Abstract

Elliptic interface boundary value problems play a major role in numerous applications involving heat, fluids, materials, and proteins, to name a few. As an example, in implicit variational solvation, for the construction of biomolecular shapes, the electrostatic contributions satisfy the Poisson-Boltzmann equation with discontinuous dielectric constants across the interface. When interface motions are involved, one often needs not only accurate solution values, but accurate derivatives as well, such as the normal derivatives at the interface. We introduce here the Compact Coupling Interface Method (CCIM), a finite difference method for the elliptic interface problem with interfacial jump conditions. The CCIM can calculate solution values and their derivatives up to second-order accuracy in arbitrary ambient space dimensions. It combines elements of the Coupling Interface Method (CIM) \cite{1} and Mayo’s approach for elliptic interface boundary value problems \cite{2}, leading to more compact finite difference stencils that are applicable to more general situations. Numerical results on a variety of geometric interfacial shapes and on complex protein molecules in three dimensions support the efficacy of our approach and reveal advantages in accuracy and robustness.

1. Introduction

The elliptic interface problem arises from various physical and biological problems such as fluid dynamics, heat conduction, electrostatics, where material interfaces or phase boundaries are involved. The interface can be static or dynamic. In these problems, material properties and sources may be discontinuous across the interface, which lead to discontinuous solution or flux across the interface.

In this paper, we look at the following elliptic interface problem:

\[
\begin{aligned}
- \nabla \cdot (\epsilon \nabla u) + au &= f & \text{in } \Omega \setminus \Gamma, \\
[u] &= \tau, \quad [\epsilon \nabla u \cdot n] &= \sigma & \text{on } \Gamma, \\
u &= g & \text{on } \partial \Omega.
\end{aligned}
\]  

(1)

Here $\Gamma$ is an interface that separates a cubical computational domain $\Omega \subset \mathbb{R}^d$ into an inside region $\Omega^-$ and an outside region $\Omega^+$. $n$ is the outward unit normal vector of the interface. See Fig.\ref{fig:interface} $g$ is the boundary condition. $\epsilon, f, a: \Omega \rightarrow \mathbb{R}$ are given functions that might be discontinuous across $\Gamma$. For some function $v: \Omega \rightarrow \mathbb{R}$ and $x \in \Gamma$, we denote the limiting value approaching from different side of the interface as

\[
v^+(x) = \lim_{x \rightarrow \Gamma^+} v(x), \quad v^-(x) = \lim_{x \rightarrow \Gamma^-} v(x),
\]  

(2)

and use the notation $[v]$ for the jump of $v$ across the interface

\[
[v] = v^+ - v^-.
\]  

(3)

The term $\epsilon \nabla v \cdot n$ is sometime called the flux. $\tau, \sigma: \Gamma \rightarrow \mathbb{R}$ are given interface jump conditions. We are interested in solving for $u$ and $\nabla u$ accurately on a Cartesian grid with finite difference method.

\textit{Email address: zzirui@ucsd.edu (Zirui Zhang)}
In some applications, the dynamics of the interface depends on gradient of the solution, therefore it is important to have accurate solutions and gradient. For a molecule in ionic solutions, a solute-solvent interface separates the solvent region from the solute region. In this context, $u$ is the electric potential, $f$ is the charge density and $\epsilon$ is the dielectric coefficient, which is about 2 in solute region and 80 in solvent region [3]. In Variational Implicit-Solvent Model [4], the solute-solvent interface is the minimizer of a free-energy functional which includes the electric potential $u$. When we use the level-set method to numerically minimize such a VISM free-energy functional [5], we evolve the surface under the effective dielectric boundary force, which depends on the jump of the normal derivative of the electrostatic potential at the interface. The Stefan problem [6] models the dynamic interface where one material is converted into the other. In this context, $u$ is the temperature and the $\epsilon$ is thermal conductivity, and the interface velocity depends on the jump in normal derivative of the temperature.

There are many finite difference methods that achieve second order accuracy in the solution and first order accuracy in the gradient, such as the Immersed Interface Method (IIM) [7], Ghost Fluid Method (GFM) [8], Coupling Interface Method (CIM) [1]. For a review on different finite difference methods, we refer the readers to the introduction in [1].

In the above finite difference methods, the standard central difference is used at grid points away from the interface, and different approaches are taken at grid points next to the interface. For dimension-splitting approach, in each dimension, usually the principal second-order derivative is approximated by $u$-values from both sides of the interface and the jump in coordinate direction. Since only the jump along the normal direction is known, a coupling equation is needed to connect information from each dimension.

The CIM [1] includes CIM1 (first order) and CIM2 (second order). They are derived from linear and quadratic approximation on both side of the interface in each dimension. The coupling equations are obtained by decomposing the jump in flux along coordinate direction into normal and tangential components, and the unknowns are the principal second-order derivatives. CIM2 is second order accurate in solution and gradient. However, CIM2 requires two grid points in the same region on each side of the interface, and on each plane the mixed derivative can be approximated by grid data. The resulting stencil for CIM2 includes 12-14 grid points in three dimensions. If these requirements are not met, which is common for complex interfaces in three dimensions, then CIM1 is used. This hybrid approach is second order accurate in solution but only first order accurate in the gradient.
The Improved Coupling Interface Method (ICIM) \cite{3} achieves second order accurate gradient by proposing 2 recipes to handle the exceptional points in CIM2: Recipe 1 is “shifting”: at points where $O(h)$ approximation of second derivative is not available, the second derivative can be approximated by central difference at a neighboring point. Recipe 2 is “flipping”: at some points, the signature of domain (inside or outside) can be flipped, so that the usual second order CIM2 discretization can be applied. Then the solution is second order accurate everywhere for the “flipped” surface, but at the flipped grid point the solution should be understood as extrapolation of the solution from the other side. Then by interpolation from the neighbors that are not flipped, we can recover the second-order accurate solution and gradient at those flipped points.

We proposed a Compact Coupling Interface Method (CCIM). Our method combines elements of the CIM and Mayo’s approach for elliptic interface boundary value problem\cite{2}. The jump in each coordinate direction is obtained by differentiating the jump condition in tangential directions. And the coupling equation involve the first-order derivatives and principal second-order derivatives. Our method is second order accurate in the solution and the gradient at the interface. The stencil is more compact, requiring a minimum of 10 grid points in three dimensions. The compactness makes the method applicable to more general situations and leads to more stable convergence results.

This paper is organized as follows. Section 2 outlines the derivation and algorithm of our CCIM method. In section 3, we show the convergence tests in three dimension on geometric surfaces and two complex protein surfaces. We also test our method on a moving surface driven by the jump in gradient at the interface. Section 4 is the conclusion.

2. Method

In $d$ dimensions, let $\Omega = [-1,1]^d$ and discretize the domain uniformly with mesh size $h = 2/N$, where $N$ is the number of subintervals on one edge $[-1,1]$ of the region $\Omega$. Let $i = (i_1,\ldots,i_d)$ be the multi-index with $i_k = 0,1,\ldots,N$ for $k = 1,2,\ldots,d$. The grid points are denoted as $x_i$ with $x_{i_k} = -1 + i_k h$. Let $e_k$, $k = 1,2,\ldots,d$ be the unit coordinate vectors. We also write $u(x_i) = u_i$. Here we use $\Delta u$ for the Laplacian of $u$ and $\nabla^2 u$ for the Hessian matrix of $u$. We assume that $\nabla^2 u$ is symmetric. We use $x_i x_i+e_k$ to denote the grid segment between $x_i$ and $x_i+e_k$, and assume that the interface intersects with any grid segment at most once.

Let $x_i$ be a grid point at which we try to discretize the PDE. For notational simplicity, we drop the argument $x_i$ and the dependency on $i$ is implicit. We rewrite the PDE \cite{1} at $x_i$ as

$$-\sum_{k=1}^{d} \frac{\partial \epsilon}{\partial x_k} \frac{\partial u}{\partial x_k} - \epsilon \sum_{j=1}^{d} \frac{\partial^2 u}{\partial x_j^2} + au = f$$

If $x_i+e_k$, $x_i$ and $x_i+e_k$ are in the same region in each coordinate direction, then we call $x_i$ an interior point, otherwise $x_i$ is called an interface point. At interior points, standard central differencing gives a local truncation error of $O(h^2)$ in $e_k$ direction. Our goal is to construct finite difference schemes with $O(h)$ local truncation error at interface points. The overall accuracy will still be second order since the interface points belongs to a lower dimensional set. Next, we derive a first-order approximation for the term $\partial u/\partial x_k$ and $\partial^2 u/\partial x_k^2$.

2.1. Dimension-by-dimension discretization

Along coordinate direction $e_k$, if the interface does not intersect the grid segment $x_i x_i+e_k$, then by Taylor expansion

$$u_{i+e_k} - u_i \approx h \frac{\partial u}{\partial x_k} + \frac{h^2}{2} \frac{\partial^2 u}{\partial x_k^2} + O(h^3).$$

Suppose the interface intersects the grid segment $x_i x_i+e_k$ at $\hat{x}_k$. Let $\alpha_k = ||\hat{x}_k - x_i||/h$ and $\beta_k = 1 - \alpha_k$. Suppose $x_i$ is located in $\Omega^-$. Denote the limit of $u(x)$ as $x$ approaches $\hat{x}_k$ from $\Omega^-$ by $u^-$, and the limit
Figure 2: \( u_i \) and \( u_{i+e_k} \) are approximated by Taylor expansion at interface

from the other side by \( u^+ \). See Fig 2. By Taylor expansion at the interface \( \mathbf{x}_k \), we can express \( u_i \) and \( u_{i+e_k} \) as

\[
\begin{align*}
  u_i &= u^- - \alpha h \frac{\partial u^-}{\partial x_k} + \frac{(\alpha h)^2}{2} \frac{\partial^2 u^-}{\partial x_k^2} + O(h^3), \\
  u_{i+e_k} &= u^+ + \beta h \frac{\partial u^+}{\partial x_k} + \frac{(\beta h)^2}{2} \frac{\partial^2 u^+}{\partial x_k^2} + O(h^3). 
\end{align*}
\]

(6)

Subtract the above two equations and write the right hand side in terms of jumps and quantities from \( \Omega^- \):

\[
\begin{align*}
  u_{i+e_k} - u_i &= [u] + \beta h \frac{\partial u^-}{\partial x_k} + h \frac{\partial u^-}{\partial x_k} + \frac{h^2}{2} \beta \left( \frac{\partial^2 u^-}{\partial x_k^2} + \frac{h^2}{2} (\beta^2 - \alpha^2) \frac{\partial^2 u^-}{\partial x_k^2} \right) + O(h^3) \\
  &= \left([u] + \beta h \frac{\partial u^-}{\partial x_k} + \frac{h^2}{2} \beta \frac{\partial^2 u^-}{\partial x_k^2} \right) + O(h^3). 
\end{align*}
\]

(7)

We can approximate components of \( \nabla u^- \) and \( \nabla^2 u^- \) by

\[
\begin{align*}
  \frac{\partial u^-}{\partial x_i} &= \frac{\partial u}{\partial x_i} + \alpha_k h \frac{\partial^2 u}{\partial x_i \partial x_k} + O(h^2), \\
  \frac{\partial^2 u^-}{\partial x_i \partial x_k} &= \frac{\partial^2 u}{\partial x_i \partial x_k} + O(h). 
\end{align*}
\]

(8)

Thus, (7) can be written as

\[
\begin{align*}
  u_{i+e_k} - u_i &= [u] + \beta h \frac{\partial u}{\partial x_k} + \frac{h^2}{2} \beta \left( \frac{\partial^2 u}{\partial x_k^2} + \frac{h^2}{2} (\beta^2 - \alpha^2) \frac{\partial^2 u}{\partial x_k^2} \right) + O(h^3). 
\end{align*}
\]

(10)

By the given jump condition, \([u] = \tau\). We denote the set of neighboring grid points of \( i \) as \( B_r = \{ j \mid \| j - i \|_\infty \leq r \} \) and call \( r \) the radius of our finite difference stencil. In three dimensions, \( B_1 \) contains 27 grid points and forms a cube. Suppose we can approximate the jump \( [\partial u/\partial x_k] \) and \( [\partial^2 u/\partial x_k^2] \) in terms of \( u_j \), \( \partial u/\partial x_k \) and \( \partial^2 u/\partial x_k^2 \), with \( 1 \leq k \leq d \) and \( j \in B_r \) for some stencil radius \( r \). Then in each coordinate direction, for \( 1 \leq k \leq d \), we can write down two equations, (10) or (5), by considering the two grid segments \( x_i x_{i+e_k} \) for \( s = \pm 1 \). In \( d \) dimensions we have \( 2d \) equations and \( 2d \) unknowns: the first-order derivatives \( \partial u/\partial x_k \) and principle second-order derivatives \( \partial^2 u/\partial x_k^2 \) for \( 1 \leq k \leq d \). This leads to a system of linear equations of the following form:

\[
M \begin{bmatrix} \frac{\partial u}{\partial x_k} \\ \frac{\partial^2 u}{\partial x_k^2} \end{bmatrix}_{1 \leq k \leq d} = \frac{1}{h^2} \begin{bmatrix} D_{k,s} u + b_{k,s} \end{bmatrix}_{1 \leq k \leq d,s = \pm 1} + O(h). 
\]

(11)
where \( D_{k,s}u = D_{k,s}(u_j), \ j \in B_r \), is some linear function of neighboring \( u \)-values and \( b_{k,s} \) is some constant.

We call (11) coupling equation and \( M \) coupling matrix. By inverting \( M \), we attain the finite difference formula to approximate \( \partial u / \partial x_k \) and \( \partial^2 u / \partial x_k^2 \) in terms of \( u \)-values.

In the next section, we describe how to remove the jumps in (10).

2.2. Approximation of the jump condition

Let \( \mathbf{n} \) be the unit normal vector at the interface, and \( \mathbf{s}_1, \ldots, \mathbf{s}_{d-1} \) be unit tangent vectors. The tangent vectors can be obtained by projecting the unit coordinate vector onto the tangent plane. We can write

\[
[\nabla u] = [\nabla u \cdot \mathbf{n}]\mathbf{n} + \sum_{j=1}^{d-1} [\nabla u \cdot \mathbf{s}_j]\mathbf{s}_j. \tag{12}
\]

In the \( \mathbf{e}_k \) coordinate direction, this gives

\[
\left[ \frac{\partial u}{\partial x_k} \right] = \frac{1}{\epsilon^+} (\sigma - [\epsilon] \nabla u^- \cdot \mathbf{n}) + \sum_{j=1}^{d-1} \frac{1}{\epsilon^+} \frac{\partial^2 u}{\partial x_j \partial x_k} \mathbf{e}_j \cdot \mathbf{s}_n \mathbf{e}_k. \tag{13}
\]

We use the following trick repeatedly in our derivation to decouple the jump

\[
[\epsilon v] = \epsilon^+[v] + [\epsilon]v^-. \tag{14}
\]

Taking \( v = \nabla u \cdot \mathbf{n} \), together with \( [\nabla u \cdot \mathbf{s}_k] = \nabla \tau \cdot \mathbf{s}_k \), the jump condition \( [\epsilon \nabla u \cdot \mathbf{n}] = \sigma \) can be rewritten as

\[
\left[ \frac{\partial u}{\partial x_k} \right] = \frac{1}{\epsilon^+} \left( \sigma - [\epsilon] \nabla u^- \cdot \mathbf{n} \right) + \sum_{j=1}^{d-1} \frac{1}{\epsilon^+} \mathbf{e}_j \cdot \mathbf{s}_n \mathbf{e}_k. \tag{15}
\]

By (12), we get

\[
\left[ \frac{\partial u}{\partial x_k} \right] = \frac{1}{\epsilon^+} \left( \sigma - [\epsilon] \sum_{j=1}^{d-1} \frac{\partial u}{\partial x_j} + \frac{\partial^2 u}{\partial x_j \partial x_k} \right) (\mathbf{n} \cdot \mathbf{e}_j) + \sum_{j=1}^{d-1} (\nabla \tau \cdot \mathbf{s}_n) (\mathbf{s}_n \cdot \mathbf{e}_k). \tag{16}
\]

Notice that now we approximate the jump in the first-order derivative at the interface in terms of the first-order and second-order derivatives at grid point.

To remove the jumps in the principal second-order derivatives \( [\partial^2 u / \partial x_k^2] \), we solve a system of linear equations. The first set of equations are obtained by differentiating the interface boundary condition in tangential directions. For \( m = 1, \ldots, d - 1 \) and \( n = m, \ldots, d - 1 \), we get \( d(d - 1)/2 \) equations

\[
\nabla[\nabla \mathbf{u} \cdot \mathbf{s}_m] \cdot \mathbf{s}_n = \nabla(\nabla \mathbf{u} \cdot \mathbf{s}_m) \cdot \mathbf{s}_n. \tag{17}
\]

Expand every term, and with the help of (14) and (15), we get

\[
\mathbf{s}_m^T \nabla^2 \mathbf{u} \mathbf{s}_m = \mathbf{s}_m^T \nabla^2 \mathbf{u} \mathbf{s}_m + \frac{1}{\epsilon^+} (\sigma - [\epsilon] \nabla u^- \cdot \mathbf{n}) \mathbf{s}_m^T \nabla \mathbf{s}_m - (\nabla \mathbf{u} \cdot \mathbf{n}) \mathbf{s}_m^T \nabla \mathbf{s}_m. \tag{18}
\]

By differentiating the jump in flux in tangential direction, we get another \( d - 1 \) equations for \( m = 1, \ldots, d - 1 \),

\[
\nabla[\epsilon \nabla \mathbf{u} \cdot \mathbf{s}_m] \cdot \mathbf{s}_m = \nabla \sigma \cdot \mathbf{s}_m. \tag{19}
\]

After expansion,

\[
\mathbf{s}_m^T \nabla^2 \mathbf{u} \mathbf{n} = \frac{1}{\epsilon^+} \nabla \sigma \cdot \mathbf{s}_m - \frac{[\epsilon]}{\epsilon^+} \mathbf{s}_m^T \nabla \mathbf{u} \cdot \mathbf{n} - \frac{[\epsilon]}{\epsilon^+} \mathbf{s}_m^T \nabla \mathbf{u} \cdot \mathbf{n} - \sum_{k=1}^{d-1} (\nabla \mathbf{u} \cdot \mathbf{s}_k) \mathbf{s}_m^T \nabla \mathbf{s}_k - \frac{1}{(\epsilon^+)^2} (\nabla \mathbf{u} \cdot \mathbf{s}_m) (\sigma - [\epsilon] \nabla u^- \cdot \mathbf{n}) - \frac{1}{\epsilon^+} \nabla \mathbf{u} \cdot \mathbf{s}_m \nabla \mathbf{u} \cdot \mathbf{n}. \tag{20}
\]
The final equation comes from the PDE

\[-\nabla \cdot (\epsilon \nabla u) + au = [f].\]  

(21)

After expansion,

\[\Delta u = - \left[ \frac{f}{\epsilon} \right] + \frac{a^+}{\epsilon^+} \tau + \left[ \frac{a}{\epsilon} \right] u^-
- \frac{1}{(\epsilon^+)^2} \sigma - [\epsilon] \nabla u^- \cdot \nabla \epsilon^+ \cdot \nabla u^- - \frac{1}{\epsilon^+} \sum_{k=1}^{d-1} (\nabla \tau \cdot s_k)(\nabla \epsilon^+ \cdot s_k) - \left[ \frac{\nabla \epsilon^-}{\epsilon} \right] \cdot \nabla u^- .\]  

(22)

We arrive at a system of linear equations of where the variables are the jump in second-order derivatives

\[G \left[ \frac{\partial^2 u}{\partial x_k \partial x_l} \right]_{1 \leq k \leq l \leq d} = L \left( u^-, \frac{\partial u^-}{\partial x_k} \right)_{1 \leq k \leq d}, \left( \frac{\partial^2 u^-}{\partial x_k \partial x_l} \right)_{1 \leq k \leq l \leq d} + b .\]  

(23)

where \( G \) is a matrix that only depends on the normal and tangent vectors, \( L \) stands for some general linear function and \( b \) stands for some constant. In two and three dimensions, through a direct calculation, the absolute value of the determinant of \( G \) is 1.

As an example, in two dimensions, let \( s = [s_1, s_2]^T \) and \( n = [n_1, n_2]^T \), and assume that \( \epsilon(x) \) is a piecewise constant function, then the system of linear equations is given by

\[
\begin{bmatrix}
  s_1^2 & s_2^2 & 2s_1s_2 \\
  s_1n_1 & s_2n_2 & s_1n_2 + s_2n_1 \\
  1 & 1 & 0
\end{bmatrix}
\begin{bmatrix}
  u_{xx} \\
  u_{xy} \\
  u_{yy}
\end{bmatrix} =
\begin{bmatrix}
  s^T \nabla^2 \tau s + \frac{1}{\epsilon^+} (\sigma - [\epsilon] \nabla u^- \cdot n) s^T \nabla ns - (\nabla \tau \cdot n)s^T \nabla ns \\
  -[\frac{1}{\epsilon^+} - \frac{s^T \nabla u^-}{\epsilon^+} + \frac{s^T \nabla u^-}{\epsilon^+} \cdot (s^T \nabla u^- - (\nabla \tau \cdot s)s^T \nabla ns) \\
  -[\frac{1}{\epsilon^+}] + \frac{s^T \nabla \tau}{\epsilon^+} - [\frac{1}{2}] u^-
\end{bmatrix} .
\]  

(24)

By Taylor’s expansion as in (5), (8), and (9), \( u^- \) and components of \( \nabla u^- \) and \( \nabla^2 u^- \) can all be approximated by \( u \) and components of \( \nabla u \) and \( \nabla^2 u \) at the grid point. Therefore, after substitution, with different \( L \) and \( b \), (23) becomes

\[G \left[ \frac{\partial^2 u}{\partial x_k \partial x_l} \right]_{1 \leq k \leq l \leq d} = L \left( u, \frac{\partial u}{\partial x_k} \right)_{1 \leq k \leq d}, \left( \frac{\partial^2 u}{\partial x_k \partial x_l} \right)_{1 \leq k \leq l \leq d} + b + O(h) .\]  

(25)

If we could approximate the mixed derivatives \( \frac{\partial^2 u}{\partial x_k \partial x_l}, k \neq l \) in terms of \( u \)-values and the jump in second-order derivatives, then by inverting \( G \), the jump in second-order derivatives can be approximated by \( u \)-values, first-order derivatives, and principal second-order derivatives, which are the terms used in the coupling equation.

By back substitution, the mixed derivatives and thus the jump in the first-order derivative can also be approximated by these terms. Next, we describe how to approximate the mixed derivatives.

2.3. Approximation of the mixed derivative

Depending on the position of the interface with respect to the grid points, different schemes are needed in order to approximate \( \frac{\partial^2 u}{\partial x_k \partial x_l}, k \neq l \). In Fig. 3 case 1, we use the usual central difference formula,

\[\frac{\partial^2 u}{\partial x_k \partial x_l} = \frac{1}{h^2} (u_{i+1}+e_k+e_l - u_{i-1}+e_k+e_l - u_{i+1}+e_k-e_l + u_{i-1}+e_k-e_l) + O(h^2) .\]  

(26)

We can also use biased differencing as in Fig. 3 case 2 and case 3

\[\frac{\partial^2 u}{\partial x_k \partial x_l} = \frac{1}{2h^2} (u_{i+1}+e_k - u_{i+1}+e_k-e_l - u_{i-1}+e_k+u_{i-1}+e_k-e_l) + O(h) .\]  

(27)
Figure 3: Approximation of mixed derivative at $x_i$. The circles and disks are grid points in $\Omega_-$ and $\Omega_+$. The squares are grid points that are used to approximate the mixed derivative. Case 1 is usual central differencing. Case 2 and 3 are biased differencing. Case 4 is coupled with the second derivative. Case 5 is coupled with the first and second derivative. Case 6 make use of the mixed derivative on the other side and the jump condition.
\[
\frac{\partial^2 u}{\partial x_k \partial x_l} = \frac{1}{h^2} (u_i - u_{i-e_k} - u_{i-e_l} + u_{i-e_k-e_l}) + O(h)
\]
\[
= \frac{\partial^2 u}{\partial x_k \partial x_l} (x_i - \frac{1}{2} he_k - \frac{1}{2} he_l) + O(h^2).
\] (28)

In case 4, we can make use of the first-order derivatives
\[
\frac{\partial^2 u}{\partial x_k \partial x_l} = \frac{1}{2h^2} \left( 2h \frac{\partial u}{\partial x_k} - u_{i+e_k} - u_{i-e_k} + u_{i+e_k-e_l} \right) + O(h)
\]
\[
= \frac{\partial^2 u}{\partial x_k \partial x_l} (x_i - \frac{1}{2} he_l) - \frac{1}{6} \frac{\partial^4 u}{\partial x_k^4} + O(h^2).
\] (29)

In case 5, we can make use of the first-order and second-order derivatives
\[
\frac{\partial^2 u}{\partial x_k \partial x_l} = \frac{1}{h^2} \left( h \frac{\partial u}{\partial x_k} - \frac{h^2}{2} \frac{\partial^2 u}{\partial x_k^2} - u_{i-e_k} - u_{i-e_k} \right) + O(h)
\]
\[
= \frac{\partial^2 u}{\partial x_k \partial x_l} (x_i - \frac{1}{2} he_l) - \frac{1}{6} \frac{\partial^4 u}{\partial x_k^4} + O(h^2).
\] (30)

In Fig. 5, case 6, when there are not enough grid points on the same side, we can make use of information from the other side of the interface and the jump in mixed derivative
\[
\frac{\partial^2 u}{\partial x_k \partial x_l} = \frac{\partial^2 u}{\partial x_k \partial x_l} (x_i + he_l) - \left[ \frac{\partial^2 u}{\partial x_k \partial x_l} \right]_{x_k} + O(h).
\] (31)

By approximating the mixed derivatives \( \partial^2 u/\partial x_k \partial x_l \), \( 1 \leq k \leq l \leq d \) in terms of \( u_j, \partial u/\partial x_k, \partial^2 u/\partial x_k^2 \) and \( \left[ \partial^2 u/\partial x_k \partial x_l \right] \), \( j \in B_r \), for some kernel radius \( r \), we can write the right hand side of (23) in terms of \( u_j, \partial u/\partial x_k \), \( \partial^2 u/\partial x_k^2 \), \( 1 \leq k \leq d \), thus eliminating the mixed derivatives. Then by solving the linear system (23), the jump in second derivative \( \left[ \partial^2 u/\partial x_k^2 \right] \) can be approximated in terms of \( u_j, \partial u/\partial x_k \) and \( \partial^2 u/\partial x_k^2, 1 \leq k \leq d \).

Finally, substituting \( \left[ \partial u/\partial x_k \right], \left[ \partial^2 u/\partial x_k^2 \right] \) into (7), we get an equation involving only \( u_j, \partial u/\partial x_k \), and \( \partial^2 u/\partial x_k^2 \), \( 1 \leq k \leq d \). Each equation has 2 equations (by looking forward and backward). Therefore, with \( 2d \) equations and \( 2d \) unknowns (first order derivatives and principal second order derivatives), we can solve for \( \partial u/\partial x_k \) and \( \partial^2 u/\partial x_k^2 \) in terms of \( u \)-values.

Multiple methods to approximate the mixed derivatives might be available at the same grid point. We would like the method to be simple and accurate. For simplicity, we prefer methods that only make use of \( u \)-value, as in case 1, 2, and 3. For accuracy, we provide a heuristic criterion: for homogeneous polynomial of degree three, the approximation on the right hand side is exact for some nearby points \( x_i \) or \( x_i - \frac{1}{2} he_k \), \( or \ x_i - \frac{1}{2} he_l \). We would like this point to be as close to \( x_i \) as possible. In this respect, we prefer case 4 to case 3. Another consideration for accuracy is the condition number of the coupling equation. Solving a linear system with large condition number is prone to large numerical errors. Therefore, in cases where both case 3 and case 4 are available, we choose the method with a smaller estimated condition number [9].

Though we can construct surfaces for a specific grid size such that none of the above schemes works, for smooth surfaces we can refine the grid such that the above schemes suffice. In addition, we note that case 5 and case 6 can be removed by refining the grid, while case 4 cannot [3].

2.4. Algorithm

We describe our method to obtain the coupling equations at an interface point in algorithmic order in Algorithm [3]. Once we have the coupling equations (11), by inverting the coupling matrix, \( \partial u/\partial x_k \) and \( \partial^2 u/\partial x_k^2, 1 \leq k \leq d \) can be approximated by linear combinations of \( u_j, j \in B_r \).

To get more stable convergence results, at grid points where case 1 and 2 not available, but case 3 and 4 are available, we use the algorithm to obtain two systems of coupling equations, and choose the system with a smaller estimated condition number of the coupling matrix. The effect of this criterion is demonstrated in Section 5.1.
systems to a tolerance of 10^{-16} memory. We use the AMG method implemented in the HYPRE library \cite{10} to solve the sparse linear system.

3. Numerical results

We test our method in three dimensions with different surfaces. The first set of tests contains six geometric surfaces that are used in \cite{3}. And the second set of tests consists of two complex biomolecular surfaces. These two sets are compared with ICIM \cite{3} with the same setup. As tests in \cite{3} do not include \( a(x) \) term, the third set of tests are the same six geometric surfaces with \( a(x) \) term. The last test is a sphere expanding under a normal velocity given by the derivative of the solution in normal direction. Let \( u_e \) be the exact solution of \cite{1}, and \( u \) be the numerical solution. For tests with a static interface, we look at the maximum error of the solution at all grid points, denoted as \( \| u_e - u \|_{\infty, \Gamma} \), and the maximum error of the gradient at all intersection of interface and grid lines, denoted as \( \| \nabla u_e - \nabla u \|_{\infty, \Gamma} \). For the expanding sphere, we look at the maximum error and Root Mean Square Error of the radius at all intersections of the interface and grid line. All the tests are performed on a 2017 iMac with 3.5 GHz Intel Core i5 and 16GB memory. We use the AMG method implemented in the HYPRE library \cite{10} to solve the sparse linear systems to a tolerance of 10^{-6}.

3.1. Example 1

We test several geometric interfaces as in \cite{3}. The surfaces are shown in Fig.4. Their level set functions are given below.

- Eight balls: \( \phi(x, y, z) = \min_{0 \leq k \leq 7} \sqrt{(x - x_k)^2 + (y - y_k)^2 + (z - z_k)^2} - 0.3 \), where \( (x_k, y_k, z_k) = ((-1)^{k/4} \times 0.5, (-1)^{k/2} \times 0.5, (-1)^{k} \times 0.5) \)
- Ellipsoid: \( \phi(x, y, z) = 2x^2 + 3y^2 + 6z^2 - 1.3 \)
- Peanut: \( \phi(x, y, z) = \phi(r, \theta, \psi) = r - 0.5 - 0.2 \sin(2\theta) \sin(\psi) \)
- Donut: \( \phi(x, y, z) = (\sqrt{x^2 + y^2} - 0.6)^2 + z^2 - 0.4^2 \)
- Banana: \( \phi(x, y, z) = (7x + 6)^4 + 2401y^4 + 3601.5z^4 + 98(7x + 6)^2(y^2 + z^2) + 4802y^2z^2 - 94(7x + 6)^2 + 3822y^2 - 4606z^2 + 1521 \)
• Popcorn: $\phi(x, y, z) = \sqrt{x^2 + y^2 + z^2} - r_0 - \sum_{k=0}^{11} \exp\left\{25((x - x_k)^2 + (y - y_k)^2 + (z - z_k)^2)\right\}$, where $(x_k, y_k, z_k) = \frac{r_0}{\sqrt{5}} \left(2 \cos \left(\frac{2k\pi}{5} - \left\lfloor \frac{k}{5} \right\rfloor \right), 2 \sin \left(\frac{2k\pi}{5} - \left\lfloor \frac{k}{5} \right\rfloor \right), (-1)^k \hat{z}\right)$, $0 \leq k \leq 9$

$$= r_0(0, 0, (-1)^k \hat{z}), 10 \leq k \leq 11.$$ 

The exact solution and the coefficient are given by

$$u_e(x, y, z) = \begin{cases} 
xy + x^4 + y^4 + xz^2 + \cos(2x + y^2 + z^3) & \text{if } (x, y, z) \in \Omega^+ \\
x^3 + xy^2 + y^3 + z^4 + \sin(3(x^2 + y^2)) & \text{if } (x, y, z) \in \Omega^- 
\end{cases} \quad (32)$$

and

$$\epsilon(x, y, z) = \begin{cases} 
80 & \text{if } (x, y, z) \in \Omega^+ \\
2 & \text{if } (x, y, z) \in \Omega^- 
\end{cases} \quad (33)$$

The source term and the jump conditions are calculated accordingly.

---

Figure 4: The six interfaces (a) eight balls; (b) ellipsoid; (c) peanut; (d) donut; (e) banana; (f) popcorn

Fig. 5 shows the convergence result of the six interfaces. The convergence of the solution at grid points is second order, and the convergence of the gradient at the interface is slightly below second order.

Next we demonstrate the effect of choosing the stencil for mixed derivatives based on estimated condition number of the coupling matrix. As mentioned in section 2.3 when both case 3 and case 4 are available to approximate the mixed derivatives, we choose the method that gives a smaller estimated condition number of the coupling matrix. We denote this scheme as CCIM. Alternatively, we can fix the order of preference
Figure 5: The log-log plot of the error versus $N$ for the six surfaces. In each figure, $N$ ranges from 50 to 140 with the increment $\Delta N = 5$. Circles are the maximum errors of the solution $\|u_e - u\|_{\infty}$. Diamonds are the maximum errors of the gradient at interface $\|\nabla u_e - \nabla u\|_{\infty, \Gamma}$.
for different methods. In scheme 1, we always prefer case 4 to case 3. Fig. [6] demonstrates the effect of this decision using the banana shape surface as an example. For different $N$ and for both schemes, Fig. 6a plots the maximum condition number of all the coupling matrices, and Fig. 6a plots the convergence results of these two schemes. For most of the $N$-values, CCIM and scheme 1 have roughly the same maximum error. We noticed that for $N = 110$, with scheme 1, at the interface point that produces the maximum error in the gradient, the coupling matrix has an exceptionally large condition number. By choosing the method with a smaller estimated condition number, we get a more stable convergence result in the gradient. If we prefer case 3 to case 4, then results are similar: at some grid points large condition number leads to large error, and CCIM gives more stable convergence results.

![Figure 6: Comparison of maximum condition numbers and convergence results with banana surface between scheme 1 and CCIM.](image)

Though we can get a more stable convergence result by considering the condition number of the coupling matrices, there is a small jump for the banana interface at $N = 110$. A detailed analysis of the error reveals that it was caused by relatively large local truncation error when approximating $u_{xz}$. Fig. 7 shows the contour plot of the mixed derivative $u_{xz}$. Notice that $u_{xz}$ change rapidly along the northeast direction. However, due to the alignment of the surface with the grid, at $x_{i,k}$, our algorithm use the 4-point stencil $x_{i,k}, x_{i-1,k}, x_{i,k-1}$ and $x_{i-1,k-1}$ to approximate $u_{xz}(x_{i,k})$ and has a local truncation error 0.160723. If we use the three point stencil $x_{i,k}, x_{i-1,k}, x_{i-1,k+1}$, the local truncation error would be 0.041853, and the coupling matrix does not have large condition number. With this surgical fix, the final error would be in line with the rest of the data points as shown in Fig 6b at $N = 110$, marked as “Surgical fix”. This type of outliers happens rarely and does not affect the overall order of convergence. We apply this surgical fix only at this specific grid point to demonstrate a possible source of large error.

In summary, though the overall order of convergence is second order no matter which method is used to approximate the mixed derivatives, a relatively large error can be caused by large condition number of the coupling matrix, or a large local truncation error when approximating the mixed derivative. When different method to approximate the mixed derivative are available, ideally, we prefer the method that produces smaller local truncation error and smaller condition number of the coupling matrix. However these two goal might be incompatible sometimes. It’s time consuming to search through all available methods to approximate the mixed derivative and find the one that leads a small condition number of the coupling
matrix. It’s also difficult to tell a priori which method gives smaller local truncation error. Therefore we try to find a middle ground by only considering the condition number when both case 3 and case 4 are available.

The resulting linear system for the PDE is sparse and asymmetric, and can be solved with any “black-box” linear solvers. Fig. 8 shows the log-log plot for the number of iteration versus $N$. We used BICGSTAB with ILU preconditioner and Algebraic Multigrid Method (AMG), both are implemented in the HYPRE library [10]. The number of iterations grows linearly with $N$ for BICGSTAB and sub-linearly for AMG. Though AMG has better scaling properties, for the range of $N$ in Fig 8 both solvers take approximately the same cpu time.

3.2. Example 2

Next we test our method on two complex molecular surfaces and compare CCIM with our implementation of ICIM [3]. The solvent accessible surface describes the interface between solute and solvent. Such interfaces are complex and important in applications. We construct the surfaces as in [3]: from the PDB file of 1D63 [11] and MDM2 [12], we use the PDB2PQR [13] software to assign charges and radii using the AMBER force field. The PQR files contain information of the positions $p_i$ and radii $r_i$ of the atoms. We scale the positions and radii such that the protein fit into the unit box. Then we construct the level set function of the interface as union of smoothed bumps:

$$\phi(x) = c - \sum_i \chi_\eta(r_i - \|x - p_i\|)$$

(34)

where $\chi_\eta$ is a smoothed characteristic function

$$\chi_\eta = \frac{1}{2} \left(1 + \tanh\left(\frac{x}{\eta}\right)\right)$$

(35)

The molecule 1D63 has 486 atoms and has a double-helix shape, as shown in Fig. 9(a). MDM2 has 1448 atoms, and the surface has a deep pocket to which other proteins can bind, as shown in Fig 10(a). We also implement ICIM [3] and compare the convergence results between CCIM and ICIM in Fig. 9 and Fig. 10.
Figure 8: The log-log plot of the number of iterations versus $N$ for the six surfaces.

Figure 9: Convergence result for 1D63 interface with $c = 0.25$ and $\eta = 1/40$. (a) The smooth surface of 1D63. (b) log-log plot of error by CCIM. (b) log-log plot of error by ICIM. $N$ ranges from 100 to 340 with the increment $\Delta N = 5$.

AMG: $m = 0.49$
(f) popcorn
ILU-BiCGSTAB: $m = 0.82$
AMG: $m = 0.61$
As shown in Fig. 9 and 10, compared with our implementation of ICIM, the convergence results of CCIM is very robust even for complex interfaces. There is little fluctuation in the convergence results. In our ICIM implementation, the order of convergence exceeds second order because large errors at coarse grid points skew the fitting line to have a more negative slope. The results demonstrate the advantage of the compactness in our CCIM formulation when dealing with complex surfaces.

3.3. Example 3

We also test our problem with the same exact solution (32) and coefficients (33), but with an \( a(x, y, z) \) term, which is not handled in the ICIM formulation.

\[
a(x, y, z) = \begin{cases} 
2 \sin(x) & \text{if } (x, y, z) \in \Omega^- \\
80 \cos(z) & \text{if } (x, y, z) \in \Omega^+ 
\end{cases}
\]  

As shown in Fig. 11, the convergence result is almost identical to those without the \( a(x, y, z) \) term. Therefore the convergence result mainly depends on the alignment of the surface with the grid line.

3.4. Example 4

In this example we look at the evolution of an interface driven by the jump in the normal derivative of the solution. Suppose the surface \( \Gamma \) is evolved with normal velocity \( v_n = [\nabla u \cdot n] \). The dynamics of the interface is given by the level set equation

\[
\phi_t + v_n |\nabla \phi| = 0.
\]  

We use the forward Euler method for first-order accurate time discretization, Godunov scheme for the Hamiltonian, and the Fast Marching Method [14] to extend \( v_n \) to the whole computational domain.

Consider the radially symmetric functions

\[
u_e(x) = \begin{cases} 
\frac{1}{1+\|x\|^2} & x \in \Omega^- \\
\frac{-1}{1+\|x\|^2} & x \in \Omega^+ 
\end{cases}
\]  

and

\[
a(x) = \begin{cases} 
2\sin(\|x\|) & x \in \Omega^- \\
80\cos(\|x\|) & x \in \Omega^+ 
\end{cases}
\]
Figure 11: The log-log plot error with $a(x)$ term versus $N$ for the six surfaces. In each figure, $N$ ranges from 50 to 140 with the increment $\Delta N = 5$. 

(a) 8 balls
Solution: $m = -2.01$
Gradient: $m = -1.77$

(b) peanut
Solution: $m = -1.99$
Gradient: $m = -1.88$

(c) ellipsoid
Solution: $m = -2.00$
Gradient: $m = -1.91$

(d) donut
Solution: $m = -2.03$
Gradient: $m = -1.84$

(e) banana
Solution: $m = -1.99$
Gradient: $m = -1.81$

(f) popcorn
Solution: $m = -1.98$
Gradient: $m = -1.98$
The coefficient $\epsilon$ is the same as (33). The source term and the jump conditions are calculated accordingly.

If the surface is a sphere of radius $r$, by symmetry, the normal velocity is uniform over the sphere and is given by

$$v_n(r) = [\nabla u \cdot n] = \frac{4r}{(1 + r^2)^2}.$$  \hfill (40)

Let the initial surface be a sphere of radius 0.5, then the motion of the surface is described by the ODE

$$\frac{dr}{dt} = v_n(r), \quad r(0) = 0.5$$  \hfill (41)

which can be computed with high accuracy. The result is a sphere expanding at varying speeding.

In Fig. 12a, we look at the maximum error and the Root Mean Squared Error (RMSE) of radius calculated at final time $t = 0.1$ for different $N$. The exact radius at final time should be 0.629428. The results are second order accurate. In Fig. 12b, we plot the initial and final surface for $N = 20$. The shape is well-preserved. Without accurate gradient approximation, the surface might become distorted or oscillatory.

4. Conclusions

In this paper, we proposed a Compact Coupling Interface Method (CCIM) to solve the elliptic interface boundary value problem in any dimension. Our method combines elements from the Coupling Interface Method (CIM) and Mayo’s approach to Poisson’s equation on irregular regions. Standard central difference schemes are used at interior grid points. At interface grid point, coupling equations of the first-order derivatives and principal second-order derivatives are derived in a dimension-splitting approach and by differentiating the jump conditions. Our method obtains second order accurate solution at the grid points and second order accurate gradient at the interface. The accurate approximation for the gradient is important in applications where the dynamics of the surface is driven by the jump in the solution gradient at the interface. Our method has a more compact finite difference stencil compared with CIM and is applicable to complex interfaces. We tested our method in three dimensions with complex interfaces, including two
protein surfaces, and demonstrated that the solution and the gradient at the interface are uniformly second-order accurate, and the convergence results are very stable. We also tested our method with a dynamic surface whose normal velocity is given by the jump in gradient at the interface and obtained second order accurate interface at the final time.
