1. Introduction

The theory of $p$-adic representations of $p$-adic Lie groups has a long history and it has played a key role in the field of Number Theory during the last decades, as witnessed, e.g., in the study of the $p$-adic Langlands correspondence [Col10], [CDP14].

In this article, we intend to reformulate the theory of locally analytic representations of $p$-adic Lie groups as developed in [ST02], [ST01], [ST03], [ST05], [Eme17], using the theory of condensed mathematics developed by Clausen and Scholze. We define and study the notions of analytic and locally analytic representations of $p$-adic Lie groups on solid modules. One of our main new results, which was the departing point of our investigations, is a generalisation of Lazard’s comparison theorem [Laz65] between continuous and locally analytic cohomology of a finite dimensional representation of a compact $p$-adic Lie group over $\mathbb{Q}_p$.

References
to arbitrary solid locally analytic representations. Generalisations of Lazard’s comparison between locally analytic and Lie algebra cohomology have already been considered in [HN11], [Lec12], [Tam15]. We also give, following the lines of [Tam15], a proof of this result in the solid context. Our second main new result is a comparison between continuous cohomology of solid representation and the continuous cohomology of its locally analytic vectors. This results can be seen as a $p$-adic analogue of a theorem of G. D. Mostow [Mos61] and P. Blanc [Bla79].

1.1. Background. Let $p$ be a prime number and $G$ a compact $p$-adic Lie group. The theory of $p$-adic representations of $G$ comes in different flavours: one has the notion of continuous, analytic and locally analytic representations $V$ of $G$ according to whether the orbit map $o_V : G \to V, g \mapsto g \cdot v$ ($v \in V$ fixed) is a continuous, resp. analytic, resp. locally analytic function of the $p$-adic variety $G$.

One usual way of studying such representations is through their cohomology. In a good situation, the cohomology groups are Ext-groups in certain abelian categories. For instance, one defines the cohomology of an abstract group $H$ by working on the abelian category of $\mathbb{Z}[H]$-modules: if $M$ is an $H$-module, the cohomology groups $H^i(H, M)$ are by definition $\text{Ext}^i_{\mathbb{Z}[H]}(\mathbb{Z}, M)$, where $\mathbb{Z}$ denotes the trivial representation.

In the case where $V$ is a continuous representation of $G$, it is natural to consider continuous group cohomology. Unfortunately, the category of topological abelian groups is not abelian. The absence of a good formalism leads to ad-hoc definitions and conditions to get some basic results. For instance, the restriction to strict short exact sequences in order to obtain a long exact sequence in cohomology, or the necessity of proving by hand certain results such as Hochschild-Serre’s spectral sequence (cf. [Ser94]), which would otherwise be formal consequences of a well behaved theory.

A possible way to remedy this issue is to cut out some subcategory of objects which is better behaved. Let us focus on a case of special interest to us. Let $K$ be a finite extension of $\mathbb{Q}_p$. The category of locally analytic representations of $G$ is not abelian. But one can consider the subcategory of admissible locally analytic representations [ST03]. These objects carry a natural topology and form an abelian category.

The theory of condensed mathematics developed by Clausen and Scholze [Sch19], [Sch20], [CS] also provides a natural approach to deal with these kind of difficulties. Very vaguely, the condensed objects in a category $\mathcal{C}$ can be defined as sheaves on the proétale site of a point with values in $\mathcal{C}$. It is shown in [Sch19] that the category of condensed abelian groups is an abelian category satisfying Grothendieck’s axioms. Hence, one is on a good footing for doing homological algebra. Notice that, as opposed to the approach described in the previous paragraph, this one consists not in imposing restrictions but rather enlarging the universe where several topological problems disappear, thus giving a very general theory.

1.2. Statement of the main results. Let us now describe with some more detail what is carried out in this article.

1.2.1. Solid non-archimedean functional analysis. Let $K$ be a finite extension of $\mathbb{Q}_p$. The field $K$ naturally defines a condensed ring which, moreover, has an analytic ring structure $K^\circ$ in the sense of [Sch19], usually called the solid ring structure on $K$. We let $\text{Mod}^\text{solid}_K$ be the category of solid $K$-vector spaces. This category is stable under limits, colimits and extensions, it has a tensor product $\otimes_K^\text{solid}$ and an internal Hom denoted by $\text{Hom}_K^\text{solid}(-, -)$ [CS]. Let us point out that all the important spaces in the classical theory of non-archimedean functional analysis [Sch02] live naturally in $\text{Mod}^\text{solid}_K$. Indeed, there is a natural functor

$$\mathcal{L}C_K \to \text{Mod}^\text{solid}_K$$

(1)

from the category of complete locally convex $K$-vector spaces to solid $K$-vector spaces, as any complete locally convex $K$-vector space can be written as a cofiltered limit of Banach spaces. Moreover, it is fully faithful on a very large class of complete locally convex $K$-vector spaces, e.g. all compactly generated ones, e.g. all metrizable ones. The main notions of the theory of condensed non-archimedean functional analysis

---

1In particular, to any complete compactly generated locally convex vector space, e.g. metrizable.
we use are due to Clausen and Scholze [Sch19, CS, Bos21]. All the vector spaces considered in this text are solid $K$-vector spaces, unless otherwise specified.

Our first result is an anti-equivalence between two special families of solid $K$-vector spaces. Let us first give some definitions. A Smith space is a $K$-vector space of the form $\text{Hom}_K(V,K)$, where $V$ is a Banach space. In classical terms, a Smith space is the dual of a Banach space equipped with the compact-open topology. An LS space is a countable filtered inductive limit of Smith spaces with injective transition maps. We then have the following result.

**Theorem 1.1** (Theorem 3.30). The functor $V \mapsto V^\vee := \text{Hom}_K(V,K)$ induces an anti-equivalence between Fréchet and LS spaces such that $\text{Hom}_K(V,V^\vee) = \text{Hom}_K(V^\vee,V^\vee)$.

**Remark 1.2.** The previous theorem restricts in particular to an anti-equivalence between classical nuclear Fréchet spaces and $LB$ spaces of compact type (see, e.g., [ST02, Theorem 1.3]).

1.2.2. **Representation theory.** Let $G$ be a compact $p$-adic Lie group. A representation of $G$ on a solid $K$-vector space $V$ is a map of condensed sets $G \times V \to V$ satisfying the usual axioms. Define the Iwasawa algebra of $G$ with coefficients in $K$ as $K[[G]]$; explicitly,

$$K[[G]] = \left( \lim_{\rightarrow} O_K[G/N] \right)[1/p],$$

where $N$ runs over all the open normal subgroups of $G$. This is the solid algebra defined by the classical Iwasawa algebra endowed with the weak topology. The category of $G$-representations on solid $K$-vector spaces is equivalent to the category $\text{Mod}_{K[[G]]}^{\text{solid}}$ of solid $K[[G]]$-modules. Observe that the category of continuous representations of $G$ on complete locally convex $K$-vector spaces lives naturally in $\text{Mod}_{K[[G]]}^{\text{solid}}$ via the functor (1).

Inspired by Emerton’s treatment [Eme17], we define analytic and locally analytic vectors of solid representations of $G$. Roughly speaking, they are defined as those vectors whose induced orbit map is analytic or locally analytic. One advantage of our approach is that definitions make sense at the level of derived categories, so one can speak about derived (locally) analytic vectors of complexes $C \in D(K[[G]])$ in the derived category of $K[[G]]$-modules. The derived functors of the locally analytic vectors (for Lie groups over finite extensions of $\mathbb{Q}_p$) for admissible representations have been considered in [Sch09].

More precisely, let $G$ be an analytic affinoid group over $\text{Spa}(\mathbb{Q}_p, \mathbb{Z}_p)$ such that $G = \mathcal{G}(\mathbb{Q}_p, \mathbb{Z}_p)$ and suppose in addition that $G$ is isomorphic to a finite disjoint union of polydiscs. In practice, the group $G$ will be constructed using some local charts of $G$, see Remark 1.4 below for a more detailed description. Let $C(G,K) := \mathcal{O}(G) \otimes_K K$ be the algebra of functions of $G$. The affinoid algebra $C(G,K)$ has a natural analytic ring structure denoted by $C(G,K)[\mathbf{a}]$, see [And21]. We denote by $D(G,K) = \mathcal{O}(G)^\vee \otimes_{\mathbb{Q}_p} K$ the distribution algebra of the affinoid group $G$. We define the derived $G$-analytic vectors of an object $C \in D(K[[G]])$ to be the complex

$$C^{RG-an} := R\text{Hom}_{K[[G]]}(K,C \otimes_K C(G,K)[\mathbf{a}])$$

(2)

where $K$ is the trivial representation, and the $G$-action on $C \otimes_K C(G,K)[\mathbf{a}]$ is the diagonal one induced by the action on $C$ and the left regular action on $C(G,K)$. We endow $C^{RG-an}$ with the regular action of $G$. It turns out that there is a natural map $C^{G-an} \to C$, and we say that $C$ is derived $G$-analytic if this map is a quasi-isomorphism. If $V$ is a Banach $G$-representation, then $V \otimes_K C(G,K)[\mathbf{a}] = V \otimes_K C(G,K)$ coincides with the projective tensor product of Banach spaces. Thus, our definition of derived $G$-analytic vectors is the derived extension of [Eme17, Definition 3.3.13].

Now let $\mathcal{G}$ be a Stein analytic group over $\text{Spa}(\mathbb{Q}_p, \mathbb{Z}_p)$ such that $G = \mathcal{G}(\mathbb{Q}_p, \mathbb{Z}_p)$. Suppose in addition that $\mathcal{G} = \bigsqcup_h \mathcal{G}^{(h)}$ is written as an increasing union of affinoid groups $\mathcal{G}^{(h)}$, where each $\mathcal{G}^{(h)}$ is as in the previous paragraph. In practice, $\mathcal{G}$ will be as in Remark 1.4 below. We also denote by $D(\mathcal{G}, K) := \mathcal{O}(\mathcal{G})^\vee \otimes_{\mathbb{Q}_p} K = \ldots$  

\footnote{The tensor product $\otimes_K C(G,K)[\mathbf{a}]$ is the derived base change of modules over analytic rings, see [Sch19, Proposition 7.7].}
of Theorems 1.1 and 1.3 to the study of the cohomology of continuous representations.

1.2.3. Comparison theorems in cohomology.

Type, this is nevertheless true, and was already known by [ST 02].

D the analogous statement of Theorem 1.3 does not hold in general for locally analytic representations and

Now let \( D \) be a Stein group neighbour-

of the group (e.g. Example 4.5). Using this chart, one can define for any \( h \in \mathbb{Q}_{>0} \) an affinoid groups \( \mathbb{G}^{(h)} \) in such a way that the \( p^h \)-analytic functions on \( \mathbb{Z}_p \) coincide with the rigid functions on \( \mathbb{G}^{(h)} \) after taking pullbacks by \( \phi \). In this situation, the \( \mathbb{G}^{(h)} \)-analytic vectors are those whose orbit map is \( p^h \)-analytic. Given \( h > 0 \), the group \( \mathbb{G}^{(h+)} := \bigcup_{h'>h} \mathbb{G}^{(h')} \) is a Stein group. In the definition of derived analytic vectors of equations (2) and (3) we will take \( \mathbb{G} = \mathbb{G}^{(h)} \) and \( \mathbb{G}^{(h+)} \). The locally analytic functions on \( G \) are

\[
C^{\text{la}}(G, K) = \lim_{h \to +\infty} C(\mathbb{G}^{(h)}, K) = \lim_{h \to +\infty} C(\mathbb{G}^{(h+)}, K).
\]

Now let \( D^{\text{la}}(G, K) = (C^{\text{la}}(G, K))^\vee \) be the algebra of locally analytic distributions. We point out that the analogous statement of Theorem 1.3 does not hold in general for locally analytic representations and \( D^{\text{la}}(G, K) \)-modules. In the particular case of locally analytic representations on LB spaces of compact type, this is nevertheless true, and was already known by [ST 02].

1.2.3. Comparison theorems in cohomology. We finish this introduction by describing the main applications of Theorems 1.1 and 1.3 to the study of the cohomology of continuous representations.

For \( C \in D(K\mathbb{G}[G]) \), we define the solid group cohomology of \( C \) to be the complex

\[
\text{RHom}_{K\mathbb{G}}(K, C).
\]

Let \( \mathfrak{g} \) be the Lie algebra of \( G \) and \( U(\mathfrak{g}) \) its universal enveloping algebra. Let \( \mathbb{G} \) be a Stein group neighbourhood of \( G \) as in Theorem 1.3 and \( D(\mathbb{G}, K) \) the distribution algebra of \( \mathbb{G} \). If in addition \( C \) is \( \mathbb{G} \)-analytic, we define the \( \mathbb{G} \)-analytic cohomology of \( C \) as \( \text{RHom}_{D(\mathbb{G}, K)}(K, C) \), and its Lie algebra cohomology to be \( \text{RHom}_{U(\mathfrak{g})}(K, C) \). Using Bar resolutions and Theorem 1.3 one verifies that these definitions recover the usual continuous, analytic, and Lie algebra cohomology groups.

Our first new result compares continuous cohomology of a solid representation and the continuous cohomology of its locally analytic vectors. This result can be seen as a \( p \)-adic analogue of a theorem of P. Blanc [Bla79] and G. D. Mostow [Mos61] in the archimedean setting, which compares continuous and differentiable cohomology of a real Lie group \( G \).

Let \( C \in D(K\mathbb{G}[G]) \), we define the derived locally analytic vectors of \( C \) as the homotopic colimit

\[
C^{\text{Rla}} = \text{hocolim}_{\mathbb{G}} C^{\text{RG} \rightarrow \text{an}}
\]

where \( \mathbb{G} \) runs over all the affinoid neighbourhoods of \( G \). We say that \( C \) is derived locally analytic if \( C^{\text{Rla}} = C \). If \( V \) is a Banach representation, then \( H^0(V^{\text{Rla}}) \) coincides with the locally analytic vectors of \( V \) in the sense of [Eme17, Definition 3.5.3]. We have the following theorem.
Theorem 1.5 (Theorem [5.2]). Let $C \in D(K\llbracket G\rrbracket)$ and let $C^{\text{Rla}}$ be the complex of derived locally analytic vectors of $C$. Then
\[ R\text{Hom}_{K\llbracket G\rrbracket}(K, C) \cong R\text{Hom}_{K\llbracket G\rrbracket}(K, C^{\text{Rla}}). \]
In particular, if $V \in \text{Mod}_{K\llbracket G\rrbracket}^{\text{solid}}$ then, setting $V^{\text{Rla}} := H^i(V^{\text{Rla}})$ for $i \geq 0$ there is a spectral sequence of solid $K$-vector spaces
\[ E_2^{i,j} := \text{Ext}^i_{K\llbracket G\rrbracket}(K, V^{\text{Rla}}) \Rightarrow \text{Ext}^{i+j}_{K\llbracket G\rrbracket}(K, V). \]

We give an application in the classical context. Let $V$ be a continuous representation of $G$ on a complete locally convex $K$-vector space. Denote $H^i_{\text{cont}}(G, V)$ the usual continuous cohomology groups. These coincide with the underlying sets of the solid cohomology groups $\text{Ext}^i_{K\llbracket G\rrbracket}(K, V)$. We say that $V$ has no higher locally analytic vectors if $V^{\text{Rla}} = 0$ for all $i > 0$. This is the case for admissible representations (cf. [Pan21] or Proposition [4.43]). One deduces the following corollary.

Corollary 1.6. If $V$ has no higher locally analytic vectors, then for all $i \geq 0$,
\[ H^i_{\text{cont}}(G, V) = H^i_{\text{cont}}(G, V^{\text{la}}). \]

Our last result concerns a generalisation of Lazard’s comparison between continuous, (locally) analytic and Lie algebra cohomology from finite dimensional representations $V$ to arbitrary solid derived (locally) analytic representations. We have the following theorem.

Theorem 1.7 (Continuous vs. analytic vs. Lie algebra cohomology, Theorem [5.4]). Let $C \in D(K\llbracket G\rrbracket)$ be a derived $G$-analytic complex. Then\[ R\text{Hom}_{K\llbracket G\rrbracket}(K, C) \cong R\text{Hom}_{D(G, K)}(K, C) \cong (R\text{Hom}_{U(G)}(K, C))^G. \]

1.3. Organization of the paper. In Section 2 we review very briefly the theory of condensed mathematics and solid abelian groups. We recall the notion of analytic ring and give some examples that will be used throughout the text.

In Section 3 we develop the theory of solid $K$-vector spaces following the appendix of [Bos21]. Most of the results exposed in this section will be presented in the forthcoming work [CS]. We review in particular the main properties of classical vector spaces: Banach, Fréchet, $LB$ and $LF$ spaces. Our main original result is Theorem 1.1 generalising the classical anti-equivalence between $LB$ spaces of compact type and nuclear Fréchet vector spaces.

In Section 4 we introduce the different analytic neighbourhoods $G^{(h)}$ of our $p$-adic Lie group $G$. We begin in §4.1 by introducing spaces of analytic functions, following [Eme17] closely. Then, we define the algebras of distributions as the duals of the spaces of analytic functions. We also introduce another class of distribution algebras, used already in [ST03], which are more adapted to the coordinates of the Iwasawa algebra. In §4.3 we define the notion of analytic and derived analytic representation, we prove Theorem 1.3 except for a technical lemma whose proof is postponed to Section 5. We finish the section with some applications to locally analytic and admissible representations.

Finally, in Section 5 we recall (Theorem 5.6) a lemma of Serre used by Lazard to construct finite free resolutions of the trivial representation when $G$ is a uniform pro-$p$-group. We use this result, as well as its enhancement due to Kohlhaase (Theorem 5.7) to prove the technical lemma necessary for Theorem 1.3. We state Theorems 1.5 and 1.7 in §5.2 and give a proof in §5.4.

1.4. Acknowledgements. The authors learnt the theory of non-archimedean functional analysis from Guido Bosco in the context of a study group held in La Tourette, November 2020. We would like to express our gratitude to Guido for this, and for sharing with us his notes and an earlier version of [Bos21]. We would also like to thank all the other participants of La Tourette, from whom we have profited from several fruitful conversations. Special thanks to Andreas Bode, George Boxer, Antonio Cauchi, Arthur-César Le

\[ R\text{Hom}_{U(G)}(K, C) \text{ lands naturally in the derived category of smooth representations of } G \text{ on solid } K\text{-vector spaces. Since } K \text{ is of characteristic } 0, \text{ taking } G\text{-invariants in this category is exact and the superscript } G \text{ means the composition with this functor, cf. Remark 6.3.} \]
Bras and Vincent Pilloni, for their comments and careful corrections of an earlier version of this paper. We also thank Gabriel Dospinescu for his interest and several useful comments regarding our cohomological comparison results, and Lucas Mann for sharing with us some sections of his Ph.D. thesis. Finally, we thank Peter Scholze for his many comments and corrections. The first named author was supported by the ERC-2018-COG-818856-HiCoShiVa.

2. RECOLLECTIONS IN CONDENSED MATHEMATICS

First, we review some elementary notions in condensed mathematics: we recall the definitions of condensed sets, solid abelian groups and analytic rings. In the future we will be only interested in the categories of solid modules, and modules of analytic rings over $\mathbb{Z}_\mathfrak{m}$.

2.0.1. Condensed objects. In their recent work [Sch19] and [Sch20], Clausen and Scholze have introduced the new world of condensed mathematics, which aims to be the good framework where algebra and topology live together. Roughly speaking, a condensed set/group/ring is a sheaf in sets/groups/rings in the pro-étale site of a geometric point $\ast_{\text{proet}}$. It is equivalent to the category of profinite sets and continuous maps, with coverings given by finitely many continuous maps which are jointly surjective.

**Definition 2.1** ([Sch19 Definitions 2.1 and 2.11]). A condensed set/group/ring/... $\mathcal{F}$ is a sheaf over $\ast_{\text{proet}}$ with values in $\text{Sets}$, $\text{Groups}$, $\text{Rings}$,... We denote by Cond the category of condensed sets and CondAb that of condensed abelian groups. If $R$ is a condensed ring, we denote by $\text{Mod}^\text{cond}_R$ the category of condensed $R$-modules $\mathbb{4}$.

There is a functor from topological spaces to condensed sets whose restriction to the category of compactly generated Hausdorff topological spaces is fully faithful. First recall that a topological space $X$ is compactly generated if a map $X \to Y$ to another topological space $Y$ is continuous if and only if the composition $S \to X \to Y$ is continuous for all maps $S \to X$ from a compact Hausdorff space. A compact Hausdorff space can be written as a quotient of a profinite set. Indeed, if $S$ is a compact Hausdorff space, let $S_{\text{dis}}$ denote the underlying set with the discrete topology, and $\beta S_{\text{dis}}$ its Stone-Čech compactification. Then $\beta S_{\text{dis}}$ is profinite and the natural map $\beta S_{\text{dis}} \to S$ is a surjective map of compact Hausdorff spaces. In particular, we can test if a topological space is compactly generated by restricting to the profinite sets.

Let $\text{Top}$ denote the category of topological spaces, we define the functor $(_\ldots) : \text{Top} \to \text{Cond}$ mapping a topological space $T$ to the condensed set
\[
T : S \mapsto \mathbb{T}(S) = \text{Cont}(S, T)
\]
where $\text{Cont}(S, T)$ is the set of continuous functions from $S$ to $T$. Recall that a condensed set $X$ is called quasi-compact if there is a profinite set $S$ and a surjective map $S \to X$. Similarly, a condensed set $X$ is quasi-separated if for any pair of profinite sets $S$ and $S'$ over $X$ the fiber product $S \times_X S'$ is quasi-compact. From now on we identify a profinite set $S$ with the condensed set $S$. Given a condensed set $X$ and a profinite set $S$ we define $\text{Cont}(S, X)$ to be the condensed set whose value at a profinite set $S'$ is
\[
\text{Cont}(S, X)(S') = \text{Hom}_{\text{CondSet}}(S \times S', X) = X(S \times S').
\]
We have the following result.

**Proposition 2.2** ([Sch20 Proposition 1.2]). Consider the functor $T \mapsto \mathbb{T}$ from $\text{Top}$ to $\text{Cond}$

1. The functor has a left adjoint $X \mapsto X(\ast)_{\text{top}}$ sending any condensed set $X$ to the set $X(\ast)$ equipped with the quotient topology arising from the map
\[
\bigsqcup_{S, a \in X(S)} S \to X(\ast)
\]
with $S$ profinite.

2. Restricted to compactly generated topological spaces, the functor is fully faithful.

3. The functor induces an equivalence between the category of compact Hausdorff spaces and qcqs condensed sets.

$\mathbb{4}$There are set theoretical issues with this definition as $\ast_{\text{proet}}$ is not small, what [Sch19] does is to cut-off by a large cardinal $\kappa$, considering the category of sheaves of $\kappa$-small profinite sets $\ast_{\text{proet}}$ and take the direct limit. Hence the category of condensed sets is not the category of sheaves of a site.
(4) The functor induces a fully faithful functor from the category of compactly generated weak Hausdorff spaces, to quasi-separated condensed sets. The category of quasi-separated condensed sets is equivalent to the ind-category of compact Hausdorff spaces \( \lim_i T_i \) where all transition maps \( T_i \to T_j \) are closed immersions. If \( X_0 \to X_1 \to \cdots \) is a sequence of compact Hausdorff spaces with closed immersions and \( X = \lim_n X_n \) as topological spaces, then the map
\[
\lim_n X_n \to X
\]
is an isomorphism of condensed sets.

Among the class of profinite sets there is the special class of extremally disconnected sets, which are the projective objects in the category \( \ast_{\text{proet}} \). Moreover, all of them are retraction of a Stone-Čech compactification of a discrete set. Let \( \text{Extdis} \) denote the full subcategory of extremally disconnected sets. The condensed sets can be defined using only this kind of profinites

**Proposition 2.3** ([Sch19 Prop. 2.7]). Consider the site of extremally disconnected sets with covers given by finite families of jointly surjective maps. Its category of sheaves is equivalent to the category of condensed sets via the restriction from profinite sets. Hence, a condensed set is a functor
\[
\text{Cont} : \text{Extdis} \to \text{Sets}
\]
is an isomorphism. Moreover, the category of condensed abelian groups is generated by compact projective \( (\ast \to M) \) and colimits \( (\ast \leftarrow M) \). All of them are retractions of a Stone-Čech compactification of a discrete set.

**Theorem 2.4** ([Sch19 Theo. 2.2]). The category of condensed abelian groups is an abelian category which satisfies the Grothendieck axioms (\( AB_3 \)), (\( AB_4 \)), (\( AB_5 \)), (\( AB_6 \)), (\( AB_3^* \)) and (\( AB_4^* \)): all limits (\( AB_3^* \)) and colimits (\( AB_3 \)) exist, arbitrary products (\( AB_4^* \)), arbitrary direct sums (\( AB_4 \)) and filtered colimits (\( AB_5 \)) are exact, and (\( AB_6 \)): for all index sets \( J \) and filtered categories \( I_j, j \in J \), with functor \( i \mapsto M_i \), from \( I_j \) to condensed abelian groups, the natural map
\[
\lim_{(i_j \in I_j) \in J} \prod_{j \in J} M_{i_j} \to \prod_{j \in J} \lim_{i_j \in I_j} M_{i_j}
\]
is an isomorphism. Moreover, the category of condensed abelian groups is generated by compact projective objects given by \( \mathbb{Z}[S] \) with \( S \) an extremally disconnected set.

**2.0.2. Analytic rings.** Next, we recall the notion of analytic ring

**Definition 2.5** ([Sch19 Def. 7.1, 7.4 and Sch20 Def. 6.12]). A pre-analytic ring \( (\mathcal{A}, \mathcal{M}) \) is the data of a condensed ring \( \mathcal{A} \) (called the underlying condensed ring of the analytic ring) equipped with a functor
\[
\text{Extdis} \to \text{Mod}_{\mathcal{A}}^{\text{cond}}, \quad S \mapsto \mathcal{M}[S],
\]
called the functor of measures\(^5\) of \( (\mathcal{A}, \mathcal{M}) \), that sends finite disjoint union into products, and a natural transformation of functors \( S \to \mathcal{M}[S] \).

\(^5\)This terminology is justified as follows. If \( (\mathcal{A}, \mathcal{M}) \) is an analytic ring, \( P \) is an \( (\mathcal{A}, \mathcal{M}) \)-module, \( S \) is an extremally disconnected set, \( f \in \text{Cont}(S, P) \) and \( \mu \in \mathcal{M}[S] \) then, using the isomorphism \( \text{Hom}_{\mathcal{A}}(\mathcal{M}[S], P) = \text{Cont}(S, P) \), one can evaluate \( f \) at \( \mu \) and define \( \int f \cdot \mu = f(\mu) \in P \), which allows to see \( \mu \) as a linear functional on the space of functions \( f \in \text{Cont}(S, P) \).
A pre-analytic ring is said to be analytic, if for any complex \( C : \ldots \rightarrow C_i \rightarrow \ldots \rightarrow C_1 \rightarrow C_0 \rightarrow 0 \) of \( \mathcal{A} \)-modules such that each \( C_i \) is a direct sum of objects of the form \( \mathcal{M}[T] \) for varying extremally disconnected sets \( T \), the map

\[
R\text{Hom}_A(\mathcal{M}[S], C) \rightarrow R\text{Hom}_A(A[S], C)
\]

is an isomorphism for all extremally disconnected sets \( S \). An analytic ring \((A, \mathcal{M})\) is complete if \( A \rightarrow \mathcal{M}[\ast] \) is an isomorphism.

**Example 2.6.**

1. Solid modules ([Sch19, Theorem 5.8]). We define the analytic ring \( \mathbb{Z} \) to have underlying ring \( \mathbb{Z} \), and functor of measures mapping an extremally disconnected \( S = \lim_i S_i \), written as an inverse limit of finite sets, to the condensed abelian group \( \mathbb{Z}[S] := \lim_i \mathbb{Z}[S_i] \).

2. ([Sch19, Theorem 8.1]). More generally, let \( A \) be a discrete commutative algebra, and let \( S = \lim_i S_i \) be an extremally disconnected set. We have an analytic ring \( A \) with underlying condensed ring \( A \), and with functor of measures given by

\[
A[S] = \lim_{B \subset A} \lim_{i} B[S_i]
\]

where \( B \) runs over all the \( \mathbb{Z} \)-algebras of finite type in \( A \).

3. Let \( p \) be a prime number, \( K \) a finite extension of \( \mathbb{Q}_p \) and \( \mathcal{O}_K \) its valuation ring. Let \( S = \lim_i S_i \) be an extremally disconnected set. We have analytic structures for the rings \( \mathcal{O}_K \) and \( K \), denoted \( \mathcal{O}_K \) and \( K \) respectively, given by

\[
\mathcal{O}_K[S] := \lim_i \mathcal{O}_K[S_i] \text{ and } K[S] := \mathcal{O}_K[S]\left[\frac{1}{p}\right] = K \otimes_{\mathcal{O}_K} \mathcal{O}_K[S].
\]

Note that \( \mathcal{O}_K[S] \) is profinite for all \( S \).

4. ([And21, Theorem 1.5]) Let \((A, A^+)\) be a Huber pair. Andreychov defines an analytic ring \((A, A^+)\) associated to \((A, A^+)\), whose underlying ring is \( A \), and with functor of measures

\[
(A, A^+)[S] = \lim_{B \rightarrow A^+, M \rightarrow i} \lim_{M[S_i]},
\]

where the colimit is taken over all the finitely generated subrings \( B \subset A^+ \) and all the quasi-finitely generated submodules \( M \) of \( A \). If \( A^+ = A^0 \) we simply write \( A \) for \((A, A^0)\).

5. A particular example of the previous case is the analytic ring associated to the Tate algebra \((K(T), \mathcal{O}_K(T))\), namely, the analytic ring \( K(T)[S] \) whose functor of measures is given by

\[
K(T)[S] = K(T) \otimes_{\mathcal{O}_K(T)} \left( \lim_{s \in \mathbb{N}, i \in I} (\mathcal{O}_K/p^s\mathcal{O}_K[T])[S_i] \right).
\]

In the previous equation, \( \mathcal{O}_K/p^s\mathcal{O}_K[T] \) is the polynomial ring over \( \mathcal{O}_K/p^s\mathcal{O}_K \) in the variable \( T \).

The following theorem explains the importance of the analytic rings

**Theorem 2.7 ([Sch19, Prop. 7.5]).** Let \((A, \mathcal{M})\) be an analytic ring.

1. The full subcategory

\[
\text{Mod}_{\text{cond}}^{\text{cond}}(\mathcal{A}, \mathcal{M}) \subset \text{Mod}_{\text{cond}}^{\text{cond}}(A)
\]

of all \( \mathcal{A} \)-modules \( M \) such that for all extremally disconnected set \( S \), the map

\[
\text{Hom}_A(\mathcal{M}[S], M) \rightarrow \text{Hom}_A(A[S], M)
\]

is an isomorphism, is an abelian subcategory stable under all limits, colimits and extensions. Objects of the form \( \mathcal{M}[S] \), where \( S \) is an extremally disconnected profinite set, constitute a family of compact projective generators of \( \text{Mod}_{\text{cond}}^{\text{cond}}(\mathcal{A}, \mathcal{M}) \). The inclusion functor admits a left adjoint

\[
\text{Mod}_{\text{cond}}^{\text{cond}}(A) \rightarrow \text{Mod}_{\text{cond}}^{\text{cond}}(\mathcal{A}, \mathcal{M}), \quad M \mapsto M \otimes_{\mathcal{A}} (A, \mathcal{M})
\]

which is the unique colimit preserving extension of the functor given by \( A[S] \rightarrow \mathcal{M}[S] \). Finally, if \( \mathcal{A} \) is commutative, there is a unique symmetric monoidal tensor product \(- \otimes_{\mathcal{A}} (A, \mathcal{M})\) on \( \text{Mod}_{\text{cond}}^{\text{cond}}(\mathcal{A}, \mathcal{M}) \) making the functor \(- \otimes_{\mathcal{A}} (A, \mathcal{M})\) symmetric monoidal.
(2) The functor of derived categories

$$D(\text{Mod}^{\text{cond}}_{(A,\mathcal{M})}) \to D(\text{Mod}^{\text{cond}}_{A})$$

is fully faithful and its essential image is stable under all limits and colimits and given by those $$C \in D(\text{Mod}^{\text{cond}}_{A})$$ for which the map

$$R\text{Hom}_{A}(\mathcal{M}[S], C) \to R\text{Hom}_{A}(A[S], C)$$

is an isomorphism for all extremally disconnected set $$S$$. In that case, the map

$$R\text{Hom}_{A}(\mathcal{M}[S], C) \to R\text{Hom}_{A}(A[S], C)$$

is also an isomorphism.

An object $$C \in D(\text{Mod}^{\text{cond}}_{A})$$ lies in $$D(\text{Mod}^{\text{cond}}_{(A,\mathcal{M})})$$ if and only if for each $$n \in \mathbb{Z}$$, the cohomology group $$H^{n}(C)$$ lies in $$\text{Mod}^{\text{cond}}_{(A,\mathcal{M})}$$. The inclusion functor $$D(\text{Mod}^{\text{cond}}_{(A,\mathcal{M})}) \subset D(\text{Mod}^{\text{cond}}_{A})$$ admits a left adjoint

$$D(\text{Mod}^{\text{cond}}_{A}) \to D(\text{Mod}^{\text{cond}}_{(A,\mathcal{M})}), \quad C \mapsto C \otimes^{L}_{A} (A,\mathcal{M})$$

which is the left derived functor of $$\mathcal{M} \mapsto \mathcal{M} \otimes_{A} (A,\mathcal{M})$$. Finally, if $$A$$ is commutative, there is a unique symmetric monoidal tensor product $$- \otimes^{L}_{(A,\mathcal{M})} -$$ on $$D(\text{Mod}^{\text{cond}}_{(A,\mathcal{M})})$$ making the functor

$$- \otimes^{L}_{A} (A,\mathcal{M})$$

symmetric monoidal.

Remark 2.8. The functor $$- \otimes^{L}_{(A,\mathcal{M})} -$$ is the derived functor of $$- \otimes_{(A,\mathcal{M})} -$$ if and only if $$\mathcal{M}[S'] \otimes^{L}_{(A,\mathcal{M})} \mathcal{M}[S''] = A[S \times S'] \otimes^{L}_{A} (A,\mathcal{M})$$ sits in degree 0, cf. [Sch19, Warning 7.6]. This is the case for the analytic rings of Example 2.6 and in fact for all analytic ring over $$\mathbb{Z}$$.

In the following we shall write $$D(A,\mathcal{M})$$ for the derived category $$D(\text{Mod}^{\text{cond}}_{(A,\mathcal{M})})$$. The functor $$- \otimes^{L}_{A} (A,\mathcal{M})$$ should be thought as a completion with respect to the measures $$\mathcal{M}$$.

One of the main theorems of [Sch19] is the proof that $$\mathbb{Z}$$ is an analytic ring, it has as input several non trivial computations of Ext-groups of locally compact abelian groups. The category $$\text{Solid}_{\mathbb{Z}}$$ is called the category of solid abelian groups.

Let $$p$$ be a prime number, then $$\mathbb{Z}_{p}$$ is a solid abelian group (being an inverse limit of discrete abelian groups) and for $$S$$ extremally disconnected we have (cf. [Sch19 Proposition 7.9])

$$\mathbb{Z}_{p} \otimes \mathbb{Z}_{p} \mathbb{Z} = \mathbb{Z}_{p} \otimes \mathbb{Z} \mathbb{Z}_{p} [S] = \mathbb{Z}_{p} \otimes \mathbb{Z} \mathbb{Z}_{p} [S].$$

(4)

Definition 2.9. Let $$K$$ be a finite extension of $$\mathbb{Q}_{p}$$ and $$\mathcal{O}_{K}$$ its ring of integers, we denote by $$\text{Mod}^{\text{solid}}_{\mathcal{O}_{K}}$$ (resp. $$\text{Mod}^{\text{solid}}_{K}$$) the category of solid $$\mathcal{O}_{K}$$-modules (resp. the category of solid $$K$$-vector spaces) and $$D(\mathcal{O}_{K})$$, $$D(K)$$ their respective derived categories.

Remark 2.10. An object in $$\text{Mod}^{\text{solid}}_{\mathcal{O}_{K}}$$ (resp. $$\text{Mod}^{\text{solid}}_{K}$$) is the same as an object in $$\text{Solid}_{\mathbb{Z}}$$ endowed with an action of $$\mathcal{O}_{K}$$ (resp. $$K$$). Indeed, this follows directly from Theorem 2.7 and (4).

2.0.3. Analytic rings attached to Tate algebras. In the case of a Tate algebra $$(A,\mathcal{M}) = \mathcal{O}_{K}(T_{1},\ldots,T_{d})$$ we have the following key description of the completion functor which follows from the observations of [Sch19 Lecture VIII].

Proposition 2.11 ([And21, Proposition 3.13]). Let $$\mathcal{O}_{K}(T) := \mathcal{O}_{K}(T_{1},\ldots,T_{d})$$. We denote $$\mathcal{O}_{K}(T)^{\vee} = \text{Hom}_{\mathcal{O}_{K}}(\mathcal{O}_{K}(T),\mathcal{O}_{K})$$. For any $$C,W \in D(\mathcal{O}_{K})$$, there is a functorial isomorphism

$$R\text{Hom}_{\mathcal{O}_{K}}(W,C \otimes_{\mathcal{O}_{K}}^{L} \mathcal{O}_{K}(T)) = R\text{Hom}_{\mathcal{O}_{K}}(W \otimes_{\mathcal{O}_{K}}^{L} \mathcal{O}_{K}(T)^{\vee},C).$$

Proof. By [And21, Proposition 3.13], for any $$C \in D(\mathcal{O}_{K})$$, there is an isomorphism

$$C \otimes_{\mathcal{O}_{K}}^{L} \mathbb{Z}[T] = R\text{Hom}_{\mathbb{Z}}(\mathbb{Z}((T^{-1})),C).$$

In particular, if $$C \in D(\mathcal{O}_{K})$$, from [And21, Lemma 4.7] we have $$\mathcal{O}_{K}(T) = \mathcal{O}_{K} \otimes_{\mathbb{Z}}^{L} \mathbb{Z}[T]$$ as analytic rings, one gets

$$C \otimes_{\mathcal{O}_{K}}^{L} \mathcal{O}_{K}(T) = R\text{Hom}_{\mathcal{O}_{K}}(\mathcal{O}_{K}((T^{-1})),C).$$
Let \( W \in D(\mathcal{O}_K) \). Applying the functor \( R\text{Hom}_{\mathcal{O}_K}(W, -) \) and the adjunction between \( \otimes^L \) and \( R\text{Hom} \), we get
\[
R\text{Hom}_{\mathcal{O}_K}(W, C \otimes^L_{\mathcal{O}_K} \mathcal{O}_K(T)) = R\text{Hom}_{\mathcal{O}_K}(W \otimes^L_{\mathcal{O}_K} \mathcal{O}_K((T^{-1})) / \mathcal{O}_K[T], C).
\]
Noting that \( \mathcal{O}_K((T^{-1})) / \mathcal{O}_K[T] = \mathcal{O}_K(T)^\vee \) as \( \mathcal{O}_K(T) \)-modules, this finishes the proof for the case of one variable.

The case of several variables is treated by induction noticing that if \( A \) is a discrete algebra of finite type over \( \mathbb{Z} \) then
\[
R\text{Hom}_A(W, C \otimes^L_A A[T]) = R\text{Hom}_A(W \otimes^L_A A((T^{-1})), C)
\]
for \( C, W \in D(A) \), which follows easily from [And21, Proposition 3.13].

\[\square\]

**Remark 2.12.** Proposition 2.11 can be seen as an instance of the six functor formalism of [Sch19, Theorem 8.2].

### 3. Non-archimedean condensed functional analysis

The main purpose of this section is to state a duality between two classes of solid vector spaces over a finite extension of \( \mathbb{Q}_p \), namely Fréchet spaces and LS spaces (to be defined below), generalising the duality between Banach spaces and Smith spaces (c.f. [Sch20, Theorem 3.8]), and the duality between nuclear Fréchet spaces and LB spaces of compact type (see, e.g., [ST02, Theorem 1.3]). For doing so, we will use many results on the theory of condensed non-archimedean functional analysis developed by Clausen and Scholze. Since results haven’t yet appeared in the literature, we give a detailed account with proofs included. The reader should be aware that many of the results in this chapter must be attributed to Clausen and Scholze [CS], and the only original results are those concerning duality, principally Theorem 3.30.

#### 3.1. Banach and Smith spaces

Let \( K \) and \( \mathcal{O}_K \) be as in the previous section, and let \( \varpi \) be a uniformiser of \( \mathcal{O}_K \). In this paragraph we focus our attention in the category of solid \( K \)-vector spaces (or \( K \)-vector spaces), i.e. the category \( \text{Mod}^{\text{solid}}_K \). We start with some basic concepts

**Definition 3.1.**

1. A solid \( K \)-Banach space (or simply a Banach space) is a solid \( K \)-vector space \( V \) admitting a \( \varpi \)-adically complete \( \mathcal{O}_K \)-module \( V^0 \subset V \) such that
   \[
   (a) \quad V = V^0 \otimes_{\mathcal{O}_K} K.
   \]
   \[
   (b) \quad V^0 / \varpi^s V^0 \text{ is discrete for all } s \in \mathbb{N}.
   \]
   We say that \( V^0 \) is a lattice of \( V \).

2. A solid \( K \)-Smith space (or simply a Smith space) is a solid \( K \)-vector space \( W \) admitting a profinite \( \mathcal{O}_K \)-submodule \( W^0 \subset W \) such that \( W = W^0 \otimes_{\mathcal{O}_K} K \). We say that \( W^0 \) is a lattice of \( W \).

**Remark 3.2.** Over \( \mathbb{R} \), a Smith space ([Sch20, Def. 3.6]) is a complete locally convex topological \( \mathbb{R} \)-vector space \( W \) containing a compact absolutely convex subset \( C \subset V \) such that \( V = \bigcup_{a \geq 0} aC \). As its \( p \)-adic analogue, we define a \( K \)-Smith space to be a topological \( K \)-vector space \( W \) containing a compact \( \mathcal{O}_K \)-module \( W^0 \subset W \) such that \( W = W^0[\frac{1}{\varpi}] \).

**Proposition 3.3.** The functor \( V \mapsto V(*)_{\text{top}} \) induces an equivalence of categories between solid and classical \( K \)-Banach spaces (resp. between solid and classical \( K \)-Smith spaces).

**Proof.** Let \( V \) be a Banach space over \( K \) in the classical sense, and let \( V^0 \subset V \) be the unit ball. Then \( V^0 \) is endowed with the \( \varpi \)-adic topology, i.e. it is the inverse limit \( V^0 = \lim_{\rightarrow} V^0 / \varpi^s V^0 \), with \( V^0 / \varpi^s V^0 \) discrete for all \( s \in \mathbb{N} \). By Proposition 2.2 we know that
\[
V = \lim_{n \in \mathbb{N}} (\lim_{s \in \mathbb{N}} V^0 / \varpi^s V^0) \varpi^{-n} = V^0 \otimes_{\mathcal{O}_K} K,
\]
so that \( V \) is a solid \( K \)-Banach space. Conversely, if \( V \) is a solid Banach space then \( V(*)_{\text{top}} \) is clearly a \( K \)-Banach space in the classical sense.

Let \( W \) be a (classical) \( K \)-Smith space and \( W^0 \subset W \) a lattice. As \( W^0 \) is compact, it is profinite and Proposition 2.2 implies that \( W = W^0 \otimes_{\mathcal{O}_K} K \) is a solid Smith space as in our previous definition. The converse is clear. \( \square \)
Proposition 3.4. There is a natural functor

$$LC_K \rightarrow Mod^\text{solid}_K : V \mapsto V$$

from the category of complete locally convex $K$-vector spaces to solid $K$-vector spaces.

Proof. This follows from the fact that any complete locally convex $K$-vector space can be written as a cofiltered limit of Banach spaces \cite[Chap. I, §4]{Sch02}, and the adjunction of Proposition 3.2.

From now, all the complete locally convex $K$-vector spaces will be considered as solid $K$-vector unless otherwise specified. The following result shows that solid Banach and Smith spaces over $K$ have orthonormal basis.

Lemma 3.5.

(1) A solid $K$-vector space is Banach if and only if it is of the form

$$\bigoplus_{i \in I} K := \left( \lim_{\rightarrow} \left( \bigoplus_{i \in I} \mathcal{O}_K/\mathcal{O}_K^s \right) \right)[\frac{1}{\mathcal{O}_K}]$$

for some index set $I$.

(2) A solid $K$-vector space is Smith if and only if it is of the form

$$(\prod_{i \in I} \mathcal{O}_K)[\frac{1}{\mathcal{O}_K}]$$

for some index set $I$. In particular, by \cite[Corollary 5.5]{Sch19} and Theorem 2.7, Smith spaces form a family of compact projective generators of the category $\text{Mod}^\text{solid}_K$ of solid $K$-vector spaces.

Proof. By definition, an object of the form $\bigoplus_{i \in I} K$ is a solid $K$-Banach space. Conversely, let $V$ be a $K^\bullet$-Banach space and $V^0 \subset V$ a lattice. By Proposition 3.3, $V(\ast)_{\text{top}}$ is a Banach space with unit ball $V^0(\ast)_{\text{top}} \subset V(\ast)_{\text{top}}$ and $V(\ast)_{\text{top}} = V$. But then $V^0(\ast)_{\text{top}}$ has an orthonormal $\mathcal{O}_K$-basis by taking any lift of a $\mathcal{O}_K/\mathcal{O}_K$-basis of $V^0/\mathcal{O}_K$. This proves (1).

To prove (2), let $W$ be a Smith space and $W^0 \subset W$ a lattice. Since $W^0$ is a profinite $\mathcal{O}_K$-module, $W^0 = W^0(\ast)_{\text{top}}$ with $W^0(\ast)_{\text{top}}$ a profinite $\mathcal{O}_K$-module in the usual sense. Moreover, $W^0(\ast)_{\text{top}}$ is flat and the topological Nakayama’s lemma implies that $W^0(\ast)_{\text{top}}$ must be of the form $\prod_{i \in I} \mathcal{O}_K$ \cite[Exposé VII, 0.3.8]{SGA70}).

We will need the following useful proposition

Proposition 3.6 \cite{CS}. Let $V$ be a solid $K$-vector space. The following statements are equivalent

(1) $V$ is a Smith space

(2) $V$ is quasi-separated, and there is a compact $\mathcal{O}_K$-submodule $M \subset V$ such that $V = M[\frac{1}{\mathcal{O}_K}]$.

Moreover, the class of Smith spaces is stable under extensions, closed subobjects and quotients by closed subobjects.

Proof. The equivalence between (1) and (2) follows immediately from the characterisation of Smith spaces of Lemma 3.5. The fact that Smith spaces are stable under extensions follows from the fact that they are projective, and hence every extension splits. The stability under closed subobjects and quotients follows from the description of a Smith space as in (2) of the equivalence.

The next lemma provides an anti-equivalence between Banach and Smith spaces for solid $K$-vector spaces, c.f. \cite{Smi52} (or also \cite[Theorem 3.8]{Sch20}) for the analogous statement over the real or complex numbers.

Lemma 3.7 \cite{CS}. The assignment $V \mapsto V^\vee$ induces an anti-equivalence between $K$-Banach spaces and $K$-Smith spaces. More precisely, the following holds.

(1) $\text{Hom}_{\mathcal{O}_K}(\bigoplus_{i \in I} \mathcal{O}_K, \mathcal{O}_K) = \prod_{i \in I} \mathcal{O}_K$ and $\text{Hom}_{\mathcal{O}_K}(\bigoplus_{i \in I} K, K) = (\prod_{i \in I} \mathcal{O}_K)[\frac{1}{\mathcal{O}_K}]$.

(2) $\text{Hom}_{\mathcal{O}_K}(\bigoplus_{i \in I} \mathcal{O}_K, \mathcal{O}_K) = \bigoplus_{i \in I} \mathcal{O}_K$ and $\text{Hom}_{\mathcal{O}_K}(\prod_{i \in I} \mathcal{O}_K)[\frac{1}{\mathcal{O}_K}], K) = \bigoplus_{i \in I} K$. 
Proof. To prove (1), notice that
\[
\text{Hom}_{\mathcal{O}_K} \left( \bigoplus_i \mathcal{O}_K, \mathcal{O}_K \right) = \lim_{s} \text{Hom}_{\mathcal{O}_K/\omega^s} \left( \bigoplus_i \mathcal{O}_K/\omega^s, \mathcal{O}_K/\omega^s \right) = \lim_{s} \prod_i \mathcal{O}_K/\omega^s = \prod_i \mathcal{O}_K.
\]

To prove the second equality it is enough to show that
\[
\text{Hom}_{\mathcal{O}_K} \left( \bigoplus_i \mathcal{O}_K, \mathcal{O}_K \right) = \text{Hom}_{\mathcal{O}_K} \left( \bigoplus_i \mathcal{O}_K, \mathcal{O}_K \right) \left[ \frac{1}{\omega} \right].
\]

Let $S$ be an extremally disconnected set, by adjunction it is enough to show that
\[
\text{Hom}_{\mathcal{O}_K} \left( \bigoplus_i \mathcal{O}_K, \text{Cont}(S, \mathcal{O}_K) \right) = \text{Hom}_{\mathcal{O}_K} \left( \bigoplus_i \mathcal{O}_K, \text{Cont}(S, \mathcal{O}_K) \right) \left[ \frac{1}{\omega} \right].
\]

But all the solid spaces involved arise as the condensed set associated to a compactly generated Hausdorff topological space, the claim follows from the fact that lattices are mapped to lattices for continuous maps of classical Banach spaces.

Part (2) follows from the fact that an object of the form $\prod_i \mathcal{O}_K$ is a retraction of a compact projective generator $\mathcal{O}_K_{[S]}$ for $S$ extremally disconnected, and the fact that
\[
\text{Hom}_{\mathcal{O}_K} (\mathcal{O}_K_{[S]}, \mathcal{O}_K) = \text{Cont}(S, \mathcal{O}_K).
\]

This finishes the proof of the Lemma. \qed

Remark 3.8. Part (2) of the previous lemma also holds with $R\text{Hom}$ since $\prod_i \mathcal{O}_K$ is a projective $\mathcal{O}_K_{[S]}$-module. The same proof of the first assertion of (1) can also be adapted to show that $R\text{Hom}_{\mathcal{O}_K} \left( \bigoplus_i \mathcal{O}_K, \mathcal{O}_K \right) = \prod_i \mathcal{O}_K$. The authors ignore how to calculate $R\text{Hom}_K \left( \bigoplus_i \mathcal{O}_K, \mathcal{O}_K \right)$.

We now study the behaviour of the tensor product.

Proposition 3.9. Let $V = \prod_{i \in I} \mathcal{O}_K$ and $W = \prod_{j \in J} \mathcal{O}_K$. Then
\[
V \otimes_{\mathcal{O}_K} \mathcal{O}_K W = \prod_{(i,j) \in I \times J} \mathcal{O}_K.
\]

Proof. See [Sch19] Proposition 6.3]. \qed

The following useful result shows that the solid tensor product coincides with the projective tensor product of $K$-Banach spaces.

Lemma 3.10 ([CS]). Let $V$ and $V'$ be classical Banach spaces over $K$, and let $V \otimes_K V'$ denote its projective tensor product. Then $V \otimes_K V' = V \otimes_{\mathcal{O}_K} V'$.

Proof. Fix an isomorphism $V = \bigoplus_{i \in I} K$. As a convergent series $\sum_i a_i$ has only countably many terms different from 0, we can write
\[
V = \lim_{\nu' \subset I} \bigoplus_{i \in I'} K
\]
where $I'$ runs over all the countable subsets of $I$. Therefore, we can assume that $V \cong V' \cong \bigoplus_{n \in \mathbb{N}} K$. Let $\mathcal{I}$ denote the direct set of functions $f : \mathbb{N} \to \mathbb{Z}$ such that $f(n) \to +\infty$ as $n \to +\infty$, endowed with the order $f \preceq g$ iff $f(n) \geq g(n)$ for all $n \in \mathbb{N}$. Thus, we can write
\[
\bigoplus_{n \in \mathbb{N}} K = \lim_{f \in \mathcal{I}} \prod_{n \in \mathbb{N}} \mathcal{O}_K \omega^{f(n)}.
\]

Indeed, by evaluating at an extremally disconnected set $S$, $V(S) = \text{Cont}(S, V) = \bigoplus_{n \in \mathbb{N}} \text{Cont}(S, \mathcal{O}_K)$ has a natural Banach space structure, for which a function $\phi : S \to V$ can be written in a unique way as a sum
\[ \phi = \sum_n \phi_n \text{ with } \phi_n \in \text{Cont}(S, K), \text{ such that } |\phi_n| \to 0 \text{ as } n \to \infty. \]

Then, from (5) and Proposition 3.9 we deduce that
\[ V \otimes_K V' = \lim_{f,g \in \mathcal{F}} \prod_{n \in \mathbb{N}} O_K \mathcal{O} f^{(n)} \otimes O_K \mathcal{O} g^{(m)} = \lim_{f,g \in \mathcal{F}} \prod_{n,m \in \mathbb{N} \times \mathbb{N}} O_K \mathcal{O} f^{(n)} + g^{(m)}. \]

Given \( f, g \in \mathcal{F} \) define the function \( h_{f,g} : \mathbb{N} \times \mathbb{N} \to \mathbb{Z} \) as \( h_{f,g}(n,m) = f(n) + g(m) \). Let \( \mathcal{F}' \) be the direct set of functions \( h : \mathbb{N} \times \mathbb{N} \to \mathbb{Z} \) such that \( h(n,m) \to +\infty \) as \( \max\{n,m\} \to +\infty \). Then the set \( \{h_{f,g}\}_{f,g \in \mathcal{F}} \) is a cofinal family in \( \mathcal{F}' \). Indeed, given \( h : \mathbb{N} \times \mathbb{N} \to \mathbb{Z} \), we define \( f(n) = \frac{1}{2} \min_{m} h(n,m) \) and \( g(m) = \frac{1}{2} \min_{n} h(n,m) \), then \( h \preceq h_{f,g} \). Therefore,
\[ \lim_{f,g \in \mathcal{F}, n,m \in \mathbb{N} \times \mathbb{N}} O_K \mathcal{O} h_{f,g}(n,m) = \lim_{h \in \mathcal{F}', n,m \in \mathbb{N}} O_K \mathcal{O} h(n,m) = \bigoplus_{n,m} K. \]

Let us recall the concept of a nuclear solid \( K \)-vector space.

**Definition 3.11** ([Sch20] Definition 13.10). Let \( V \in \text{Solid}_K \). We say that \( V \) is nuclear if, for all extremally disconnected set \( S \), we have
\[ \text{Hom}_K(K \llbracket S \rrbracket, V) = \text{Hom}_K(K \llbracket S \rrbracket, K) \otimes_K V. \]

**Remark 3.12.** We warn the reader that this notion of nuclearity differs from the classical one, say in [Sch02]. Indeed, if a Banach space is nuclear in the classical sense then it is finite dimensional (cf. loc. cit. §19). On the other hand, solid \( K \)-Banach spaces are always nuclear in the condensed sense.

**Corollary 3.13** ([CS]). Let \( V \) be a Banach space over \( K \), then \( V \) is a nuclear \( K \)-vector space.

**Proof.** The result follows from Lemma 3.10 by applying the \( \otimes \) and \( \text{Hom} \) adjunction, and the duality between Banach and Smith spaces.

**Corollary 3.14.** Let \( V \in \text{Solid}_K \) be a Banach space and \( W \in \text{Solid}_K \) be Smith. Then
\[ \text{Hom}_K(V, W) = V^\vee \otimes_K W, \]
\[ \text{Hom}_K(W, V) = W^\vee \otimes_K V. \]

**Proof.** The second equality follows from nuclearity of \( V \). For the first equality, tensor-Hom adjunction gives
\[ \text{Hom}_K(V, W) = \text{Hom}_K(V \otimes_K W^\vee, K), \]
and the results follows immediately from the description of the tensor product of two Banach spaces (Lemma 3.10) and duality between Banach and Smith spaces (Lemma 3.7).

We finish this section with an elementary lemma that will be needed later.

**Lemma 3.15.**

1. Let \( V \) be a solid \( K \)-vector space such that the maximal quasi-separated quotient \( V^{qs} \) is zero. Then \( \text{Hom}(V, K) = 0 \).
2. A map of Banach spaces \( V \to V' \) is injective (resp. with dense image) if and only if its dual \( V' \to V^\vee \) has dense image (resp. is injective).

**Proof.** Let \( S \) be an extremally disconnected set, then
\[ \text{Hom}_K(V, K)(S) = \text{Hom}_K(V \otimes_K [S], K) = \text{Hom}_K(V, \text{Cont}(S, K)). \]
But \( \text{Cont}(S, K) \) is a Banach space. Then, by adjunction (Proposition 2.2), we get
\[ \text{Hom}_K(V, K)(S) = \text{Hom}_K(V(\ast)_{top}, \text{Cont}(S, K)). \]
Since \( V^{qs} = 0 \), the maximal Hausdorff quotient of \( V(\ast)_{top} \) is zero. This implies that
\[ \text{Hom}_K(V(\ast)_{top}, \text{Cont}(S, K)) = 0 \]
proving (1).
To prove (2), let \( f : V \to V' \) be a map of Banach spaces. Suppose that \( f \) has not dense image and let \( f(V) \subset V' \) be the closure of its image. Then \( V'/f(V) \) is a non-zero Banach space and we have a short exact sequence
\[
0 \to f(V) \to V' \to V'/f(V) \to 0
\]
which splits as any Banach space over a local field is orthonormalizable. Taking duals we get a short exact sequence
\[
0 \to (V'/f(V))' \to V'' \to f(V)' \to 0.
\]
Since \( f' : V'' \to V' \) factors through \( f(V)' \), the map \( f' \) is not injective. Conversely, suppose that the map \( f' \) is not injective, then its kernel \( \ker f' \) is a closed subspace of \( V'' \) which is a Smith space by Proposition 3.16. Since the quotient \( V''/\ker(f') \) is also a Smith space, there is a retraction \( r : V'' \to \ker(f') \). Taking duals one sees that the composition \( V \to V' \to \ker(f')' \) is zero and that the last map is surjective (because of \( r \)), this implies that \( f' \) has not dense image.

Finally, suppose that \( f : V \to V' \) is injective. If \( f' : V'' \to V' \) does not have dense image, \( f(V)' \subset V' \) is a closed Smith subspace and its quotient \( V''/f(V') \) is a non-zero Smith space. Taking duals we get a short exact sequence
\[
0 \to (V''/f(V'))' \to V'' \to f(V)' \to 0.
\]
But \( f : V \to V' \) factors through \( f(V)' \), this is a contradiction with the injectivity of \( f \). Conversely, Suppose that \( f' : V'' \to V' \) has dense image, consider the quotient
\[
0 \to V'' \to V' \to Q \to 0
\]
Taking duals one obtains an exact sequence
\[
0 \to \text{Hom}_K(Q, K) \to V \to V'.
\]
But part (1) implies that \( \text{Hom}_K(Q, K) = 0 \), proving that \( f \) is injective. \( \square \)

3.2. Quasi-separated solid \( K \)-vector spaces. We shall use the following results throughout the text without explicit mention. They are due to Clausen and Scholze, and explained to us by Guido Bosco in the study group of La Tourette.

**Proposition 3.16 ([CS]).** Let \( V \) be a solid \( K \)-vector space. The following are equivalent,

(1) \( V \) is quasi-separated.

(2) \( V \) is equal to the filtered colimit of its Smith subspaces.

**Proof.** Let \( V \) be a quasi-separated \( K \)-vector space, let \( W_1, W_2 \) be Smith subspaces of \( V \). As \( V \) is quasi-separated, \( W_1 \cap W_2 \) is a closed Smith subspace of \( W_1 \), and the sum \( W_1 + W_2 \subset V \) is isomorphic to \( (W_1 \oplus W_2)/W_1 \cap W_2 \). This shows that the Smith subspaces of \( V \) form a direct system, let \( V_0 \) denote their colimit. We claim that \( V/V_0 = 0 \), let \( W' \) be a Smith space and \( f : W' \to V/V_0 \) a map of solid \( K \)-vector spaces. As \( W' \) is projective, there is a lift \( f' : W' \to V \). But \( \ker f' \subset W' \) is a closed Smith subspace since \( V \) is quasi-separated. This implies that \( f' \) factors through \( V_0 \) and that \( f = 0 \). Since the Smith spaces form a family of compact projective generators of \( K \)-vector spaces, one must have \( V/V_0 = 0 \) proving (1) \( \Rightarrow \) (2).

Conversely, let \( V = \varinjlim_{i \in I} V_i \) be a vector space written as a filtered colimit of Smith spaces by injective transition maps. Let \( S_1, S_2 \) be two profinite sets and \( f_j : S_j \to V \) be two maps for \( j = 1, 2 \). As the \( S_i \) are profinite, there exists \( i \in I \) such that \( f_j \) factors through \( V_i \) for \( j = 1, 2 \). Then, as the map \( V_i \to V \) is injective, one has
\[
S_1 \times_V S_2 = S_1 \times_{V_i} S_2.
\]
The implication (2) \( \Rightarrow \) (1) follows as a Smith space is quasi-separated. \( \square \)

**Lemma 3.17 ([CS]).** A quasi-separated \( K \)-solid space is flat. In other words, if \( V \) is a quasi-separated \( K \)-vector space, then \( - \otimes_K V = - \otimes^K V \).

**Proof.** Let \( V \) be a quasi-separated \( K \)-vector space. Since filtered colimits are exact in the category of condensed abelian groups, and the solid tensor product commutes with colimits, by Proposition 3.16 it is enough to prove the lemma for \( V = \prod_{i_1} \mathcal{O}_K(\frac{1}{p_i}) \) a Smith space. Let \( W \in \text{Mod}^\text{solid}_K \). We want to show that \( V \otimes^K_W W \) is concentrated in degree zero. As the Smith spaces are compact projective generators, \( W \) can
be written as a quotient $0 \to W'' \to W' \to W \to 0$ where $W'$ is a direct sum of Smith spaces. Then we are reduced to showing that $0 \to W'' \otimes KV \to W' \otimes KV$ is injective. Since $W''$ is quasi-separated, by Proposition 3.16 it can be written as filtered colimit of its Smith subspaces. Therefore, by compactness of Smith spaces, the arrow $W'' \to W'$ is a filtered colimit of injections of Smith spaces. It is hence enough to show that if $\prod_{J_1} O_{K[\frac{1}{p}]} \to \prod_{J_2} O_{K[\frac{1}{p}]} \otimes KV$ is an injective map, then

$$\prod_{J_1} O_{K[\frac{1}{p}]} \otimes KV \to \prod_{J_2} O_{K[\frac{1}{p}]} \otimes KV$$

is injective. This follows from the tensor product of two Smith Spaces (Proposition 3.9)

$$\prod_{I} O_{K[\frac{1}{p}]} \otimes K (\prod_{J} O_{K[\frac{1}{p}]} ) = \prod_{I \times J} O_{K[\frac{1}{p}]} .$$

This finishes the proof. □

3.3. Fréchet and LS spaces. Our next goal is to extend the duality between Banach and Smith spaces to a larger class of solid $K$-vector spaces. We need a definition

Definition 3.18.

1. A solid Fréchet space (or simply a Fréchet space) is a solid $K$-vector space which can be written as a countable cofiltered limit of Banach spaces.

2. A solid LS (resp. LB, resp. LF) space is a solid $K$-vector space which can be written as a countable filtered colimit of Smith (resp. Banach, resp. Fréchet) spaces with injective transition maps.

Lemma 3.19.

1. The functor $V \mapsto V(*)_{\text{top}}$ induces an equivalence of categories between solid and classical Fréchet spaces and $V = V(*)_{\text{top}}$.

2. An LS space is quasi-separated. Conversely, a quasi-separated $K$-vector space $W$ is an LS space if and only if it is countably compactly generated, i.e., for every surjection $\bigoplus_{i \in I} P_i \rightarrow W$ by direct sums of Smith spaces, there is a countable index subset $I_0 \subset I$ such that $\bigoplus_{i \in I_0} P_i \rightarrow W$ is surjective.

Proof. Part (1) follows from the fact that a classical Fréchet space is complete for a countable family of seminorms (i.e. it can be written as a countable cofiltered limit of Banach spaces), Proposition 2.21 (1), and Proposition 3.3. For part (2), the fact that an LS space is quasi-separated follows from Proposition 3.16. Let $W$ be quasi-separated $K$-vector space. Assume it is countably compactly generated. Write $W = \lim_{W' \subset W} W'$ as a colimit of its Smith subspaces. As $W$ is quasi-separated, the sum of two Smith subspaces is Smith, so the colimit is filtered. By hypothesis, there are countably many $W'$ such that $W = \lim_{W' \subset W}$.

Moreover, we can assume that $W_0 \subset W_1 \subset \cdots$. This proves that $W$ is an LS space. Conversely, let $W$ be an LS space and let $\bigoplus_{i \in I} P_i \rightarrow W$ be a surjective map with $P_i$ Smith. The image $P'_i$ of $P_i$ in $W$ is a Smith space since $W$ is quasi-separated, hence $W = \sum_i P'_i$. Thus, without loss of generality we can assume that $\lim_{P'_{i+1}} P'_i$ is filtered and equal to $W$. Let $W = \lim_{W' \subset W} W_s$ be a presentation as a countable colimit of Smith spaces by injective transition maps. By compactness of the Smith spaces, for all $s$ there exists $s_i$ such that $M_i \subset P'_{s_i} \subset M$. We can assume that $P'_{s_i} \subset P'_{s_{i+1}}$ for all $s \in \mathbb{N}$. Thus, $\bigoplus_{s \in \mathbb{N}} P_i \rightarrow W$ is surjective, finishes the lemma. □

The following lemma says that we can always choose a presentation of a Fréchet space as an inverse limit of Banach spaces with dense transition maps.

Lemma 3.20. Let $V$ be a solid Fréchet space, then we can write $V = \lim_{n \in \mathbb{N}} V_n$ with $V_n$ Banach spaces such that $V(*)_{\text{top}} \rightarrow V_n(*)_{\text{top}}$ has dense image for all $n \in \mathbb{N}$. Conversely, let $\{V_n\}_{n \in \mathbb{N}}$ be a cofiltered limit of Banach spaces such that $V_{n+1}(*)_{\text{top}} \rightarrow V_n(*)_{\text{top}}$ has dense image, and let $V = \lim_{n \in \mathbb{N}} V_n$ be its inverse limit. Then $V(*)_{\text{top}} \rightarrow V_n(*)_{\text{top}}$ has dense image for all $n \in \mathbb{N}$.

Proof. Let $V = \lim_{n \in \mathbb{N}} V_n$ be a presentation of the Fréchet space as an inverse limit of Banach spaces. Changing $V_n$ by the completion of the image of $V$, we obtain a desired presentation with $V(*)_{\text{top}} \rightarrow V_n(*)_{\text{top}}$ of dense image. Conversely, let $V_n$ be an inverse system of Banach spaces with maps $V_{n+1} \rightarrow V_n$ of dense image, let $V = \lim_{n \in \mathbb{N}} V_n$ be a Fréchet space, we want to show that the image of $V(*)_{\text{top}} \rightarrow V_n(*)_{\text{top}}$
is dense for all \( n \in \mathbb{N} \). Fix \( n_0 \in \mathbb{N} \), let \( w \in V_{n_0}(*_{\text{top}}) \) and \( 1 > \varepsilon > 0 \). Let \( | \cdot |_n \) denote the norm of \( V_n(*_{\text{top}}) \), without loss of generality we assume that \( | \cdot |_n \leq | \cdot |_{n+1} \). By density of the transition maps \( \phi_n^{n+1} : V_{n+1}(*_{\text{top}}) \to V_n(*_{\text{top}}) \), there exists \( v_{n_0+1} \in V_{n+1}(*_{\text{top}}) \) such that \( |\phi_n^{n+1}(v_{n+1}) - w| \leq \varepsilon \). By induction, for all \( n \geq n_0 + 1 \) we can find \( v_n \in V_n(*_{\text{top}}) \) such that \( |\phi_n^{n+1}(v_{n+1}) - v_n| \leq \varepsilon^n \). Let \( n \geq n_0 + 1 \) be fixed and let \( k \geq 0 \), then by construction the sequence \( \{\phi_n^{n+k}(v_{n+k})\} \) converges in \( V_n(*_{\text{top}}) \) to an element \( v'_n \). Moreover, it is immediate to check that \( \phi_n^{n+1}(v'_n) = v_n \) so that \( v' = (v'_n) \in V(*)_{\text{top}} \), and \( |\phi_n^{n+1}(v'_{n_0+1}) - w| \leq \varepsilon \). This proves the lemma. \( \square \)

### 3.3.1. Properties of Fréchet spaces

We now present some basic properties of Fréchet spaces, most of the results in the context of condensed mathematics are due to Clausen and Scholze [CS].

**Lemma 3.21** (Topological Mittag-Leffler [CS]). Let \( V = \lim_{\to n} V_n \) be Fréchet space written as an inverse limit of Banach spaces with dense transition maps. Then

\[
R^j \lim_{\to n} V_n = 0
\]

for all \( j > 0 \). In particular, \( V = R\text{Hom}_{K}(V^\vee, K) \).

**Proof.** See [Bos21, Lemma A.18]. \( \square \)

**Lemma 3.22** ([CS]). Let \( (V_n)_{n\in\mathbb{N}} \) and \( (W_m)_{m\in\mathbb{N}} \) be countable families of Banach spaces.

1. We have

\[
\left( \prod_n V_n \right) \otimes_{K} \left( \prod_m W_m \right) = \prod_{n,m} V_n \otimes_{K} W_m.
\]

2. More generally, if \( V = \lim_{\to n} V_n \) and \( W = \lim_{\to m} W_m \) are Fréchet spaces written as inverse limits of Banach spaces by dense transition maps, one has

\[
V \otimes_{K} W = \lim_{\to n,m} V_n \otimes_{K} W_m.
\]

**Proof.** Property (AB6) of Theorem 2.1 and Proposition 3.16 imply that products of quasi-separated solid \( K \)-vector spaces are quasi-separated. Then, by Lemma 3.17 all the derived tensor products in the statements are already concentrated in degree \( 0 \). By Lemma 3.21 we have a short exact sequences

\[
0 \to \lim_{\to n} V_n \to \prod_n V_n \to \prod_n V_n \to 0
\]

Then (2) follows from (1) by taking the tensor product of the above sequences.

For (1), suppose that the statement is true for all \( V_n \) and \( W_n \) possessing countable orthonormal bases. Let \( V_n \cong \bigoplus_{I_n} K \) and \( W_m \cong \bigoplus_{J_m} K \) for all \( n, m \in \mathbb{N} \). We write \( V_n = \lim_{I_n \subset I_n} \bigoplus_{I_n} K \) and \( W_m = \lim_{J_m \subset J_m} \bigoplus_{J_m} K \) with \( I_n' \) and \( J_m' \) running among all the countable subsets of \( I_n \) and \( J_m \) respectively. Then

\[
\left( \prod_n V_n \right) \otimes_{K} \left( \prod_m W_m \right) = \prod_n \left( \lim_{I_n' \subset I_n} \bigoplus_{I_n'} K \right) \otimes_{K} \prod_m \left( \lim_{J_m' \subset J_m} \bigoplus_{J_m'} K \right)
\]

\[
= \lim_{\forall (n,m) \in \mathbb{N} \times \mathbb{N}} \left\{ \prod_n \left( \lim_{I_n' \subset I_n} \bigoplus_{I_n'} K \right) \right\} \otimes_{K} \left\{ \prod_m \left( \lim_{J_m' \subset J_m} \bigoplus_{J_m'} K \right) \right\}
\]

\[
= \lim_{\forall (n,m) \in \mathbb{N} \times \mathbb{N}} \prod_{n,m} \left( \lim_{I_n' \times J_m' \subset I_n \times J_m} \bigoplus_{I_n' \times J_m'} K \right)
\]

\[
= \prod_{n,m} \left( \lim_{I_n' \times J_m' \subset I_n \times J_m} \bigoplus_{I_n' \times J_m'} K \right)
\]

\[
= \prod_{n,m} \left( \bigoplus_{I_n \times J_m} K \right)
\]

\[
= \bigoplus_{I_n \times J_m} K.
\]
Hence, we are left to prove (1) for \( W_m = V_n = \bigoplus_{n} K \) for all \( n, m \in \mathbb{N} \). Let \( \mathcal{F} \) be the filtered set of functions \( f : \mathbb{N} \to \mathbb{Z} \) such that \( f(k) \to +\infty \) as \( k \to +\infty \). For all \( n, m \in \mathbb{N} \) we can write

\[
V_n = \bigoplus_{n} K = \lim_{f_n \in \mathcal{F}} \prod_{k \in \mathbb{N}} O_{K} \varpi^{f_n(k)}
\]

\[
W_m = \bigoplus_{m} K = \lim_{g_m \in \mathcal{F}} \prod_{s \in \mathbb{N}} O_{K} \varpi^{g_m(s)}.
\]

Therefore we get

\[
\left( \prod_{n} V_n \right) \otimes_{K} \left( \prod_{m} W_m \right) = \lim_{\forall (n,m), f_n, g_m \in \mathcal{F}} \prod_{n} \prod_{k} O_{K} \varpi^{f_n(k)} \otimes_{K} \prod_{m} \prod_{s} O_{K} \varpi^{g_m(s)}
\]

\[
= \lim_{\forall (n,m), f_n, g_m \in \mathcal{F}} \prod_{n,m} \prod_{k,s} O_{K} \varpi^{f_n(k)+g_m(s)}
\]

Given \( f, g \in \mathcal{F} \) we define \( h_{f,g} : \mathbb{N} \times \mathbb{N} \to \mathbb{Z} \) as \( h_{f,g}(k,s) = f(k) + g(s) \). Let \( \mathcal{F}' \) be the set of functions \( h : \mathbb{N} \times \mathbb{N} \to \mathbb{Z} \) such that \( h(n,m) \to \infty \) as \( \min\{n,m\} \to \infty \). Then the family of functions \( \{h_{f,g}\}_{f,g \in \mathcal{F}} \) is cofinal in \( \mathcal{F}' \) (see the proof of Lemma 3.16). One obtains

\[
\left( \prod_{n} V_n \right) \otimes_{K} \left( \prod_{m} W_m \right) = \lim_{\forall (n,m), h_{n,m} \in \mathcal{F}'} \prod_{n,m} \prod_{k,s} O_{K} \varpi^{h_{n,m}(k,s)}
\]

\[
= \prod_{n,m} \prod_{h_{n,m} \in \mathcal{F}' \cap \mathcal{F}'} \prod_{k,s} O_{K} \varpi^{h_{n,m}(k,s)}
\]

\[
= \prod_{n,m} \bigoplus_{k,s} K
\]

\[
= \prod_{n,m} (V_n \otimes_{K} W_m),
\]

this finishes the proof. \( \square \)

**Proposition 3.23 ([CS]).** A Fréchet space is a nuclear \( K \)-vector space.

**Proof.** Let \( V = \lim_{n} V_n \) be a Fréchet space written as an inverse limit of Banach spaces with dense transition maps. Let \( S \) be an extremally disconnected set, then by Corollary 3.13

\[
\text{Hom}_{K}(K[S], V) = \lim_{n} \text{Hom}_{K}(K[S], V_n)
\]

\[
= \lim_{n} \text{Hom}_{K}(K[S], K) \otimes_{K} V_n
\]

\[
= \text{Hom}_{K}(K[S], K) \otimes_{K} (\lim_{n} V_n)
\]

\[
= \text{Hom}_{K}(K[S], K) \otimes_{K} V,
\]

this finishes the proof. \( \square \)

The following two lemmas describe the maps between \( LF \), Fréchet and Banach spaces

**Lemma 3.24.** Let \( V = \lim_{n} V_n \) be a Fréchet space written as a countable cofiltered limit of Banach spaces with projection maps \( V \to V_n \) of dense image. Let \( W \) be a Banach space. Then any continuous linear map \( f : V \to W \) factors through some \( V_n \). More generally, we have \( \text{Hom}_{K}(V,W) = \lim_{n} \text{Hom}_{K}(V_n,W) \).

**Proof.** First, evaluating \( \text{Hom}_{K}(V,W) \) at an extremally disconnected set, using adjunction and the nuclearity of \( W \), one reduces to showing that \( \text{Hom}_{K}(V,W) = \lim_{n} \text{Hom}_{K}(V_n,W) \). Since all the spaces involved come from compactly generated topological \( K \)-vector spaces, we might assume that \( V \) and \( W \) are classical Fréchet and Banach spaces respectively. Let \( | \cdot |_n \) be the seminorm of \( V \) given by \( V_n \), without loss of generality we may assume that \( | \cdot |_n \leq | \cdot |_{n+1} \). We denote the norm of \( W \) by \( || \cdot || \). The map \( f \) factors through \( V_n \) if and
only if it is continuous with respect to the seminorm $|\cdot|_n$. Suppose that $f$ does not factor through any $n$, then there exist sequences of vectors $(v_{n,m})_m$ in $V$ for all $n$ such that

$$|v_{n,m}|_n \xrightarrow{m \to \infty} 0 \text{ and } ||f(v_{n,m})|| \geq 1 \ \forall m.$$  

Moreover, we may assume that $|v_{n,m}|_n < \frac{1}{n}$. Then the sequence $(v_{n,m})_n$ converges to 0 in $V$ but $||f(v_{n,m})|| \geq 1$ for all $n$, which is a contradiction with the continuity of $f$. 

\[\square\]

**Lemma 3.25.** Let $W = \varinjlim_n W_n$ and $W' = \varinjlim_m W'_m$ be LF spaces presented as a filtered colimit of Fréchet spaces by injective transition maps. Then

$$\text{Hom}_K(W, W') = \varinjlim_n \varprojlim_m \text{Hom}_K(W_n, W'_m).$$

**Proof.** First observe that formally

$$\text{Hom}_K(W, W') = \varinjlim_n \text{Hom}_K(W_n, W'),$$

so we can assume that $W = W_0$ is a Fréchet space. Let $S$ be an extremally disconnected set, then by nuclearity of $W'$

$$\text{Hom}_K(W, \varinjlim_m W'_m)(S) = \text{Hom}_K(W \otimes_K K[S], \varinjlim_m W'_m) = \text{Hom}_K(W, \varinjlim_m W'_m \otimes_K \text{Cont}(S, K)),$$

which shows that one can reduce to proving

$$\text{Hom}(W, \varinjlim_m W'_m) = \varinjlim_m \text{Hom}(W, W'_m).$$

So let

$$W \xrightarrow{m \to \infty} W'_m$$

be a map of solid $K$-vector spaces. Evaluating at an extremally disconnected set $S$, we get a map

$$f : W(S) \to \varinjlim_m W'_m(S)$$

between a (classical) Fréchet space and a (classical) LF space. We claim that this map factors through some $m$. Indeed, this follows from [Sch02, Corollary 8.9], but we also give a direct argument. Assume not. Then there exists a sequence $(x_m)_{m \geq 1}$ in $W(S)$ such that $f(x_m) \notin W'_m(S)$. Multiplying $x_m$ by big powers of $p$, we can assume $x_m \to 0$ as $m \to +\infty$. This translates into the existence of a map

$$\mathbb{N} \cup \{\infty\} \to \varinjlim_m W'_m(S), \quad m \mapsto f(m), \infty \mapsto 0$$

from the profinite set $\mathbb{N} \cup \{\infty\}$ into an LF-space. Since $\mathbb{N} \cup \{\infty\}$ is profinite, this maps must factorise through some $m$, which is a contradiction. This shows that, for each extremally disconnected set $S$, there exists a smallest $n(S) \in \mathbb{N}$ such that the map

$$W(S) \to \varinjlim_m W'_m(S)$$

factors through $W(S) \to W'_{n(S)}(S) \to \varinjlim_m W'_m(S)$. We conclude the proof by showing that the $n(S)$’s are uniformly bounded. We argue again by contradiction. Assume that there are extremally disconnected sets $S_1, S_2, \ldots$ such that $n(S_i) \to +\infty$ as $i \to +\infty$. Let $S = \prod_i S_i$, which is a profinite set. Let $\tilde{S}$ be an extremally disconnected set surjecting to $S$. Let $i \in \mathbb{N}$ be such that $n(S_i) > n(\tilde{S})$ and let $S_i \to \tilde{S}$ be a section of the surjection $\tilde{S} \to S \to S_i$. Then the map $W(S_i) \to \varinjlim_m W'_m(S_i)$ factors through

$$W(S_i) \to W(\tilde{S}) \to W'_{n(\tilde{S})}(\tilde{S}) \to W'_{n(\tilde{S})}(S_i),$$

which is a contradiction. This finishes the proof.

\[\square\]
3.3.2. Spaces of compact type. Before proving the duality between Fréchet and LS spaces let us recall the definition of (classical) nuclear Fréchet space and a LB space of compact type. Due to the fact that Fréchet spaces are always nuclear in the world of solid $K$-vector spaces (Proposition 3.23), we will say that a classical nuclear Fréchet space is a Fréchet space of compact type. We recall the definition of trace class maps and compact maps for $K$-vector spaces.

**Definition 3.26** ([Sch20 Definition 13.11]).

(1) A trace class map of Smith spaces is a $K$-linear map $f : Q_1 \to Q_2$ such that there is a map $g : K \to Q_1^\vee \otimes_K Q_2$ such that $f$ is the composition $Q_1 \xrightarrow{1 \otimes g} Q_1 \otimes Q_2^\vee \otimes Q_2 \to Q_2$.

(2) A map of Banach spaces is compact if its dual is a trace class map.

**Definition 3.27.**

(1) A Fréchet space $V$ is of compact type if it has a presentation $V = \lim_{\leftarrow n} V_n$ as an inverse limit of Banach spaces where the maps $V_{n+1} \to V_n$ are compact.

(2) A LS space is of compact type if it admits a presentation $W = \lim_{n \in \mathbb{N}} W_n$ by injective trace class maps of Smith spaces.

(3) Let $W$ be a Smith space with lattice $W^0 \subseteq W$. We denote by $W^B$ the Banach space whose underlying space is

$$W^B = \lim_{s \in \mathbb{N}} (W^0(*)_{\text{dis}}/\omega^s)[1/\omega].$$

In other words, $W^B$ is the Banach space structure attached to the underlying set $W(*)$ with unit ball $W^0(*)$. Note that there is a natural injective map with dense image $W^B \to W$.

(4) Let $V$ be a Banach space, we denote $V^S = (V^\vee)^\vee$ and call this space the “Smith completion of $V$”. Note that there is an injective map with dense image $V \to V^S$.

The following two results will be very useful later when studying spaces of compact type. The reader can compare them to the ideas appearing in [Sch02 §16] (see, e.g., the discussion after [Sch02 Proposition 16.5]).

**Lemma 3.28.**

(1) A map of Smith spaces $W \to W'$ is trace class if and only if it factors as $W \to W'^B \to W'$. Dually, a map of Banach spaces $V \to V'$ is of compact type if and only if it can be extended to $V \to V'^S \to V'$. 

(2) Let $f : V \to W$ be a map from a Banach space to a Smith space, then $f$ extends to a commutative diagram

$$
\begin{array}{c}
V \\
\downarrow \\
W^B \\
\downarrow \\
W
\end{array}
\longrightarrow
\begin{array}{c}
V^S \\
\downarrow \\
V'^S \\
\downarrow \\
V'.
\end{array}
$$

**Proof.** (1) The factorization for a morphism of Banach spaces follows from the one of Smith spaces. Let $f : W \to W'$ be a map of Smith spaces and suppose that it factors through $W'^B$. Then $f$ belongs to $\text{Hom}(W, W'^B) = W^\vee \otimes_K W'^B$ as $W'^B$ is Banach. This shows that $f$ if a trace class map. Conversely, let $f : W \to W'$ be trace class, then there is $g : K \to W^\vee \otimes W'$ such that $f$ factors as a composition $W \xrightarrow{1 \otimes g} W \otimes W^\vee \otimes W' \to W'$. But taking $\omega$-completions of the underlying discrete objects, the map $g$ factors through $K \to W^\vee \otimes W'^B$, so that $f$ factors through $W'^B$ as expected.

(2) Clearly $f$ factors as $V \to W^B \to W$. Taking duals we see that $f^\vee : V^\vee \to V'^\vee$ factors as $V^\vee \to V'^B \to V$, taking duals again one gets the factorization $f : V \to V'^S \to W$. □

**Corollary 3.29.**

(1) Let $V = \lim_{\leftarrow n} V_n$ be a Fréchet space of compact type. Then we can write $V = \lim_{n \in \mathbb{N}} V_n^S$ as an inverse limit of Smith spaces with trace class transition maps. Conversely, any such vector space is a Fréchet space of compact type.
Let \( W = \lim_{n} W_n \) be an LS space of compact type, then \( W = \lim_{n} W_n^B \) can be written as a filtered colimit of Banach spaces with injective compact maps. Conversely, a colimit of Banach spaces by injective compact maps is an LS space of compact type. In particular, being a LB or a LS space of compact type is equivalent.

3.3.3. Duality. We conclude with the main result of this chapter.

**Theorem 3.30.**

1. The functor \( V \mapsto \text{Hom}_K(V, K) \) induces an antiequivalence between Fréchet and LS spaces such that \( \text{Hom}_K(V, V') = \text{Hom}_K(V^\vee, V') \), extending the one between Banach and Smith spaces. Moreover, \( V \) is Fréchet of compact type if and only if \( V^\vee \) is an LS space of compact type.

2. Let \( V = \lim_{n} V_n \) be a Fréchet space and \( W = \lim_{n} W_n \) be an LS space. Then

\[
\text{Hom}_K(W, V) = W^\vee \otimes_K V \quad \text{and} \quad \text{Hom}_K(V, W) = V^\vee \otimes_K W.
\]

In particular, if \( V \) and \( V' \) are Fréchet spaces (resp. LS spaces) then

\[
(V \otimes_K V')^\vee = V^\vee \otimes_K V'^\vee.
\]

**Proof.** (1) Let \( V \) be a Fréchet space and let \( V = \lim_{n} V_n \) be a presentation as an inverse limit of Banach spaces with transition maps of dense image. Let \( S \) be an extremally disconnected set, we want to compute

\[
\text{Hom}_K(V, K)(S) = \text{Hom}_K(V \otimes \mathcal{O}_K, \mathcal{O}_K[S], K) = \text{Hom}_K(\lim_{n} V_n, \text{Cont}(S, K)).
\]

By Lemma 3.24 we have

\[
\text{Hom}_K(\lim_{n} V_n, \text{Cont}(S, K)) = \lim_{n} \text{Hom}_K(V_n, \text{Cont}(S, K)) = \lim_{n} \text{Hom}_K(V_n \otimes \mathcal{O}_K, \mathcal{O}_K[S], K).
\]

In other words, we have a natural isomorphism

\[
\text{Hom}_K(V, K) = \lim_{n} V_n^\vee.
\]

By Lemma 3.15 (2), the transition maps \( V_n^\vee \to V_{n+1}^\vee \) are injective, proving that \( V^\vee \) is an LS space.

Conversely, let \( W \) be an LS space and \( W = \lim_{n} W_n \) a presentation as a colimit of Smith spaces with injective transition maps. Then if follows formally that

\[
\text{Hom}_K(W, K) = \lim_{n} W_n^\vee.
\]

By Lemma 3.15 (2) again, the transition maps \( W_{n+1}^\vee \to W_n^\vee \) have dense image. It is clear from the construction that \((V^\vee)^\vee = V\) and \((W^\vee)^\vee = W\) for \( V \) Fréchet and \( W \) an LS space. This implies formally that \( \text{Hom}_K(V, V') = \text{Hom}_K(V^\vee, V^\vee) \), which gives the antiequivalence between Fréchet and LS spaces. Finally, by Corollary 3.29 and the previous computation, the duality restricts to Fréchet and LS spaces of compact type.

We now extend the equality of homomorphisms to the internal \( \text{Hom} \). Let \( V \) and \( V' \) be Fréchet spaces and \( S \) an extremally disconnected set. We have

\[
\text{Hom}_K(V, V')(S) = \text{Hom}_K(V \otimes_K K[S], V') = \text{Hom}_K(V, \text{Cont}(S, K) \otimes_K V') = \text{Hom}_K((\text{Cont}(S, K) \otimes_K V')^\vee, V^\vee) = \text{Hom}_K(V'^\vee \otimes_K K[S], V^\vee) = \text{Hom}_K(V'^\vee, V^\vee)(S).
\]

The second equality follows from adjunction and nuclearity of \( V' \). The third equality is the duality between Fréchet and LS spaces. The fourth equality follows from the compatibility of the tensor product and duality between Fréchet and LS spaces of part (2).
(2) Let \( V = \lim_{\leftarrow n} V_n \) and \( W = \lim_{\to m} W_m \) be a Fréchet and an \( \mathbb{L}S \) space respectively. We can write
\[
\text{Hom}_K(W, V) = \lim_{\leftarrow m} \text{Hom}_K(W_m, V) = \lim_{m} W_m^\vee \otimes_K V = W^\vee \otimes_K V
\]
where the first equality is formal, the second equality follows from nuclearity of Fréchet spaces, and the third equality from the tensor product of Fréchet spaces (Proposition 3.22). Dually, we have
\[
\text{Hom}_K(V, W) = \text{Hom}_K(V \otimes_K W^\vee, K) = \lim_{n,m} V_n \otimes_K W_m^\vee, K = \lim_{n,m} \text{Hom}_K(V, W) = \lim_{n,m} V_n^\vee \otimes_K W_m = V^\vee \otimes_K W,
\]
where the first equality follows from self duality of \( \mathbb{L}S \) spaces and the tensor-Hom adjunction, the second equality from the tensor product of Fréchet spaces, the third equality from Lemma 3.24, and the last two equalities from Corollary 3.14 and the commutativity between tensor product and colimits.

4. Representation Theory

Let \( G \) be a compact \( p \)-adic Lie group. In this section we translate the theory of analytic and locally analytic representations of \( G \) from the classical framework to condensed mathematics. We hope that this new point of view could simplify some proofs and provide a better understanding of the theory. Our main sources of inspiration are the works of Lazard [Laz65], Schneider-Teitelbaum [ST02, ST03] and Emerton [Eme17].

We begin with the introduction of different algebras of distributions, each one serves to a particular purpose in the theory. Namely, there are distribution algebras arising from affinoid groups which appear naturally in the analytification functor of Proposition 2.11, distribution algebras which are localizations of the Iwasawa algebra, and distribution algebras algebras attached to Stein analytic groups relating the previous two.

Next, we introduce the category of solid \( G \)-modules, it is a generalisation of the category of non-archimedean topological spaces endowed with a continuous action of \( G \) (Banach, Fréchet, \( \mathbb{L}B \), \( \mathbb{L}F \), ...).

We continue with the definition of analytic representations for the affinoid and Stein analytic groups of Definition 4.4. We recall how the analytic vectors for a Banach representation are defined, and how it serves as motivation for the derived analytic vectors of solid \( G \)-modules. We prove the main Theorem 4.34 which, roughly speaking, says that being analytic for a Stein analytic group as in Definition 4.4 is the same as being a module over its distribution algebra.

We end with an application to locally analytic representations, reproving a theorem of Schneider-Teitelbaum describing a duality between locally analytic representations on \( \mathbb{L}B \) spaces of compact type, and Fréchet modules of compact type over the algebra of locally analytic distributions, cf. Proposition 4.36. We state a conjectural generalisation to a duality between locally analytic bounded complexes of \( \mathbb{L}B \) compact type and bounded Fréchet complexes of compact type endowed with an action of the algebra of locally analytic distributions.

4.1. Function spaces and distribution algebras. In the following paragraph we define different classes of spaces of functions and distributions that will be used throughout this text. These are algebras already appearing in the literature ([ST03, §4], [Eme17, §5]) that we introduce in a way adapted to our interests and purposes.

Let \( G \) be a compact \( p \)-adic Lie group of dimension \( d \).
Definition 4.1. The Iwasawa algebra of $G$ is defined as the solid ring
\[
\mathcal{O}_K\llbracket G \rrbracket = \lim_{H \leq G} \mathcal{O}_K[G/H] \in \text{Mod}^{\text{solid}}_{\mathcal{O}_K},
\]
\[
K\llbracket G \rrbracket = \mathcal{O}_K\llbracket G \rrbracket[1/p] = \left( \lim_{H \leq G} \mathcal{O}_K[G/H] \right)[1/p] \in \text{Mod}^{\text{solid}}_K,
\]
where $H$ runs over all the open and normal subgroups of $G$.

Remark 4.2. Classically, the Iwasawa algebra is denoted by $\Lambda(G, \mathcal{O}_K)$ and $\Lambda(G, K)$. We decide to adopt the new notations from the theory of condensed mathematics to best fit our results in this language.

Remark 4.3. According to the notations of Example 2.7, the Iwasawa algebra corresponds precisely to the evaluation at $G$ of the functor of measures of the analytic rings $(\mathcal{O}_K, \mathcal{O}_K)\llbracket$ and $(K, \mathcal{O}_K)\llbracket$ which, in turn, are commonly denoted by $\mathcal{O}_K\llbracket$ and $K\llbracket$ respectively.

In order to define the space of locally analytic functions attached to $G$, we need to work with coordinates locally around the identity. By [DdSMS99 Cor. 8.34], there exists an open normal subgroup $G_0$ of $G$ which is a uniform pro-$p$ group. Such a group can be equipped with a valuation $w$ and an ordered basis $g_1, \ldots, g_d \in G_0$. By [Laz65 III 3.1.3, Proposition], after shrinking $G_0$ if necessary, we can assume that $w(g_1) = \ldots = w(g_d) = w_0 > 1$ is an integer. This basis induces charts
\[
\phi : \mathbb{Z}_p^d \to G_0, \quad (x_1, \ldots, x_d) \mapsto g_1^{x_1} \cdot \ldots \cdot g_d^{x_d}
\]
such that $\phi$ is an homeomorphism between $G_0$ and $\mathbb{Z}_p^d$ with $w(g_1^{x_1} \cdot \ldots \cdot g_d^{x_d}) = w_0 + \min_{1 \leq i \leq d} v_p(x_i)$, and such that the map $\psi : G_0 \times G_0 \to G_0, \ (g, h) \mapsto gh^{-1}$, defining the group structure of $G_0$, is given by an analytic function $\psi : \mathbb{Z}_p^d \times \mathbb{Z}_p^d \to \mathbb{Z}_p^d$ with coefficients in $\mathbb{Z}_p$. By further shrinking $G_0$ if necessary we can also assume that conjugation on $G_0$ by any element of $G$ is given by a family of power series with bounded coefficients.

Let $r = p^{-s} > 0$ for $s \in \mathbb{Q}$, and $\mathbb{D}_{\mathbb{Q}_p}(r) \subset \mathbb{A}_{\mathbb{Q}_p}$ the affinoid polydisc of radius $r$. If $s \in \mathbb{Z}$ then $\mathbb{D}_{\mathbb{Q}_p}(r)$ is the affinoid space defined by the algebra $\mathbb{Q}_p[T_1, \ldots, T_d]$, where $T_1, \ldots, T_d$ are the coordinates of $\mathbb{A}_{\mathbb{Q}_p}$. We let $\overset{\sim}{\mathbb{D}}(r) = \bigcup_{r < r} \mathbb{D}(r)$ denote the open polydisc of radius $r$.

Definition 4.4. We define the following rigid analytic groups

1. $\mathcal{G}_0 = (\mathbb{D}_{\mathbb{Q}_p}(1), \psi)$; the affinoid group defined by the group law $\psi$ of $G_0$.

2. For any $h \in \mathbb{Q}_{\geq 0}$, the affinoid groups $\mathcal{G}_h = (\mathbb{D}_{\mathbb{Q}_p}(p^{-h}), \psi)$ of radius $p^{-h}$. We also denote $\mathcal{G}_0^{(h)} = G_0 \mathcal{G}_h \subset \mathcal{G}_0$.

3. For any $h \in \mathbb{Q}_{\geq 0}$ the Stein groups $\mathcal{G}_h^+ = \cup_{h' > h} \mathcal{G}_h^{h'}$ and $\mathcal{G}_0^{(h^+)} = G_0 \mathcal{G}_h^+ = \cup_{h' > h} \mathcal{G}_0^{(h')}$. 

Example 4.5. If $G = \text{GL}_2(\mathbb{Z}_p)$, an example of a uniform pro-$p$-subgroup $G_0$ is
\[
G_0 = \left( \begin{array}{cc} 1 + p^n \mathbb{Z}_p & p^n \mathbb{Z}_p \\ p^n \mathbb{Z}_p & 1 + p^n \mathbb{Z}_p \end{array} \right),
\]
for $n \geq 2$ if $p = 2$ and $n \geq 1$ if $p > 2$. Let’s take $p > 2$ and $n = 1$. In this case $\mathcal{G}_h$ is the rigid analytic group
\[
\mathcal{G}_h = \left( \begin{array}{cc} 1 + \mathbb{D}_{\mathbb{Q}_p}(p^{-h-1}) & \mathbb{D}_{\mathbb{Q}_p}(p^{-h-1}) \\ \mathbb{D}_{\mathbb{Q}_p}(p^{-h-1}) & 1 + \mathbb{D}_{\mathbb{Q}_p}(p^{-h-1}) \end{array} \right) = \left( \begin{array}{cc} 1 + p^{h+1} \mathbb{D}_{\mathbb{Q}_p}(1) & p^{h+1} \mathbb{D}_{\mathbb{Q}_p}(1) \\ p^{h+1} \mathbb{D}_{\mathbb{Q}_p}(1) & 1 + p^{h+1} \mathbb{D}_{\mathbb{Q}_p}(1) \end{array} \right),
\]
whereas the Stein group $\mathcal{G}_h^+$ is equal to
\[
\mathcal{G}_h^+ = \left( \begin{array}{cc} 1 + p^{h+1} \mathbb{D}_{\mathbb{Q}_p}(1) & p^{h+1} \mathbb{D}_{\mathbb{Q}_p}(1) \\ p^{h+1} \mathbb{D}_{\mathbb{Q}_p}(1) & 1 + p^{h+1} \mathbb{D}_{\mathbb{Q}_p}(1) \end{array} \right).
\]

The following lemma says that the rigid spaces of Definition 4.4 are indeed rigid analytic groups.

Lemma 4.6. The affinoid $\mathcal{G}_h$ is an open normal subgroup of $\mathcal{G}_0$ stable by conjugation of $G$.

---

6Recall that a uniform pro-$p$ group $H$ is a pro-$p$ group which is finitely generated, torsion free and powerful, i.e., $[H, H] \subseteq H^p$ if $p > 2$ or $[H, H] \subseteq H$ if $p = 2$. 
Proof. By simplicity we suppose that \( h \in \mathbb{N} \). The map 
\[
\psi : \mathbb{G}_0 \times \mathbb{G}_0 \to \mathbb{G}_0 : (x, y) \mapsto xy^{-1}
\]
is defined by a family of power series \( (Q_1(X, Y), \ldots, Q_d(X, Y)) \) with integral coefficients satisfying the group axioms. In particular, one has \( Q_i(0, 0) = 0 \). The inclusion \( \mathbb{G}_h \to \mathbb{G}_0 \) is given by the map \( \mathbb{Q}_p(T_1, \ldots, T_d) \to \mathbb{Q}_p(T_1/p^h, \ldots, T_d/p^h) \). Thus, the image of \( \frac{T}{p^h} \) by the multiplication map \( \psi \) is equal to
\[
\frac{1}{p^h}Q_i(X, Y) = \frac{1}{p^h} \sum_{(\alpha, \beta) \neq 0} a_{\alpha, \beta} X^\alpha Y^\beta = \sum_{(\alpha, \beta) \neq 0} a_{\alpha, \beta} p^{h(|\alpha| + |\beta| - 1)} \left( \frac{X}{p^h} \right)^\alpha \left( \frac{Y}{p^h} \right)^\beta.
\]
This shows that \( \psi \) restricts to a map \( \mathbb{G}_h \times \mathbb{G}_h \to \mathbb{G}_h \), proving that \( \mathbb{G}_h \) is a subgroup of \( \mathbb{G}_0 \). A similar argument shows that \( \mathbb{G}_h \) is normal in \( \mathbb{G}_0 \) and that it is stable by the conjugation of elements of \( G \). \( \square \)

4.1.1. Analytic distributions. Classically, the analytic vectors of Banach representations are defined via the affine algebras of the analytic groups of Definition 4.1, see [Eme17 §3]. In order to develop properly this theory for solid \( K \)-vector spaces we shall need to introduce some notation for the algebras of the analytic groups, as well as for their analytic distributions. Recall once more that we see all complete locally convex \( K \)-vector spaces as solid objects.

Definition 4.7.

(1) We consider the following spaces of functions
\begin{enumerate}
\item \( C(\mathbb{G}_0, O_K) := O^+(\mathbb{G}_0) \otimes _{\mathbb{Z}_p} O_K \); the power bounded analytic functions of the affinoid group.
\item \( C(\mathbb{G}_0, K) := O(\mathbb{G}_0) \otimes _{\mathbb{Q}_p} K \); the regular functions of the affinoid group.
\item \( C(\mathbb{G}_0, K) := \lim_{\substack{\text{h↓} \to 0}} C(\mathbb{G}_0, K) \); the regular functions of the Stein group.
\end{enumerate}

(2) We define the following spaces of distributions
\begin{enumerate}
\item \( D(h)(\mathbb{G}_0, O_K) := \text{Hom}_O K \otimes (\mathbb{G}_0, O_K) \); the convolution product.
\item \( D(h)(\mathbb{G}_0, K) := \text{Hom}_K (\mathbb{G}_0, K) \); the regular functions of the Stein group.
\item \( D(h)(\mathbb{G}_0, K) := \text{Hom}_K (\mathbb{G}_0, K) \); the regular functions of the Stein group.
\end{enumerate}

Remark 4.8. Let \( h \in \mathbb{N} \), the algebra \( C(\mathbb{G}_0, K) \) is the space of functions on \( \mathbb{G}_0 \) with values in \( K \) which are analytic of radius \( p^{-h} \). More precisely, using the coordinates \( g_1, \ldots, g_d \in \mathbb{G}_0 \), and identifying \( \mathbb{G}_0 \) with \( \mathbb{Z}_p^d \), \( C(\mathbb{G}_0, K) \) is the space of functions \( f : \mathbb{Z}_p^d \to K \) whose restriction at cosets \( x + p^h \mathbb{Z}_p^d \) is given by a convergent power series with coefficients in \( K \).

Remark 4.9. Observe that, by Theorem 3.30 one has \( C(\mathbb{G}_0, K) = D(h)(\mathbb{G}_0, K) \) \( n \) as well as \( D(h)(\mathbb{G}_0, K) = \lim_{h \to 0} D(h)(\mathbb{G}_0, K) \).

Lemma 4.10. The solid \( O_K \)-module \( D(h)(\mathbb{G}_0, O_K) \) has a natural structure of associative unital \( O_K \)-algebra induced by the multiplication map \( \mathbb{G}_0 \times \mathbb{G}_0 \to \mathbb{G}_0 \). In particular, \( D(h)(\mathbb{G}_0, K) \) and \( D(h)(\mathbb{G}_0, K) \) are associative unital \( O_K \)-algebras.

Proof. The multiplication \( \mathbb{G}_0 \times \mathbb{G}_0 \to \mathbb{G}_0 \) defines a comultiplication map
\[
\nabla : C(\mathbb{G}_0, O_K) \to C(\mathbb{G}_0, O_K) \otimes _O C(\mathbb{G}_0, O_K).
\]
As \( C(\mathbb{G}_0, O_K) \) is an orthonormalizable Banach \( O_K \)-module, taking the dual of \( \nabla \) one obtains a map \( D(h)(\mathbb{G}_0, O_K) \otimes _O C(\mathbb{G}_0, O_K) \to D(h)(\mathbb{G}_0, O_K) \) which is easily seen to be the convolution product. \( \square \)

4.1.2. Localizations of the Iwasawa algebra. Recall that we have fixed an open normal subgroup \( \mathbb{G}_0 \) which is a uniform pro-\( p \)-group with basis \( g_1, \ldots, g_d \) of constant valuation \( w_0 > 1 \). Let \( b_i = [g_i] - 1 \in O_K[\mathbb{G}_0](*) \), one has [ST03 §4]
\[
O_{K[\mathbb{G}_0]} = \prod_{\alpha \in \mathbb{N}^d} O_K b^\alpha
\]
where \( b^\alpha = b_1^{\alpha_1} \cdots b_d^{\alpha_d} \) for \( \alpha = (\alpha_1, \ldots, \alpha_d) \in \mathbb{N}^d \).
Remark 4.11. Taking Mahler expansion of continuous functions on $\phi : G_0 \cong \mathbb{Z}_p^d$, an explicit computation of finite differences shows that the elements $b^{\alpha}$ correspond to the dual basis of the Mahler basis $(x_i^h)$ i.e., $b^{\alpha}(f) = c_\alpha$ for any continuous function $f \in \text{Cont}(G_0, K)$ such that $\phi^*(f) = \sum_{\alpha \in \mathbb{N}^d} c_\alpha x^\alpha$.

We now introduce a second family of distribution algebras using the basis $(b_i)_{1 \leq i \leq d}$, these can be thought of as localizations of the Iwasawa algebra $K\square [G_0]$.

**Definition 4.12.** Let $h > 0$ be rational. We define the condensed rings $D_{(h)}(G_0, O_K)$ and $D_{(h)}(G_0, K)$ so that, for any extremally disconnected set $S$, one has

- $D_{(h)}(G_0, O_K)(S) = \{ \sum_{\alpha \in \mathbb{N}^d} a_\alpha b^{\alpha} : \sup_\alpha \{|a_\alpha| p^{-h|\alpha|} \} \leq 1, \ a_\alpha \in \text{Cont}(S, O_K) \}$,

- $D_{(h)}(G_0, K)(S) = \{ \sum_{\alpha \in \mathbb{N}^d} a_\alpha b^{\alpha} : \sup_\alpha \{|a_\alpha| p^{-h|\alpha|} \} < +\infty, \ a_\alpha \in \text{Cont}(S, K) \}$.

**Remark 4.13.** The condensed module $D_{(h)}(G_0, O_K)$ is in fact a profinite $O_K$-module provided $b(h) = \frac{1}{p^h-1} \in v_p(K) \otimes \mathbb{Z} \mathbb{Q}$. Indeed, if $b(h)$ is the valuation of an element of $K$, we have an isomorphism of profinite $O_K$-modules

$$D_{(h)}(G_0, O_K) \cong \prod_{\alpha \in \mathbb{N}^d} O_K \left( \frac{b_1}{p^h} \right)^{\alpha_1} \ldots \left( \frac{b_d}{p^h} \right)^{\alpha_d}.$$ 

**Remark 4.14.** The distribution algebras $D_{(h)}(G_0, K)$ are variations of the $(p)$-adic completions of the rings $A^{(m)}$ of [Emc17, §5.2], adapted to the Iwasawa algebra instead of the enveloping algebra of Lie $G$.

**Lemma 4.15.** The multiplication map of $K\square [G_0]$ extends uniquely to a multiplication map of $D_{(h)}(G_0, O_K)$.

**Proof.** This follows directly from Proposition 4.2 of [ST03].

One can describe the analytic distributions of Definition 4.17 in terms of the the basis $b_i$ of the Iwasawa algebra.

**Proposition 4.16.** Let $S$ be an extremally disconnected set, then

$$D_{(h)}(G_0, K)(S) = \left\{ \sum_{\alpha \in \mathbb{N}^d} a_\alpha b^{\alpha} : \sup_\alpha \{|a_\alpha| p^{-h|\alpha|} \} < +\infty, \ a_\alpha \in \text{Cont}(S, K) \right\},$$

where $s(\alpha) = \sum_{1 \leq i \leq d} s(\alpha_i)$ and $s(\alpha_i)$ is the sum of the $p$-adic digits of $\alpha_i$. In particular, one has

$$D_{(h^+)}(G_0, K)(S) = \left\{ \sum_{\alpha \in \mathbb{N}^d} a_\alpha b^{\alpha} : \sup_\alpha \{|a_\alpha| p^{-h|\alpha|} \} < +\infty \text{ for some } h' > h, \ a_\alpha \in \text{Cont}(S, K) \right\}.$$ 

**Proof.** Let $\phi : \mathbb{Z}_p^d \to G_0$ be the chart defined by the basis $g_1, \ldots, g_d$. By a theorem of Amice (c.f. [Laz65, III.(1.3.8)]), a continuous function $f : G_0 \to K$ is $h$-analytic (i.e. belongs to $C(G_0^{(h)}, K)$) if and only if

$$v(c_\alpha) - \frac{p^{-h|\alpha|} - s(\alpha)}{p-1} \to +\infty$$

whenever $\alpha \to +\infty$, where $\phi^* f(g) = \sum_{\alpha \in \mathbb{N}^d} c_\alpha (x^\alpha)$. After dualizing this gives the claimed result as the algebra of analytic distributions is attached to its underlying topological space.

**Remark 4.17.** One can rewrite the above condition on the valuation of the coefficients as

$$\sup_{\alpha} \{|a_\alpha \alpha!| p^{-a(h)|\alpha|} \} < +\infty,$$

where $a(h) = \frac{p^h-1}{p-1}$.

**Corollary 4.18.** There is an isomorphism of solid $O_K$-algebras

$$D_{(h^+)}(G_0, K) \cong \lim_{\substack{\rightarrow h' > h}} D_{(h')}(G_0, K).$$
Proof. Let $h'' > h'$, then one can write
\[
p h'' = \frac{h'' - h'}{h'' - h'} = \frac{h'' - h'}{p - 1} = \frac{h'' - h'}{p - 1} \cdot p - \frac{h'' - h'}{1 - s(\alpha)}.
\]
Since $p - h'' > 0$, we see that $(p - h')\alpha - s(\alpha) \to +\infty$ as $|\alpha| \to +\infty$. This implies that for any $h'' > h'$ we have
\[
D(h')(G,0) \subset D(h')(G,0) \subset D(h')(G,0).
\]
Taking limits as $h' \to h^+$ and $h'' \to h^+$ one obtains the corollary. 

4.1.3. Distribution algebras over $G$. The algebras we have defined can be extended to the whole compact group $G$ in an obvious way. Indeed, by Lemma 4.19 the spaces $D(h)(G,0)$ and $D(h)(G,0)$ admit an action of $G$ extending the inner action of $K[G_0]$. Let us define the distributions
\[
D(h)(G,K) = K[G] \otimes K[G_0] D(h)(G,0),
\]
\[
D(h^+)(G,K) = \lim_{h' > h} D(h')(G,K)
\]
\[
D(h)(G,0) = K[G] \otimes K[G_0] D(h)(G,0),
\]
where in the tensor products we see $D(h)(G,0)$ as a left $K[G_0]$-module. They are unital associative algebras admitting $K[G]$ as a dense subspace. Notice that even though the distributions algebras over $G$ depend on the choice of the open normal subgroup $G_0 \subset G$, the projective systems $\{D(h)(G,K)\}_{h \in \mathbb{N}}$ and $\{D(h)(G,K)\}_{h > 0}$ do not. We define the algebra of locally analytic distributions of $G$ as the Fréchet algebra
\[
D(h)(G,K) = \lim_{h \to \infty} D(h)(G,K) = \lim_{h \to \infty} D(h)(G,K).
\]

For future reference let us introduce algebras of analytic functions over $G$. Let $h \geq 0$ be a rational number and $G_0(h)$ the rigid analytic groups of Definition 4.4. Recall that they are stable under conjugation by $G$. Let $G(h)$ be the rigid analytic group given by $G_0(h)$, i.e. if $s_1, \ldots, s_n$ are representatives of the cosets $G/G_0$ then
\[
G(h) = \bigcup_{i=1}^n s_i G_0(h).
\]
We also define
\[
G(h^+) = \bigcup_{h' > h} G(h).
\]

Let $C(G(h),K) = G(G(h)) \otimes K$ be the affinoid algebra of analytic functions of $G$ over $K$ of radius $p^{-h}$, it is immediate to check that $D(h)(G,K) \subseteq \lim_{h \to \infty} D(h)(G,K)$. We define $C(G(h),O_K)$ and $C(G(h^+),O_K)$ in the obvious way.

Lemma 4.19. Let $V$ be a solid $O_K$-module. The following are equivalent.

1. $V$ has a structure of $O_K[G]$-module
2. For any extremally disconnected set $S$ there is a functorial $O_K$-linear action
\[
C(S,G) \times V(S) \to V(S).
\]

In this case, we say that $V$ is a solid $G$-module over $O_K$. We denote the category of solid $O_K[G]$-modules by $\text{Mod}_{\text{solid}}O_K[G]$ and its derived category by $\text{D}(O_K[G])$.

Proof. Let $V$ be an $O_K[G]$-module and $S$ an extremally disconnected set. There is a natural map of condensed sets $[\ ] : G \to O_K[G]$. The action of $O_K[G]$ over $V$ is provided by a linear map $O_K[G] \otimes O_K[V \to V]$ satisfying the usual axioms. Composing with $[\ ]$ and evaluating at $S$ we obtain a map $C(S,G) \times V(S) \to V(S)$, it is easy to check that this provides a functorial action as in (2).

Conversely, to have such a functorial action is equivalent to having a map of condensed sets $G \times V \to V$ making the usual diagrams commutative. By adjunction of the functor $X \to Z[X]$, this provides a linear map $Z[G] \otimes Z[V \to V$. As $V$ is a solid $O_K$-module it extends uniquely to a map $O_K[G] \otimes O_K[V \to V$ which is easily seen to satisfy the obvious diagrams of an $O_K[G]$-module. 

\begin{flushright}
\end{flushright}
Let us extend the definition of the condensed set of “continuous functions” to complexes:

**Definition 4.20.** Let $V$ be a solid $\mathcal{O}_K$-module and $S$ a profinite set, we denote by $\text{Cont}(S, V)$ the $\mathcal{O}_K$-module $\text{Hom}(\mathbb{Z}[S], V) = \text{Hom}_{\mathcal{O}_K}(\mathcal{O}_K[S], V)$. More generally, for $C \in D(\mathcal{O}_K)$, we denote $\text{Cont}(S, C) := \text{RHom}_{\mathcal{O}_K}(\mathcal{O}_K[S], C)$, which is consistent with the previous definition as $\mathcal{O}_K[S]$ is a projective module.

**Proposition 4.21.** The functor $V \mapsto \text{Cont}(G, V)$ is exact and factors through a functor $\text{Mod}^{\text{solid}}_{\mathcal{O}_K} \to \text{Mod}^{\text{solid}}_{\mathcal{O}_K[G^2]}$ induced by the left and right regular actions respectively. Moreover, it extends to an exact functor of derived categories $D(\mathcal{O}_K) \to D(\mathcal{O}_K[G^2])$.

**Proof.** As $G$ is profinite, $\mathcal{O}_K[G]$ is a compact projective $\mathcal{O}_K$-module. This makes the functor $\text{Cont}(G, V)$ exact. Thus, the second statement reduces to the first one. We prove the first statement. Let $S$ be an extremally disconnected set, then $\text{Cont}(G, V)(S) = \text{Cont}(G \times S, V) = V(G \times S)$. Let us define a map

$$\text{Cont}(S, G^2) \times V(G \times S) \to V(G \times S)$$

as in (2) of Lemma 4.19. Let $f = (f_1, f_2) : S \to G^2$ and $v : G \times S \to V$ be objects in $\text{Cont}(S, G^2)$ and $V(G \times S)$ respectively. We define the product $f \cdot v$ to be the composition

$$S \times G \xrightarrow{s \cdot g} S \times G \xrightarrow{v} V$$

$$(s, g) \mapsto (s, f_1(s)^{-1}gf_2(s)) \mapsto v(s, f_1(s)^{-1}gf_2(s)).$$

It is immediate so check that this endows $\text{Cont}(G, V)$ with a action of $G^2$ which is the left and right regular action on the first and second component respectively. \hfill \square

**Remark 4.22.** If we suppose in addition that $V$ is a $\mathcal{O}_K[G]$-module, then $\text{Cont}(G, V)$ is naturally a $\mathcal{O}_K[G^3]$-module. Namely, for $S$ be an extremally disconnected set, $f_1, f_2, f_3 \in \text{Cont}(S, G)$ and $v \in V(G \times S)$, we have the action

$$[(f_1, f_2, f_3) \cdot v](g, s) = f_3(s)v(f_1(s)^{-1}gf_2(s), s).$$

This action induces an exact functor of derived categories $D(\mathcal{O}_K[G]) \to D(\mathcal{O}_K[G^3])$.

**Definition 4.23.** Let $V$ be a solid $G^n = G \times \cdots \times G$-representation over $\mathcal{O}_K$. Given $I \subset \{1, 2, \ldots, n\}$ we denote by $*_I$ the diagonal action of $G$ on $V$ induced by the embedding $\iota_I : G \to G^n$ in the components of $I$. We denote by $V_*^I$ the module $V$ endowed with the action $*_I$. If $I = \emptyset$ we write $V_0 := V_\emptyset$ for the $\mathcal{O}_K$-module $V$ endowed with the trivial action of $G$.

The following proposition basically says that any action on a solid module is continuous (compare it with [Eme17, Definition 3.2.8]).

**Proposition 4.24.** Let $C$ be an object in $D(\mathcal{O}_K[G])$. Then there is a natural quasi-isomorphism of $\mathcal{O}_K[G]$-modules

$$\text{RHom}_{\mathcal{O}_K[G]}(\mathcal{O}_K, \text{Cont}(G, C)_{*_{1,3}}) \xrightarrow{\sim} C,$$

where the action of $\mathcal{O}_K[G]$ in the left-hand-side is via the $*_2$-action. The inverse of this map is called the orbit map of $C$.

**Proof.** First, we claim that there exists a natural quasi-isomorphism $\text{Cont}(G, C)_{*_{1,3}} \simeq \text{Cont}(G, C)_{*_1}$ for $C \in D(\mathcal{O}_K[G])$. Suppose that the previous is true, then we have

$$\text{RHom}_{\mathcal{O}_K[G]}(\mathcal{O}_K, \text{Cont}(G, C)_{*_{1,3}}) \simeq \text{RHom}_{\mathcal{O}_K[G]}(\mathcal{O}_K, \text{Cont}(G, C)_{*_1})$$

$$\text{RHom}_{\mathcal{O}_K[G]}(\mathcal{O}_K, \text{Cont}(G, C)_{*_1}) = \text{RHom}_{\mathcal{O}_K[G]}(\mathcal{O}_K, \text{RHom}_{\mathcal{O}_K[G]}(\mathcal{O}_K[G], C)_{*_1})$$

$$\text{RHom}_{\mathcal{O}_K[G]}(\mathcal{O}_K, \text{RHom}_{\mathcal{O}_K[G]}(\mathcal{O}_K[G], C)_{*_1}) = \text{RHom}_{\mathcal{O}_K[G]}(\mathcal{O}_K \otimes_{\mathcal{O}_K[G]} \mathcal{O}_K[G], C)$$

$$\text{RHom}_{\mathcal{O}_K[G]}(\mathcal{O}_K \otimes_{\mathcal{O}_K[G]} \mathcal{O}_K[G], C) = \text{RHom}_{\mathcal{O}_K[G]}(\mathcal{O}_K, C) = C.$$
To prove the claim, it is enough to define a natural isomorphism $\text{Cont}(G, V)_{1,3} \to \text{Cont}(G, V)_{1,1}$ for $V \in \text{Mod}_{\text{solid}}^{\bullet} G$. Let $S$ be an extremally disconnected set, and take $v \in V(G \times S)$. Consider the inverse map $u : G \to G$, $g \mapsto g^{-1}$ and the multiplication map $m_V : G \times V \to V$. Define $\psi_V(v)$ to be the composition

$$\psi_V(v) : G \times S \xrightarrow{u \times v} G \times V \xrightarrow{m_V} V.$$ 

The application

$$\psi_V : V(G \times S) \to V(G \times S)$$

$v \mapsto \psi_V(v)$

induces an isomorphism of solid $O_K$-modules $\psi_V : \text{Cont}(G, V) \to \text{Cont}(G, V)$. It is easy to check that it transfers the $\star_{1,3}$-action to the $\star_1$-action and the $\star_2$-action to the $\star_{2,3}$-action. This proves the claim and that the isomorphism (4) is $G$-equivariant. \hfill $\square$

**Remark 4.25.** The previous proof shows that if $V$ is a $O_K[G]$-module arising from a topological space, the isomorphism $V \to (\text{Cont}(G, V)_{1,3})^G$ is given by the usual orbit map.

### 4.3. Analytic representations

Let $h \geq 0$ and $\mathbb{G}^{(h)}$ the rigid analytic group of $\mathbb{G}^{(1)}$ extending the group law of $G$. We recall that $\mathbb{G}^{(h)}$ depends on the choice of an open normal uniform pro-$p$-subgroup $G_0 \subset G$. To motivate the forthcoming definitions of analytic vectors let us first recall how this works for Banach spaces, where we follow [Eme17, §3].

Let $V$ be a $K$-Banach space endowed with a continuous action of $G$, the space of $V$-valued $\mathbb{G}^{(h)}$-analytic functions is by definition the $p$-adically complete tensor product $C(\mathbb{G}^{(h)}, V) := C(\mathbb{G}^{(h)}, K) \hat{\otimes}_K V$. As $V$ and $C(\mathbb{G}^{(h)}, K)$ are Banach spaces, the $p$-adically complete tensor product coincides with the solid tensor product $C(\mathbb{G}^{(h)}, K) \otimes_K V$ (Lemma 3.10). This space has an action of $G^2$ given by the left and right regular actions of $G$, and an extra action of $G$ induced by the one of $V$. Following the notation of Definition 1.23 the $\mathbb{G}^{(h)}$-analytic vectors of $V$ is the Banach space

$$V^{\mathbb{G}^{(h)}}_{\text{an}} := (C(\mathbb{G}^{(h)}, V)_{1,3})^G.$$

There is a natural map $V^{\mathbb{G}^{(h)}}_{\text{an}} \to V$ given by evaluating at $1 \in \mathbb{G}^{(h)}$, and $V$ is $\mathbb{G}^{(h)}$-analytic if the previous arrow is an isomorphism.

To generalise the previous construction of analytic vectors to solid $K[G]$-modules we need to rewrite (7) in a slightly different way. Consider the affinoid ring $(C(\mathbb{G}^{(h)}, K), C(\mathbb{G}^{(h)}, O_K))$, it is a finite product of Tate power series rings in $d$-variables. In Example 2.6 (4) and (5), we saw how the affinoid ring provides a natural analytic ring that we denote as $C(\mathbb{G}^{(h)}, K)$. We also denote by $C(\mathbb{G}^{(h)}, O_K)$ the analytic ring attached to its subalgebra of power-bounded elements. Now, as $V$ is a $K$-Banach vector space, one has

$$C(\mathbb{G}^{(h)}, V) = C(\mathbb{G}^{(h)}, K) \hat{\otimes}_K V = C(\mathbb{G}^{(h)}, K) \hat{\otimes}_K V,$$

where the last tensor product is the completion functor with respect to the measures of $C(\mathbb{G}^{(h)}, K)$, see Theorem 2.7 and Proposition 2.11. Hence, we can write the $\mathbb{G}^{(h)}$-analytic vectors of $V$ in the form

$$V^{\mathbb{G}^{(h)}}_{\text{an}} = \text{Hom}_{K[G]_{\text{an}}}(K, (C(\mathbb{G}^{(h)}, K) \hat{\otimes}_K V)_{1,3}).$$

In order to generalise the construction of analytic vectors we need some basic properties of the tensor $C(\mathbb{G}^{(h)}, O_K) \hat{\otimes}_K O_K$. \hfill $\square$

**Proposition 4.26.** Consider the functor $V \mapsto C(\mathbb{G}^{(h)}, O_K) \hat{\otimes}_K V$ for $V \in \text{Mod}_{\text{solid}}^{\bullet}$. The following statements hold.

1. The functor is exact.
2. It induces an exact functor of derived categories $D(O_K) \to D(O_K[G^2])$ given by the left and right regular actions.
3. There is a functorial map $C(\mathbb{G}^{(h)}, O_K) \hat{\otimes}_K C \to \text{Cont}(G, C)$ for $C \in D(O_K)$ compatible with the left and right regular actions.
Proof. Exactness follows from Proposition 2.11. Indeed, as $\mathbb{G}^{(h)}$ is a finite disjoint union of polydiscs one has

$$C(\mathbb{G}^{(h)}, \mathcal{O}_K) \boxtimes \mathcal{O}_K \Rightarrow V = R\text{Hom}_{\mathcal{O}_K}(\mathcal{D}^{(h)}(G, \mathcal{O}_K), V).$$

But $\mathcal{D}^{(h)}(G, \mathcal{O}_K)$ is a projective $\mathcal{O}_K$-module, this implies that

$$C(\mathbb{G}^{(h)}, \mathcal{O}_K) \boxtimes \mathcal{O}_K \Rightarrow V = \text{Hom}_{\mathcal{O}_K}(\mathcal{D}^{(h)}(G, \mathcal{O}_K), V) = C(\mathbb{G}^{(h)}, \mathcal{O}_K) \boxtimes \mathcal{O}_K \Rightarrow V$$

is exact.

To prove (2), it is enough to show that $C(\mathbb{G}^{(h)}, \mathcal{O}_K) \boxtimes \mathcal{O}_K \Rightarrow V$ has natural left and right regular actions for $V \in \text{Mod}^{\text{solid}}_{\mathcal{O}_K}$. Writing $V$ as a quotient $P_1 \to P_0 \to V$ of objects of the form $P_i = \bigoplus I_i \prod J_i \mathcal{O}_K$, we have an exact sequence

$$C(\mathbb{G}^{(h)}, \mathcal{O}_K) \boxtimes \mathcal{O}_K \Rightarrow P_1 \to C(\mathbb{G}^{(h)}, \mathcal{O}_K) \boxtimes \mathcal{O}_K \Rightarrow P_0 \to C(\mathbb{G}^{(h)}, \mathcal{O}_K) \boxtimes \mathcal{O}_K \Rightarrow V \Rightarrow 0.$$

The functor $C(\mathbb{G}^{(h)}, \mathcal{O}_K) \boxtimes \mathcal{O}_K \Rightarrow$ commutes with colimits and, by Equation (3), it also commutes with products. Hence

$$C(\mathbb{G}^{(h)}, \mathcal{O}_K) \boxtimes \mathcal{O}_K \Rightarrow P_i = \bigoplus_{I_i} \prod_{J_i} C(\mathbb{G}^{(h)}, \mathcal{O}_K)$$

and these modules are equipped with the natural left and right regular actions of $G$. Moreover, the map $f$ is equivariant for these actions. We endow $C(\mathbb{G}^{(h)}, \mathcal{O}_K) \boxtimes \mathcal{O}_K \Rightarrow V$ with the action induced by the quotient map. It is easy to check that this action is independent of the presentation of $V$, and that it is functorial.

For the last statement, it is enough to construct a functorial equivariant map

$$C(\mathbb{G}^{(h)}, \mathcal{O}_K) \boxtimes \mathcal{O}_K \Rightarrow \text{Cont}(G, V)$$

for $V \in \text{Mod}^{\text{solid}}_{\mathcal{O}_K}$. Recall that by definition $\text{Cont}(G, V) = \text{Hom}_{\mathcal{O}_K}(\mathcal{O}_K \boxtimes \mathcal{O}_K \Rightarrow [G], V)$. Similarly as before, we are reduced to constructing the map for an object of the form $P = \bigoplus I \prod J \mathcal{O}_K$. As both functors commute with colimits and products, one reduces to treat the case $P = \mathcal{O}_K$, for which we have the natural inclusion $C(\mathbb{G}^{(h)}, \mathcal{O}_K) \Rightarrow \text{Cont}(G, \mathcal{O}_K)$ provided by $G \subset \mathbb{G}^{(h)}$, which is equivariant for the left and right regular actions of $G$. This ends the proof. \qed

Remark 4.27. It is clear that if $V$ is a solid $G$-module then $C(\mathbb{G}^{(h)}, \mathcal{O}_K) \boxtimes \mathcal{O}_K \Rightarrow V$ can be endowed with an action of $G^3$.

Definition 4.28. Let $h \geq 0$

1. Let $V \in \text{Mod}^{\text{solid}}_{K[G]}$, the space of $\mathbb{G}^{(h)}$-analytic vectors of $V$ is the solid $K[G]$-module

$$V^{\mathbb{G}^{(h)}-\text{an}} := \text{Hom}_{K[G]}(K, \mathcal{C}(\mathbb{G}^{(h)}, K) \boxtimes K \Rightarrow V)_{1,3}$$

where the action of $G$ is induced by the $\star_2$-action. Similarly, we define the $\mathbb{G}^{(h+)}$-analytic vectors of $V$ to be

$$V^{\mathbb{G}^{(h+)}-\text{an}} := \lim_{h' > h} V^{\mathbb{G}^{(h')}-\text{an}}.$$

2. Given a complex $C \in D(K[G])$ we define the derived $\mathbb{G}^{(h)}$-analytic vectors of $C$ as the complex in $D(K[G])$

$$C^{\mathbb{G}^{(h)}-\text{an}} := R\text{Hom}_{K[G]}(K, \mathcal{C}(\mathbb{G}^{(h)}, K) \boxtimes K \Rightarrow C)_{1,3}$$

where the action of $G$ is induced by the $\star_2$-action. Similarly, we define the derived $\mathbb{G}^{(h+)}$-analytic vectors of $C$ to be

$$C^{\mathbb{G}^{(h+)}-\text{an}} := R\lim_{h' > h} C^{\mathbb{G}^{(h')}-\text{an}}.$$

Remark 4.29. As $C(\mathbb{G}^{(h)}, K) \boxtimes K$ is exact, $C \mapsto C^{\mathbb{G}^{(h)}-\text{an}}$ is the right derived functor of $V \mapsto V^{\mathbb{G}^{(h)}-\text{an}}$. Similarly, $C \mapsto C^{\mathbb{G}^{(h+)}-\text{an}}$ is the right derived functor of $V \mapsto V^{\mathbb{G}^{(h+)}-\text{an}}$.

Lemma 4.30. Let $h \geq 0$ and $C \in D(K[G])$. There is a natural morphism of objects in $D(K[G])$

$$C^{\mathbb{G}^{(h)}-\text{an}} \Rightarrow C.$$
Proof. Notice that we have a natural map
\[C(\mathbb{G}^{(h)}, K) \otimes_K L C \to \text{Cont}(G, C)\]
which commutes with the three actions of \(G\). Taking \(*_{1,3}\)-invariant one gets the lemma by Proposition 4.24. \(\square\)

**Definition 4.31.** Let \(h \geq 0\)

1. A solid \(K[G]\)-module \(V\) is called \(\mathbb{G}^{(h)}\)-analytic if the natural map \(V^{\mathbb{G}^{(h)}-\text{an}} \to V\) is an isomorphism.
2. Similarly, it is called \(\mathbb{G}^{(h)}\)-analytic if \(V^{\mathbb{G}^{(h)}-\text{an}} \to V\) is an isomorphism.

**Corollary 4.33.** The category \(\text{Mod}_{\mathbb{D}^{(h)}}^{\text{solid}}(G, K)\) (resp. \(\mathbb{D}^{(h)}(G, K))\) is a full subcategory of \(\text{Mod}_{K[G]}^{\text{solid}}\) (resp. \(\text{Mod}_{K[G]}\)). In other words, if \(V, V' \in \text{Mod}_{\mathbb{D}^{(h)}}^{\text{solid}}(G, K)\) and \(C, C' \in \text{Mod}_{\mathbb{D}^{(h)}}(G, K)\) then
\[
\text{RHom}_{K[G]}(V, V') = \text{Hom}_{\mathbb{D}^{(h)}}(V, V')
\]

Theorem 4.34. Let \(W \in \text{D}(K[G])\) and \(C \in \text{D}(K[G])\). The following holds.

1. There are a natural isomorphisms of \(K[G]\)-modules
\[
\text{RHom}_{K[G]}(\mathbb{D}^{(h)}(G, K) \otimes L_K W, C) = \text{RHom}_K(W, C^{\mathbb{G}^{(h)}-\text{an}})
\]
\[
\text{RHom}_{K[G]}(\mathbb{D}^{(h)}(G, K) \otimes L_K W, C) = \text{RHom}_K(W, C^{\mathbb{G}^{(h)}-\text{an}})
\]
The \(K[G]\)-module structure of the terms inside the \(\text{RHom}_{K[G]}\) in the LHS are the left multiplication on the distribution algebras and the action of \(C\). The \(G\)-action of the LHS \(\text{RHom}_{K[G]}(-,-)\) is induced by the right multiplication on the distribution algebras.

2. The category of \(\mathbb{G}^{(h)}\)-analytic representations of \(G\) is equal to \(\text{Mod}_{\mathbb{D}^{(h)}}^{\text{solid}}(G, K)\). In other words, a \(K[G]\)-module \(V\) is \(\mathbb{G}^{(h)}\)-analytic if and only if the action of \(K[G]\) extends to an action of \(\mathbb{D}^{(h)}(G, K)\).
(3) Furthermore, a complex $C \in D(K\llbracket G \rrbracket)$ is derived $\mathbb{G}^{(h^+)}$-analytic if and only if for all $n \in \mathbb{Z}$ the cohomology groups $H^n(C)$ are $\mathbb{G}^{(h^+)}$-analytic. Equivalently, $C$ is derived $\mathbb{G}^{(h^+)}$-analytic if and only if it belongs to the essential image of $D(D(h^+)(G,K))$.

Proof. (1) Let $W \in D(K\llbracket G \rrbracket)$ and $C \in D(K\llbracket G \rrbracket)$, by Proposition 2.4 there is a natural quasi-isomorphism
\[ R\text{Hom}_K(D^{(h^+)}(G,K) \otimes_{K\llbracket G \rrbracket} W, C) = R\text{Hom}_K(W, C(G^{(h^+)}K) \otimes_{K\llbracket G \rrbracket} C). \] (9)

It is easy to verify that the left and right regular actions of the RHS are translated in the left and right multiplication of the distributions in the LHS. Indeed, one can reduce to $W = \prod_i \mathcal{O}_K[1/p]$ and $C = K\llbracket G \rrbracket$ in which case it is straightforward. Then, the $\ast_{1,3}$-action in the RHS translates in the left multiplication on the distributions and the action on $C$ in the LHS. Taking $R\text{Hom}_{K\llbracket G \rrbracket}(G, -)$ in (9) one gets
\[ R\text{Hom}_{K\llbracket G \rrbracket}(D^{(h^+)}(G,K) \otimes_{K\llbracket G \rrbracket} W, C) = R\text{Hom}_K(W, C^{RG(h^+)-an}). \]

Taking derived inverse limits and using that $R\text{Hom}$ commutes with colimits in the first factor and limits in the second factor, one gets
\[ R\text{Hom}_{K\llbracket G \rrbracket}(D^{(h^+)}(G,K) \otimes_{K\llbracket G \rrbracket} W, C) = R\text{Hom}_K(W, C^{RG(h^+)-an}). \]

(2) Consider the pre-analytic ring $(K\llbracket G \rrbracket, \mathcal{M}^{(h^+)})$ such that for any extremally disconnected $S$ one has
\[ \mathcal{M}^{(h^+)}(S) = D^{(h^+)}(G,K) \otimes_{K\llbracket G \rrbracket} K\llbracket S \rrbracket. \]

Corollary 4.33 implies that it is in fact an analytic ring. Indeed, let $P^\bullet$ be a complex of $K\llbracket G \rrbracket$-modules concentrated in positive homological degrees whose terms are direct sums of $\mathcal{M}^{(h^+)}[S]$ for $\{S_i\}_{i \in I}$ a family of profinite sets. Let $S$ be a profinite set, then
\[ R\text{Hom}_{K\llbracket G \rrbracket}(\mathcal{M}^{(h^+)}[S], P^\bullet) = R\text{Hom}_{D^{(h^+)}(G,K)}(\mathcal{M}^{(h^+)}[S], P^\bullet) = R\text{Hom}_{K\llbracket S \rrbracket}(K\llbracket S \rrbracket, P^\bullet). \]

Moreover, the category of solid $(K\llbracket G \rrbracket, \mathcal{M}^{(h^+)}$)-modules is equal to the category of solid $D^{(h^+)}(G,K)$-modules. More precisely, by Theorem 2.6 a family of compact projective generators of $\text{Mod}^{\text{solid}}(K\llbracket G \rrbracket, \mathcal{M}^{(h^+)}$) is given by $\mathcal{M}^{(h^+)}(S)$ for $S$ extremally disconnected, which are naturally $D^{(h^+)}(G,K)$-modules, and any $K\llbracket G \rrbracket$-linear map between these objects is automatically $D^{(h^+)}(G,K)$-linear again by Corollary 4.33 again. Hence, part (1) and Theorem 2.6 imply that a $K\llbracket G \rrbracket$-module $V$ is $\mathbb{G}^{(h^+)}$-analytic if and only if it is a $D^{(h^+)}(G,K)$-module.

(3) Theorem 2.6 and the same argument as before tells us that a complex $C \in D(K\llbracket G \rrbracket)$ is derived $\mathbb{G}^{(h^+)}$-analytic if and only if it belongs to the essential image of $D(D^{(h^+)}(G,K))$, if and only if for all $n \in \mathbb{Z}$ the module $H^n(C)$ is a $D^{(h^+)}(G,K)$-module, finishing the proof. \hfill $\square$

4.4. Locally analytic representations. We finish this section with some applications of Theorem 4.34 to the theory of locally analytic representations. Let us begin with the definition of the locally analytic vectors.

**Definition 4.35.**

(1) Let $V$ be a solid $K\llbracket G \rrbracket$-module, the space of locally analytic vectors of $V$ is the solid $K\llbracket G \rrbracket$-module
\[ V^{la} := \lim_{h \to \infty} V^{G^{(h^+)}-an} = \lim_{h \to \infty} V^{G^{(h^+)}-an}. \]

We say that $V$ is locally analytic if the natural map $V^{la} \to V$ is an isomorphism.

(2) Let $C \in D(K\llbracket G \rrbracket)$, the derived locally analytic vectors of $C$ is the complex
\[ C^{Rla} := \text{hocolim}_{h \to \infty} C^{RG^{(h^+)}-an} = \text{hocolim}_{h \to \infty} C^{RG^{(h^+)}-an}. \]

We say that $C$ is derived locally analytic if the natural map $C^{Rla} \to C$ is a quasi-isomorphism.
In §1.3 we defined the algebra of locally analytic distributions of $G$ as the Fréchet algebra of compact type
\[
\mathcal{D}^{la}(G, K) = \lim_{\to} \mathcal{D}^{(h)}(G, K) = \lim_{\to} \mathcal{D}^{(h^+)}(G, K).
\]

Since a locally analytic representation $V$ is (a homotopic) colimit of $\mathbb{G}^{(h^+)}$-analytic representations, Theorem 4.34 implies that $V$ is naturally a $\mathcal{D}^{la}(G, K)$-module. Furthermore, this structure is unique as $\mathcal{D}^{la}(G, K) \otimes_{K[G]} \mathcal{D}^{la}(G, K) = \mathcal{D}^{la}(G, K)$, see Corollary 5.10. Nevertheless, not all the $\mathcal{D}^{la}(G, K)$-modules are locally analytic representations of $G$, e.g. $\mathcal{D}^{la}(G, K)$ is not a locally analytic representation as it cannot be written as a colimit of $\mathcal{D}^{(h^+)}(G, K)$-modules. Indeed, if $\mathcal{D}^{la}(G, K)$ was locally analytic then $1 \in \mathcal{D}^{la}(G, K)$ would be analytic for certain group $\mathbb{G}^{(h^+)}$, this would provide a section of the map $\mathcal{D}^{la}(G, K) \to \mathcal{D}^{(h^+)}(G, K)$ which is a contradiction as it is never surjective. In the following propositions we will try to give some conditions for a $\mathcal{D}^{la}(G, K)$-module to be a locally analytic representation of $G$.

**Proposition 4.36.** Let $V$ be a Banach $K[G]$-module. The following are equivalent.

1. the $K[G]$-module structure of $V$ extends to $\mathcal{D}^{la}(G, K)$.
2. the $K[G]$-module structure of $V^\vee$ extends to $\mathcal{D}^{la}(G, K)$.
3. $V$ is $\mathbb{G}^{(h^+)}$-analytic for some $h \geq 0$.

**Proof.** Formally, (1) and (2) are equivalent as the dual of a solid $\mathcal{D}^{la}(G, K)$-module is naturally a solid $\mathcal{D}^{la}(G, K)$-module, (3) implies (1) is clear from the previous discussion. Let us show that (1) implies (3). Suppose that $V$ is a $\mathcal{D}^{la}(G, K)$-module. Consider the multiplication map $m_V : \mathcal{D}^{la}(G, K) \otimes_{K[G]} V \to V$. As $V$ is Banach and $\mathcal{D}^{la}(G, K) \otimes_{K[G]} V$ is a Fréchet space, Lemma 3.24 implies that there exists $h \geq 0$ such that $m_V$ factors as
\[
\mathcal{D}^{la}(G, K) \otimes_{K[G]} V \to \mathcal{D}^{(h)}(G, K) \otimes_{K[G]} V \to V.
\]
It is immediate to check that this endows $V$ with an structure of $\mathcal{D}^{(h)}(G, K)$-module. By Theorem 4.34 $V$ is $\mathbb{G}^{(h^+)}$-analytic for $h' > h$. □

**Proposition 4.37** (Schneider-Teitelbaum). Let $V$ be an LS space of compact type, cf. Definition 3.27.

The following are equivalent

1. the $K[G]$-module structure of $V$ extends to $\mathcal{D}^{la}(G, K)$-module.
2. the $K[G]$-module structure of $V^\vee$ extends to $\mathcal{D}^{la}(G, K)$-module.
3. $V$ is a locally analytic representation of $G$.

**Proof.** By Theorem 3.30 (1) and (2) are equivalent. It is also clear that (3) implies (1). Suppose that $V$ is a $\mathcal{D}^{la}(G, K)$-module which is an LS space of compact type. The multiplication map $m_V : \mathcal{D}^{la}(G, K) \otimes_{K[G]} V \to V$ gives an element of Hom($\mathcal{D}^{la}(G, K) \otimes_{K[G]} V, V$). Let $V = \lim_{\to} V_n$ be a presentation as a colimit of Smith spaces by injective transition maps, and let $V^B_n$ be the underlying Banach space of $V_n$ (cf. Definition 3.27). As $V$ is of compact type we have $V = \lim_{\to} V^B_n$. Therefore
\[
\text{Hom}_K(\mathcal{D}^{la}(G, K) \otimes_{K[G]} V, V) = \lim_{\to} \text{Hom}_K(\mathcal{D}^{la}(G, K) \otimes_{K[G]} V^B_n, V)
\]
\[
= \lim_{\to} \text{Hom}_K(\mathcal{D}^{la}(G, K), (V^B_n)^\vee \otimes K[G])
\]
\[
= \lim_{\to} C^{la}(G, K) \otimes_{K[G]} (V^B_n)^\vee \otimes K[V^B_n]
\]
where the first equality is formal, the second follows from the fact that $V$ is nuclear, and the third equality follows from Theorem 3.30. This shows that given $n \in \mathbb{N}$ there is $m \in \mathbb{N}$ such that the map $m_V : \mathcal{D}^{la}(G, K) \otimes_{K[G]} V^B_n \to V$ factors through $m_V : \mathcal{D}^{la}(G, K) \otimes_{K[G]} V^B_n \to V^B_m$. By Lemma 3.24 there exists $h \geq 0$ such that $m_V$ factors as $\mathcal{D}^{la}(G, K) \otimes_{K[G]} V^B_n \to \mathcal{D}^{(h)}(G, K) \otimes_{K[G]} V^B_m$. Equivalently, there is $h \geq 0$ (maybe different) such that $m_V$ factors as $\mathcal{D}^{la}(G, K) \otimes_{K[G]} V_n \to \mathcal{D}^{(h)}(G, K) \otimes_{K[G]} V_n \to V_m$. Let $V'_n$ be the image of $\mathcal{D}^{(h)}(G, K) \otimes_{K[G]} V_n \to V_m$, it is a Smith space endowed with an action of $\mathcal{D}^{(h)}(G, K)$
extending the one of $\mathcal{D}^{ia}(G, K)$. It is immediate to see that $V = \lim_{\to_n} V_n$, this shows that $V$ is written as a colimit of $\mathcal{D}^{(h')}(G, K)$-modules (for $h' > h$), which implies that it is a locally analytic representation of $G$ by Theorem 4.34.

One may wonder whether the previous propositions can be extended to the bounded derived category. One way to attack the problem is to use the derived enhancement of Lemma 3.24, which we do not know whether is true or not.

**Conjecture 1.** Let $V = \lim_{\to_n} V_n$ be a Fréchet space of compact type written as a limit of Banach spaces with compact and dense transition maps, then

$$R\text{Hom}_K(V, K) = \hocolim\text{Hom}_K(V_n, K)$$

**Corollary 4.38.** Suppose that Conjecture 1 is true. Let $V = \lim_{\to_n} V_n$ be a Fréchet space of compact type and $B$ a Banach space, then

1. $R\text{Hom}_K(V, B) = \text{hocolim}_n R\text{Hom}_K(V_n, B)$.
2. We have

$$R\text{Hom}_K(V, B) = V\vee \otimes_K B.$$  

In particular $V\vee$ is the derived dual of $V$.

3. The duality Theorem 3.39 gives a derived duality between bounded complexes of Fréchet spaces of compact type and bounded complexes of LS spaces of compact type.

4. Let $C$ be a bounded complex of Fréchet spaces of compact type and $D$ a bounded complex of LS spaces of compact type. Then

$$R\text{Hom}_K(C, D) = R\text{Hom}_K(C, K) \otimes_{K}^L D$$

and

$$R\text{Hom}_K(D, C) = R\text{Hom}_K(D, K) \otimes_{K}^L C.$$  

5. Let $C$ and $C'$ be bounded complexes of Fréchet spaces of compact type. Then

$$R\text{Hom}_K(C, C') = R\text{Hom}_K(C'\vee, C\vee).$$

**Proof.** Part (1) follows from Conjecture 1 using the fact that $K\boxtimes S \otimes_{K}^L K\boxtimes S' = K\boxtimes [S \times S']$ for $S$ and $S'$ profinite sets, that

$$R\text{Hom}_K(V, K)(S) = R\text{Hom}(V \otimes_{K}^L K\boxtimes S, K) = R\text{Hom}(V, \text{Cont}(S, K))$$

and that any Banach space over $K$ is a direct summand of a space of the form $\text{Cont}(S, K)$ for $S$ a profinite set.

If $V$ is Fréchet of compact type, we can write $V = \lim_{\to_n} V_n^S$ where $V_n^S$ is the Smith completion of $V_n$ (cf. Corollary 3.29). Then

$$R\text{Hom}_K(V, B) = \text{hocolim}_n R\text{Hom}_K(V_n, B)$$

$$= \text{hocolim}_n R\text{Hom}_K(V_n^S, B)$$

$$= \text{hocolim}_n (V_n^S)\vee \otimes_K B$$

$$= \lim_{\to_n} (V_n^S)\vee \otimes_K B = V\vee \otimes_K B.$$  

Part (3) follows immediately from part (2) and an easy induction via the stupid truncation. For part (4), notice that if $C$ is a bounded Fréchet complex of compact type, and $D$ is a bounded LS complex of compact type, then

$$R\text{Hom}_K(C, D) = R\text{Hom}_K(C \otimes_{K}^L D\vee, K)$$

$$= C\vee \otimes_{K}^L D$$

since $C \otimes_{K}^L D\vee$ is a bounded Fréchet compact type complex. Similarly one shows $R\text{Hom}_K(D, C) = D\vee \otimes_{K}^L C$. 

Finally, by a devisage using the stupid filtration, (5) is reduced to showing that if \( V \) and \( V' \) are Fréchet spaces of compact type then

\[
R\text{Hom}_K(V, V') = R\text{Hom}_K(V^\vee, V^\vee).
\]

Writing \( V' = \lim_{\xi \to n} V'_n \) one gets, by (1),

\[
R\text{Hom}_K(V, V') = R\lim_{\xi \to n} R\text{Hom}_K(V, V'_n) = R\lim_{\xi \to n} (V^\vee \otimes K^n V'_n).
\]

Dually, we have that

\[
R\text{Hom}_K(V'^\vee, V'^\vee) = R\lim_{\xi \to n} R\text{Hom}_K(V'_n, V'^\vee) = R\lim_{\xi \to n} (V'_n \otimes K^n V^\vee)
\]

which gives the desired equality. \( \square \)

Under the assumption of the previous Conjecture we could improve Propositions 4.36 and 4.37 to bounded derived complexes:

**Proposition 4.39.** Suppose that Conjecture 4 holds. Let \( C \in D(\mathcal{D}^{la}(G, K)[\mathbb{G}])^b \) be a bounded solid \( \mathcal{D}^{la}(G, K) \)-module. Assume that either

(a) \( C \) is quasi-isomorphic to a bounded complex of \( K \)-Banach spaces as \( K[n] \)-complex.

(b) \( C \) is quasi-isomorphic to a bounded complex of \( LS \) spaces of compact type as \( K[n] \)-complex.

Then \( C \) is a derived locally analytic representation of \( G \). In particular there is a derived duality between locally analytic complexes quasi-isomorphic to bounded complexes of \( LS \) spaces of compact type, and \( \mathcal{D}^{la}(G, K) \)-complexes quasi-isomorphic to bounded complexes of Fréchet spaces of compact type.

**Proof.** We will prove in Corollary 5.10 that

\[
\mathcal{D}^{la}(G, K) \otimes_{K[n]} L_{\mathbb{G}} \mathcal{D}^{la}(G, K) = \mathcal{D}^{la}(G, K). \tag{10}
\]

Let \( C \) be a complex in \( D(\mathcal{D}^{la}(G, K)) \) which is quasi-isomorphic to a bounded complex of Banach spaces as \( K[n] \)-complex. By Corollary 4.38 (1) we have

\[
R\text{Hom}_K(\mathcal{D}^{la}(G, K), C) = \text{hocolim}_h R\text{Hom}_K(\mathcal{D}^{la}(G, K), C).
\]

Taking \( K[n]G \)-invariants one gets that

\[
R\text{Hom}_K[G](\mathcal{D}^{la}(G, K), C) = \text{hocolim}_h R\text{Hom}_K[G](\mathcal{D}^{la}(G, K), C).
\]

But (10) implies that the LHS is equal to \( C \) while Theorem 4.34 implies that the RHS is equal to \( \text{hocolim}_h C_R^{G[\mathbb{G}]} \). This shows that \( C \) is derived locally analytic.

Now suppose that \( C \) is quasi-isomorphic to a bounded complex of \( LS \) spaces of compact type. Then from Corollary 4.38 (3) and (4) one has

\[
R\text{Hom}_K(\mathcal{D}^{la}(G, K), C) = C^{la}(G, K) \otimes_{K[n]} L_{\mathbb{G}} C = \text{hocolim}_h C(G^{(h)}, K)[n] \otimes_{K[n]} C.
\]

Taking \( K[n]G \)-invariants one gets again by (10) that \( C = C_R^{la} \), i.e. that \( C \) is a derived locally analytic representation of \( G \). \( \square \)

**Remark 4.40.** In the situation (a) of the previous proposition, one can show in addition that \( C \) is derived \( \mathbb{G}^{(h)} \)-analytic for some \( h > 0 \). Indeed, it is enough to prove that for all \( n \in \mathbb{Z} \) there is \( h > 0 \) such that \( H^n(C) \) is derived \( \mathbb{G}^{(h)} \)-analytic. As \( C \) is bounded, we are left to show that if \( V \) is a \( \mathcal{D}^{la}(G, K) \)-module which is a quotient of two \( K \)-Banach spaces (not necessarily \( \mathcal{D}^{la}(G, K) \)-modules), then \( V \) is already a \( \mathcal{D}^{la}(G, K) \)-module for some \( h > 0 \). Let \( m_V : \mathcal{D}^{la}(G, K) \otimes_{K[n]} V \to V \) be the multiplication map, by Corollary 4.38 (4) one has that

\[
R\text{Hom}_K(\mathcal{D}^{la}(G, K) \otimes_{K[n]} V, V) = \text{hocolim}_h R\text{Hom}_K(D(G^{(h)}, K) \otimes_{K[n]} V, V).
\]
Thus, $m_V$ factors as $m_V : \mathcal{D}(\mathbb{G}(h), K) \otimes_{K \llbracket G \rrbracket} V \to V$ for some $h > 0$. After taking $h' > h$ one shows that the map $\mathcal{D}(\mathbb{G}(h'), K) \otimes_{K \llbracket G \rrbracket} V \to V$ is in fact an action of $\mathcal{D}(\mathbb{G}(h'), K)$, proving that $V$ is derived $\mathbb{G}(h')$-analytic as desired.

4.5. Admissible representations. Before writing down the statements of the cohomological comparison results, let us show how the theory developed till now together with some algebraic facts about the Iwasawa and the distribution algebras, provide a description of the locally analytic vectors of an admissible representation in terms of its dual. All results in this sections were already known ([ST03, Pan21]).

**Definition 4.41.** A Banach representation $V$ of $G$ is admissible if its dual is a finite module over the Iwasawa algebra. Equivalently, if $V$ admits a closed immersion into a finite direct sum of $\text{Cont}(G, K)$.

We recall the following important results of the classical Iwasawa and distribution algebras

**Theorem 4.42** (Lazard, Schneider-Teitelbaum). *The following holds*

1. The (classical) Iwasawa algebra $K \llbracket G \rrbracket(*)$ is a coherent algebra.
2. The (classical) distribution algebras $\mathcal{D}(\mathbb{G}(h), K)(*)$ are flat over $\mathcal{O}_{K, \llbracket G \rrbracket}(*)$ algebraically.
3. Let $h' > h$, then $\mathcal{D}(\mathbb{G}(h'), K)(*)$ is a flat algebra over $\mathcal{D}(\mathbb{G}(h), K)(*)$ algebraically.
4. The (classical) locally analytic distribution algebra $\mathcal{D}^{la}(G, K)(*)$ is faithfully flat over $K \llbracket G \rrbracket$ algebraically.

*Proof.* Part (1) is [ST03, Rem. 4.6], part (2) is [ST03, Prop. 4.7], part (3) is [ST03, Theo. 4.9] and part (4) is [ST03, Theo. 4.11].

**Proposition 4.43.** Let $V$ be a Banach $G$-representation, then

$$V^{RG(h^+)-an} = \mathcal{R}\text{Hom}_{K}(\mathcal{D}(h^+)(G, K) \otimes_{K \llbracket G \rrbracket} V^\vee, K).$$

*In particular, if $V$ is admissible then*

$$V^{RG(h^+)-an} = V^{G(h^+)-an} = \mathcal{H}\text{om}_{K}(\mathcal{D}(h^+)(G, K) \otimes_{K \llbracket G \rrbracket} V^\vee, K).$$

*Furthermore, $V^{la} = \mathcal{H}\text{om}_{K}(\mathcal{D}^{la}(G, K) \otimes_{K \llbracket G \rrbracket} V^\vee, K)$.**

*Proof.* By Theorem 4.34, we have

$$V^{RG(h^+)-an} = \mathcal{R}\text{Hom}_{K[G]}(\mathcal{D}(h^+)(G, K), V) = \mathcal{R}\text{Hom}_{K[G]}(\mathcal{D}(h^+)(G, K), \mathcal{R}\text{Hom}_{K}(V^\vee, K)) = \mathcal{R}\text{Hom}_{K}(\mathcal{D}(h^+)(G, K) \otimes_{K \llbracket G \rrbracket} V^\vee, K).$$

Moreover, if $V$ is admissible then $V^\vee$ is a finite $K \llbracket G \rrbracket$-module. By flatness of the distribution algebra one gets that $\mathcal{D}(h^+)(G, K) \otimes_{K \llbracket G \rrbracket} V^\vee = \mathcal{D}(h^+)(G, K) \otimes_{K \llbracket G \rrbracket} V^\vee$ is concentrated in degree 0 (we warn that the flatness is only algebraic, and that we use the fact that $V^\vee$ is a finite module over the Iwasawa algebra), this implies the second claim. For the last statement, one gets by Lemma 3.24 that

$$V^{la} = \lim_{h \to} V^{G(h^+)-an} = \lim_{h \to} \mathcal{H}\text{om}_{K}(\mathcal{D}(h^+)(G, K) \otimes_{K \llbracket G \rrbracket} V^\vee, K) = \mathcal{H}\text{om}_{K}(\mathcal{D}^{la}(G, K) \otimes_{K \llbracket G \rrbracket} V^\vee, K).$$

*Corollary 4.44.** Let $V$ be an admissible Banach $G$-representation, then $V^{la} \subset V$ is a dense subspace.

*Proof.* As the category of admissible representations is an abelian category, and a closed subrepresentation of an admissible representation is admissible, one is left to prove that the functor $V \mapsto V^{la}$ is non zero. This follows from Proposition 4.33 and the fact that $\mathcal{D}^{la}(G, K)$ is faithfully flat over $K \llbracket G \rrbracket$. 

5. Cohomology

In this last chapter we present our main applications to group cohomology. We obtain in particular

1. An isomorphism between the continuous cohomology and the cohomology of the derived locally analytic vectors for solid representations. This can be seen as a p-adic version of theorems of P. Blanc and G. D. Mostow for real Lie groups, cf. [Bla79] [Mos61].

2. A comparison theorem, for a locally analytic G-representation V, between its continuous and its locally analytic cohomology. This generalises the classical result of Lazard [Laz63] for finite dimensional Qp-representations to arbitrary solid K-vector spaces.

3. A comparison theorem between locally analytic cohomology and Lie algebra cohomology. This recovers and generalises a result of Tamme [Tam15] (cf. also [HKN11] and [Lec12]), which in turns was a generalisation of the other main result of Lazard for finite dimensional representations.

The proof of (1) is an immediate consequence of our main Theorem [4.34] and a result of Kohlhaase (Theorem [5.7]).

The key input for the comparison result in (2) is the existence of a finite free resolution of the trivial representation, as a module over the Iwasawa algebra of a small neighbourhood of 1 in G. This is an application of a lemma of Serre used by Lazard in [Laz63] V Def. 2.2.2. We shall also need a version of the lemma proved by Koohlhase for distribution algebras, cf. [Koh11] Theo. 4.4. Once one has this lemma at hand, the proof of (2) is rather formal using the machinery developed throughout this text.

Finally, to show (3) we follow the proof of Tamme constructing a resolution of the trivial representation in terms of the de Rham complex of the analytic groups. Then, we apply the same formal computation as before.

5.1. Continuous, analytic and locally analytic cohomology. In this section we define different cohomology groups, they correspond to continuous, analytic and locally analytic cohomology in the literature. Indeed, using the Bar resolutions and Proposition [2.11] one verifies that whenever V is a solid representation coming from a “classical space” (i.e. a Banach, Fréchet, LB or LF space) our definitions coincide with the usual ones.

In the following we will use the conventions of Section [4.1]. In particular, we fix a compact p-adic Lie group G and an open normal uniform pro-p-group G0 ⊂ G, we denote the h-analytic neighbourhood of G as G(h), and define its open h-analytic neighbourhood as G(h+) = \bigcup_{j > h} G(hj). Recall from Lemma [4.19] that a solid O-K module V is an O-K-linear G-representation if and only if it is a module over the Iwasawa algebra O-G. If V is in addition a G(h+)-analytic representation, by the main Theorem [4.34] V is naturally equipped with a D(h+)(G,K)-module structure.

Definition 5.1.

1. Let C ∈ D(O-K)[G]). We define the continuous group cohomology of C as R\text{Hom}_{O-K}(O-G,C).

2. Let C ∈ D(O-K)[G]) be a derived G(h+)-analytic representation. We define the G(h+)-analytic cohomology of C as R\text{Hom}_{D(h+)(G,K)}(K,C).

3. Let C ∈ D(O-K)[G]) be a derived locally analytic representation. We define the locally analytic cohomology of C as lim h→K R\text{Hom}_{D(h+)(G,K)}(K,C).

5.2. Comparison results. Next we state the main theorems of this section, which will be proved in §5.4

Theorem 5.2. Let C ∈ D(K)[G]), then

\[ R\text{Hom}_{K}[G](K,C) = R\text{Hom}_{K}[G](K,C^{R^{\text{Ila}}}) \]

Remark 5.3. More concretely, we will show that

\[ R\text{Hom}_{K}[G](K,C) = R\text{Hom}_{K}[G](K,C^{R^{G(h+)-an}}) \]

for h >> 0.

Theorem 5.4 (Continuous vs. analytic vs. Lie algebra cohomology). Let C ∈ D(K)[G]) be a derived G(h+)-analytic representation. Then

\[ R\text{Hom}_{K}[G](K,C) ∼ R\text{Hom}_{D(h+)(G,K)}(K,C) ∼ (R\text{Hom}_{(C)}(K,C))^G. \]
Remark 5.5. The RHS term of the equation above means the following: if $C$ is a derived $\mathbb{G}^{(h^+)}$-analytic complex, then there is an open normal subgroup $H \subset G$ such that

$$RHom_{U(\mathfrak{g})}(K, C) = RHom_{K[H]}(K, C),$$

and the group $G/H$ acts on the previous cohomology complex. As we are working in characteristic $0$ and $G/H$ is a finite group, taking invariants in the category of solid $K[G/H]$-modules is exact and one can form the complex

$$RHom_{U(\mathfrak{g})}(K, C)^G := RHom_{U(\mathfrak{g})}(K, C)^{G/H}.$$ 5.3. Key lemmas. In the following we will work with complexes with equal terms but different differential maps. To make explicit the differentials we use the following notation: let $C$ be a (homological) complex of $O_K$-modules with $i$-th term $C_i$ and $i$-th differential $d_i : C_i \to C_{i-1}$, we note

$$C = [\cdots \to C_{i+1} \to C_i \to C_{i-1} \to \cdots].$$

5.3.1. Iwasawa and distribution algebras. The following result is the main input for our calculations.

Theorem 5.6 (Lazard-Serre). Let $G_0$ a uniform pro-$p$ group of dimension $d$. Then there exists a projective resolution of the trivial module $Z_p$ of the form

$$P := [0 \to Z_p[\mathfrak{g}_0]^{(\alpha)} \to \cdots \to Z_p[\mathfrak{g}_0]^{(\alpha)} \to \cdots \to Z_p[G_0]^{(\alpha)}; \alpha_*].$$

Proof. We briefly sketch how the complex $P$ is constructed from [Laz65] Definition 2.2.2.1, Lemma 2.1.1]. Let $g_1, \ldots, g_d \in G_0$ be a basis of the group and $b_i = [g_i] - 1 \in Z_p[\mathfrak{g}_0](*)$. The valuation of $G_0$ defines a filtration in $Z_p[\mathfrak{g}_0](*)$ whose graded algebra $gr^p(Z_p[\mathfrak{g}_0](*))$ is isomorphic to $\mathbb{F}_p[\pi][\overline{b}_1, \ldots, \overline{b}_d]$, where $\mathbb{F}_p[\pi] = gr^p(Z_p)$. Then, the Koszul complex of $\mathbb{F}_p[\pi][\overline{b}_1, \ldots, \overline{b}_d]$ with respect to the regular sequence $(\overline{b}_1, \ldots, \overline{b}_d)$ can be lifted by approximations to the complex $P$ of the theorem. Furthermore, the proof also lifts a chain homotopy $\tilde{s}_\bullet$ between the identity and the augmentation map $\varepsilon : K[\overline{b}_1, \ldots, \overline{b}_d] \to \mathbb{F}_p[\pi]$, to a chain homotopy $s_\bullet$ between the identity and the augmentation map $\varepsilon : Z_p[\mathfrak{g}_0] \to Z_p$. □

Theorem 5.7 (Kohlhaase). Let $G_0$ a uniform pro-$p$ group of dimension $d$ and $h > 0$. Then

$$O_K \otimes_{O_K[G_0]} D(h)(G_0, K) = K.$$ More precisely, the differentials $\alpha_i : O_K[G_0]^{(d)} \to O_K[G_0]^{(d-1)}$ of the resolution given by Theorem 5.6 extend to maps $\alpha_i : D(h)(G_0, K)^{(d)} \to D(h)(G_0, K)^{(d-1)}$, inducing a resolution of the trivial module $K$ of the form

$$P(h) := [0 \to D(h)(G_0, K)^{(d)} \to \cdots \to D(h)(G_0, K)^{(d)} \to \cdots \to D(h)(G_0, K)^{(d)}; \alpha_*].$$

Proof. This is essentially [Koh11] Theorem 4.4]. Let $g_1, \ldots, g_d \in G_0$ be a basis and $b_i \in Z_p[\mathfrak{g}_0](*)$. The idea of the proof is to show that the differentials $\alpha_\bullet$ and the chain homotopy $s_\bullet$ of Theorem 5.6 are continuous with respect to the norms $\sum_{a} a^o b^o = \sup_{r} |a| r^{|a|}$ for $\frac{1}{p} < r < 1$. Thus, the differentials $\alpha_\bullet$ and the chain homotopy $s_\bullet$ extend to the weak completion of these norms (i.e. the completion with respect to a radius $r$ seen as a subspace in the completion of a slightly bigger radius $r' < 1$). Note that the distribution algebras constructed in this way are precisely the algebras $D(h)(G_0, K)$ of Definition 4.12. □

Remark 5.8. By definition $D(h)(G, K) := K[G] \otimes_{K[G_0]} D(h)(G_0, K)$. Therefore $D(h)(G, K) \otimes_{K[G]} K = D(h)(G_0, K) \otimes_{K[G_0]} K = K$, as $K$ is of characteristic $0$. This implies that

$$D(h)(G, K) \otimes_{K[G]} D(h)(G, K) = K[G] \otimes_{K[G]} (D(h)(G_0, K) \otimes_{K[G_0]} D(h)(G_0, K)).$$

With the help of the previous theorem we can compute the following derived tensor product

Proposition 5.9. We have

**Proof.** First, we reduce to the case when $G$ is a uniform pro-$p$-group by Remark 5.8. By Theorem 5.6 we can write

$$[0 \to K^\bullet[G] \to \cdots \to K^\bullet[G]^d \to K^\bullet[G]; \alpha] \simeq K.$$ 

Tensoring with $\mathcal{D}(h)(G, K)$ over $K$ we get

$$[0 \to K^\bullet[G] \otimes_K \mathcal{D}(h)(G, K) \to \cdots K^\bullet[G]^d \otimes_K \mathcal{D}(h)(G, K) \to K^\bullet[G] \otimes_K \mathcal{D}(h)(G, K); \alpha \otimes 1] \simeq \mathcal{D}(h)(G, K).$$

The quasi-isomorphism above is of $K^\bullet[G]$-modules for the diagonal action of $G$ in the terms of the complex.

Let $\iota : K^\bullet[G] \to K^\bullet[G]$ be the antipode, i.e. the map induced by the inverse of the group, and denote in the same way its extension to the distribution algebra $\mathcal{D}(h)(G, K)$. Consider the composition

$$K^\bullet[G] \otimes_K \mathcal{D}(h)(G, K) \xrightarrow{(1 \otimes \iota) \otimes 1} K^\bullet[G] \otimes_K K^\bullet[G] \otimes_K \mathcal{D}(h)(G, K) \xrightarrow{1 \otimes m} K^\bullet[G] \otimes_K \mathcal{D}(h)(G, K),$$

where $m$ is the left multiplicaiton of $K^\bullet[G]$ on the distribution algebra. This map defines a $G$-equivariant isomorphism

$$\phi : K^\bullet[G] \otimes_K \mathcal{D}(h)(G, K) \simeq K^\bullet[G] \otimes_K \mathcal{D}(h)(G, K)_0$$

where the action of $G$ in the image is left multiplication on $K^\bullet[G]$ and trivial on $\mathcal{D}(h)(G, K)_0$. Notice that $\phi$ can be extended naturally to a $G$-equivariant isomorphism

$$\phi : \mathcal{D}(h)(G, K) \otimes_K \mathcal{D}(h)(G, K) \simeq \mathcal{D}(h)(G, K) \otimes_K \mathcal{D}(h)(G, K)_0.$$

We define the complex

$$[0 \to K^\bullet[G] \otimes_K \mathcal{D}(h)(G, K)_0 \to \cdots \to K^\bullet[G] \otimes_K \mathcal{D}(h)(G, K)_0; \beta_{\bullet}] \tag{11}$$

to be the complex whose differentials are given by $\beta_{\bullet} = \phi \circ \alpha_{\bullet} \circ \phi^{-1}$. Notice that the maps $\beta$ extend to respective complex with terms direct sums of $\mathcal{D}(h)(G, K) \otimes_K \mathcal{D}(h)(G, K)_0$.

Using this complex one can easily compute the derived tensor product by replacing the right $\mathcal{D}(h)(G, K)$ with (11):

$$\mathcal{D}(h)(G, K) \otimes_{K^\bullet[G]} \mathcal{D}(h)(G, K) \simeq [\cdots \to \mathcal{D}(h)(G, K) \otimes_K K^\bullet[G] (K^\bullet[G]^d \otimes_K \mathcal{D}(h)(G, K)_0) \to \cdots; 1 \otimes \beta]$$

$$= [\cdots \to \mathcal{D}(h)(G, K)^d \otimes_K \mathcal{D}(h)(G, K)_0 \to \cdots; \beta]$$

$$\simeq [\cdots \to \mathcal{D}(h)(G, K)^d \otimes_K \mathcal{D}(h)(G, K) \to \cdots; \alpha \otimes 1]$$

$$\simeq \mathcal{D}(h)(G, K).$$

In the above sequence of isomorphisms, the first quasi-isomorphism follows from the observation that the action of $G$ on the complex (11) representing $\mathcal{D}(h)(G, K)$ is trivial on the factor $\mathcal{D}(h)(G, K)_0$. The second step is trivial. The third one follows by applying $\phi^{-1}$. The fourth quasi-isomorphism follows from Theorem 5.7. This finishes the proof. \hfill \square

**Corollary 5.10.** We have

$$\mathcal{D}^{(h^+)}(G, K) \otimes_{K^\bullet[G]} \mathcal{D}^{(h^+)}(G, K) = \mathcal{D}^{(h^+)}(G, K)$$

$$\mathcal{D}^{(la)}(G, K) \otimes_{K^\bullet[G]} \mathcal{D}^{(la)}(G, K) = \mathcal{D}^{(la)}(G, K).$$

**Proof.** This follows from the previous proposition and the fact that $\mathcal{D}^{(h^+)}(G, K)$ can be written as a colimit of distribution algebras $\mathcal{D}(h)(G, K)$, cf. Corollary 4.18. The case of $\mathcal{D}^{(la)}(G, K)$ follows from the same proof of Proposition 5.9 knowing that the complex of Theorem 5.7 extends to $\mathcal{D}^{(la)}(G, K)$. \hfill \square

5.3.2. **Enveloping and distribution algebras.** Let $\mathfrak{g} = \mathfrak{lie} G$ be the Lie algebra of $G$ and $U(\mathfrak{g})$ its enveloping algebra. Let $\mathbb{G}_h$ be a rigid analytic group of Definition 4.4 and let $G_h = \mathbb{G}_h(\mathbb{Q}_p)$ be its rational points. Note that $G_h \subset G$ is an open compact subgroup. We denote by $\mathcal{D}(\mathbb{G}_h, K)$ the distribution algebra of $\mathbb{G}_h$-analytic functions, i.e. the dual of $\mathcal{C}(\mathbb{G}_h, K)$. We also denote $\mathcal{D}(\mathbb{G}_{h^+}, K) = \lim_{\to h' > h} \mathcal{D}(\mathbb{G}_{h'}, K)$, in other words, the distribution algebra of the rigid analytic group defined by the open unit polydisc $\mathbb{G}_{h^+} = \bigcup_{h' > h} \mathbb{G}_{h'}$. We assume that $\mathbb{G}_{h^+}(\mathbb{Q}_p) = G_h$. 

Proposition 5.11 (Tamme). Keep the above notation, and let

$$CE(g) := [0 \to U(g) \otimes \mathcal{O}_g \to \cdots \to U(g) \otimes g \to U(g); d]$$

be the Chevalley-Eilenberg complex resolving the trivial representation $K$. Then $D(G_{h+}, K) \otimes^L_{U(g)} K = K$. Moreover, the complex $D(G_{h+}, K) \otimes^L_{U(g)} CE(g)$ is the dual of the global sections of the de Rham complex of $G_{h+}$.

Proof. Let $[\Omega^*_L, d]$ be the de Rham complex of $G_{h+}$, notice that the global sections of $\Omega^*_L$ are equal to $C(G_{h+}, K) \otimes_K \mathcal{O}_g \mathcal{O}_g$. As $G_{h+}$ is an open polydisc, the Poincaré lemma holds and the global sections of the de Rham complex is

$$C(G_{h+}, K) \xrightarrow{d} C(G_{h+}, K) \otimes_K \mathcal{O}_g \mathcal{O}_g \xrightarrow{d} \cdots \xrightarrow{d} C(G_{h+}, K) \otimes_K \bigwedge g \mathcal{O}_g \to 0,$$

(12)

which is quasi-isomorphic to $K$ via the inclusion of the constant functions $K \subset C(G_{h+}, K)$. It is easy to show that the dual of (12) is equal to $D(G_{h+}, K) \otimes^L_{U(g)} CE(g)$. Finally, the fact that $D(G_{h+}, K) \otimes^L_{U(g)} CE(g)$ is a projective resolution of $K$ as $D(G_{h+}, K)$-module follows from the exactness of (12) and the duality Theorem 3.30.

Remark 5.12. The same proof of Proposition 5.9 applies in this situation. In particular, one can show that $D(G_{h+}, K) \otimes^L_{U(g)} D(G_{h+}, K) = D(G_{h+}, K)$ and that $\text{Mod}^{\text{solid}}_{D(G_{h+}, K)}$ is a full subcategory of the category of solid $U(g)$-modules.

5.4. Proofs.

Proof of Theorem 4.2. Let $C \in D(K \bullet[G])$. By Theorem 4.34 we have

$$CRG^{(h+)} - an = R\text{Hom}_{K \bullet[G]}(D^{(h+)}(G, K), C).$$

We now compute

$$R\text{Hom}_{K \bullet[G]}(K, CRG^{(h+)} - an) = R\text{Hom}_{K \bullet[G]}(K, R\text{Hom}_{K \bullet[G]}(D^{(h+)}(G, K), C)) = R\text{Hom}_{K \bullet[G]}(K \otimes^L_{K \bullet[G]} D^{(h+)}(G, K), C) = R\text{Hom}_{K \bullet[G]}(K, C),$$

where the second equality is the tensor-Hom adjunction, and the third one follows from Theorem 5.7.

Proof of Theorem 5.4. Let $C$ be a derived $G^{(h+)}$-analytic representation of $G$. Theorem 4.34 says that $C$ is a $D^{(h+)}(G, K)$-module. By Theorem 5.7 one has

$$R\text{Hom}_{K \bullet[G]}(K, C) = R\text{Hom}_{D^{(h+)}(G, K)}(D^{(h+)}(G, K) \otimes^L_{K \bullet[G]} K, C) = R\text{Hom}_{D^{(h+)}(G, K)}(K, C).$$

On the other hand, since $D^{(h+)}(G, K) = O_{K \bullet[G]} \otimes_{O_{K \bullet[G]}} D(G_{h+}, K)$, one has

$$R\text{Hom}_{D^{(h+)}(G, K)}(K, C) = R\text{Hom}_{D(G_{h+}, K)}(K, C)^{G/G_{h+}}.$$

By Proposition 5.11 we get

$$R\text{Hom}_{U(g)}(K, C) = R\text{Hom}_{D(G_{h+}, K)}(D(G_{h+}, K) \otimes^L_{U(g)} K, C) = R\text{Hom}_{D(G_{h+}, K)}(K, C).$$

Putting all together we obtain

$$R\text{Hom}_{K \bullet[G]}(K, C) = R\text{Hom}_{D^{(h+)}(G, K)}(K, C) = R\text{Hom}_{U(g)}(K, C)^G$$

as we wanted. □
