \longrightarrow H^1(F, G_\gamma[2]) \longrightarrow H^1(F, G_\gamma) \xrightarrow{[2]} H^1(F, G_\gamma) \] (2.4)

where the last arrow is the squaring map. Now \( G_\gamma \) is a maximal torus in a unitary group and hence is isomorphic to one of the following [Rog90, §3.6]:

I Res\( E/F \) \( \mathbb{G}_m \times U_{1,E/F} \).

II \( U_{1,E/F} \times U_{1,E/F} \times U_{1,E/F} \).

III Res\( F'/F \) \( U_{1,E'/F'} \times U_{1,E/F} \) with \( F'/F \) quadratic, \( F' \neq E \), and \( E' = EF' \).

IV Res\( F'/F \) \( U_{1,E'/F} \) with \( F'/F \) cubic and \( E' = EF' \).

Here \( U_{1,F_1/F_2} \) is the absolute rank 1 unitary group attached to the quadratic extension \( F_1/F_2 \). We will refer to these tori as type I-IV.

Using the long exact sequence in Galois cohomology attached to the sequence

\[ 1 \longrightarrow U_{1,F_1/F_2} \longrightarrow \text{Res}_{F_1/F_2} \mathbb{G}_m \longrightarrow \mathbb{G}_m \longrightarrow 1 \] (2.5)
one computes that

\[ H^1(F, G_\gamma) = \begin{cases} 
\mathbb{Z}/2\mathbb{Z} & \text{in type I,} \\
(\mathbb{Z}/2\mathbb{Z})^3 & \text{in type II,} \\
(\mathbb{Z}/2\mathbb{Z})^2 & \text{in type III,} \\
\mathbb{Z}/2\mathbb{Z} & \text{in type IV.} 
\end{cases} \]

We conclude in particular that \( H^1(F, G_\gamma) \) is 2-torsion. This implies that the last arrow in (2.4) is trivial, and we deduce an exact sequence

\[ 1 \rightarrow G_\gamma(F)/G_\gamma(F)^2 \rightarrow H^1(F, G_\gamma[2]) \rightarrow H^1(F, G_\gamma) \rightarrow 1 \]  

(2.6)

The first nontrivial map is given explicitly as follows. For any \( g \in G_\gamma(F) \), choose an \( h \in G_\gamma(F) \) such that \( h^2 = g \). Then associate to \( g \) the cocycle \( \sigma \mapsto h^{-1} \sigma(h) \) [Ser02, §I.5.4].

**Lemma 2.5.** Let \( F \) be a nonarchimedean local field. Then

\[ H^1(F, \mathbb{Z}/2\mathbb{Z}) \simeq (\mathbb{Z}/2\mathbb{Z})^2. \]

Here \( \mathbb{Z}/2\mathbb{Z} \) is regarded as a trivial \( \text{Gal}_F \)-module. In particular, one knows that \( H^1(F, \mathbb{Z}/2\mathbb{Z}) \) is a group generated by the cocycles \( \sigma \mapsto \sigma(\omega^{1/2}) \) and \( \sigma \mapsto \frac{\sigma(\xi)}{\xi} \).

**Proof.** Consider the exact sequence

\[ 1 \rightarrow \{\pm 1\} \rightarrow \mathbb{G}_m \xrightarrow{[2]} \mathbb{G}_m \rightarrow 1 \]

with the second nontrivial arrow being the squaring map. Note that \( \{\pm 1\} \) is a trivial Galois module isomorphic to \( \mathbb{Z}/2\mathbb{Z} \).

In particular, the exact sequence of Galois cohomology induced from it implies that

\[ H^1(F, \mathbb{Z}/2\mathbb{Z}) \simeq \mathbb{G}_m/\mathbb{G}_m^2. \]

Thus \( H^1(F, \mathbb{Z}/2\mathbb{Z}) \) is in bijection to the quadratic extensions over \( F \). The second assertion on the generators follows from [Ser02, §I.5.4]. \( \square \)

**Lemma 2.6.** Let \( E'/F' \) be an unramified quadratic extension of nonarchimedean local fields that contains \( F \) as a subfield. Then \( H^1(F, \text{Res}_{E'/F'} U_{1,E'/F'}) \simeq \mathbb{Z}/2\mathbb{Z} \) is represented by the cocycle \( \sigma \mapsto \frac{\sigma(\omega^{1/2})}{\omega^{1/2}} \). Moreover, one has \( U_{1,E'/F'}(F')/U_{1,E'/F'}(F')^2 \simeq \mathbb{Z}/2\mathbb{Z} \).

**Proof.** The first assertion follows from the long exact sequence in Galois cohomology induced by (2.5) and the discussion in [Ser02, §I.5.4]. We consider (2.5) for \( E'/F' \), and the exact sequence is therefore defined over \( F' \). On the other hand, by Shapiro’s Lemma, one has

\[ H^1(F, \text{Res}_{E'/F'} U_{1,E'/F'}) \simeq H^1(F', U_{1,E'/F'}). \]
Consider the exact sequence
\[ 1 \rightarrow U_{1,E'/F'}[2] \rightarrow U_{1,E'/F'} \rightarrow U_{1,E'/F'} \rightarrow 1 \]
defined over \( F' \) with the second nontrivial arrow being the squaring map. Note that \( U_{1,E'/F'}[2] \simeq \mathbb{Z}/2\mathbb{Z} \).

In particular, the exact sequence of Galois cohomology induced from it implies
\[ 1 \rightarrow U_{1,E'/F'}(F')/U_{1,E'/F'}(F') \rightarrow H^1(F', \mathbb{Z}/2\mathbb{Z}) \rightarrow H^1(F', U_{1,E'/F'}) \rightarrow 1, \]
where the last nontrivial arrow is the squaring map. This map is trivial since \( H^1(F', U_{1,E'/F'}) \) is 2-torsion.

Thus we have an exact sequence
\[ 1 \rightarrow U_{1,E'/F'}(F')/U_{1,E'/F'}(F') \rightarrow (\mathbb{Z}/2\mathbb{Z}) \rightarrow \mathbb{Z}/2\mathbb{Z} \rightarrow 0. \]

**Corollary 2.7.** Let I-IV denote the four types in [Rog90, §3.6]. Then, we have
\[ H^1(F, G_{1\gamma}) = \begin{cases} 
(\mathbb{Z}/2\mathbb{Z})^2 & \text{in type I} \\
(\mathbb{Z}/2\mathbb{Z})^4 & \text{in type II} \\
(\mathbb{Z}/2\mathbb{Z})^2 & \text{in type III} \\
1 & \text{in type IV} 
\end{cases} \]
In particular, for any \( \gamma \) in a type IV torus, \( \mathcal{D}(F, G_{1\gamma}, G_1) = 0 \).

**Proof.** Consider the exact sequence (2.6). We may write
\[ H^1(F, G_{\gamma[2]}) = G_{\gamma}(F)/G_{\gamma}(F) \times H^1(F, G_{1\gamma}). \]
Note that all the other terms except for \( H^1(F, G_{1\gamma}) \) have been computed in previous derivation. □

For \( \nu \in E^\times \) let \( T_\nu \subset G \) be the \( \sigma \)-split torus whose points in an \( F \)-algebra \( R \) are given by
\[ T_\nu(R) = \left\{ \begin{pmatrix} x & y \\ vy & x \end{pmatrix} \in G(R) \mid x, y, z \in E \otimes_F R \right\}. \] (2.7)

**Lemma 2.8.** Any regular semisimple element \( \gamma \in \mathcal{S}(F) \) in a torus of type I-III, \( [\gamma]_{st} \) intersects \( T_\nu(F) \) for some \( \nu \in \{1, \xi^2, \varpi, \xi^2 \varpi\} \).

**Proof.** Recall that a maximal torus in \( G \) is isomorphic to a torus of type I-IV, and two regular semisimple elements \( \gamma \) and \( \gamma' \in G(F) \) are \( G(\overline{F}) \)-conjugate if and only if their centralizers \( G_{\gamma} \) and \( G_{\gamma'} \) are isomorphic [Rog90, Lemma 3.4.1]. This occurs if and only if there is a \( g \in G(\overline{F}) \) such that conjugation by \( g \) induces an isomorphism \( G_{\gamma} \xrightarrow{\sim} G_{\gamma'} \) over \( F \). Thus if we choose a set of maximal tori in \( G \) whose isomorphism classes form a set of representatives
for the isomorphism classes in types I-IV, then every element of $G(F)$ is $G(F)$-conjugate to an element in one of these representative tori.

Using Lemma 2.1 we know that every element of $S(F)$ is $G_1(F)$-conjugate to an element in one of these representative tori. As representatives for the isomorphism classes I, II, and III we may take $T_\nu$ with $\nu = \xi^2$, $\nu = 1$, and $\nu = \varpi$ or $\xi^2\varpi$ respectively. The two possibilities for III correspond to the two ramified choices for $F'/F$.

**Remark 2.** Assuming that $\nu \in \{1, \xi^2, \varpi, \xi^2\varpi\}$, one has $T_\nu \simeq T_{\nu'}$ if and only if $\nu = \nu'$. Thus $\nu$ is an invariant of the stable class $[\gamma]_{\text{st}}$.

For the rest of the paper, we will focus only on type I-III and omit type IV tori when we mention types. For any tori of type I-III, let

$$\gamma = \begin{pmatrix} x & y \\ \nu y & z \end{pmatrix} \in T_\nu(F)$$

be regular semisimple as an element of $G(F)$. Then $G_\gamma = T_\nu$, and thus $G_{1,\gamma} = T_\nu \cap G_1$ is a finite étale group scheme over $F$ (see Lemma 2.9 for details).

We can choose an isomorphism $E \otimes_F \overline{F} \simeq \overline{F} \oplus \overline{F}$ intertwining $\theta$ with $(x, y) \mapsto (y, x)$. Using this isomorphism we can construct an isomorphism $G_{\overline{F}} \simeq GL_3(\overline{F})$ sending $G_{1,\overline{F}}$ to $SO_3(\overline{F})$, where

$$SO_3(R) := \{g \in GL_3(R) \mid g^* J_3 g = J_3 \text{ and } \det g = 1\}$$

for $F$-algebras $R$. We use this isomorphism to identify $G_{\overline{F}}$ and $GL_3(\overline{F})$, hence identifying $G(F)$ and $GL_3(F)$.

Then

$$T_{\nu,F}(F) = \left\{ \begin{pmatrix} x & y \\ \nu y & z \end{pmatrix} \in GL_3(F) \mid x, y, t \in \overline{F} \right\}.$$

**Lemma 2.9.** Under the isomorphism above,

$$G_{1,\gamma}(F) = \left\langle \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}, \begin{pmatrix} \nu^{1/2} & 0 \\ 0 & \nu^{-1/2} \end{pmatrix} \right\rangle \simeq (\mathbb{Z}/2\mathbb{Z})^2. \quad (2.8)$$

**Proof.** Since $G_{1,\gamma} = T_\nu \cap G_1$, to compute $G_{1,\gamma}$ we solve for $g \in T_\nu(F)$ that satisfy $gg^* = 1$. Here $1$ is the identity in $G(F)$.

The conditions for $g = \begin{pmatrix} x & y \\ \nu y & z \end{pmatrix}$ to satisfy $gg^* = 1$ are $z^2 = 1$, $x^2 + \nu y^2 = 1$, and $z(x^2 - \nu y^2) = 1$. In particular, we have $t = \pm 1$.

If $z = 1$, then $x^2 = 1$ and $y = 0$. We thus have

$$g = \begin{pmatrix} \pm 1 & 0 \\ 0 & \pm 1 \end{pmatrix}.$$

If $z = -1$, then $\nu y^2 = 1$ and $x = 0$. We thus have

$$g = \begin{pmatrix} \pm \nu^{1/2} & 0 \\ 0 & \pm \nu^{-1/2} \end{pmatrix}.$$
Lemma 2.10. Let $\nu \in \{1, \xi^2, \varpi, \xi^2 \varpi\}$ and $\gamma \in T_\nu(F)$ be regular semisimple. Then the group $\mathfrak{D}(F, G_{1\gamma}, G_1)$ is isomorphic to

$$\mathfrak{D}(F, G_{1\gamma}, G_1) \cong \begin{cases} \mathbb{Z}/2\mathbb{Z} & \text{in type I} \\ (\mathbb{Z}/2\mathbb{Z})^2 & \text{in types II and III} \end{cases}$$

respectively. More precisely, there are isomorphisms

$$H \to \mathfrak{D}(F, G_{1\gamma}, G_1)$$

$$\mu \mapsto \begin{pmatrix} \mu^{1/2} \\ 1 \\ \mu^{-1/2} \end{pmatrix}$$

where $H = \begin{cases} F^\times / N_{E/F}(E^\times) & \text{if } \nu = \xi^2, \\ F^\times / (F^\times)^2 & \text{if } \nu = 1, \varpi, \xi^2 \varpi. \end{cases}$

Proof. In the course of the proof here, we will work out explicit cocycles that represent elements of $\mathfrak{D}(F, G_{1\gamma}, G_1)$. These will be recorded in Corollary 2.11.

If we follow the argument of the proof to Corollary 2.7, we can write down explicitly the cocycles in $H^1(F, G_{1\gamma})$. Consider those who are represented by a coboundary in $G_1(F) = \text{SO}_3(F)$. It turns out that $\mathfrak{D}(F, G_{1\gamma}, G_1)$ is generated by cocycles $\sigma \mapsto \sigma(x)x^{-1}$ with $x$ of the form

$$x = \begin{pmatrix} \mu^{1/2} \\ 1 \\ \mu^{-1/2} \end{pmatrix}.$$ 

In particular we can choose

$$\mu = \begin{cases} \varpi & \text{in type I} \\ \xi^2, \varpi & \text{in types II and III} \end{cases}$$

to generate $\mathfrak{D}(F, G_{1\gamma}, G_1)$. Note that $\mathfrak{D}(F, G_{1\gamma}, G_1)$ is in bijection to $F^\times / N_{E/F}(E^\times)$ for type I, and to $F^\times / (F^\times)^2$ for type II and III canonically. The group structure on $\mathfrak{D}(F, G_{1\gamma}, G_1)$ can thereby be determined. \qed

Corollary 2.11. The rational orbits lying within $[\gamma]_{st}$ with $\gamma \in T_\nu(F)$ can be represented by

$$\begin{pmatrix} x \\ \mu^{-1}\nu y \\ \mu y \\ x \end{pmatrix}$$

with $\mu$ chosen in

$$\begin{cases} \{1, \varpi\} & \text{in type I}, \\ \{1, \xi^2, \varpi, \xi^2 \varpi\} & \text{in types II or III}. \end{cases}$$
Proof. The rational classes are represented by \( g^{-1} \gamma g \) with \( g \in G_1(\overline{F}) \) that represents the corresponding coboundary in \( \mathfrak{D}(F, G_1, G_{1\gamma}) \). The corollary then follows from the proof of Lemma 2.10. □

Using Corollary 2.11, we will identify group elements in \( \mathfrak{D}(F, G_1, G_{1\gamma}) \) with the representatives \( \gamma_\mu \) of the rational orbit they parametrize. To study the endoscopic orbital integral we have to compute \( O_{\gamma_\mu}(1_{\mathcal{O}(F)}) \) for each of the rational classes within a stable class, parametrized as in the corollary.

3. A PRELIMINARY FORMULA FOR THE ORBITAL INTEGRALS

Consider the regular semisimple orbits with stabilizer in \( G(F) \) being \( U_{1,E/F} \times U_{1,E'/F'} \) with \( F' \) an étale \( F \)-algebra of degree 2 and \( E' = E \otimes_F F' \). As indicated by Lemma 2.8, these are the only cases of interest. Those stable orbits can be represented by elements of the form

\[
\begin{pmatrix}
  x & y \\
  \nu y & z
\end{pmatrix}
\]

with \( \nu \in \{1, \xi^2, \varpi, \xi^2 \varpi\} \).

For \( \gamma \) in a torus of type I-III, the rational orbits within \([\gamma]_{\text{st}}\) are

\[
\gamma_\mu = \begin{pmatrix}
  x & y \\
  \mu^{-1} \nu y & z
\end{pmatrix},
\]

with \( \mu \) described as in Corollary 2.11. In particular, we fix the stable orbit representative \( \gamma = \gamma_1 \).

We apply Iwasawa decomposition to write \( G_1(F) = B(F)K = N(F)A(F)K \) with \( B \) being the Borel subgroup consists of upper-triangular matrices in \( G_1 \) and

\[
\begin{align*}
N(F) &= \left\{ \begin{pmatrix}
  1 & u^2/2 & u \\
  0 & 1 & -u \\
  0 & 0 & 1
\end{pmatrix} \mid u \in F \right\}, \\
A(F) &= \left\{ \begin{pmatrix}
  t & 1 \\
  1 & t^{-1}
\end{pmatrix} \mid t \in F^\times \right\}, \\
K &= \text{SO}_3(\mathcal{O}_F).
\end{align*}
\]

For \( \gamma \in \mathcal{S}(F), \varphi \in C^\infty(\mathcal{S}(F)), \) and \( \kappa \in \mathfrak{D}(F, G_{1\gamma}, G_1)^* \), the \( \kappa \)-orbital integral of (1.3) is equal to

\[
SO_\gamma^\kappa(\varphi) = \sum_\mu \kappa(\mu)O_{\gamma_\mu}(\varphi).
\]
Let us consider $O_{\gamma}(1_{S(\O_F)})$. We normalize the Haar measure on $G_1(F)$ so that $SO_3(\O_F)$ has measure 1, and assign on $G_1(F)$ the counting measure. Then

$$O_{\gamma}(1_{S(\O_F)}) = \frac{1}{\text{vol}(G_1(F))} \int_{G_1(F)} 1_{S(\O_F)}(g^{-1}\gamma g)dg$$

$$= \frac{1}{\text{vol}(G_1(F))} \int_{F \times F^\times} 1_{S(\O_F)} \left( \left( \begin{array}{ccc} t & 1 & 1 \\ \mu y & x & 1 \\ \mu y & x & 1 \end{array} \right) \right) \left( \left( \begin{array}{ccc} t & 1 & 1 \\ \mu y & x & 1 \\ \mu y & x & 1 \end{array} \right) \right) \frac{dudx}{|t|}.$$ 

Consider the matrix

$$A := \left( \begin{array}{ccc} t & 1 & 1 \\ \mu y & x & 1 \\ \mu y & x & 1 \end{array} \right) \left( \begin{array}{ccc} t & 1 & 1 \\ \mu y & x & 1 \\ \mu y & x & 1 \end{array} \right).$$

(3.1)

It is an element of $G(F)$, a unitary group. Hence its determinant is a unit. The entries of $A$ are

1. $x - \frac{1}{2}u^2\mu^{-1}\nu y,$
2. $t^{-1}(ux - uz - \frac{1}{2}u^3\mu^{-1}\nu y),$
3. $t^{-2}(\mu y - u^2x + u^2z + \frac{1}{4}u^4\mu^{-1}\nu y),$
4. $t\mu y,$
5. $u^2\mu^{-1}\nu y + z,$
6. $t^2\mu^{-1}\nu y.$

So we have to take the integral over the set of $u$ and $t$ such that these entries are integers. Note that $z \in U_{1,E/F}(F)$ and is therefore integral. The entries (1), (4), (5) and (6) are integral if and only if $x$ is integral and

$$t^2\mu^{-1}\nu y \in \O_E \quad \text{and} \quad u^2\mu^{-1}\nu y \in \O_E$$

(3.2)

We write $v(t) = m$ and $v(u) = k$, then (3.2) are equivalent to

$$2m \geq -v(y) + v(\mu) - v(\nu) \quad \text{and} \quad 2k \geq -v(y) + v(\mu) - v(\nu).$$

(3.3)

Thus

$$\text{vol}(G_1(F))O_{\gamma}(1_{S(\O_F)})$$

$$= \int_{F \times F^\times} 1_{\O_F^2}(t^{-1}(ux - uz - \frac{1}{2}u^3\mu^{-1}\nu y), t^{-2}(\mu y - u^2x + u^2z + \frac{1}{4}u^4\mu^{-1}\nu y))$$

$$\times 1_{\O_E^3}(t^2\mu^{-1}\nu y, u^2\mu^{-1}\nu y, x) \frac{dudx}{|t|}$$

(3.4)

$$= \sum_{m} q^m \int_{F} 1_{\O_E^2} \left( \frac{ux - uz - \frac{1}{2}u^3\mu^{-1}\nu y}{\omega^m}, \frac{\mu y - u^2x + u^2z + \frac{1}{4}u^4\mu^{-1}\nu y}{\omega^{2m}} \right)$$

$$\times 1_{\O_E^3}(u^2\mu^{-1}\nu y, x) du$$
with the sum taken over \( m \geq \lceil \frac{-v(y)+v(\mu)+v(\nu)}{2} \rceil \).

Let
\[
J(u, m) = \mathbb{1}_{\mathcal{O}_E^2} \left( \mathcal{O}_E^{-m}(ux - uz - \frac{1}{2}u^3\mu^{-1}\nu y), \mathcal{O}_E^{-2m}(\mu y - u^2 x + u^2 z + \frac{1}{4}u^4\mu^{-1}\nu y) \right). \tag{3.5}
\]
If we assume that \( u^2\mu^{-1}\nu y, x, z \in \mathcal{O}_E \), then for \( v(u) \geq m \),
\[
J(u, m) = \mathbb{1}_{\mathcal{O}_E}(\mathcal{O}_E^{-2m}\mu y). \tag{3.6}
\]

**Lemma 3.1.** If \( u^2\mu\nu y, x, T \in \mathcal{O}_E \), then we have
\[
\int_F J(u, m) \mathbb{1}_{\mathcal{O}_E}(u^2\mu^{-1}\nu y) \, du = \sum_k \int_{\mathcal{O}_E^k(\mathcal{O}_E^{k+1})} J(u, m) \, du + \mathbb{1}_{\mathcal{O}_E}(\mathcal{O}_E^{-2m}\mu y)q^{-m}
\]
with the sum taken over \( m > k \geq \lceil \frac{-v(y)+v(\mu)+v(\nu)}{2} \rceil \).

Proof. We split the integral about \( u \) with respect to valuations on \( F \). The last term comes from the contribution of \( k \geq m \), which can be computed by (3.6). \( \Box \)

**Lemma 3.2.** If \( u^2\mu\nu y, x, T \in \mathcal{O}_E \), then
\[
O_{\gamma_{\mu}}(1_{S(\mathcal{O}_F)}) = \frac{1}{\text{vol}(S(\mathcal{O}_F))} \left( \sum_{m \geq a} q^m \sum_{k=a}^{m-1} \int_{\mathcal{O}_E^k(\mathcal{O}_E^{k+1})} J(u, m) \, du \right. \quad \tag{3.7}
\]
\[
\left. + v(y) + 1 - d(M_{13}, \mu) (1 - v(\nu)) \right) \mathbb{1}_{\mathcal{O}_E}(x)
\]
where \( a := \lceil \frac{-v(y)+v(\mu)+v(\nu)}{2} \rceil \).

Proof. With (3.4) and Lemma 3.1, it remains to show that
\[
\sum_{m \geq \lceil (-v(y)+v(\mu)+v(\nu))/2 \rceil} \mathbb{1}_{\mathcal{O}_E}(\mathcal{O}_E^{-2m}\mu y) = v(y) + 1 - d(M_{13}, \mu) (1 - v(\nu)).
\]
Indeed, this is counting the number of solutions \( m \) so that
\[
v(y) + v(\mu) \geq 2m \geq -v(y) + v(\mu) + v(\nu)
\]
which is as described in the Lemma. \( \Box \)

For the purpose of computation it is convenient to write the pair of congruences in \( \mathcal{O}_E \) contained in the definition of \( J(u, m) \) as a quadruple of congruences over \( \mathcal{O}_F \). This will allow us to exploit the fact that \( u \in F \). We leave the computation of the orbital integral for a moment and write \( z \) in terms of a convenient basis of \( E \) over \( F \).

**Lemma 3.3.** When \( x, y \) are nonzero, \( \{x, y\} \) forms a basis for \( E \) over \( F \).
Proof. Since $\gamma_\mu \in G(F)$, we have $x\overline{y} + \overline{x}y = 0$. When $x$ and $y$ are nonzero, this implies that they are $F$-linearly independent and hence $\{x, y\}$ forms an basis of $E$ over $F$. □

Note that since the eigenvalues $x + \nu^{1/2}y$ and $x - \nu^{1/2}y$ coincide when $y = 0$, we know that $y$ is nonzero if $\gamma$ is regular. With Lemma 3.3, from this point on we will assume that for any $\gamma = \left( \begin{array}{ccc} x & y \\ \nu & z & x \end{array} \right)$ considered, $\gamma$ is regular with $x$ being nonzero. Then $z$ can be written uniquely as

$$z = z_xx + z_yy$$

(3.8)

with $z_x, z_y \in F$. Recall that as in (1.5) we write the eigenvalues of $\gamma_\nu$ as

$$\lambda_1 := x + \nu^{1/2}y, \quad \lambda_2 := z, \quad \lambda_3 := x - \nu^{1/2}y.$$  

We observe that these eigenvalues are invariants of the stable orbit of $\gamma_\nu$ under $G_1(F)$-action. When we say $x$ is an invariant in the sense of it being equal to the invariant $\frac{1}{2}(\lambda_1 + \lambda_3)$. Since $\nu \in \{1, \xi^2, \overline{\nu}, \xi^2\overline{\nu}\}$ is also an invariant (see the remark after Lemma 2.8) we deduce that $x, y$ and $z$ are also invariants of the stable class. In the notation of (1.6) we have

$$M_{ij} = v(\lambda_i - \lambda_j)$$

$$N_{ij} = v(\lambda_i + \lambda_j)$$

We now relate $z_x, z_y$ and these eigenvalues:

**Lemma 3.4.** We have

$$z_x \pm 1 = \frac{(z \pm x + \nu^{1/2}y)(z \pm x - \nu^{1/2}y)}{2xz}$$

and

$$z_y \pm \nu^{1/2} = \frac{(z - x \pm \nu^{1/2}y)(z \pm x + \nu^{1/2}y)}{2yz}.$$  

In particular, we have

$$v(z_x - 1) = M_{12} + N_{23} - N_{13},$$

$$v(z_y + \nu^{1/2}) = M_{23} + N_{12} - M_{13} - \frac{1}{2}v(\nu),$$

$$v(z_y - \nu^{1/2}) = M_{13} + N_{23} - M_{13} - \frac{1}{2}v(\nu).$$

**Proof.** Write $x = x_1 + x_2\xi$, $y = y_1 + y_2\xi$ and $z = z_1 + z_2\xi$. Then the coefficients $z_x$ and $z_y$ can be obtained from

$$z = \left( \begin{array}{cc} z_1 & z_2 \\ \frac{1}{\xi} & \xi \end{array} \right) = \left( \begin{array}{cc} z_1 & z_2 \\ y_1 & y_2 \end{array} \right)^{-1} \left( \begin{array}{cc} x \\ y \end{array} \right) = \left( \begin{array}{cc} z_x & z_y \\ y \end{array} \right) \left( \begin{array}{cc} x \\ y \end{array} \right)$$
which implies that

\[
\begin{align*}
z_x &= \frac{z_1 y_2 - z_2 y_1}{x_1 y_2 - x_2 y_1}, \\
z_y &= \frac{z_2 x_1 - z_1 x_2}{x_1 y_2 - x_2 y_1}.
\end{align*}
\]

Tautologically,

\[
\begin{align*}
z y - z \overline{y} &= \frac{1}{2 \nu^{1/2}} \left( \overline{z} ((x + \nu^{1/2} y) - (x - \nu^{1/2} y)) - z ((\overline{x} + \nu^{1/2} \overline{y}) - (\overline{x} - \nu^{1/2} \overline{y})) \right) \\
&= \frac{1}{2 \nu^{1/2}} \left( \overline{z} (x + \nu^{1/2} y) - z (x + \nu^{1/2} y) + z (\overline{x} + \nu^{1/2} \overline{y}) - \overline{z} (x + \nu^{1/2} y) \right) \\
&= \frac{1}{2 \nu^{1/2}} \left( \overline{z} (x + \nu^{1/2} y) - z (x + \nu^{1/2} y) \right) - \nu y \frac{1}{2} (x + \nu^{1/2} y) (x + \nu^{1/2} y).
\end{align*}
\]

Since \( \gamma \in U_3(F) \), we have

\[
(x + \nu^{1/2} y)(\overline{x} + \nu^{1/2} \overline{y}) = (x - \nu^{1/2} y)(\overline{x} - \nu^{1/2} \overline{y}) = 1.
\]

Then, we have

\[
\begin{align*}
\overline{x} y - x \overline{y} &= 2 \overline{x} y = \frac{1}{2 \nu^{1/2}} \left( (\overline{x} + \nu^{1/2} \overline{y}) + (\overline{x} - \nu^{1/2} \overline{y}) \right) \left( (x + \nu^{1/2} y) - (x - \nu^{1/2} y) \right) \\
&= \frac{1}{2 \nu^{1/2}} (\overline{x} + \nu^{1/2} \overline{y})(x - \nu^{1/2} y) - (\overline{x} - \nu^{1/2} \overline{y})(x + \nu^{1/2} y).
\end{align*}
\]

We can further rearrange as

\[
\begin{align*}
z y - z \overline{y} &= \frac{1}{2 \nu^{1/2}} \cdot \left( \frac{(x+\nu^{1/2} y)^2 - z^2}{z (x+\nu^{1/2} y)} - \frac{(x-\nu^{1/2} y)^2 - z^2}{z (x-\nu^{1/2} y)} \right), \\
\overline{x} y - x \overline{y} &= \frac{1}{2 \nu^{1/2}} \cdot \frac{(x+\nu^{1/2} y)^2 - (x-\nu^{1/2} y)^2}{(x+\nu^{1/2} y)(x-\nu^{1/2} y)}.
\end{align*}
\]

Thus

\[
z_x = \frac{x^2 - \nu y^2 + z^2}{2 x z}.
\]

Analogously, for \( z_y \) we write

\[
z_y = \frac{\overline{x} z - x \overline{z}}{\overline{x} y - x \overline{y}}
\]

and compute the numerator by

\[
\overline{x} z - x \overline{z} = \frac{1}{2} \cdot \left( \frac{z^2 -(x+\nu^{1/2} y)^2}{z (x+\nu^{1/2} y)} + \frac{z^2 -(x-\nu^{1/2} y)^2}{z (x-\nu^{1/2} y)} \right).
\]

Then, we have

\[
z_y = \frac{-x^2 + \nu y^2 + z^2}{2 y z}.
\]

A simple computation shows that

\[
z_x \pm 1 = \frac{z^2 \pm 2 x z + x^2 - \nu y^2}{2 x z} = \frac{(z \pm x)^2 - \nu y^2}{2 x z}
\]

and

\[
z_y \pm \nu^{1/2} = \frac{z^2 \pm 2 \nu^{1/2} y z + \nu y^2 - x^2}{2 y z} = \frac{(z \pm \nu^{1/2} y)^2 - x^2}{2 y z}
\]

which leads to the desired result. \( \square \)
We now give an expression for the orbital integral which we use for computation moving forward:

**Lemma 3.5.** Suppose $x \neq 0$. Then $O_{\gamma}(1_S(\mathcal{O}_F))$ equals

$$\frac{1}{\text{vol}(G_{1_3}(F))} \left( \sum_{m \geq a} q^m \sum_{k} \int_{x^k \mathcal{O}_F - x^{k+1} \mathcal{O}_F} 1_{\mathcal{O}_F^2} \left( \frac{(\mu + z_y u^2 + \frac{1}{4} \mu^{-1} \nu u^4) y}{\varrho^{2m}} , \frac{(\mu - \frac{1}{4} \mu^{-1} \nu u^4) y}{\varrho^{m+k}} \right) du + v(y) + 1 - d(M_{13}, \mu) (1 - v(\nu)) \right) 1_{\mathcal{O}_E}(x).$$

where $a := \left\lceil \frac{-v(y) + v(\mu) + v(\nu)}{2} \right\rceil$, and the second sum on $k$ runs over

$$m > k \geq \max(a, m - \frac{M_{12} + M_{23} + N_{13}}{2}).$$

**Proof.** By linear independence, the function $J(u, m)$ is equal to the characteristic function of the set of $u$ such that

$$v(u^2(z_x - 1)x) \geq 2m,$$

$$v((\mu + z_y u^2 + \frac{1}{4} \mu^{-1} \nu u^4)y) \geq 2m,$$

$$v(u(z_x - 1)x) \geq m,$$

Assuming $m > v(u)$ (which is true for $u$ in the support of the integral in Lemma 3.2), the first inequality implies the third. By Lemma 3.4, the first inequality is equivalent to

$$2k \geq 2m - M_{12} - M_{23} + N_{13}. \quad (3.10)$$

Thus by Lemma 3.2 we have that $\text{vol}(G_{1_3}(F))O_{\gamma}(1_S(\mathcal{O}_F))$ equals

$$\left( \sum_{m \geq a} q^m \right) \sum_{k} \int_{x^k \mathcal{O}_F - x^{k+1} \mathcal{O}_F} 1_{\mathcal{O}_F^2} \left( \frac{(\mu + z_y u^2 + \frac{1}{4} \mu^{-1} \nu u^4) y}{\varrho^{2m}} , \frac{(\mu - \frac{1}{4} \mu^{-1} \nu u^4) y}{\varrho^{m+k}} \right) du + v(y) + 1 - d(M_{13}, \mu) (1 - v(\nu)) \right) 1_{\mathcal{O}_E}(x)$$

with the second sum on $k$ taken over $m > k \geq \max(a, m - \frac{M_{12} - M_{23} + N_{13}}{2}).$

Since $m > k$ for $k$ and $m$ in the support of the integral, this is equal to

$$\left( \sum_{m \geq a} q^m \sum_{k} \int_{x^k \mathcal{O}_F - x^{k+1} \mathcal{O}_F} 1_{\mathcal{O}_F^2} \left( \frac{(\mu + z_y u^2 + \frac{1}{4} \mu^{-1} \nu u^4) y}{\varrho^{2m}} , \frac{(\mu - \frac{1}{4} \mu^{-1} \nu u^4) y}{\varrho^{m+k}} \right) du + v(y) + 1 - d(M_{13}, \mu) (1 - v(\nu)) \right) 1_{\mathcal{O}_E}(x).$$

$\square$
Before delving into case by case considerations in the following sections, let us make the following observation:

**Lemma 3.6.** The orbital integral $O_{\gamma_\nu}(I_{S(O_F)})$ vanishes unless $M_{ij}$ and $N_{ij}$ are non-negative for all $i$ and $j$.

**Proof.** Since the eigenvalues of $\gamma_\nu$ are invariants of the stable class of $\gamma_\nu$, they must be integral for the stable orbit to intersect $S(O_F)$.

If the stable orbit does not have an integral point, then $O_{\gamma_\mu}(I_{S(O_F)}) = 0$ trivially. □

We also define a function $d(N, \cdot) : \mathcal{D}(F, G_{1\gamma}, G_1) \rightarrow \{0, 1\}$ as follows. We have an isomorphism

$$\phi : \mathcal{D}(F, G_{1\gamma}, G_1) \sim H$$

where $H$ is either $F^\times/N_{E/F}(F^\times)$ or $F^\times/(F^\times)^2$ (Lemma 2.10). Thus $v(\phi(d)) \pmod{2}$ is well-defined in either case.

We define

$$d(N, x) := \begin{cases} 1 & \text{if } N + v(\phi(x)) \text{ is odd,} \\ 0 & \text{otherwise.} \end{cases}$$

4. **Computation for type I tori**

Assume that $\gamma \in T_{E^2}(F)$ in the notation of Lemma 2.8. Thus, $\gamma$ is in a type I torus. By Lemma 2.10,

$$\mathcal{D}(F, G_{1\gamma}, G_1) \simeq \mathbb{Z}/2\mathbb{Z}$$

and we know that the parameter $\mu$ will be chosen from $\{1, \varpi\}$ by Corollary 2.11.

The eigenvalues of $\gamma$, written in terms of the coordinates, are

$$\lambda_1 = x + \xi y, \quad \lambda_2 = z, \quad \lambda_3 = x - \xi y.$$  

The condition $\gamma \in G(F)$ implies that $\lambda_3 = \overline{\lambda_1}^{-1}$ and $\lambda_2 \in U_{1, E/F}(F)$.

**Definition 4.1.** For any $F$-algebra $R$ and any nonzero element $x \in \overline{F} \otimes_F R$, we define a quadratic symbol

$$\left( \frac{x}{R} \right) := \begin{cases} 1 & \text{if } x \text{ is a square in } R, \\ 0 & \text{if } x = 0, \\ -1 & \text{otherwise.} \end{cases}$$
Remark 3. By definition, \((\frac{x}{R}) = -1\) if \(x \notin R\). When \(R/F\) is a finite extension of nonarchimedean local fields, from Hensel’s lemma we know that \((\frac{x}{R}) = 1\) if and only if \(v_R(x)\) is an even integer and the leading coefficient of \(x\) is a square.

By Lemma 3.6, for our computations below we assume that \(M_{ij}\) and \(N_{ij}\) are non-negative.

**Theorem 4.2.** Assume that \(M_{ij}\) and \(N_{ij}\) are non-negative for all \(i\) and \(j\).

1. When \(M_{13} = 0\)
   \[O_{\gamma}(1_{S(O_F)}) = \frac{1}{2}(1 - d(M_{13}, \mu))\]

2. When \(M_{13} > M_{12} = 0\)
   \[O_{\gamma}(1_{S(O_F)}) = \frac{1}{2}(M_{13} + 1 - d(M_{13}, \mu))\]

3. When \(M_{13} > M_{12} > 0\)
   \[O_{\gamma}(1_{S(O_F)}) = \frac{1}{2}\left((M_{13} - M_{12} + 1 + d(M_{12}, 1)) q^{\lfloor M_{12}/2 \rfloor} + 2d(M_{12} - M_{13}, \mu) q^{\lfloor M_{12}/2 \rfloor - 1} - d(M_{13}, \mu)\right)\]

4. When \(M_{12} = M_{13} = M_{23} > 0\)
   \[O_{\gamma}(1_{S(O_F)}) = \frac{1}{2}\left((1 + (\frac{z^2 - f^2}{F})) (1 - v(\mu)) + 2d(M_{12} - M_{13}, \mu) q^{\lfloor M_{12}/2 \rfloor - 1} - d(M_{12}, \mu)\right)\]

Let \(\kappa_1 \in \mathfrak{D}(F, G_{1\gamma}, G_1)^* \simeq \mathbb{Z}/2\mathbb{Z}\) be the unique nontrivial character (see §1).

**Corollary 4.3.** Assume that \(M_{ij}\) and \(N_{ij}\) are non-negative. For \(\gamma \in T_{E\gamma}(F)\), the endoscopic orbital integral \(SO^e_{\gamma}(1_{S(O_F)})\) is computed as in the following table:

<table>
<thead>
<tr>
<th>(M_{13})</th>
<th>(M_{12})</th>
<th>(M_{23})</th>
<th>(\kappa = \kappa_1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(M_{13} = 0)</td>
<td>(M_{13} &gt; M_{12} = 0)</td>
<td>(M_{13} &gt; M_{12} &gt; 0)</td>
<td>(\frac{1}{2}(-1)^{M_{13}})</td>
</tr>
<tr>
<td>(M_{12} = M_{13} = M_{23} &gt; 0)</td>
<td>(\frac{1}{2}(-1)^{M_{13}})</td>
<td>((-1)^{M_{12} - M_{13} - 1} q^{\lfloor M_{12}/2 \rfloor - 1} + \frac{1}{2}(-1)^{M_{13}})</td>
<td>(\frac{1}{2}(1 + (\frac{z^2 - f^2}{F})) q^{\lfloor M_{12}/2 \rfloor - 1} + \frac{1}{2}(-1)^{M_{12}})</td>
</tr>
</tbody>
</table>

**Proof.** This follows directly from Theorem 4.2 and the observation that
\[
\sum_{\mu} \kappa(\mu)d(N, \mu) = (-1)^{N-1}.
\]
The rest of the section will be devoted to proving Theorem 4.2.

By Lemma 3.5, when \( x \neq 0 \), the orbital integral \( O_{\gamma} (1_{S(\mathcal{O}_F)}) \) equals

\[
\frac{1}{\text{vol}(G_{1,\gamma}(F))} \left( \sum_{m \geq a} \sum_{k} q^m \int_{\varpi^k \mathcal{O}_F - \varpi^{k+1} \mathcal{O}_F} \mathbf{1}_{\mathcal{O}_F^2} \left( \frac{\mu + z_y u^2 + \frac{1}{4} \mu^{-1} \nu u^4}{\varpi^2 m - M_{13}}, \frac{\mu - \frac{1}{4} \mu^{-1} \nu u^4}{\varpi^2 m + k - M_{13}} \right) du + M_{13} + 1 - d(M_{13}, \mu) \right) \mathbf{1}_{\mathcal{O}_E}(x)
\]

with \( a = \left\lceil -v(y)^2 + v(\mu) \right\rceil \).

We separate the computation for the orbital integral into several cases with respect to the orderings of \( M_{ij} \). In each case, we further separate the computation with respect to the choice of domain in the indices \( m \) and \( k \) for the sums of Lemma 3.5.

Suppose \( m > k \). By (3.10), we know that

\[
2k \geq 2m - M_{12} - M_{23} + N_{13}.
\]

By Lemma 3.6, the orbital integral vanishes unless \( M_{ij} \geq 0 \). Assume from now on \( M_{ij} \geq 0 \). This condition is equivalent to \( \lambda_1 \) being an integral unit.

Note that by Lemma 3.5, the equations we focus on here are

\[
\begin{align*}
v \left( (\mu + z_y u^2 + \frac{1}{4} \mu^{-1} \xi u^4)y \right) &\geq 2m, \quad (4.1) \\
v \left( (\mu - \frac{1}{4} \mu^{-1} \xi u^4)y \right) &\geq m + k. \quad (4.2)
\end{align*}
\]

4.1. Case (1). Suppose \( M_{13} = 0 \).

In this case \( Y \in \mathcal{O}_E^* \) and there does not exist nontrivial solution for (4.2): \( m + k > v(\mu) \) by (3.3). Thus

\[
v \left( u^4 - 4 \mu^2 \xi^{-2} \right) \geq m + k + v(\mu)
\]

is equivalent to

\[
u = 4 \mu^2 \xi^{-2} \pmod{\varpi^{m+k+v(\mu)}}.
\]

Which does not have a solution since \( \xi^2 \) is not a square in \( F^* \) (so nor is its leading coefficient).

Thus, in this case we have

\[
O_{\gamma} (1_{S(\mathcal{O}_F)}) = \frac{1}{2} \left( 1 - d(M_{13}, \mu) \right).
\]

□

For the rest of the proof we assume \( M_{13} > 0 \).

Note that \( M_{13} = v(y) \) and in this case (4.1) can be written as

\[
v \left( (u^2 + 2 \mu \xi^{-2} z_y)^2 - 4 \mu^2 \xi^{-4} (z_y^2 - \xi^2) \right) \geq 2m - M_{13} + v(\mu).
\]
Analogously, (4.2) can be written as
\[ v(u^4 - 4\mu^2\xi^{-2}) \geq m + k - M_{13} + v(\mu). \]  
(4.2)

By Lemma 3.4, we know that
\[ v(z^2_y - \xi^2) = N_{12} + M_{12} + N_{23} + M_{23} - 2M_{13}. \]

Since \((\lambda_1 + \lambda_2) - (\lambda_1 - \lambda_2) = 2z \in \mathcal{O}_E^x\), at least one of \(M_{i2}\) or \(N_{i2}\) vanishes for \(i = 1\) and \(3\). Moreover, \((\lambda_1 - \lambda_2) + (\lambda_2 - \lambda_3) = (\lambda_1 + \lambda_2) - (\lambda_2 + \lambda_3) = 2\xi y\) has valuation \(M_{13} > 0\). In terms of \(M_{ij}\), the possible scenarios are:

(a) Either \(M_{12} = M_{23} = 0\), or
(b) both \(M_{12}\) and \(M_{23}\) are positive.

On the other hand, in (b) we have \(N_{12} = N_{23} = 0\). Note that \(N_{13} = 0\) since we have assumed \(M_{13} > 0\).

4.2. Case (2). Suppose \(M_{13} > M_{12} = 0\).

For case (a) above, there does not exist \(k\) so that \(2m > 2k \geq 2m - M_{12} - M_{23}\).

Therefore, we know that
\[ O_{\gamma u}(1, S(\mathcal{O}_F)) = \frac{1}{2} (M_{13} + 1 - d(M_{13}, \mu)). \]

In case (b), by assumption we have \(N_{12} = N_{23} = 0\). Thus \(v(z^2_y - \xi^2) = M_{12} + M_{23} - 2M_{13}\).

**Lemma 4.4.** When \(M_{ij} \geq 0\), we have
\[ M_{13} \geq M_{12} = M_{23} \geq 0. \]

**Proof.** First, note that \(M_{ij} \geq 0\) implies that \(\lambda_1, \lambda_3 \in \mathcal{O}_E^x\). Furthermore, \(\gamma \in U_{3,\tau}(F)\) implies that \(\lambda_3 = \lambda_1^{-1}\) and \(\lambda_2 = \lambda_2^{-1}\).

So whenever
\[ \lambda_1 \equiv \lambda_2 \pmod{\varpi^f}, \]
one also has
\[ \lambda_3 = \lambda_1^{-1} \equiv \lambda_2^{-1} = \lambda_2 \pmod{\varpi^f}. \]

Thus \(M_{23} \geq M_{12}\). Therefore \(M_{12} = M_{23}\) by symmetry. The conclusion then follows since \(\lambda_1 - \lambda_3 = (\lambda_1 - \lambda_2) + (\lambda_2 - \lambda_3)\).
4.3. **Case (3).** Suppose $M_{13} > M_{12} > 0$.

We thus have $v(z_y^2 - \xi^2) = 2M_{12} - 2M_{13} < 0$ and so $v(z_y) = M_{12} - M_{13} < 0$. We separate the domain in the indices $m$ and $k$ according to the nature of equations (4.1) and (4.2).

**Lemma 4.5.** If $M_{13} > M_{12} > 0$, we know that $z_y^2 - \xi^2$ is a square in $F^\times$. Moreover, one of $v(z_y \pm \sqrt{z_y^2 - \xi^2})$ equals $M_{12} - M_{13}$, and the other valuation would equal $M_{13} - M_{12}$.

**Proof.** For the first assertion, it suffices to note that $z_y^2 - \xi^2 \in F$, and that the leading coefficient and the valuation of $z_y^2 - \xi^2$ is the same as those of $z_y^2$ by omission of terms of higher valuation.

Given the existence of $\sqrt{z_y^2 - \xi^2}$, we have $v(\sqrt{z_y^2 - \xi^2}) = v(z_y)$. Since $\text{char } F \neq 2$, at least one of $v(z_y \pm \sqrt{z_y^2 - \xi^2})$ must has the same valuation as $z_y$, which is $M_{12} - M_{13}$.

The key observation to the last part of the assertion is that

$$(z_y + \sqrt{z_y^2 - \xi^2})(z_y - \sqrt{z_y^2 - \xi^2}) = \xi^2$$

and so $v(z_y + \sqrt{z_y^2 - \xi^2}) + v(z_y - \sqrt{z_y^2 - \xi^2}) = 0$. \qed

There are parts of the orbital integral (written in the form of Lemma 3.5) that we have not yet computed. We will separate them into three parts and discuss them one at a time. Those are (as shown in the figure below):

- $(A)$ $m > k$ and $m + k > M_{13} + v(\mu)$.
- $(B)$ $m > k$, $m + k \leq M_{13} + v(\mu)$, and $2m > 2M_{12} - M_{13} + v(\mu)$.
- $(C)$ $m > k$, $m + k \leq M_{13} + v(\mu)$, and $2m \leq 2M_{12} - M_{13} + v(\mu)$.

The figure shows the divisions for the domain of $m$ and $k$ when $v(\mu) = 0$, $M_{13} = 4$, and $M_{12} = 3$. 
4.3.1. **Contribution from (A).** In this case (4.2) implies that

\[ u^4 \equiv 4\mu^2 \xi^{-2} \pmod{\varpi^{m+k-M_{13}+v(\mu)}} \]

which does not have a solution \( u \in F \) because \( \xi^2 \) is not a square in \( F^\times \). Therefore this part does not contribute in the orbital integral.

4.3.2. **Contribution from (B).** In this case \( m + k \leq M_{13} + v(\mu) \). From (4.2) we derive that

\[ 4k \geq m + k - M_{13} + v(\mu) \]

Consider (4.1). From it we have

\[ v \left( u^2 + 2\mu \xi^{-2}(z_y + \sqrt{z_y^2 - \xi^2}) \right) \geq 2m - M_{12} \]

Here, the \( \pm \) sign means that at least one of the congruences holds.

For convenience on the notation, we will fix the choice of square roots on \( \sqrt{z_y^2 - \xi^2} \) so that \( z_y + \sqrt{z_y^2 - \xi^2} \) has valuation \( M_{12} - M_{13} \) (see Lemma 4.5).

Here, we state a lemma about solving quadratic congruence for later use. Recall that the valuation \( v \) on \( F \) extends to the maximal unramified extension \( F^{ur} \) of \( F \). We will continue to denote this extension by \( v \).

**Lemma 4.6.** Let \( a \in F^{ur} \) and assume \( 2v(a) < n \). Then

\[ v(x^2 - a^2) \geq n \]

if and only if

\[ v(x + a) \geq n - v(a) \quad \text{or} \quad v(x - a) \geq n - v(a). \]

**Proof.** The if assertion holds for obvious reason.

For the only if assertion, we assume that \( v(x^2 - a^2) \geq n \). Then \( v(x) = v(a) \) and we can therefore write \( x = x_0 \varpi^{v(a)} \) and \( a = a_0 \varpi^{v(a)} \). This implies that

\[ v((x_0 + a_0)(x_0 - a_0)) \geq n - v(a). \]

Note that since \( \text{char } F \neq 2 \), one of \( x_0 + a_0 \) and \( x_0 - a_0 \) must be a unit. Thus one of \( v(x + a) \) or \( v(x - a) \) is greater than \( n - v(a) \).

Note that if \( 2v(a) \geq n \), then \( v(x^2 - a^2) \geq n \) if and only if \( 2v(x) \geq n \).

We fix a choice of the square root as above. Then

\[ v(2\mu \xi^{-2}(z_y + \sqrt{z_y^2 - \xi^2})) = M_{12} - M_{13} + v(\mu) < 2m - M_{12} \]

by the assumption on the domain (B). Observe that the leading coefficient of \(-2\mu \xi^2(z_y + \sqrt{z_y^2 - \xi^2})\) is the same as that of \(-4\mu \xi^2 z_y\). Thus it can only be a square if there exist
\( \mu \in \{1, \varpi\} \) so that \( \left( \frac{-\mu \xi^2 z_u}{F} \right) = 1 \). Suppose such choice exists, and \( \mu \) is fixed so that \( \left( \frac{-\mu \xi^2 z_u}{F} \right) = 1 \). Then
\[
k = \frac{1}{2} (M_{12} - M_{13} + v(\mu))
\]
and \( u \) is pairwise determined up to any element in \( \varpi^{2m-M_{12}-k}O_F \) (see Lemma 4.6).

The choice of \( m \) would have to satisfy the following inequalities:
\[
M_{13} - k + v(\mu) \geq m,
3k + M_{13} - v(\mu) \geq m,
k + M_{12} \geq m,
m > k,
2m > -M_{13} + v(\mu),
2m > 2M_{12} - M_{13} + v(\mu).
\]

The third inequality implies the other upper-bounds. Since \( M_{13} > M_{12} \), the first inequality is redundant here because
\[
M_{13} - k + v(\mu) = k + M_{12} + 2(M_{13} - M_{12}) > k + M_{12}.
\]
Likewise, substitute \( 2k = M_{12} - M_{13} + v(\mu) \) into the second inequality shows that it is equivalent to the third inequality.

The last inequality implies the other lower-bounds. The second-to-last inequality is implied by the last inequality since \( M_{12} > 0 \). The forth is also implied by it because
\[
2M_{12} - M_{13} + v(\mu) = 2k + M_{12} > 2k.
\]

Thus the sum (that occurs in Lemma 3.5) will be taken over \( m \) that satisfies
\[
2k + 2M_{12} \geq 2m > 2k + M_{12}.
\]

Suppose \( \left( \frac{-\mu \xi^2 z_u}{F} \right) = 1 \), then \( u \) is pairwise determined up to any element in \( \varpi^{2m-M_{12}-k}O_F \). Otherwise, this part of the orbital integral vanishes. Note that
\[
\text{vol} (\varpi^{2m-M_{12}-k}O_F) = k + M_{12} - 2m.
\]
Thus the contribution from this part is
\[
\left( \left( \frac{-\mu \xi^2 z_u}{F} \right) + 1 \right) \sum_m q^{k-m+M_{12}} = \left( \left( \frac{-\mu \xi^2 z_u}{F} \right) + 1 \right) \sum_{l=0}^{\frac{M_{12}}{2}} q^l
\]
\[= \left( \left( \frac{-\mu \xi^2 z_u}{F} \right) + 1 \right) q^{\frac{M_{12}}{2} - 1} (q^{-1})^{-1} \quad (4.1)\]
since
\[ \frac{M_{12}}{2} > k - m + M_{12} \geq 0. \]

On the other hand, if we consider
\[ v\left(u^2 + 2\mu \xi^2(z_y - \sqrt{z_y^2 - \xi^2})\right) \geq 2m - M_{12}, \quad (4.2) \]
the discussion would depend upon the ordering of
\[ 2m - M_{12} \quad \text{and} \quad v\left(2\mu \xi^2(z_y - \sqrt{z_y^2 - \xi^2})\right) = M_{13} - M_{12} + v(\mu). \]

Suppose \( 2m > M_{13} + v(\mu) \). Since the leading coefficient of \( z_y - \sqrt{z_y^2 - \xi^2} \) is the same as that of \( \frac{\xi^2}{2z_y} \) (recall the proof of Lemma 4.5), we have a solution for \( u \) only when \( \left( -\frac{\mu z_y}{F} \right) = 1 \). If that is the case, we know that \( k = 1 \) (\( M_{13} - M_{12} + v(\mu) \)) and \( u \) is pairwise determined up to any element in \( \mathcal{O}_F^{2m-M_{12}-k} \).

In this case, the bounds for \( m \) is again
\[ 2k + 2M_{12} \geq 2m > 2k + M_{12} \]
and this part contributes to the orbital integral
\[ \left( \left( -\frac{\mu z_y}{F} \right) + 1 \right) \frac{M_{12}}{2} q^{\frac{\left| M_{12} \right|}{2}} - 1. \quad (4.3) \]

Suppose \( 2m \leq M_{13} + v(\mu) \). Then the equation to solve for (4.2) reduces to
\[ 2k \geq 2m - M_{12}. \]

In this case we have
\[ M_{13} + v(\mu) \geq 2m > 2M_{12} - M_{13} + v(\mu). \]

Moreover, for any fixed \( m \), the range for \( k \) is given by
\[ 2m > 2k \geq 2m - M_{12}. \]

As a result, this part of the orbital integral contributes to the orbital integral
\[ \sum_{m} \sum_{k=m-\lfloor \frac{M_{12}}{2} \rfloor}^{m-1} q^{m-k}(1 - q^{-1}) = \sum_{m} (q^{\left| \frac{M_{12}}{2} \right|} - 1) \]
\[ = (M_{13} - M_{12})(q^{\left| \frac{M_{12}}{2} \right|} - 1). \quad (4.4) \]

Note that the conclusion is drawn from the bounds for \( m \):
\[ M_{13} + v(\mu) \geq 2m > 2M_{12} - M_{13} + v(\mu). \]

The bounds indicate that there are a total of \( M_{13} - M_{12} \) choices for \( m \).
Thus, the total contribution from \((B)\) is the sum of \((4.1), (4.3),\) and \((4.4).\) That is,
\[
2d (v(\mu) + M_{12} - M_{13}, \varpi) \left( \frac{M_{12}}{2} \right) - 1 + (M_{13} - M_{12})(q^{\left\lfloor \frac{M_{12}}{2} \right\rfloor} - 1). \tag{4.5}
\]
Note that we have applied the identity
\[
\left( -\frac{\mu z}{F} + 1 \right) + \left( -\frac{\mu z^2}{F} + 1 \right) = 2d (v(\mu) + M_{12} - M_{13}, \varpi)
\]
in \((4.5).\)

4.3.3. Contribution from \((C)\). From \((4.2)\) we derive that
\[
4k \geq m + k - M_{12} + v(\mu).
\]

Suppose \(2m \leq 2M_{12} - M_{13} + v(\mu),\) then \((4.1)\) becomes
\[
v \left( (u^2 + 2\mu \xi^{-2} z y)^2 \right) \geq 2m - M_{13} + v(\mu),
\]
or equivalently,
\[
v \left( u^2 + 2\mu \xi^{-2} z y \right) \geq m - \frac{M_{13} - v(\mu)}{2}.
\]
By the assumption on the domain \((C),\)
\[
v(2\mu \xi^{-2} z y) = 2v(\mu) + M_{12} - M_{13} \geq m - \frac{M_{13} - v(\mu)}{2}.
\]
It follows that
\[
2k \geq m - \frac{M_{13} - v(\mu)}{2}.
\]
In this case, the bounds for \(m\) are
\[
2M_{12} - M_{13} + v(\mu) \geq 2m > -M_{13} + v(\mu).
\]
Meanwhile, \(k\) satisfies
\[
4m > 4k \geq 2m - M_{13} + v(\mu).
\]
As a result, this part sums to
\[
\sum_{m} \sum_{k} q^{m-k} (1 - q^{-1}) = \sum_{m} \left( q^{\left\lfloor \frac{2m + M_{13} - v(\mu)}{4} \right\rfloor} - 1 \right)
\]
\[
= \sum_{l=1}^{M_{12}} q^{\left\lfloor \frac{l}{2} \right\rfloor} - M_{12}
\]
\[
= 2 \cdot q^{\left\lfloor \frac{M_{12}/2}{2} \right\rfloor} - 1 + (1 + d(M_{12}, 1)) q^{\left\lfloor M_{12}/2 \right\rfloor} - M_{12} \tag{4.6}
\]
Thus, in this case the orbital integral can be obtained by Lemma 3.5 when we plug in the contribution from (4.5) and (4.6). Therefore

\[
O_{\gamma_u}(\mathbf{1}_{S(O_F)}) = \frac{1}{2} \left( (M_{13} - M_{12} + 1 + d(M_{12}, 1)) q^{[M_{12}/2]}
+ 2d(M_{12} - M_{13}, \mu) \frac{q^{[M_{12}/2]-1}}{q-1} - d(M_{13}, \mu) \right).
\]

\[
\square
\]

4.4. Case (4). Suppose \(M_{12} = M_{13} = M_{23} > 0\).

Lemma 4.7. If \(M_{12} = M_{13} = M_{23} > 0\), we have \(v(z_y + \sqrt{z_y^2 - \xi^2}) = 0\) when provided \(z_y^2 - \xi^2\) is a square in \(F\).

Proof. By Lemma 3.4, we have \(v(z_y - \xi) = 0\). The first assertion follows.

Suppose \(v(z_y) > 0\). Then the second assertion holds because the leading coefficient of \(z_y \pm \sqrt{z_y^2 - \xi^2}\) is the same as that of \(\pm \sqrt{z_y^2 - \xi^2}\), which is an integral unit.

Suppose \(v(z_y) = 0\). The second assertion follows from that the leading coefficients of \(z_y\) and \(\pm \sqrt{z_y^2 - \xi^2}\) are not equal (by simply considering their respective squares).

\[
\square
\]

There are again three parts of the integral which we will discuss independently. Those are:

(A) \(m > k, m + k > M_{12} + v(\mu)\),
(B) \(m > k, m + k \leq M_{12} + v(\mu)\), and \(2m > M_{12} + v(\mu)\).
(C) \(m > k, m + k \leq M_{12} + v(\mu)\), and \(2m \leq M_{12} + v(\mu)\).

4.4.1. Contribution from (A). As argued in the previous case, by assumption

\[
u^4 = 4\mu^2 \xi^{-2} \pmod {\varpi^{m+k-M_{12}+v(\mu)}}.
\]

This has no solution \(u \in F\) because \(\xi\) is not a square in \(F\). Therefore, this part does not contribute in the orbital integral.

4.4.2. Contribution from (B). From (4.2) we derive that

\[
4k \geq m + k - M_{12} + v(\mu).
\]

Consider (4.1). When \(2m > M_{12} + v(\mu)\) we have

\[
u^2 = -2\mu \xi^2 (z_y \pm \sqrt{z_y^2 - \xi^2}) \pmod {\varpi^{2m-M_{12}}}
\]

if \(\left(\frac{z_y^2-\xi^2}{\varpi}\right) = 1\). Otherwise, this part of the integral vanishes due to the absence of a solution \(u \in F\) for (4.1).

By the assumption on (B), we know that the right-hand sides of either of the congruences (depending on the \(\pm\) sign) above are nonzero.
Note that when \( \mu = \varpi \), the congruences above do not have any solution. So we will assume \( \mu = 1 \) from this point on until the end of this part.

Since \( (z_y + \sqrt{z_y^2 - \xi^2})(z_y - \sqrt{z_y^2 - \xi^2}) = \xi^2 \) is a non-square in \( \mathcal{O}_F^* \), precisely one of \(-2\mu(z_y \pm \sqrt{z_y^2 - \xi^2})\) will be a square in \( F \). Thus \( u \) is pairwise determined up to any element in \( \varpi^{2m - M_{12}}\mathcal{O}_F \). Moreover, we have \( k = 0 \).

In this case, the bounds for \( m \) are given by \( M_{12} \geq m > \left\lceil \frac{M_{12}}{2} \right\rceil \). To conclude, when \( \left( \frac{z_y^2 - \xi^2}{F} \right) = 1 \), this part contributes
\[
2 (1 - v(\mu)) \sum_m q^{M_{12} - m}
\]
with index \( m \) running over \( M_{12} \geq m > \left\lceil \frac{M_{12}}{2} \right\rceil \).

As mentioned, the contribution of this part is 0 when \( \left( \frac{z_y^2 - \xi^2}{F} \right) = -1 \). To incorporate this last piece of information, we write the contribution as
\[
(1 + \left( \frac{z_y^2 - \xi^2}{F} \right)) (1 - v(\mu)) \frac{q^{\left\lceil \frac{M_{12}}{2} \right\rceil - 1}}{q - 1}. \tag{4.1}
\]

4.4.3. Contribution from \((C)\). From (4.2) we derive that
\[
4k \geq m + k - M_{12} + v(\mu).
\]

In this case (4.1) simplifies to
\[
2v(u^2 + 2\mu\xi^{-2}z_y) \geq 2m - M_{12} + v(\mu),
\]
or equivalently,
\[
v(u^2 + 2\mu\xi^{-2}z_y) \geq m - \frac{M_{12} - v(\mu)}{2}.
\]

Note that by the assumption on \((C)\),
\[
m \leq \frac{M_{12} - v(\mu)}{2} + v(\mu) \leq \frac{M_{12} - v(\mu)}{2} + v(\mu) + v(z_y).
\]
Therefore
\[
2k \geq m - \frac{M_{12} - v(\mu)}{2}.
\]

\( m \) satisfies
\[
M_{12} + v(\mu) \geq 2m > -M_{12} + v(\mu).
\]

Furthermore, for \( m \) fixed, \( k \) satisfies
\[
2m > 2k \geq m - \frac{M_{12} - v(\mu)}{2}.
\]

Thus, for a fixed \( m \) the contribution is \( \sum \frac{q}{q} q^{m-k} \) with the index \( k \) satisfying \( 2m > 2k \geq m - \frac{M_{12} - v(\mu)}{2} \). Equivalently, \( \left\lceil \frac{2m + M_{12} - v(\mu)}{4} \right\rceil \geq m - k > 0 \). The contribution for each \( m \) is
therefore \[ \frac{q-1}{q} \sum_k q^{m-k} = q^{\left\lfloor \frac{(2m+M_{12} - v(\mu)) - d(M_{12}, \mu)}{4} \right\rfloor} - 1. \]

Summed over \( m \) to give the total contribution of this part:

\[
\sum_m \sum_k q^{m-k} (1 - q^{-1}) = \sum_m \left( q^{\frac{2m+M_{12} - v(\mu)}{4}} - 1 \right)
= \sum_{l=1}^{M_{12}} q^{|\frac{l}{2}|-1} - M_{12}
= 2 \cdot \frac{q^{[M_{12}/2]-1}}{q-1} - 1 + (1 + d(M_{12}, 1)) q^{[M_{12}/2]} - M_{12} \tag{4.2}
\]

We applied the change of variable \( 2m + M_{12} - v(\mu) = 2l \).

The orbital integral can be computed by plugging in the sum of the contribution from all the cases above, namely (4.1), and (4.2) into Lemma 3.5. Thus in this case

\[
O_{\gamma}(\mathbb{1}_{S(O_F)}) = \frac{1}{4} \left( (1 + \left( \frac{\xi^2 - \xi'^2}{F} \right) (1 - v(\mu)) + 2 \right) \frac{q^{[M_{12}/2]-1}}{q-1}
+ (1 + d(M_{12}, 1)) q^{[M_{12}/2]} - d(M_{12}, \mu) \right). \]

\[ \square \]

5. Computation for type II tori

In this section we consider type II tori in Lemma 2.8. That is, we assume \( \gamma \in T_1(F) \).

Then \( \text{vol}(G_{1, \gamma}) = 4 \), and \( \mu \in \{1, \xi^2, \overline{w}, \xi^2 \overline{w}\} \) by Corollary 2.11.

**Theorem 5.1.** For \( \gamma \in T_1(F) \), we have

(1) When \( M_{13} = 0 \),

\[
O_{\gamma}(\mathbb{1}_{S(O_F)}) = \frac{1}{4} \left( 1 + (1 + \left( \frac{2\mu}{F} \right)) \left[ \frac{M_{23}}{2} \right] + (1 + \left( -\frac{2\mu}{F} \right)) \left[ \frac{M_{12}}{2} \right] \right). 
\]

(2) When \( M_{13} > M_{12} = 0 \),

\[
O_{\gamma}(\mathbb{1}_{S(O_F)}) = \frac{1}{4} \left( M_{13} + 1 - d(M_{13}, \mu) \right). 
\]

(3) When \( M_{13} > M_{12} > 0 \),

\[
O_{\gamma}(\mathbb{1}_{S(O_F)}) = \frac{1}{4} \left( 2 \left( \left( \frac{-\mu^2}{F} \right) + 1 \right) \frac{q^{[M_{12}/2]-1}}{q-1} + 2 \cdot \frac{q^{[M_{12}/2]-1}}{q-1}
+ (M_{13} - M_{12} + 1 + d(M_{12}, 1)) q^{[M_{12}/2]} - d(M_{12}, \mu) \right). 
\]
(4) When $M_{12} > M_{13} > 0$,
\[
O_{\gamma} \left( \mathfrak{I}_S(Q_F) \right) = \frac{1}{4} \left( \left( \frac{z_2^2 - 1}{F} \right) + 1 \right) \left( \left( \frac{-2\mu}{F} \right) + 1 \right) q^{\left\lceil M_{13}/2 \right\rceil - 1} q^{-1} + M_{13} \\
+ \left( \frac{-2\mu}{F} \right) + 1 \left( \left\lfloor M_{12}/2 \right\rfloor - \left\lfloor M_{13}/2 \right\rfloor \right) q^{\left\lfloor M_{13}/2 \right\rfloor} + 2 \cdot \frac{q^{\left\lfloor M_{13}/2 \right\rfloor - 1} q^{-1}}{q^{-1}} + (1 + (M_{13}, 1)) q^{\left\lfloor M_{13}/2 \right\rfloor} - d(M_{13}, \mu) \right).
\]

(5) When $M_{12} = M_{13} = M_{23} > 0$,
\[
O_{\gamma} \left( \mathfrak{I}_S(Q_F) \right) = \frac{1}{4} \left( \left( (1 + \left( \frac{z_2^2 - 1}{F} \right)) \left( (1 + \left( \frac{-2\mu + \sqrt{z_2^2 - 1}}{F} \right)) + 2 \right) q^{\left\lceil M_{12}/2 \right\rceil - 1} q^{-1} \\
+ (1 + d(M_{12}, 1)) q^{\left\lfloor l/2 \right\rfloor} - d(M_{12}, \mu) \right) \right).
\]

**Theorem 5.2.** Suppose $\gamma \in T_1$. Let $\kappa_\gamma \in \mathfrak{D}(F, G_{1\gamma}, G_1)^* \simeq \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ be chosen as in §1.

Then, depending on the choice of $\kappa_\gamma$, the endoscopic orbital integrals $SO^\kappa_\gamma(\mathfrak{I}_S(Q_F))$ are computed as in the following tables:

### Table 1

<table>
<thead>
<tr>
<th>$M_{13}$</th>
<th>$\kappa$ = $\kappa_\gamma$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$M_{13} = 0$</td>
<td>$\frac{1}{2}(\left\lceil \frac{M_{12}}{2} \right\rceil + \left\lceil \frac{M_{12}}{2} \right\rceil)$</td>
</tr>
<tr>
<td>$M_{13} &gt; M_{12} = 0$</td>
<td>$\frac{1}{2}(\left\lceil \frac{M_{12}}{2} \right\rceil + \left\lceil \frac{M_{12}}{2} \right\rceil)$</td>
</tr>
<tr>
<td>$M_{13} &gt; M_{12} &gt; 0$</td>
<td>$\frac{1}{2}(\left\lceil \frac{M_{12}}{2} \right\rceil + \left\lceil \frac{M_{12}}{2} \right\rceil)$</td>
</tr>
<tr>
<td>$M_{12} &gt; M_{13} &gt; 0$</td>
<td>$\frac{1}{2}(\left\lceil \frac{M_{12}}{2} \right\rceil + \left\lceil \frac{M_{12}}{2} \right\rceil)$</td>
</tr>
<tr>

</tr>
</tbody>
</table>
**Proof.** It follows directly from Theorem 5.1. Note that
\[ \sum_{\mu} \kappa_s(\mu)d(N, \mu) = 2 \cdot (-1)^{N-1} \]
when \( s = \xi^2 \), and the sum vanishes otherwise. The case where \( M_{23} > M_{13} > 0 \) is symmetrically analogous to the case of \( M_{12} > M_{13} > 0 \). □

We now begin the proof of Theorem 5.1. Observe that since \( \lambda_i \in \mathcal{U}_1, E/F \) for any \( i \), we may always assume \( M_{ij} \geq 0 \).

The \( y \)-coefficients in (3.9) are now
\[ v \left( \mu + z_y u^2 + \frac{1}{4} \mu^{-1} u^4 \right) \geq 2m - M_{13}, \quad (5.1) \]
\[ v \left( \mu - \frac{1}{4} \mu^{-1} u^4 \right) \geq m + k - M_{13}. \quad (5.2) \]
Also, when \( m > k \), the \( x \)-coefficient congruences implies (3.10).

5.1. **Case (1).** Suppose \( M_{13} = 0 \).

In this case we have
\[ 1 + (1 + \left( \frac{2\mu}{\mathfrak{p}} \right)) \left[ \frac{M_{23}}{2} \right] + (1 + \left( -\frac{2\mu}{\mathfrak{p}} \right)) \left[ \frac{M_{12}}{2} \right]. \]

**Proof.** By (3.3) we have \( k \geq v(\mu) \geq 0 \) and hence we can rewrite (5.2) as
\[ u^1 \equiv 4\mu^2 \pmod{\mathfrak{p}^{m+k+v(\mu)}}. \]

By Lemma 5.3, the congruence above is equivalent to
\[ u^2 \equiv \pm 2\mu \pmod{\mathfrak{p}^{m+k}}, \]
which can have a solution only when at least one of \( \pm 2\mu \) is a square in \( F \). In particular, this excludes the two cases when \( v(\mu) = 1 \).

Suppose \( \left( \frac{2\mu}{\mathfrak{p}} \right) = 1 \). Then, we can denote one of the square root for \( 2\mu \) as \( u_0 \) and write \( u = \pm u_0 + u_1 \) with \( v(u_1) \geq m + k \). Here both \( m \) and \( k \) are non-negative. Therefore
\[ u^2 = 2\mu + 2u_0u_1 \pmod{\mathfrak{p}^{2m}}, \]
\[ u^4 = 4\mu^2 + 8\mu u_0u_1 \pmod{\mathfrak{p}^{2m}}. \]

For \( u \) to be a solution for (5.1), \( m \) must satisfies
\[ 2(\mu + u_0u_1)(z_y + 1) = 0 \pmod{\mathfrak{p}^{2m}}. \]

By Lemma 3.4, we know that \( v(z_y + 1) = M_{23} + N_{12} \), so the above equation implies
\[ 2m \leq M_{23} + N_{12}. \]

On the other hand, since \( k = 0 \), by (3.10), we also have \( 2m \leq M_{23} + M_{12} \). Furthermore, at least one of \( M_{12} \) or \( N_{i2} \) vanishes for \( i = 1 \) and 3. Thus \( \min(N_{12}, M_{12}) = 0 \) and the available...
domain for $m$ here is $M_{12} \geq 2m > 0$. The choice of $u_1$ is up to elements in $\omega^{m+k} \mathcal{O}_F$ and therefore only contributes one solution per choice of $\pm u_0$.

To conclude, this case contributes

$$(1 + \left(\frac{2\mu}{F}\right)) \lfloor \frac{M_{23}}{2} \rfloor$$

to the orbital integral.

Suppose $\left(\frac{-2\mu}{F}\right) = 1$, then a completely symmetric argument implies that

$$(1 + \left(\frac{-2\mu}{F}\right)) \lfloor \frac{M_{12}}{2} \rfloor.$$  

Plugging the above contributions into Lemma 3.5 yields the result.□

Assume for the rest of the section $M_{13} > 0$. In this case, (5.1) can be rewritten as

$$v \left( (u^2 + 2\mu z_y)^2 - 4\mu^2 (z_y^2 - 1) \right) \geq 2m - M_{13} + v(\mu).$$  (5.1)

Analogously, (5.2) can be written as

$$v \left( u^4 - 4\mu^2 \right) \geq m + k - M_{13} + v(\mu).$$  (5.2)

By Lemma 3.4, we know that

$$v(z_y^2 - 1) = N_{12} + M_{12} + N_{23} + M_{23} - 2M_{13}.$$  

As seen before in §4, the possible cases for $M_{ij}$ are:

(a) $M_{12} = M_{23} = 0$, or
(b) both $M_{12}$ and $M_{23}$ are positive. In which case we have $N_{12} = N_{23} = 0$.

5.2. Case (2). Suppose $M_{13} > M_{12} = 0$.

For case (a), there does not exist $k$ so that $2m > 2k \geq 2m - M_{12} - M_{23}$. Thus

$$O_{\mathfrak{m}}(\mathbb{L}(\mathcal{O}_F)) = \frac{1}{2} (M_{13} + 1 - d(M_{13}, \mu)).$$

In case (b), by assumption we have $N_{12} = N_{23} = 0$. Thus $v(z_y^2 - 1) = M_{12} + M_{23} - 2M_{13}$.

5.3. Case (3). Suppose $M_{13} > M_{12} > 0$.

In this case, we have $v(z_y^2 - 1) = 2M_{12} - 2M_{13} < 0$. Also, $v(z_y) = M_{12} - M_{13} < 0$.

Lemma 5.3. If $M_{13} > M_{12}$, $z_y^2 - 1$ is a square in $F^\times$. Furthermore, one of $v(z_y \pm \sqrt{z_y^2 - 1})$ equals $M_{12} - M_{13}$, and the other valuation equals $M_{13} - M_{12}$.

Proof. For the first assertion, it suffices to note that $z_y \in F$ and the leading coefficient of $z_y^2 - 1$ is the same as that of $z_y^2$, and $\left(\frac{z_y^2}{F}\right) = 1$ as $z_y \in F$.

Given the existence of $\sqrt{z_y^2 - 1}$. We know in addition $v(\sqrt{z_y^2 - 1}) = v(z_y)$. Since $\text{char } F \neq 2$, at least one of the above must has valuation of $z_y$, which is $M_{12} - M_{13}$.
The key observation leading to the last assertion is that
\[(z_y + \sqrt{z_y^2 - 1})(z_y - \sqrt{z_y^2 - 1}) = 1\]
and so \(v(z_y - \sqrt{z_y^2 - 1}) = -v(z_y + \sqrt{z_y^2 - 1})\). \(\square\)

Discussion will expand as we separate the domain for choosing \(m\) and \(k\) into three parts. Those domains are

(A) \(m > k\) and \(m + k > M_{13} + v(\mu)\).
(B) \(m > k\), \(m + k \leq M_{13} + v(\mu)\), and \(2m > 2M_{12} - M_{13} + v(\mu)\).
(C) \(m > k\), \(m + k \leq M_{13} + v(\mu)\), and \(2m \leq 2M_{12} - M_{13} + v(\mu)\).

5.3.1. Contribution from (A). If \(m + k > M_{13} + v(\mu)\), by (5.2) we have
\[u^2 \equiv \pm 2\mu \pmod{\varpi^{m+k-M_{13}+v(\mu)}}.\]
It follows that \(v(\mu) = 0\). These combined would imply that \(k = 0\).

On the other hand, since \(2m > 2M_{12} - M_{13} + v(\mu)\), we can apply Lemma 4.6 to (5.1) and yield
\[v\left(u^2 + 2\mu(z_y \pm \sqrt{z_y^2 - 1})\right) \geq 2m - M_{12}.\]
The terms \(2\mu(z_y \pm \sqrt{z_y^2 - 1})\) has nonzero valuation by Lemma 5.3. However, \(u \in \mathcal{O}_F^\times\) if (5.2) is satisfied. Thus a common solution \(u\) for (5.1) and (5.2) does not exist. The contribution of this part to the integral is therefore 0.

5.3.2. Contribution from (B). From (5.2) we derive that
\[4k \geq m + k - M_{13} + v(\mu).\]

Consider (5.1). For convenience on the notation, we will fix the choice of square roots on \(\sqrt{z_y^2 - 1}\) so that \(v(z_y + \sqrt{z_y^2 - 1}) = M_{12} - M_{13}\) (see Lemma 5.3).

Since \(2m > 2M_{12} - M_{13} + v(\mu)\) we have
\[u^2 \equiv -2\mu(z_y + \sqrt{z_y^2 - 1}) \pmod{\varpi^{2m-M_{12}}}.\]
The leading coefficient and the valuation of \(-2\mu(z_y + \sqrt{z_y^2 - 1})\) is the same as those of \(-4\mu z_y\), which is a square with some unique choice of \(\mu \in \{1, \xi, \varpi, \xi^2 \varpi\}\).

Suppose for now \(\mu\) is fixed so that \((\frac{-\mu z_y}{\varpi}) = 1\). Then
\[k = \frac{1}{2} (M_{12} - M_{13} + v(\mu))\]
and \(u\) is pairwise determined up to any element in \(\varpi^{2m-M_{12}-k}\mathcal{O}_F\).

The choice of \(m\) satisfies
\[2k + 2M_{12} \geq 2m > 2k + M_{12}.\]
From the above analysis, we know that in this case \( k = \frac{M_{12} - M_{13} + v(\mu)}{2} \) and \( m \) lies within the domain above. The contribution of this part to the orbital integral is therefore

\[
O_{\gamma_\mu} (1_{S(O_F)}) = \left( \left( \frac{-\mu z_y}{F} \right) + 1 \right) \sum_{m} q^{k - m + M_{12}}
\]

\[
= \left( \left( \frac{-\mu z_y}{F} \right) + 1 \right) \sum_{l=0}^{[\frac{M_{12}}{2}] - 1} q^l
\]

\[
= \left( \left( \frac{-\mu z_y}{F} \right) + 1 \right) \frac{q^{[M_{12}/2] - 1}}{q - 1}.
\] (5.1)

On the other hand, if we consider

\[
v \left( u^2 + 2\mu (z_y - \sqrt{z_y^2 - 1}) \right) \geq 2m - M_{12},
\]

the discussion naturally depends upon the ordering of

\[2m - M_{12} \quad \text{and} \quad M_{13} - M_{12} + v(\mu).\]

We begin by assuming \( 2m > M_{13} + v(\mu) \). Since the leading coefficient of \( z_y - \sqrt{z_y^2 - 1} \) is the same as that of \((2z_y)^{-1}\), we have a solution for \( u \) only if \( \left( \frac{-\mu z_y}{F} \right) = 1 \). Suppose so, then we know that \( k = \frac{1}{2} (M_{13} - M_{12} + v(\mu)) \) and \( u \) is pairwise determined up to any element in \( \mathcal{O}_{2m - M_{12} - k} \).

By an argument analogous to the previous case, the inequalities for \( m \) to satisfy simplifies to

\[2k + 2M_{12} \geq 2m > 2k + M_{12}\]

and this part contributes another

\[
\left( \left( \frac{-\mu z_y}{F} \right) + 1 \right) \frac{q^{[M_{12}/2] - 1}}{q - 1} \] (5.2)

to the orbital integral.

For the situation when \( 2m \leq M_{13} + v(\mu) \), the equation from above reduces to

\[2k \geq 2m - M_{12}.
\]

The range of \( m \) is now

\[M_{13} + v(\mu) \geq 2m > 2M_{12} - M_{13} + v(\mu),
\]

and for any \( m \) fixed we have

\[2m > 2k \geq 2m - M_{12}.
\]
As a result, this part contributes a sums of
\[
\sum_{m} \sum_{k=m-1}^{m-1} q^{m-k}(1-q^{-1}) = \sum_{m} (q^{\lfloor \frac{M_{12}}{2} \rfloor} - 1)
\]
\[= (M_{13} - M_{12})(q^{\lfloor \frac{M_{12}}{2} \rfloor} - 1). \tag{5.3}
\]
Note that the concluding equation follows from the inequalities
\[M_{13} + v(\mu) \geq 2m > 2M_{12} - M_{13} + v(\mu),\]
which indicates that there are \(M_{13} - M_{12}\) choices for \(m\).

The total contribution for (B) is therefore the sum of (5.1), (5.2), and (5.3). That is,
\[
2\left(\left(\frac{\mu z_{y}}{p}\right) + 1\right) \frac{q^{\lfloor M_{12}/2 \rfloor} - 1}{q-1} + (M_{13} - M_{12})(q^{\lfloor M_{12}/2 \rfloor} - 1). \tag{5.4}
\]

5.3.3. Contribution from (C). From (5.2) we derive that
\[4k \geq m + k - M_{13} + v(\mu).\]

Now (5.1) becomes
\[v\left((u^2 + 2\mu z_y)^2\right) \geq 2m - M_{13} + v(\mu)\]
or equivalently,
\[v(u^2 + 2\mu z_y) \geq m - \frac{M_{13} - v(\mu)}{2}.\]

So in this case we have
\[2k \geq m - \frac{M_{13} - v(\mu)}{2}.\]

Here, the range of \(m\) is
\[2M_{12} - M_{13} + v(\mu) \geq 2m > -M_{13} + v(\mu).\]

Meanwhile, when \(m\) is fixed, the range of \(k\) is given by
\[4m > 4k \geq 2m - M_{13} + v(\mu).\]

As a result, this part of the integral sums up to
\[
\sum_{m} \sum_{k} q^{m-k}(1-q^{-1}) = \sum_{m} (q^{\lfloor \frac{2m-M_{13}-v(\mu)}{4} \rfloor} - 1)
\]
\[= \sum_{l=1}^{M_{12}} q^{\lfloor \frac{l}{2} \rfloor} - M_{12}
= 2 \cdot \frac{q^{\lfloor M_{12}/2 \rfloor} - 1}{q-1} - 1 + (1 + d(M_{12}, 1)) q^{\lfloor M_{12}/2 \rfloor} - M_{12} \tag{5.5}
\]

For \(M_{13} > M_{12} > 0\), the orbital integral is obtained by plugging (5.4), and (5.5) into Lemma 3.5. Thus
\[ O_{\gamma_{\mu}}(1_{S(O_F)}) = \frac{1}{4} \left( 2 \left( \left( -\frac{\mu_{zy}}{F} \right) + 1 \right) \frac{q^{[M_{12}/2]} - 1}{q - 1} + 2 \cdot \frac{q^{[M_{12}/2]} - 1}{q - 1} \right) \]

\[ + (M_{13} - M_{12} + 1 + d(M_{12}, 1)) q^{[M_{12}/2]} - d(M_{12}, \mu) \].

\[ \square \]

5.4. Case (4). Suppose \( M_{12} > M_{13} > 0 \).

We begin with a lemma analogous to Lemma 5.3.

Lemma 5.4. If \( M_{12} > M_{13} \), we know that \( v(z_{zy} - 1) = M_{12} - M_{13} > 0 \), so the leading coefficient of \( z_{yy} \) is 1. In particular, \( v(z_{zy}) = 0 \).

Proof. By Lemma 3.4, under the current assumption we have

\[ v(z_{zy} - 1) = M_{12} + N_{23} - M_{13}. \]

Note that \( N_{23} = 0 \) since \( M_{23} = M_{13} > 0 \). \[ \square \]

As before we split the integral by parts in accordance with the nature of equations (5.1) and (5.2). There are a total of four parts:

- \( (A) \) \( m > k, m + k > M_{13} + v(\mu), \) and \( 2m > M_{12} + v(\mu) \).
- \( (B) \) \( m > k, m + k > M_{13} + v(\mu), \) and \( 2m \leq M_{12} + v(\mu) \).
- \( (C) \) \( m > k, m + k \leq M_{13} + v(\mu), \) and \( 2m > M_{12} + v(\mu) \).
- \( (D) \) \( m > k, m + k \leq M_{13} + v(\mu), \) and \( 2m \leq M_{12} + v(\mu) \).

The figure shows the divisions for the domain of \( m \) and \( k \) when \( v(\mu) = 0 \), \( M_{13} = 4 \), and \( M_{12} = 7 \).
5.4.1. *Contribution from (A).* As argued before, we know that in this case \( v(\mu) = 0 \) and
\[
u^2 \equiv \pm 2\mu \pmod{\omega^{m+k-M_{13}+v(\mu)}}.\]
It follows that \( k = 0 \). Thus we consider only \( M_{12} + M_{23} \geq 2m > 0 \).

Also, by (5.1) and Lemma 4.6 we have
\[
v \left( u^2 + 2\mu(z_y \pm \sqrt{z_y^2 - 1}) \right) \geq 2m - \frac{M_{12} + M_{13}}{2} \]
if \( \left( \frac{z_y^2 - 1}{F} \right) = 1 \). Otherwise, this part of the integral vanishes due to the absence of a solution for (5.1).

Note that by Lemma 5.4, \( \left( \frac{z_y^2 - 1}{F} \right) = \left( \frac{2}{F} \right) \left( \frac{z_y - 1}{F} \right) \). In particular, \( v(z_y - 1) = M_{12} - M_{13} \) is even whenever \( \left( \frac{z_y^2 - 1}{F} \right) = 1 \). Suppose from now on that is the case.

The leading coefficient of \( -2\mu(z_y \pm \sqrt{z_y^2 - 1}) \) is the same as that of \( -2\mu \). Since
\[
u^2 \equiv \pm 2\mu \pmod{\omega^{m+k-M_{13}}} \]
can be derived from (5.2), no solution for \( u \) exist unless the signs coincide.

Thus, the congruences to solve for are
\[
u^2 \equiv -2\mu \pmod{\omega^{m-M_{13}}},
\]
\[
u^2 \equiv -2\mu(z_y \pm \sqrt{z_y^2 - 1}) \pmod{\omega^{2m-M_{12}+M_{13}}}.\]

In order for the equations above to be consistent, we need
\[-(z_y - 1) \equiv \pm \sqrt{z_y^2 - 1} \pmod{\omega^{m-M_{13}}} .\]
Since \( k = 0 \), we have
\[
m \leq \frac{M_{12} + M_{13}}{2}\]
from (3.10) and so the congruence above always holds.

The inequalities that \( m \) satisfies are
\[
M_{12} + M_{13} \geq 2m \\
m > M_{13} \\
2m > M_{12}\]
Solutions for \( u \) are then determined in quadruples up to any element in \( \omega^{2m-M_{12}+M_{13}} \mathcal{O}_F \).

Therefore, we may write the contribution of this part to the orbital integral as
\[
\frac{1}{4} \left( \frac{z_y^2 - 1}{F} \right) + 1 \left( -\frac{2\mu}{F} \right) + 1 \sum_{m = \max(\lfloor M_{12}/2 \rfloor, M_{13}) + 1}^{(M_{12}+M_{13})/2} q^{M_{12}+M_{13} - m} (5.1) \]
5.4.2. Contribution from \((B)\). Since \(m + k \geq M_{13} + v(\mu)\), by \((5.2)\) we have

\[ u^2 \equiv \pm 2\mu \pmod{\varpi^{m+k-M_{13}}} \]

and therefore \(v(\mu) = 0\). It follows that \(k = 0\). Thus we consider only \(M_{12} + M_{23} \geq 2m > 0\).

In this case \((5.1)\) simplifies to

\[ 2v(u^2 + 2\mu z_y) \geq 2m - M_{13}. \]

Matching the signs to \((5.2)\) as done in \((B)\), we have

\[ u^2 \equiv -2\mu \pmod{\varpi^{m-M_{13}}} \]

The two congruences are consistent because

\[ v(z_y - 1) = M_{12} - M_{13} > m - M_{13}. \]

This part of the integral contributes

\[ \frac{1}{4}((\frac{-2\mu}{F}) + 1) \max(|\frac{M_{12}}{2}| - M_{13}, 0) \cdot q^{\frac{M_{13}}{2}}. \quad (5.2) \]

since \(u\) is determined pairwise up to any element in \(\varpi^{m-\frac{M_{12}}{2}} \mathcal{O}_F\).

5.4.3. Contribution from \((C)\). In this case \((5.2)\) implies

\[ 4k \geq m + k - M_{13} + v(\mu). \]

Since \(2m > M_{12} + v(\mu)\), by \((5.1)\),

\[ u^2 \equiv -2\mu(z_y \pm \sqrt{z_y^2 - 1}) \pmod{\varpi^{2m - \frac{M_{12} + M_{13}}{2}}} \]

if \(\left(\frac{z_y^2 - 1}{F}\right) = 1\). Otherwise, this part of the integral vanishes due to the absence of a solution for \((5.1)\).

Suppose \(\left(\frac{z_y^2 - 1}{F}\right) = 1\). By Lemma 5.4, the leading coefficient of \(-2\mu(z_y \pm \sqrt{z_y^2 - 1})\) is the same as that of \(-2\mu\). Therefore a solution does not exist unless \(\left(\frac{-2\mu}{F}\right) = 1\). Suppose the criterion is met, then \(u\) is determined in quadruple up to an element in \(\varpi^{2m - \frac{M_{12} + M_{13}}{2}} \mathcal{O}_F\).

We also have \(v(\mu) = 0\) and \(k = 0\). Now \(m\) has to satisfy

\[ 2M_{13} \geq 2m > M_{12}. \]

The contribution of this part to the integral is

\[ \frac{1}{4}((\frac{z_y^2 - 1}{F}) + 1) \cdot \left((\frac{-2\mu}{F}) + 1\right) \sum_{m=|M_{12}/2|+1}^{M_{13}} q^{\frac{M_{12}+M_{13}}{2} - m}. \quad (5.3) \]
5.4.4. Contribution from (D). In this case (5.1) simplifies to
\[ v(u^2 + 2\mu z_y) \geq m - \frac{M_{13} - v(\mu)}{2}. \]

Since \( v(z_y) = 0 \), here we have to discuss separately the different orderings of \( v(\mu) \) and \( m - \frac{M_{13} - v(\mu)}{2} \).

Suppose \( m > \frac{M_{13} + v(\mu)}{2} \). In this case, a solution exists only when \((-2\mu / F) = 1\). Suppose so, then \( v(\mu) = 0 \) and \( k = 0 \). Solutions for \( u \) are pairwise determined up to any element in \( \mathcal{O}_F \).

\[ m \text{ satisfies} \]
\[ M_{13} \geq m, \]
\[ M_{12} \geq 2m, \]
\[ m > \left\lceil \frac{M_{13}}{2} \right\rceil. \]

and this part of the integral contributes
\[ \left( (\frac{-2\mu}{F}) + 1 \right) \left( \min(M_{13}, \left\lfloor \frac{M_{12}}{2} \right\rfloor) - \left\lfloor \frac{M_{13}}{2} \right\rfloor \right) \cdot q^{\frac{M_{13}}{2}}. \tag{5.4} \]

Suppose now \( m \leq \frac{M_{13} + v(\mu)}{2} \). Then, we have
\[ 2k \geq m - \frac{M_{13} - v(\mu)}{2}. \]

In this case \( m \) satisfies
\[ M_{13} + v(\mu) \geq 2m > -M_{13} + v(\mu). \]

Furthermore, for any \( m \) fixed, \( k \) satisfies
\[ 4m > 4k \geq 2m - M_{13} + v(\mu) \]

or equivalently,
\[ \left\lfloor \frac{2m + M_{13} - v(\mu)}{4} \right\rfloor \geq m - k > 0. \]

Thus for each fixed \( m \), the contribution from the sum over \( k \) is
\[ q^{\left\lfloor (2m + M_{13} - v(\mu))/4 \right\rfloor} - 1. \]

By the domain of which \( m \) can be chosen from, we derive that
\[ 2M_{13} \geq 2m + M_{13} - v(\mu) > 0. \]

Therefore by letting \( 2l = 2m + M_{13} - v(\mu) \), we know that this part contributes
\[ \frac{1}{4} \sum_{l=1}^{M_{13}} (q^{l/2} - 1) = \frac{1}{4} \left( 2 \cdot q^{\left\lfloor \frac{M_{13}}{2} \right\rfloor - 1} - 1 + (1 + d(M_{13}, 1)) q^{\left\lfloor M_{13}/2 \right\rfloor} \right). \tag{5.5} \]
The orbital integral can be obtained by plugging the contribution from (5.1) - (5.5) into Lemma 3.5. Note that the sum of (5.1) and (5.3) is
\[
\left(\left(\frac{z^2-1}{F}\right) + 1\right) \cdot \left(\left(-\frac{2\mu}{F}\right) + 1\right) \sum_{m=\lfloor M_{12}/2\rfloor + 1}^{\lfloor M_{12}+M_{13}/2\rfloor} q^{M_{12}+M_{13}/2} - m = \left(\left(\frac{z^2-1}{F}\right) + 1\right) \cdot \left(\left(-\frac{2\mu}{F}\right) + 1\right) \sum_{l=0}^{\lfloor M_{13}/2\rfloor - 1} q^l
\]
and the sum of (5.2) and (5.4)
\[
\left(\left(-\frac{2\mu}{F}\right) + 1\right) \left(\lfloor M_{12}/2 \rfloor - \lfloor M_{13}/2 \rfloor\right) q^{\lfloor M_{13}/2 \rfloor}.
\]
Before the conclusion of this case, let us state a lemma.

Lemma 5.5. For any \(\nu\), whenever \(M_{13} \geq \frac{1}{2}v(\nu)\), we have
\[
\left(\frac{z^2-\nu}{F}\right) = 1.
\]

Proof. By lemma 3.4, we know that the leading coefficient of \(z^2 - \nu\) is the same as that of
\[
\frac{(z-x)^2(z+x)^2}{4x^2y^2},
\]
which is a square in \(F^\times\).

Thus we have
\[
O_{\gamma_{\mu}}(18(\mathcal{O}_F)) = \frac{1}{4} \left(\left(\frac{z^2-1}{F}\right) + 1\right) \cdot \left(\left(-\frac{2\mu}{F}\right) + 1\right) q^{\lfloor M_{13}/2 \rfloor} - 1 + M_{13} + \left(\left(-\frac{2\mu}{F}\right) + 1\right) \left(\lfloor M_{12}/2 \rfloor - \lfloor M_{13}/2 \rfloor\right) q^{\lfloor M_{13}/2 \rfloor} + 2 \cdot q^{\lfloor M_{13}/2 \rfloor} - 1 + (1 + d(M_{13}, 1)) q^{\lfloor M_{13}/2 \rfloor} - d(M_{13}, \mu).
\]

Remark 4. When \(M_{23} > M_{12} > 0\), the result is symmetrically analogous to the Case (4).

5.5. Case (5). Suppose \(M_{12} = M_{13} = M_{23} > 0\).

Under this assumption, by Lemma 3.4, \(z_y + 1\) and \(z_y - 1\) are units.

Lemma 5.6. Suppose \(M_{12} = M_{13} = M_{23} > 0\). Then \(v(z_y) \geq 0\), and \((z_y \pm \sqrt{z_y^2 - 1}) \in \mathcal{O}_F^\times\) provided \(z_y^2 - 1\) is a square in \(F\).

Proof. By Lemma 3.4, \(v(z_y - 1) = 0\). Therefore \(v(z_y) \geq 0\).

If \(v(z_y) > 0\) then the second assertion holds because the leading coefficient of \(z_y \pm \sqrt{z_y^2 - 1}\) is the same as that of \(\pm \sqrt{z_y^2 - 1}\).

Suppose on the contrary \(v(z_y) = 0\). Then, the leading coefficients of \(z_y\) and \(\pm \sqrt{z_y^2 - 1}\) cannot be equal (consider the squares of them respectively). Thus \(v(z_y \pm \sqrt{z_y^2 - 1}) = 0\). \(\square\)
The discussion will be separated into the following cases:

(A) \( m > k \) and \( m + k > M_{12} + v(\mu) \).

(B) \( m > k, m + k \leq M_{12} + v(\mu) \), and \( 2m > M_{12} + v(\mu) \).

(C) \( m > k, m + k \leq M_{12} + v(\mu) \), and \( 2m \leq M_{12} + v(\mu) \).

5.5.1. **Contribution from (A).** As before

\[
u^2 \equiv \pm 2\mu \pmod{\mathcal{O}^{m+k-M_{13}}}.
\]

Therefore \( v(\mu) = 0 \) and \( k = 0 \).

Note that and by (5.1) we have

\[
u^2 \equiv -2\mu(z_y \pm \sqrt{z_y^2 - 1}) \pmod{\mathcal{O}^{2m-M_{12}}}
\]

if \( \left( \frac{z_y-1}{F} \right) = 1 \). Otherwise, this part of the orbital integral vanishes due to the absence of a solution for (5.1).

Assume that \( \left( \frac{z_y-1}{F} \right) = 1 \). By Lemma 5.6 and the assumptions on (B) we know that the right-hand side of the congruence above does not vanish.

Thus the congruences to solve for here are

\[
u^2 \equiv \pm 2\mu \pmod{\mathcal{O}^{m-M_{12}}},
\]
\[
u^2 \equiv -2\mu(z_y \pm \sqrt{z_y^2 - 1}) \pmod{\mathcal{O}^{2m-M_{12}}}
\]

For compatibility, \( m \) would make at least one of

\[
z_y + 1 \equiv \pm \sqrt{z_y^2 - 1} \pmod{\mathcal{O}^{m-M_{12}}},
\]
\[
z_y - 1 \equiv \pm \sqrt{z_y^2 - 1} \pmod{\mathcal{O}^{m-M_{12}}}
\]

holds. As a result, the contribution of this part to the orbital integral is 0. The argument goes as follows.

From the derivation above, it suffices to prove that there does not exist \( m \) so that at least one of the congruences

\[
z_y + 1 \equiv \pm \sqrt{z_y^2 - 1} \pmod{\mathcal{O}^{m-M_{12}}},
\]
\[
z_y - 1 \equiv \pm \sqrt{z_y^2 - 1} \pmod{\mathcal{O}^{m-M_{12}}}
\]

holds. Note that \( m > M_{12} \) so the congruences is well-defined over \( \mathcal{O}_F \).

When \( v(z_y) > 0 \), the square of the leading coefficient on each sides are 1 and \(-1\) respectively. Since \( \text{char} F \neq 2 \), there does not exist a solution for \( m \).

Suppose on the other hand that \( v(z_y) = 0 \). The square of the leading coefficients for \( z_y + 1 \) and \( \pm \sqrt{z_y^2 - 1} \) are the same as that of \( 1 + 2z_y + z_y^2 \) and \( z_y^2 - 1 \) respectively. If the two were to
be equal, we would have \( v(z_y + 1) > 0 \), which is a contradiction to Lemma 3.4. This proves that the first congruence to consider has no solution. The argument for the non-existence of a solution \( m \) for other congruence is analogous.

5.5.2. **Contribution from** \((B)\). In this case, we know that (5.2) implies

\[ 4k \geq m + k - M_{12} + v(\mu). \]

By (5.1) we have

\[ 2v \left( u^2 + 2\mu(z_y \pm \sqrt{z_y^2 - 1}) \right) \geq 2m - M_{12}. \]

if \( \left( \frac{z_y^2 - 1}{F} \right) = 1 \). Otherwise, this part of the integral vanishes due to the absence of a solution for (5.1). Note that by the assumption on \((C)\), we know that \( 2m - M_{12} > v(\mu) \).

There exists a choice of \( \mu \in \{1, \xi^2\} \) to let \(-2\mu(z_y \pm \sqrt{z_y^2 - 1})\) both be square. Then \( u \) is determined in quadruples up to an element in \( \mathbb{Z}^{2m-M_{12}} \mathcal{O}_F \). Furthermore, \( k = 0 \) and \( v(\mu) = 0 \) with such choice of \( \mu \).

The bounds for \( m \) are given by

\[ 2M_{12} \geq 2m > M_{12} \]

To conclude, when \( \left( \frac{z_y^2 - 1}{F} \right) = 1 \), this part contributes

\[ 2 \cdot (1 + \left( \frac{-2\mu(z_y - \sqrt{z_y^2 - 1})}{F} \right)) \sum_m q^{M_{12} - m} \]

with range of \( m \) for the first sum being \( M_{12} \geq m > \left\lfloor \frac{M_{12}}{2} \right\rfloor \).

\[ 2 \cdot (1 + \left( \frac{-2\mu(z_y - \sqrt{z_y^2 - 1})}{F} \right)) \sum_m q^{M_{12} - m} = 2 \cdot (1 + \left( \frac{-2\mu(z_y - \sqrt{z_y^2 - 1})}{F} \right)) \sum_{l=0}^{\left\lfloor M_{12}/2 \right\rfloor - 1} q^l \]

\[ = 2 \cdot (1 + \left( \frac{-2\mu(z_y - \sqrt{z_y^2 - 1})}{F} \right)) q^{\left\lfloor M_{12}/2 \right\rfloor - 1}, \]

and the contribution of this part is 0 when \( \left( \frac{z_y^2 - 1}{F} \right) = -1 \). To include this last piece of information, we write the contribution as

\[ \frac{1}{4} (1 + \left( \frac{z_y^2 - 1}{F} \right)) (1 + \left( \frac{-2\mu(z_y + \sqrt{z_y^2 - 1})}{F} \right)) q^{\left\lfloor M_{12}/2 \right\rfloor - 1}. \]

(5.1)
5.5.3. **Contribution from (C).** Equation (5.2) implies

\[ 4k \geq m + k - M_{12} + v(\mu). \]

In this case (5.1) simplifies to

\[ 2v(u^2 + 2\mu z_y) \geq 2m - M_{12} + v(\mu), \]

or equivalently,

\[ v(u^2 + 2\mu z_y) \geq m - \frac{M_{12} - v(\mu)}{2}. \]

Note that by the assumption on (D),

\[ m \leq \frac{M_{12} - v(\mu)}{2} + v(\mu) \leq \frac{M_{12} - v(\mu)}{2} + v(z_y). \]

Therefore we have

\[ 2k \geq m - \left\lceil \frac{M_{12} - v(\mu)}{2} \right\rceil. \]

Now \( m \) satisfies

\[ M_{12} + v(\mu) \geq 2m > -M_{12} + v(\mu). \]

Furthermore, for a fixed \( m \), the contribution is

\[ \frac{q-1}{q} \sum_k q^{m-k} \text{ with the sum ranged over } 2m > 2k \geq m - \frac{M_{12} - v(\mu)}{2}. \]

Equivalently,

\[ \lceil \frac{2m + M_{12} - v(\mu)}{4} \rceil \geq m - k > 0. \]

Thus the contribution for each \( m \) is

\[ \frac{q-1}{q} \sum_k q^{m-k} = q^{\lceil (2m + M_{12} - v(\mu))/4 \rceil} - 1. \]

Sum that over \( m \), we get

\[ \frac{1}{4} \left( \sum_{M_{12} + v(\mu)} \right) \left( q^{\lceil (2m + M_{12} - v(\mu))/4 \rceil} - 1 \right) \]

\[ = \frac{1}{4} \left( \sum_{l=1}^{M_{12}} q^{l/2} - (M_{12} - 1 + v(\mu)) \right) \]

\[ = \frac{1}{4} \left( 2 \cdot \frac{q^{(M_{12}/2)-1}}{q-1} - 1 + (1 + d(M_{12}, 1)) q^{l/2} - M_{12} \right). \quad (5.2) \]

The orbital integral is then obtained by plugging (5.1) and (5.2) into Lemma 3.5.

\[ O_{\gamma_\mu}(1_{S(O_F)}) = \frac{1}{4} \left( (1 + \left( \frac{z_0 - 1}{F} \right))(1 + \left( \frac{-2\mu (z_0 + \sqrt{z_0^2 - 1})}{F} \right)) + 2 \right) \frac{q^{(M_{12}/2)-1}}{q-1} \]

\[ + (1 + d(M_{12}, 1)) q^{l/2} - d(M_{12}, \mu) \].
6. Computation for type III tori

In this section we consider type III in Lemma 2.8. That is, when $\gamma \in T_{\varpi} \cup T_{\xi^2\varpi}$. The group $\mathcal{D}(F, G_{1\gamma}, G_1)$ is isomorphic to $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ and the parameter $\mu$ will be chosen in $\{1, \xi^2, \varpi, \xi^2\varpi\}$ by Corollary 2.11.

The eigenvalues of $\gamma$, written in terms of its coordinates, are $\lambda_1 = x + \nu^{1/2}y$, $\lambda_2 = z$, and $\lambda_3 = x - \nu^{1/2}y$. Note that in particular $\lambda_1$ and $\lambda_3$ lies in $E(\nu^{1/2})$.

As a quadratic extension over $E$, we know $E(\nu^{1/2}) = E(\sqrt{\varpi})$ and will simply write $E' = E(\sqrt{\varpi})$. Nevertheless, we will extend $\theta$ to $\text{Aut} (E(\sqrt{\varpi}))$ according to the parameter $\nu \in \{\varpi, \xi^2\varpi\}$. For either case, we will denote by $\theta \in \text{Aut} (E(\sqrt{\varpi}))$ the involution that extends $\theta$ on $E$ such that $\nu^{1/2}$ is fixed. In particular, the invariant subfield of $E(\sqrt{\varpi})$ under such conjugation is $F(\nu^{1/2})$, which we will denote as $F'$. Note that in particular $F'/F$ is a ramified quadratic extension.

Then the stabilizer of $\gamma$ in $G$ is isomorphic to $\text{Res}_{F'/F} U_{E'/F'} \times U_{E/F}$ over $F$ canonically via the map

$$
\begin{pmatrix} x' \\ y' \\ z' \\ x' \end{pmatrix} \mapsto (x' + \nu^{1/2}y', z').
$$

The condition $\gamma \in U_{3, r}(F)$ implies that the eigenvalues satisfies $\lambda_1, \lambda_3 \in U_{1, E'/F'}(F)$, and $\lambda_2 \in U_{1, E/F}(F)$. In particular, since $\nu(\nu) = 1$, we have $\nu(x) = 0$ and $\nu(y) \in \mathbb{Z}_{\geq 0}$.

For compatibility, the valuation on $E'$ will be normalized so that $\nu_{E'}(\varpi) = 1$ throughout. Note that different from the previous types, the invariant $M_{13} = \nu(y) + \frac{1}{2}$ is a positive half-integer here (while $M_{12}$ and $M_{23}$ are in $\mathbb{Z}$ as before).

The main result for this section will be stated now.

**Theorem 6.1.** When $\gamma \in T_{\varpi} \cup T_{\xi^2\varpi}$,

1. When $M_{13} = \frac{1}{2}$,

$$O_{\gamma_\mu}(\mathbb{I}_{S(O_F)}) = \frac{1}{4}.$$

2. When $M_{13} > M_{12} = 0$,

$$O_{\gamma_\mu}(\mathbb{I}_{S(O_F)}) = \frac{1}{4}(M_{13} + \frac{1}{2}).$$

3. When $M_{13} > M_{12} > 0$,

$$O_{\gamma_\mu}(\mathbb{I}_{S(O_F)}) = \frac{1}{4}\left(\left(\left(-\frac{M_{12}}{2}\right) + \left(-\frac{M_{12}}{2}\right) + 2\right) \frac{M_{12}}{q-1} + (M_{13} - M_{12} + \frac{1}{2} + d(M_{12}, 1))(\frac{M_{12}}{q-1} + 2 \cdot \frac{M_{12}}{q-1})\right).$$

Let $\kappa_\nu \in \mathcal{D}(F, G_{1\gamma}, G_1)^* \simeq \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ be the unique nontrivial character so that $\kappa_\nu(\gamma_\mu) = 1$.
Theorem 6.2. Suppose $\gamma \in T_\varpi \cup T^{2\varpi}_\varpi$. Let $\kappa_\gamma$ be defined as in §1. Then $SO_\gamma^c(1_S(\mathcal{O}_F)) = 0$ unless $\kappa = \kappa_\nu$. When that is the case, the endoscopic orbital integrals are computed as follows:

1. When $M_{13} = \frac{1}{2}$,
   \[ SO_\gamma^c(1_S(\mathcal{O}_F)) = 0. \]

2. When $M_{13} > M_{12} = 0$,
   \[ SO_\gamma^c(1_S(\mathcal{O}_F)) = 0. \]

3. When $M_{13} > M_{12} > 0$,
   \[ SO_\gamma^c(1_S(\mathcal{O}_F)) = \frac{g^{M_{12}} - 1}{q - 1}. \]

Proof. It follows directly from Theorem 6.1. Note that
\[ \sum_{\mu} \kappa_\nu(\mu)(\left(\left(\frac{-\mu z_y}{F}\right) + \left(\frac{-\mu z_y}{F}\right) + 2\right) = 1. \]

We now begin the proof of Theorem 6.1.

When $m > k$, by Lemma 3.4, we know that the $x$-coefficient equations in (3.9) implies that
\[ 2k \geq 2m - M_{12} - M_{23} - N_{13}. \]

Recall characteristic equations inside the integral of Lemma 3.5 are
\[ v(\mu + z_y u^2 - \frac{1}{2} \mu^{-1} \nu u^4) \geq 2m - M_{13} + \frac{1}{2}, \]
\[ v(\mu - \frac{1}{2} \mu^{-1} \nu u^4) \geq m + k - M_{13} + \frac{1}{2}. \]

6.1. Case (1). Suppose $M_{13} = \frac{1}{2}$.

Proof of (1) In this case $y \in \mathcal{O}_E^\times$ and there does not exist nontrivial solution for (6.2) when $m > k$: since $2k \geq v(\mu)$ by (3.3), we have $m + k > v(\mu)$ and so
\[ u^4 \equiv 4 \mu^2 \nu^{-1} \pmod{\varpi^{m+k+v(\mu)-1}} \]
with the right-hand side nonzero. A solution $u \in F$ does not exist because $\nu^{1/2} \notin F$. Thus $O_{\gamma_\mu}(1_S(\mathcal{O}_F)) = M_{13} + \frac{1}{2} = 1$.

Assume for the rest of the section that $M_{13} > \frac{1}{2}$. In this case (6.1) will be written as
\[ v \left( (u^2 + 2 \nu^{-1} \mu z_y)^2 - 4 \mu^2 \nu^{-2}(z_y^2 - \nu) \right) \geq 2m - M_{13} + v(\mu) - \frac{1}{2}. \]
Analogously, \((6.2)\) is written as
\[
v(u^4 - 4\mu^2\nu^{-1}) \geq m + k - M_{13} + v(\mu) - \frac{1}{2}.
\] \(6.2\)

By Lemma 3.4, we know that
\[
v(z_y^2 - \nu) = N_{12} + M_{12} + N_{23} + M_{23} - 2M_{13} + 1.
\]

Since \((\lambda_1 + \lambda_2) - (\lambda_i - \lambda_2) = 2z \in \mathcal{O}_E^\times\), at least one of \(M_{12}\) or \(N_{12}\) vanishes for \(i = 1\) and 3. Moreover, since \((\lambda_1 - \lambda_2) + (\lambda_2 - \lambda_3) = (\lambda_1 + \lambda_2) - (\lambda_2 + \lambda_3) = 2\nu^{1/2}y\) is of positive valuation.

In terms of \(M_{ij}\), the possible scenarios are:

(a) Either \(M_{12} = M_{23} = 0\), or

(b) both \(M_{12}\) and \(M_{23}\) are positive.

On the other hand, in (b) we have \(N_{12} = N_{23} = 0\) because the eigenvalues lies in \(\mathcal{O}_E^\times\), and \(M_{12} + N_{12} = 2\lambda_i\) for \(i = 1\) or 3. Note that we have also assumed that \(M_{13} > \frac{1}{2}\) and so \(N_{13} = 0\).

6.2. Case (2). Suppose \(M_{13} > M_{12} = 0\).

For case (a), since there does not exist \(k\) so that \(2m > 2k \geq 2m - M_{12} - M_{23}\),
\[
\mathcal{O}_{gy}(1_S(\mathcal{O}_F)) = M_{13} + \frac{1}{2}
\]
by Lemma 3.5.

In case (b), by assumption we have \(N_{12} = N_{23} = 0\). Thus \(v(z_y^2 - \nu) = M_{12} + M_{23} - 2M_{13} + 1\).

Lemma 6.3. Following the notation in this section, we have
\[
M_{13} \geq M_{12} = M_{23} \geq 0.
\]

Proof. Since \(\nu^{1/2}\) is of half-integer valuation, any cancellation in the valuations of the difference \(\lambda_1 - \lambda_2\) or \(\lambda_2 - \lambda_3\) can only occur on the \(x\)-coefficients. However, the \(x\)-coefficients of \(\lambda_1\) and \(\lambda_3\) are identical. Thus \(M_{12} = M_{23}\) and the conclusion follows.

By the Lemma above, we know that there is essentially only one available ordering for \(M_{ij}\) since \(M_{13}\) is an half-integer left.

6.3. Case (3). Suppose \(M_{13} > M_{12} > 0\).

Under the assumption, we have \(v(z_y^2 - \nu) = 2M_{12} - 2M_{13} + 1 < 0\) and so \(v(z_y) = M_{12} - M_{13} + \frac{1}{2} < 0\). We will specify on the different domains for the indices \(m\) and \(k\) to be chosen from. The choice respects the congruences to solve. Before that, we state a lemma analogous to Lemma 4.5.

Lemma 6.4. If \(M_{13} > M_{12} > 0\), we know that \(z_y^2 - \nu\) is a square in \(F^\times\). Moreover, one of \(v(z_y \pm \sqrt{z_y^2 - \nu})\) equals \(M_{12} - M_{13} + \frac{1}{2}\), and the other valuation equals \(M_{13} - M_{12} + \frac{1}{2}\).
**Proof.** For the first assertion, it suffices to note that \( z_y^2 - \nu \in F \) and the leading coefficient of \( z_y^2 - \nu \) is the same as that of \( z_y^2 \) by omitting terms of higher valuation.

Given the existence of \( \sqrt{z_y^2 - \nu} = v(\sqrt{z_y^2 - \nu}) = v(z_y) \). Since \( \text{char } F \neq 2 \), at least one of the above must has valuation of \( z_y \), which is \( M_{12} - M_{13} + \frac{1}{2} \).

The key observation leading to the last assertion here is that

\[
(z_y + \sqrt{z_y^2 - \nu})(z_y - \sqrt{z_y^2 - \nu}) = \nu
\]

and so \( v(z_y + \sqrt{z_y^2 - \eta}) + v(z_y - \sqrt{z_y^2 - \eta}) = 1 \). \( \square \)

We will separate the discussion into three cases:

- **(A)** \( m > k \) and \( m + k > M_{13} + v(\mu) - \frac{1}{2} \).
- **(B)** \( m > k \), \( m + k \leq M_{13} + v(\mu) - \frac{1}{2} \), and \( 2m > 2M_{12} - M_{13} + v(\mu) - \frac{1}{2} \).
- **(C)** \( m > k \), \( m + k \leq M_{13} + v(\mu) + \frac{1}{2} \), and \( 2m \leq 2M_{12} - M_{13} + v(\mu) - \frac{1}{2} \).

### 6.3.1. Contribution from (A).

As before, in this case (6.2) has no solution \( u \in F \) because \( \nu \) is not a square in \( F \). Therefore this part does not contribute in the orbital integral.

### 6.3.2. Contribution from (B).

From (6.2) we derive that

\[
4k \geq m + k - M_{13} + v(\mu) - \frac{1}{2}.
\]

Consider (6.1). When \( 2m > 2M_{12} - M_{13} + v(\mu) - \frac{1}{2} \), we have

\[
v \left( u^2 + 2\mu\nu^{-1}(z_y + \sqrt{z_y^2 - \nu}) \right) \geq 2m - M_{12}.
\]

For convenience on the notation, we will fix the choice of square roots on \( \sqrt{z_y^2 - \nu} \) so that \( z_y + \sqrt{z_y^2 - \nu} \) has valuation \( M_{12} - M_{13} + \frac{1}{2} \) (see Lemma 6.4).

After the choice of the square root is fixed, consider the equation

\[
v \left( u^2 + 2\mu\nu^{-1}(z_y + \sqrt{z_y^2 - \nu}) \right) \geq 2m - M_{12}.
\]

Note that in particular

\[
v \left( 2\mu\nu^{-1}(z_y + \sqrt{z_y^2 - \nu}) \right) = M_{12} - M_{13} + v(\mu) - \frac{1}{2} < 2m - M_{12}.
\]

The leading coefficient of \(-2\mu\nu^{-1}(z_y + \sqrt{z_y^2 - \nu})\) is the same as which of \(-4\nu^{-1}\mu z_y\). Thus it can only be a square when \( \mu \) is chosen so that \( \left( \frac{-\mu z_y}{F} \right) = 1 \).

Suppose that \( \mu \) is fixed so that \( \left( \frac{-\mu z_y}{F} \right) = 1 \). Then

\[
k = \frac{1}{2} (M_{12} - M_{13} + v(\mu) - \frac{1}{2})
\]

and \( u \) is pairwise determined up to any element in \( \mathbb{O}_F^{2m-M_{12}-k} \).

---

**ENDOSCOPIC RELATIVE ORBITAL INTEGRALS ON U_3**

49
\( m \) satisfies
\[
M_{13} - k + v(\mu) - \frac{1}{2} \geq m,
3k + M_{13} - v(\mu) + \frac{1}{2} \geq m,
\]
\[
k + M_{12} \geq m,
\]
\[
m > k,
2m > -M_{13} + v(\mu) - \frac{1}{2},
2m > 2M_{12} - M_{13} + v(\mu) - \frac{1}{2}.
\]

When plug in \( k \), we notice that the second inequality implies both the first and the third. Likewise, the last inequality implies both the fourth and the fifth.

Thus with a proper substitution,
\[
2k + 2M_{12} \geq 2m > 2k + M_{12}.
\]

Since \( u \) is determined in pairs up to \( \varpi^{2m-M_{12}-k}O_F \), the contribution of this part to the orbital integral is
\[
\left( \left( -\frac{\mu z_y}{\varpi} \right) + 1 \right) \sum_m q^{k-m+M_{12}} = \left( \left( -\frac{\mu z_y}{\varpi} \right) + 1 \right) q^{\frac{M_{12}}{2}} \left( \frac{q}{q-1} \right) - 1 \] (6.1)

because
\[
\frac{M_{12}}{2} > k - m + M_{12} \geq 0.
\]

On the other hand, if we consider
\[
v \left( u^2 + 2v^{-1} \mu (z_y - \sqrt{z_y^2 - \nu}) \right) \geq 2m - M_{12},
\]
then the discussion would depend upon the ordering of
\[
M_{13} - M_{12} + v(\mu) - \frac{1}{2} \quad \text{and} \quad 2m - M_{12}.
\]

Assume \( 2m > M_{13} + v(\mu) - \frac{1}{2} \). Then
\[
v(2v^{-1} \mu (z_y - \sqrt{z_y^2 - \nu}) \geq 2m + M_{12}.
\]

Since the leading coefficient of \( z_y - \sqrt{z_y^2 - \eta} \) is the same as that of \( \frac{\mu}{2z_y} \) (see the argument in the proof of Lemma 6.4), we have a solution for \( u \) only when \( \left( -\frac{\mu z_y}{\varpi} \right) = 1 \). If that happens to be the case, we know that \( k = \frac{1}{2} \left( M_{13} - M_{12} + v(\mu) - \frac{1}{2} \right) \) and \( u \) is determined pairwise up to \( \varpi^{2m-M_{12}-k}O_F \).

The inequalities for \( m \) to satisfy again simplifies to
\[
2k + 2M_{12} \geq 2m > 2k + M_{12}.
\]
and this part contributes

\[
((\frac{-\mu z}{p}) + 1) q^{\frac{M_{12} - 2}{2}}_{q - 1}^{-1}
\]

(6.2)
to the orbital integral.

For the situation when \(2m \leq M_{13} + v(\mu) - \frac{1}{2}\), we have

\[2k \geq 2m - M_{12}.\]

\(m\) satisfies

\[M_{13} + v(\mu) - \frac{1}{2} \geq 2m > 2M_{12} - M_{13} + v(\mu) - \frac{1}{2}.\]

For any \(m\) fixed, we have

\[2m > 2k \geq 2m - M_{12}.\]

As a result, this part of the computation sums to

\[
\sum_{m} \sum_{k = m - \lfloor \frac{M_{13}}{2} \rfloor}^{m-1} q^{m-k}(1 - q^{-1}) = \sum_{m} (q^{\lfloor \frac{M_{13}}{2} \rfloor} - 1)
\]

\[= (M_{13} - M_{12} - \frac{1}{2} + d(M_{13} - \frac{1}{2}, \mu))(q^{\lfloor \frac{M_{13}}{2} \rfloor} - 1).\]

(6.3)

6.3.3. **Contribution from (C).** From (6.2) we derive that

\[4k \geq m + k - M_{13} + v(\mu) - \frac{1}{2}.\]

We assumed \(2m \leq 2M_{12} - M_{13} + v(\mu)\), so (6.1) becomes

\[2v(u^2 + 2\mu v^{-1}z_y) \geq 2m + M_{13} + v(\mu) - \frac{1}{2}.\]

Or equivalently,

\[2k \geq m + \frac{M_{13}}{2} + \frac{v(\mu)}{2} - \frac{1}{4}.\]

\(m\) satisfies

\[2M_{12} - M_{13} + v(\mu) - \frac{1}{2} \geq 2m > -M_{13} + v(\mu) - \frac{1}{2}.\]

Meanwhile, for \(m\) fixed, \(k\) satisfies

\[M_{13} - m + v(\mu) - \frac{1}{2} \geq k\]

\[m > k\]

\[3k \geq m - M_{13} + v(\mu) - \frac{1}{2}\]

\[k \geq m - M_{12}\]

\[2k \geq m + \frac{M_{13}}{2} + \frac{v(\mu)}{2} - \frac{1}{4}.\]
Thus the domain of \( k \) is therefore given by

\[
4m > 4k \geq 2m - M_{13} + v(\mu) - \frac{1}{2}.
\]

As a result, this part of the computation sums to

\[
\sum_m \sum_k q^{m-k}(1-q^{-1}) = \sum_m (q^{\frac{2m+M_{13} - v(\mu) + 1/2}{4}} - 1)
\]

\[
= \sum_l q^{\lfloor \frac{l}{2} \rfloor} - M_{12} + d(M_{13} - \frac{1}{2}, \mu)
\]

\[
= 2 \cdot q^{\lfloor \frac{M_{12}/2}{q-1} \rfloor} - 1 + \left( 1 + d(M_{12}, 1) - d(M_{13} - \frac{1}{2}, \mu) \right) q^{\lfloor \frac{M_{12}/2}{q-1} \rfloor} - M_{12} + d(M_{13} - \frac{1}{2}, \mu).
\]

(6.4)

Note that the index \( l \) in the sum ranges over \( M_{12} - d(M_{13} - \frac{1}{2}, \mu) \geq l > 0 \).

Suppose \( M_{13} > M_{12} > 0 \). Then as computed above we can plug (6.1) - (6.4) into Lemma 3.5.

That gives

\[
O_{\gamma_\nu}(1_{S(O_F)}) = \frac{1}{4} \left( \left( -\frac{\mu \nu z y F}{\mu} \right) + \left( -\frac{\mu z y F}{\mu} \right) + 2 \cdot \frac{M_{12}}{q-1} - 1 + (M_{13} - M_{12} + \frac{1}{2} + d(M_{12}, 1)) q^{\frac{M_{12}}{2}} + 2 \cdot \frac{M_{13}}{q-1} - \right).
\]
