THE MULTIPLICATION FORMULAS OF QUANTUM CLUSTER ALGEBRAS

ZHIMIN CHEN, JIE XIAO, AND FAN XU

Abstract. By applying the property of Ext-symmetry and the vector bundle structures of certain fibres, we introduce the notion of weight function and prove the multiplication formulas for weighted quantum cluster characters associated to abelian categories with the property of Ext-symmetry and 2-Calabi-Yau triangulated categories with cluster-tilting objects.

1. Introduction, notations and main results

Cluster algebras were introduced by Fomin and Zelevinsky [12] in order to find an algebraic framework for understanding total positivity in algebraic groups and canonical bases in quantum groups. They are commutative algebras over $\mathbb{Z}$ generated by certain elements called cluster variables. There is an iterative procedure called mutation to obtain new cluster variables from initial cluster variables. In the most canonical examples, cluster variables are indexed by almost positive roots of the Kac-Moody algebras.

Cluster algebras have close connections to representation theory of algebras via cluster category and cluster character. Cluster categories constructed by Buan–Marsh–Reineke–Reiten–Todorov [4] are certain categories of representations over
acyclic quivers. Given an acyclic quiver $Q$, the cluster category $\mathcal{C}_Q$ associated with $Q$ is the orbit category $\mathcal{D}^b(Q)/\tau \circ [-1]$. Indecomposable objects in $\mathcal{C}_Q$ correspond to the almost positive roots in the root system of the Lie algebra $\mathfrak{g}$ of type $Q$. The cluster category has the 2-Calabi-Yau property, i.e.,

$$\text{Hom}_{\mathcal{C}_Q}(M, N[1]) \cong D\text{Hom}_{\mathcal{C}_Q}(N, M[1])$$

for any $M, N \in \mathcal{C}_Q$.

For a Dynkin quiver $Q$ with $n$ vertices, Caldero and Chapoton [5] defined a map $X_?^Q$ from the set of objects in the cluster category $\mathcal{C}_Q$ to $\mathbb{Q}(x_1, \ldots, x_n)$ such that

$$X_M = \sum_{\varepsilon} \chi(\text{Gr}_\varepsilon(M))x_1^{-B_\varepsilon-(I_n-B)n}$$

for a $\mathbb{C}Q$-module $M$ and $X_{P[1]} = x^{\dim P/\text{rad} P}$ for a projective $\mathbb{C}Q$-module $P$. In particular, it gives a bijection between the indecomposable rigid objects and cluster variables and then the mutation rule of cluster variables is written as the following property. For indecomposable rigid objects $M, N$ in $\mathcal{C}_Q$ with $\dim \text{Hom}_{\mathcal{C}_Q}(M, N[1]) = 1$, we have

$$X_M \cdot X_N = X_L + X_{L'}$$

where $L, L'$ are the middle terms of two non-split triangles induced by $\varepsilon \in \text{Hom}_{\mathcal{C}_Q}(M, N[1])$ and $\varepsilon' \in \text{Hom}_{\mathcal{C}_Q}(N, M[1])$, respectively. This map is called the cluster character. Then the cluster character $X_M$ for an indecomposable rigid object $M$ can be viewed as the general formula of the sequence of cluster variables with the mutation rules as recurrence relations and $X_{P_1[1]}, \ldots, X_{P_n[1]}$ as initial terms. Caldero and Keller [7] generalized these results to any acyclic quiver and then categorified all cluster algebras with acyclic initial clusters. As a corollary, the cluster algebra $\mathcal{A}(Q)$ is generated by $X_M$ for all rigid objects $M \in \mathcal{C}_Q$. Palu [18] generalized the definition of cluster character to a 2-Calabi-Yau triangulated category $\mathcal{C}$ with a cluster-tilting object $T$, denoted by $X_T^Q$, i.e.,

$$X_M^T = \sum_{\varepsilon} \chi(\text{Gr}_\varepsilon(T, M))x_1^{\dim P - I(\varepsilon)}$$

for $M \in \mathcal{C}$ (see Section 4.1 for more details).

In [6], Caldero and Keller proved a higher-dimensional multiplication formula between cluster characters for the cluster category $\mathcal{C}_Q$ of a Dynkin quiver $Q$. They showed that for any indecomposable objects $M, N \in \mathcal{C}_Q$,

$$\chi(\mathbb{P}\text{Hom}_{\mathcal{C}_Q}(M, N[1]))X_M \cdot X_N = \sum_{[L]} (\chi(\mathbb{P}\text{Hom}_{\mathcal{C}_Q}(M, N[1])L[1]) + \chi(\mathbb{P}\text{Hom}_{\mathcal{C}_Q}(N, M[1])L[1]))X_L.$$

where $\chi$ is the Euler-Poincaré characteristic. The proof heavily depends on the 2-Calabi-Yau property of $\mathcal{C}_Q$. The multiplication formula is generalized firstly to acyclic quivers [25, 26] and then to any 2-Calabi-Yau triangulated category with a cluster-tilting object [19].
are certain vector spaces generated by \( \Lambda Q \) for \( n \) and set \( \mathcal{L} \) to be certain noncommutative algebras over \( \mathbb{C} \). Rupel [23] defined a quantum cluster character as a quantum analogue of sequences \( i = (i_1, \ldots, i_n) \), \( a = (a_1, \ldots, a_m) \) where \( i_j \in \{1, \ldots, n\} \) and \( a_j \in \{0, 1\} \) for \( j = 1, \ldots, m \). Lusztig introduced the constructible functions \( d_{i,a} : \text{nil}(\Lambda Q) \to \mathbb{C} \) defined by

\[
d_{i,a}(M) = \chi(\mathcal{F}_{i,a}(M))
\]

where \( \mathcal{F}_{i,a}(M) \) is the set of flags of type \((i, a)\) (see Section 2.4 for the definition). He proved that the enveloping algebra \( U(n) \) is isomorphic to \( \mathcal{M} = \bigoplus \mathcal{M}_d \), where the \( \mathcal{M}_d \) are certain vector spaces generated by \( d_{i,a} \) for proper pairs \((i, a)\). Geiss, Leclerc and Schröer showed that the category \( \text{nil}(\Lambda Q) \) has the Ext-symmetry property, i.e.,

\[
\text{Ext}_{\Lambda Q}^1(M, N) \cong D\text{Ext}_{\Lambda Q}^1(N, M)
\]

for \( M, N \in \text{nil}(\Lambda Q) \). Let \( \mathcal{M}^* \) be the graded dual of \( \mathcal{M} \). For \( M \in \text{nil}(\Lambda Q) \), they defined an evaluation form \( \delta_M \in \mathcal{M}^* \), which is a map from \( \mathcal{M} \) to \( \mathbb{C} \) by mapping \( d_{i,a} \) to \( d_{i,a}(M) \) for any pair \((i, a)\). We denote by \( \Lambda_d \) the variety of nilpotent \( \Lambda \)-modules of dimension vector \( d \) and set \( \langle M \rangle = \{ X \in \Lambda_d \mid \delta_X = \delta_M \} \). Then there exists a finite subset \( S(d) \) of \( \Lambda_d \) such that \( \Lambda_d = \bigcup_{M \in S(d)} \langle M \rangle \). For \( M \in \Lambda_d \) and \( N \in \Lambda_d \), they obtained the following multiplication formula:

\[
\chi(\mathbb{P}\text{Ext}_{\Lambda Q}^1(M, N))\delta_M \cdot \delta_N = \sum_{L \in S(d)} (\chi(\mathbb{P}\text{Ext}_{\Lambda Q}^1(M, N)_{(L)}) + \chi(\mathbb{P}\text{Ext}_{\Lambda Q}^1(N, M)_{(L)}))\delta_L.
\]

The similarity between \( C_Q \) and \( \text{nil}(\Lambda Q) \) was further studied by many authors (see [1, 15]). Let \( W \) be the Weyl group of \( \mathfrak{g}_Q \). For \( w \in W \), Buan, Iyama, Reiten, and Scott [1] constructed a 2-Calabi-Yau Frobenius subcategory \( C_w \) of \( \text{nil}(\Lambda Q) \). When \( w = (s_n \cdots s_1)^2 \), the stable category \( C_w \) of \( C_w \) is just \( C_Q \). Given a reduced expression \( i = (i_r, \ldots, i_1) \) of \( w \) and \( M \in C_w \), \( \delta_M \) can be reformulated into the following form:

\[
\Delta_M = \sum_{a \in \mathbb{N}^r} \delta_M(d_{i,a})t^a = \sum_{a \in \mathbb{N}^r} \chi(\mathcal{F}_{i,a,M})t^a.
\]

Geiss, Leclerc and Schröer made explicit correspondences between two multiplication formulas as follows. They defined a cluster tilting object \( W_i \) in \( C_w \) and set \( A = \mathcal{D}\text{End}_{C_w}(W_i)_{op} \). For \( X \in C_w \), \( F(X) = \text{Ext}^1_A(W_i, X) \) is an \( A \)-module. There is a bijection \( d_{i,M} \) between \( \{ a \in \mathbb{N}^r \mid \mathcal{F}_{i,a,M} \neq 0 \} \) and \( \{ d \in \mathbb{N}^n \mid Gr_d(F(M)) \} \). Furthermore, there is an isomorphism of algebraic varieties between \( \mathcal{F}_{i,a,M} \) and \( Gr_{d_{i,a,M}}(F(M)) \). These deduce a correspondence between \( \Delta_M \) and \( X_{T_M}^r \) for \( M \in C_w \) where \( T = W_i \) and \( M \) are respectively the image of \( W_i \) and \( M \) under the natural functor from \( C_w \) to \( C_w \).

Quantum cluster algebras were introduced by Berenstein and Zelevinsky [3] as the quantization of cluster algebras. Given a compatible pair \((B, \Lambda)\), they are defined to be certain noncommutative algebras over \( \mathbb{Z}[q^\pm] \) generated by quantum cluster variables. Rupel [23] defined a quantum cluster character as a quantum analogue
of the Caldero-Chapoton map. Let $Q$ be an acyclic valued quiver over a finite field $\mathbb{F} = \mathbb{F}_q$. For $M \in \text{Rep}_\mathbb{F} Q$, 

$$X^\mathbb{F}_M = \sum \frac{1}{2} q^{-\frac{1}{2}(e, m - e)} | \text{Gr}_e(M) | x^{R_M - B_M - (I - R_M)m}$$

(see Section 5 for the explicit definition). Qin [21] gave an alternative definition for the quantum cluster characters of rigid objects in the cluster category of an acyclic equally valued quiver. The definition does not involve the choice of the ground finite field. Then he proved that the definition is consistent with the mutation rules between quantum cluster variables, i.e., for indecomposable rigid objects $M, N$ in $C_Q$ with $\dim \text{Hom}_{C_Q}(M, N[1]) = 1$, we have

$$X^\mathbb{F}_M \cdot X^\mathbb{F}_N = q^{\frac{1}{2} \Lambda(\text{ind} M, \text{ind} L)} X^\mathbb{F}_L + q^{\frac{1}{2} \Lambda(\text{ind} M, \text{ind} L') \text{ind} L'} X^\mathbb{F}_{L'}.$$

The multiplication formula of quantum cluster characters was generalized in [11]. More generally, we give a quantum analogue of Caldero-Keller’s multiplication formula in Section 4. Recently, another quantum analogue was proved in [9]. The exact relation between two formulas should be discovered in near future.

Different from the case of the cluster character, the general definition of the quantum cluster character is still unknown. The aim of this paper is to define the weighted quantum cluster characters for both abelian category $\mathcal{A}$ with the Ext-symmetry property and a 2-Calabi-Yau triangulated category $\mathcal{C}$ with a cluster tilting object. A weighted quantum cluster character is of the form $f \star \delta_M$ or $f \star X_M$ with a weight function $f$. The first main result in this paper is the following theorem.

**Theorem 1.1.** Let $\mathcal{A}$ be a Hom-finite, Ext-finite abelian category over finite field $k = \mathbb{F}_q$ with Ext-symmetry and all isoclasses of objects form a set. For any weighted quantum cluster characters $f_{\epsilon_M} \star \delta_M$ and $f_{\epsilon_N} \star \delta_N$ satisfying $\text{Ext}^1_{\mathcal{A}}(M, N) \neq 0$, we have

$$|\text{Ext}^1_{\mathcal{A}}(M, N)|(f_{\epsilon_M} \star \delta_M) \star (f_{\epsilon_N} \star \delta_N)$$

$$= \int_{F \in \text{Ext}^1_{\mathcal{A}}(M, N)} f_{\text{ext}} \star S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) \star \delta_{\text{int}}$$

$$+ \int_{F \eta \in \text{Ext}^1_{\mathcal{A}}(N, M)} f_{\text{hom}} \star S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) \star \delta_{\text{int}}$$

$$= \int_{F \in \text{Ext}^1_{\mathcal{A}}(M, N)} S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) \star \delta_{\text{int}}$$

$$+ \int_{F \eta \in \text{Ext}^1_{\mathcal{A}}(N, M)} f_{\text{ext}}^{-1} \star f_{\text{hom}} \star S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) \star \delta_{\text{int}}.$$

This theorem gives the explicit multiplication between two weighted quantum cluster characters over an abelian category $\mathcal{A}$ with the Ext-symmetry property. It can be viewed as the quantum analogue of Geiss-Leclerc-Schröer’s multiplication formula. The second main result is as follows.
Theorem 1.2. Let $C$ be a Hom-finite, 2-Calabi-Yau, Krull-Schmidt triangulated category over finite field $k = \mathbb{F}_q$ with a cluster tilting object $T$. For any weighted quantum cluster characters $g_{\epsilon_M} * X_M$ and $g_{\epsilon_N} * X_N$ satisfying $\text{Hom}_C(M, \Sigma N) \neq 0$, we have

$$|\text{PHom}_C(M, \Sigma N)|(g_{\epsilon_M} * X_M) \cdot (g_{\epsilon_N} * X_N)$$

$$= \int_{\mathcal{P} \in \mathcal{P}} \text{Hom}_C(M, \Sigma N) \cdot g_{\epsilon_M}^+ \cdot g_{MN} \cdot T(\epsilon, g_{\epsilon_M}, g_{\epsilon_N}) \cdot X_{m_{\epsilon}}$$

$$+ \int_{\mathcal{P} \eta \in \mathcal{P}} \text{Hom}_C(N, \Sigma M) \cdot g_{skew} \cdot g_{NM} \cdot T(\eta, g_{\epsilon_N}, g_{\epsilon_M}) \cdot X_{m_{\eta}}$$

$$= \int_{\mathcal{P} \in \mathcal{P}} \text{Hom}_C(M, \Sigma N) \cdot g_{MN} \cdot T(\epsilon, g_{\epsilon_M}, g_{\epsilon_N}) \cdot X_{m_{\epsilon}}$$

$$+ \int_{\mathcal{P} \eta \in \mathcal{P}} \text{Hom}_C(N, \Sigma M) \cdot g_{\epsilon_M}^- \cdot g_{skew} \cdot g_{NM} \cdot T(\eta, g_{\epsilon_N}, g_{\epsilon_M}) \cdot X_{m_{\eta}}.$$

This theorem gives the explicit multiplication between two weighted quantum cluster characters over a 2-Calabi-Yau triangulated category $C$ with a cluster tilting object $T$. It can be viewed as the quantum analogue of Caldero-Keller’s multiplication formula.

The paper is organized as follows. In Section 2, we first define the chain of monomorphisms as a generalization of flag and then define the set of the chain of monomorphisms of certain type. In Section 3, we introduce the quantum cluster character attached to an abelian category with the Ext-symmetry in a general context. Lemmas 3.3 and 3.7 play an important role in characterizing the quantum cluster character. Then we define the weight function and weighted quantum cluster character. By choosing appropriate pair of weight functions, we prove the multiplication formula of weighted quantum cluster characters in Section 3.9. Section 4 is contributed to define weighted quantum cluster character for a 2-Calabi-Yau triangulated category with a cluster tilting object. Lemmas 4.9 and 4.10 help to describe the structure of the quantum cluster character. We prove the multiplication formula of weighted quantum cluster characters in Section 4.9. Section 5 establishes the explicit connection between Theorem 3.29 and Theorem 4.30. We make a correspondence $F$ between weighted quantum cluster characters in Section 3 and 4 by applying Geiss-Leclerc-Schröer’s correspondence as above. In Section 6, we show that Theorem 4.30 deduces the multiplication formula in [9] by assigning proper weight functions.

2. Ext-symmetry abelian category and structure of vector bundles

2.1. Chains of morphisms. Let $A$ be a Hom-finite, Ext-finite abelian category over finite field $k = \mathbb{F}_q$ with Ext-symmetry and all isoclasses of objects form a set. We assume that there is a complete set of isomorphism classes of simple objects $\{S_1, \ldots, S_n\}$ in $A$. We denote by $\mathcal{F}^\text{mor}$ the set of all chains of morphisms

$$c = (L_m \xrightarrow{L_{m-1}} L_{m-1} \to \cdots \to L_1 \xrightarrow{L_1} L_0)$$
where $L_0, \ldots, L_m \in \mathcal{A}, t_{L,1}, \ldots t_{L,m} \in \text{Mor}\mathcal{A}$.

Up to the isomorphic relations $L \cong L'$ in $\mathcal{A}$, we can induce the isomorphic relations in $\mathcal{F}^{\text{mor}}$.

**Definition 2.1.** Two chains of morphisms $c = (L_m \xrightarrow{t_{L,m}} L_{m-1} \rightarrow \cdots \rightarrow L_1 \xrightarrow{t_{L,1}} L_0)$ and $c' = (L'_m \xrightarrow{t'_{L,m}} L'_{m-1} \rightarrow \cdots \rightarrow L'_1 \xrightarrow{t'_{L,1}} L'_0)$ in $\mathcal{F}^{\text{mor}}$ are called isomorphic if there are isomorphisms $L_i \xrightarrow{f_i} L'_i$ in $\text{Mor}\mathcal{A}$ such that $f_{i-1} \circ t_{L,i} = t'_{L,i} \circ f_i$, i.e., we have the following commutative diagram

$$
\begin{array}{ccccccccc}
L_m & \xrightarrow{t_{L,m}} & L_{m-1} & \xrightarrow{t_{L,m-1}} & \cdots & \xrightarrow{t_{L,1}} & L_1 & \xrightarrow{t_{L,1}} & L_0 \\
\downarrow f_m & & \downarrow f_{m-1} & & \cdots & & \downarrow f_1 & & \downarrow f_0 \\
L'_m & \xrightarrow{t'_{L,m}} & L'_{m-1} & \xrightarrow{t'_{L,m-1}} & \cdots & \xrightarrow{t'_{L,1}} & L'_1 & \xrightarrow{t'_{L,1}} & L'_0
\end{array}
$$

We denote all isomorphism classes in $\mathcal{F}^{\text{mor}}$ by $\mathcal{F}^{\text{mor}}$ and we still write $c$ for its isomorphism class in $\mathcal{F}^{\text{mor}}$.

2.2. **Exact structure.** Given a short exact sequence

$$
e : 0 \longrightarrow N \longrightarrow L \longrightarrow M \longrightarrow 0$$

in $\mathcal{A}$, write $[\epsilon]$ for its equivalence class in $\text{Ext}^1_{\mathcal{A}}(M, N)$. Then, any morphism $\lambda \in \text{Mor}(N, N')$ induces an equivalence class $\lambda \circ [\epsilon]$ in $\text{Ext}^1_{\mathcal{A}}(M, N')$ which is called the pushout of $[\epsilon]$ along $\lambda$. Similarly, for any $\rho \in \text{Mor}(M'', M)$, there is an equivalence class $[\epsilon] \circ \rho$ in $\text{Ext}^1_{\mathcal{A}}(M'', N)$ which is called the pullback of $[\epsilon]$ along $\rho$. We have the following commutative diagram

$$
\begin{array}{ccccccccc}
\lambda \circ [\epsilon] : & 0 & \longrightarrow & N' & \longrightarrow & L' & \longrightarrow & M & \longrightarrow & 0 \\
& \downarrow \lambda & & \downarrow & & \downarrow & & \downarrow & & \\
[\epsilon] : & 0 & \longrightarrow & N & \longrightarrow & L & \longrightarrow & M & \longrightarrow & 0 \\
& \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
[\epsilon] \circ \rho : & 0 & \longrightarrow & N'' & \longrightarrow & L'' & \longrightarrow & M'' & \longrightarrow & 0
\end{array}
$$

Conversely, if given $[\epsilon'] \in \text{Ext}^1_{\mathcal{A}}(M', N')$, $[\epsilon''] \in \text{Ext}^1_{\mathcal{A}}(M'', N'')$, $\lambda \in \text{Mor}(N'', N')$ and $\rho \in \text{Mor}(M'', M')$ as

$$
\begin{array}{ccccccccc}
[\epsilon'] : & 0 & \longrightarrow & N' & \longrightarrow & L' & \longrightarrow & M' & \longrightarrow & 0 \\
& \downarrow \lambda & & \downarrow & & \downarrow & & \downarrow \rho & & \\
[\epsilon''] : & 0 & \longrightarrow & N'' & \longrightarrow & L'' & \longrightarrow & M'' & \longrightarrow & 0
\end{array}
$$

we can complete the commutative diagram by adding an appropriate morphism in $\text{Mor}(L'', L')$ if and only if the pushout and pullback coincide, i.e.,

$$
\lambda \circ [\epsilon''] = [\epsilon'] \circ \rho
$$
Moreover, in this case, the morphism in $\text{Mor}(L'', L')$ is induced by $g \circ f$ as shown in the following diagram

\[ [\epsilon'] : \quad 0 \rightarrow N' \rightarrow L' \rightarrow M' \rightarrow 0 \]

\[ \lambda \circ [\epsilon''] = [\epsilon'] \circ \rho : \quad 0 \rightarrow N' \rightarrow L \rightarrow M'' \rightarrow 0 \]

\[ [\epsilon''] : \quad 0 \rightarrow N'' \rightarrow L'' \rightarrow M'' \rightarrow 0 \]

Note that the corresponding short exact sequence of element $[\epsilon'] \in \text{Ext}^1_A(M', N')$ is not unique. For any two appropriate choices of short exact sequences, there is an automorphism $a_{L'}$ of $L'$ such that we have the following commutative diagram

\[ [\epsilon'] : \quad 0 \rightarrow N' \rightarrow L' \rightarrow M' \rightarrow 0 \]

\[ a_{L'} \]

\[ [\epsilon'] : \quad 0 \rightarrow N' \rightarrow L' \rightarrow M' \rightarrow 0 \]

Parallely, for $[\epsilon'']$, there is an automorphism $a_{L''}$ of $L''$ for any two choices such that

\[ [\epsilon''] : \quad 0 \rightarrow N'' \rightarrow L'' \rightarrow M'' \rightarrow 0 \]

\[ a_{L''} \]

\[ [\epsilon''] : \quad 0 \rightarrow N'' \rightarrow L'' \rightarrow M'' \rightarrow 0 \]

So the choice of appropriate morphism in $\text{Mor}(L'', L')$ to complete the commutative diagram is also not unique and any two choices can be related by

\[ [\epsilon'] : \quad 0 \rightarrow N' \rightarrow L' \rightarrow M' \rightarrow 0 \]

\[ a_{L'} \]

\[ [\epsilon'] : \quad 0 \rightarrow N' \rightarrow L' \rightarrow M' \rightarrow 0 \]

\[ \lambda \circ [\epsilon''] = [\epsilon'] \circ \rho : \quad 0 \rightarrow N' \rightarrow L \rightarrow M'' \rightarrow 0 \]

\[ f \]

\[ [\epsilon''] : \quad 0 \rightarrow N'' \rightarrow L'' \rightarrow M'' \rightarrow 0 \]

\[ a_{L''} \]

\[ [\epsilon''] : \quad 0 \rightarrow N'' \rightarrow L'' \rightarrow M'' \rightarrow 0 \]
Since every $[\epsilon] \in \text{Ext}^1_A(M, N)$ which can be represented by
\[ \epsilon : 0 \rightarrow N \rightarrow L \rightarrow M \rightarrow 0 \]
with $M, N, L$ being unique up to isomorphism, we denote $q_\epsilon = M$, $s_\epsilon = N$ and $m_\epsilon = L$ in the following sections.

Now, more generally, if given $[\epsilon_i] \in \text{Ext}^1_A(M_i, N_i)$ for $i = 0, \ldots, m$, and two isomorphism classes of chains of morphisms
\[ c_M = (M_m \xrightarrow{\iota_{M,m}} M_{m-1} \rightarrow \cdots \rightarrow M_1 \xrightarrow{\iota_{M,1}} M_0 = M) \]
\[ c_N = (N_m \xrightarrow{\iota_{N,m}} N_{m-1} \rightarrow \cdots \rightarrow N_1 \xrightarrow{\iota_{N,1}} N_0 = N) \]
in $\mathcal{F}^{\text{mor}}$ as
\[
\begin{align*}
\epsilon_0 : & \quad 0 \rightarrow N_0 \rightarrow L_0 \rightarrow M_0 \rightarrow 0 \\
\epsilon_1 : & \quad 0 \rightarrow N_1 \rightarrow L_1 \rightarrow M_1 \rightarrow 0 \\
& \vdots \quad \vdots \quad \vdots \\
\epsilon_{m-1} : & \quad 0 \rightarrow N_{m-1} \rightarrow L_{m-1} \rightarrow M_{m-1} \rightarrow 0 \\
\epsilon_m : & \quad 0 \rightarrow N_m \rightarrow L_m \rightarrow M_m \rightarrow 0.
\end{align*}
\]

In order to decide whether there exists a chain of morphisms as
\[ c_L = (L_m \xrightarrow{\iota_{L,m}} L_{m-1} \rightarrow \cdots \rightarrow L_1 \xrightarrow{\iota_{L,1}} L_0 = L) \]
to complete the above commutative diagram, we introduce a linear map $\beta_{c_M,c_N}$
\[ \beta_{c_M,c_N} : \bigoplus_{j=0}^m \text{Ext}^1(M_j, N_j) \rightarrow \bigoplus_{j=0}^{m-1} \text{Ext}^1(M_{j+1}, N_j) \]
\[ ([\epsilon_0], \ldots, [\epsilon_m]) \mapsto ([\epsilon_{j-1}] \circ \iota_{M,j} - \iota_{N,j} \circ [\epsilon_j], j = 1, \ldots, m). \]

Definition and some properties of maps $\beta_{c_M,c_N}$ and $\beta_{c_N,c_M}'$ which should be introduced later as linear dual of $\beta_{c_M,c_N}$ are firstly given in [6] on module category. We generalize the two maps to abelian category and prove some necessary properties here.

**Lemma 2.2.** There exists a chain of morphisms
\[ c_L = (L_m \xrightarrow{\iota_{L,m}} L_{m-1} \rightarrow \cdots \rightarrow L_1 \xrightarrow{\iota_{L,1}} L_0 = L) \]
which can complete the commutative diagram if and only if

\[ ([\epsilon_0], \ldots, [\epsilon_m]) \in \text{Ker} \beta_{c_M, c_N} \]

**Proof.** A family of elements \((([\epsilon_0], \ldots, [\epsilon_m]) \in \text{Ker} \beta_{c_M, c_N}\) is exactly the one which makes pushout and pullback coincide at every level. \(\square\)

In this case, we get the morphism \(\iota_{L,i}\) by compositing two vertical morphisms in the following diagram:

\[
\begin{array}{c}
\varepsilon_{i-1} : \\
0 \rightarrow N_{i-1} \rightarrow L_{i-1} \rightarrow M_{i-1} \rightarrow 0 \\
\end{array}
\]

\[
\begin{array}{c}
\iota_{N,i} \circ [\varepsilon_i] = [\varepsilon_{i-1}] \circ \iota_{M,i} : \\
0 \rightarrow N_{i-1} \rightarrow L_i' \rightarrow M_i \rightarrow 0 \\
\end{array}
\]

\[
\begin{array}{c}
\varepsilon_i : \\
0 \rightarrow N_i \rightarrow L_i \rightarrow M_i \rightarrow 0 \\
\end{array}
\]

We denote such assignment by

\[
B_{c_M, c_N} : \text{Ker} \beta_{c_M, c_N} \rightarrow \mathcal{F}^{\text{mor}}
\]

\[
([\epsilon_0], \ldots, [\epsilon_m]) \mapsto ((L_m \xrightarrow{\iota_{L,m}} L_{m-1} \rightarrow \cdots \rightarrow L_1 \xrightarrow{\iota_{L,1}} L_0 = L)).
\]

**Lemma 2.3.** For any chains of morphisms \(c_M, c_N\), the map \(B_{c_M, c_N}\) is well-defined and injective.

**Proof.** The proof is similar to the discussion in the case when \(m = 1\). The choice of short exact sequences representing \(([\epsilon_0], \ldots, [\epsilon_m])\) is not unique, but is unique up to following commutative diagrams

\[
\begin{array}{c}
\varepsilon_i : \\
0 \rightarrow N_i \rightarrow L_i \rightarrow M_i \rightarrow 0 \\
\end{array}
\]

\[
\begin{array}{c}
\varepsilon'_i : \\
0 \rightarrow N_i \rightarrow L_i \rightarrow M_i \rightarrow 0 \\
\end{array}
\]

where \(a_i \in \text{Aut}(L_i)\). Then we get two chains of morphisms as \(B_{c_M, c_N}([\epsilon_0], \ldots, [\epsilon_m])\) and \(B_{c_M, c_N}([\epsilon'_0], \ldots, [\epsilon'_m])\). One can check they are isomorphic in \(\mathcal{F}^{\text{mor}}\) through the family of isomorphisms \(a_i\).

Conversely, if given two choices of exact sequences which induce the same chain of morphisms in \(\mathcal{F}^{\text{mor}}\), then the automorphisms \(a_i \in \text{Aut}(L_i)\) also give the equivalence between two exact sequences.
Since all extension groups considered here are finite dimensional over a finite field, we have

**Corollary 2.4.** Given chains of morphisms \( c_M, c_N \), the map \( B_{c_M, c_N} : \text{Ker} \beta_{c_M, c_N} \to \text{Im} B_{c_M, c_N} \) is bijection and \( |\text{Im} B_{c_M, c_N}| = |\text{Ker} \beta_{c_M, c_N}| \).

### 2.3. Chains of monomorphisms.

**Definition 2.5.** Given a chain of morphisms

\[ c = (L_m \xrightarrow{\iota_L,m} L_{m-1} \to \cdots \to L_1 \xrightarrow{\iota_L,1} L_0) \]

in \( \tilde{\mathcal{F}}^{\text{mor}} \), it is called a chain of monomorphisms if all \( \iota_{L,i} \) are monomorphisms and \( L_m = 0 \).

One can easily check this definition is independent of choice of chain in an isomorphism class and we denote by \( \mathcal{F}^{\text{mono}} \) the subset of \( \mathcal{F}^{\text{mor}} \) consisting of all isomorphism classes of chains of monomorphisms. We also denote by \( \mathcal{F}^{\text{mono}}_L \) the subset of \( \mathcal{F}^{\text{mono}} \) of all isomorphism classes of chains of monomorphisms with \( L_0 \cong L \).

**Lemma 2.6.** If \( c_M, c_N \in \mathcal{F}^{\text{mono}} \), then \( \text{Im} B_{c_M, c_N} \subseteq \mathcal{F}^{\text{mono}} \).

**Proof.** By the snake lemma, all rows in the following commutative diagram are exact.

Since \( c_M, c_N \) are chains of monomorphisms, \( \text{Ker} \iota_{L,1} = 0 \) and \( \text{Ker} \iota_{M,1} = 0 \). So is \( \text{Ker} \iota_{L,1} \).
2.4. Type. Recall that $\mathcal{A}$ admits a complete set of isomorphism classes of simple objects $\{S_1, \ldots, S_n\}$. So we can consider composition factors of an object in $\mathcal{A}$ with finite length.

**Definition 2.7.** Given a chain of monomorphisms
\[ \mathbf{c} = (L_m \xrightarrow{t_{L_m}} L_{m-1} \rightarrow \cdots \rightarrow L_1 \xrightarrow{t_{L_1}} L_0) \]
and two sequences
\[ \mathbf{i} = (i_1, \ldots, i_m), \mathbf{a} = (a_1, \ldots, a_m) \]
where $i_j \in \{1, \ldots, n\}, a_j \in \{0, 1\}$, $\mathbf{c}$ is called of type $(\mathbf{i}, \mathbf{a})$ if the composition factors of $\text{Coker} t_{L,j}$ are $S_{i_j}$ if $a_j = 1$ and 0 otherwise for each $j = 1, \ldots, m$.

We denote the set of all chains of monomorphisms of type $(\mathbf{i}, \mathbf{a})$ by $\mathcal{F}^{\text{mono}}_{\mathbf{i}, \mathbf{a}}$ and the set of all chains of monomorphisms of type $(\mathbf{i}, \mathbf{a})$ with $L_0 \cong L$ by $\mathcal{F}^{\text{mono}}_{\mathbf{i}, \mathbf{a}, L}$.

**Lemma 2.8.** If $(\mathbf{c}_M, \mathbf{c}_N) \in \mathcal{F}^{\text{mono}}_{\mathbf{i}, \mathbf{a}',M} \times \mathcal{F}^{\text{mono}}_{\mathbf{i}, \mathbf{a}'',N}$ and $a'_j + a''_j = 1$ for $j = 1, \ldots, m$, then $\text{Im} B_{\mathbf{c}_M, \mathbf{c}_N} \subseteq \mathcal{F}^{\text{mono}}_{\mathbf{i}, \mathbf{a}' + \mathbf{a}''}$.

**Proof.** By the snake lemma, we have an exact sequence
\[ \text{Ker} t_{M,j} \rightarrow \text{Coker} t_{N,j} \rightarrow \text{Coker} t_{L,j} \rightarrow \text{Coker} t_{M,j} \rightarrow 0. \]
Since $\mathbf{c}_M$ is a chain of monomorphisms, $\text{Ker} t_{M,j} = 0$. So the composition factors of $\text{Coker} t_{L,j}$ are the union of composition factors of $\text{Coker} t_{M,j}$ and $\text{Coker} t_{N,j}$, which are $a'_j + a''_j$ times of $S_{i_j}$.

If $\mathbf{a} = (1, \cdots, 1)$, we simply write $\mathcal{F}^{\text{mono}}_{\mathbf{i}}$ instead of $\mathcal{F}^{\text{mono}}_{\mathbf{i}, \mathbf{a}}$.

3. Ext'-Symmetry Abelian Category and Multiplication Formula

3.1. Character. Now we introduce the concept of the character of an object in $\mathcal{A}$.

Let $d_{\mathbf{i}, \mathbf{a}}$ be a formal notation representing a type of chains of monomorphisms and
\[ \mathcal{M}_q = \bigoplus_{(\mathbf{i}, \mathbf{a})} \mathbb{Q} d_{\mathbf{i}, \mathbf{a}} \]
be the $\mathbb{Q}$-space spanned by all $d_{\mathbf{i}, \mathbf{a}}$.

For each object $L$ in $\mathcal{A}$, we define a $\mathbb{Q}$-valued linear function $\delta_L$ on $\mathcal{M}_q$ as
\[ \delta_L(d_{\mathbf{i}, \mathbf{a}}) = |\mathcal{F}^{\text{mono}}_{\mathbf{i}, \mathbf{a}, L}| \]
and call such function quantum cluster character of $L$.

The core purpose of this section is to study the relation between quantum cluster characters of different objects in $\mathcal{A}$ along short exact sequences.
3.2. Vector bundle. We denote by

\[ EF_{i,a}(M, N) = \{ ([\epsilon], c_L) | [\epsilon] \in \text{Ext}_A^1(M, N), L = \text{mt} \epsilon, c \in \mathcal{F}^{\text{mono}}_L \} \]

the set of all pairs of extension of \( M, N \) and chain of monomorphisms of the middle term of type \((i, a)\).

From \(([\epsilon], c_L) \in EF_{i,a}(M, N)\), we can induce two chains of monomorphisms ending with \( M, N \) respectively. More precisely, we have

\[
\begin{array}{ccccccccc}
0 & \rightarrow & N & \overset{i}{\rightarrow} & L & \overset{p}{\rightarrow} & M & \rightarrow & 0 \\
\downarrow^{i_{N,1}} & & \downarrow^{i_{L,1}} & & \downarrow^{i_{M,1}} & & & & \\
0 & \rightarrow & N_1 & \overset{i_1}{\rightarrow} & L_1 & \overset{p_1}{\rightarrow} & M_1 & \rightarrow & 0 \\
& \vdots & & \vdots & & \vdots & & \vdots & \\
0 & \rightarrow & N_{m-1} & \overset{i_{m-1}}{\rightarrow} & L_{m-1} & \overset{p_{m-1}}{\rightarrow} & M_{m-1} & \rightarrow & 0 \\
\downarrow^{i_{N,m}} & & \downarrow^{i_{L,m}} & & \downarrow^{i_{M,m}} & & & & \\
0 & \rightarrow & N_m & \overset{i_m}{\rightarrow} & L_m & \overset{p_m}{\rightarrow} & M_m & \rightarrow & 0 \\
\end{array}
\]

where

\[ N_j = i^{-1}(\text{Im} \circ \cdots \circ i_{L,j}), \]
\[ M_j = p(\text{Im} \circ \cdots \circ i_{L,j}), \]

\( i_{N,j}, i_{M,j} \) are natural embeddings and \( i_j, p_j \) are naturally induced by \( i \) and \( p \) respectively for \( j = 1, \ldots, m \).

We write such assignment as

\[ \phi_{MN} : EF_{i,a}(M, N) \rightarrow \coprod_{a' + a'' = a} \mathcal{F}^{\text{mono}}_{i,a',M} \times \mathcal{F}^{\text{mono}}_{i,a'',N}. \]

The coproduct runs over all pairs \((a', a'')\) with \( a' + a'' = a \) since the union of composition factor at each level is fixed by \( a \).

Now, if given two chains of monomorphisms \( c_M, c_N \) ending with \( M, N \) respectively, then there are two methods to induce chain of monomorphisms \( c_L \):

1. Take a sequence of extensions \(([\epsilon_0], \ldots, [\epsilon_m]) \in \text{Ker} \beta_{c_M,c_N} \) and calculate \( B_{c_M,c_N}([\epsilon_0], \ldots, [\epsilon_m]); \)
2. Calculate the fiber \( \phi_{MN}^{-1}(c_M, c_N). \)

The following lemma shows the relation between two methods.

**Lemma 3.1.** Given chains of monomorphisms \( c_M, c_N \) ending with \( M, N \) respectively and \([\epsilon] \in \text{Ext}_A^1(M, N)\) with \( \text{mt} \epsilon = L \) as
For any $c_L \in F_{L}^{\text{mono}}$, the following are equivalent:

1. There are extensions $([\epsilon_1], \ldots, [\epsilon_m])$ satisfying $([\epsilon], [\epsilon_1], \ldots, [\epsilon_m]) \in \text{Ker} \beta_{c_M, c_N}$ such that $B_{c_M, c_N}([\epsilon], [\epsilon_1], \ldots, [\epsilon_m]) = c_L$. By definition of $B_{c_M, c_N}$, there is a commutative diagram

$$
\begin{array}{c}
\epsilon : & 0 & \rightarrow & N & \rightarrow & L & \rightarrow & M & \rightarrow & 0 \\
\downarrow & & \downarrow & \epsilon_{N,1} & & \downarrow & \epsilon_{M,1} & & \downarrow & \\
N_1 & \rightarrow & M_1 & \rightarrow & \vdots & \rightarrow & \vdots & \rightarrow & \vdots & \rightarrow & 0 \\
\downarrow & & \downarrow & \uparrow & & \uparrow & & \uparrow & & \uparrow & \\
N_{m-1} & \rightarrow & M_{m-1} & \rightarrow & \vdots & \rightarrow & \vdots & \rightarrow & \vdots & \rightarrow & 0 \\
\downarrow & & \downarrow & \epsilon_{N,m} & & \downarrow & \epsilon_{M,m} & & \downarrow & & \\
N_m & \rightarrow & M_m & & & & & & & & \\
\end{array}
$$

where $\iota_{L,i}$ are naturally induced by compositions of vertical morphisms in pushout and pullback as

$$
\begin{array}{c}
\epsilon : & 0 & \rightarrow & N & \rightarrow & L & \rightarrow & M & \rightarrow & 0 \\
\downarrow & & \downarrow & \iota_{L,1} & & \downarrow & & \downarrow & & \\
N_i & \rightarrow & L_i & \rightarrow & M_i & \rightarrow & M_{i-1} & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
N_{i-1} & \rightarrow & L_{i-1} & \rightarrow & M_{i-1} & \rightarrow & 0 \\
\end{array}
$$

2. $\phi_{MN}([\epsilon], c_L) = (c_M, c_N)$. By definition of $\phi_{MN}$, there is a commutative diagram
\[ \epsilon : \quad 0 \longrightarrow N \overset{i}{\longrightarrow} L \overset{p}{\longrightarrow} M \longrightarrow 0 \]

\[ \begin{array}{c}
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
N_1 \longrightarrow \overset{i_1}{\longrightarrow} L_1 \overset{p_1}{\longrightarrow} M_1 \\
\uparrow \quad \uparrow \quad \uparrow \quad \uparrow \\
\vdots \quad \vdots \quad \vdots \quad \vdots \\
N_{m-1} \longrightarrow \overset{i_{m-1}}{\longrightarrow} L_{m-1} \overset{p_{m-1}}{\longrightarrow} M_{m-1} \\
\uparrow \quad \uparrow \quad \uparrow \quad \uparrow \\
N_m \longrightarrow \overset{i_m}{\longrightarrow} L_m \longrightarrow \overset{p_m}{\longrightarrow} M_m \\
\end{array} \]

where \( i_j, p_j \) are naturally induced by \( i, p \) and \( N_j = i_j^{-1}(L_j), M_j = p_j(L_j) \).

**Proof.** Since all rows in (1) are short exact sequences, naturally \( N_j = i_j^{-1}(L_j) \) and \( M_j = p_j(L_j) \) hold, i.e., (2) holds.

Conversely, given (2), we have the commutative diagram

\[ \begin{array}{c}
0 \longrightarrow N \overset{i}{\longrightarrow} L \overset{p}{\longrightarrow} M \longrightarrow 0 \\
\uparrow \quad \uparrow \quad \uparrow \\
\text{Ker}i_1 \longrightarrow N_1 \longrightarrow \overset{i_1}{\longrightarrow} L_1 \longrightarrow \overset{p_1}{\longrightarrow} M_1 \longrightarrow \text{Coker}p_1 \\
\uparrow \quad \uparrow \quad \uparrow \\
0 \longrightarrow \text{Ker}i_{N,1} = 0 \longrightarrow \text{Ker}i_{L,1} = 0 \longrightarrow \text{Ker}i_{M,1} = 0 \longrightarrow 0. \\
\end{array} \]

From the exactness of the most left and the most right columns, \( \text{Ker}i_1 = 0, \text{Coker}p_1 = 0 \). That is to say, the row \( j = 1 \) is exact. By doing induction on \( j \), we deduce that each row in (2) is exact and then obtain a commutative diagram

\[ \begin{array}{c}
\epsilon : \quad 0 \longrightarrow N \overset{i}{\longrightarrow} L \overset{p}{\longrightarrow} M \longrightarrow 0 \\
\uparrow \quad \uparrow \quad \uparrow \\
\epsilon_1 : \quad 0 \longrightarrow N_1 \longrightarrow \overset{i_1}{\longrightarrow} L_1 \longrightarrow \overset{p_1}{\longrightarrow} M_1 \longrightarrow 0 \\
\uparrow \quad \uparrow \quad \uparrow \\
\epsilon_{m-1} : \quad 0 \longrightarrow N_{m-1} \longrightarrow \overset{i_{m-1}}{\longrightarrow} L_{m-1} \longrightarrow \overset{p_{m-1}}{\longrightarrow} M_{m-1} \longrightarrow 0 \\
\uparrow \quad \uparrow \quad \uparrow \\
\epsilon_m : \quad 0 \longrightarrow N_m \longrightarrow \overset{i_m}{\longrightarrow} L_m \longrightarrow \overset{p_m}{\longrightarrow} M_m \longrightarrow 0 \\
\end{array} \]
which consists of chains of monomorphisms as columns and short exact sequences as rows. From the uniqueness of pushout and pullback, the middle column \(c_L\) must be isomorphic to \(B_{c_M,c_N}([\epsilon],[\epsilon_1],\ldots,[\epsilon_m])\) where \(([\epsilon_1],\ldots,[\epsilon_m])\) are given by \(i,j,p\) as shown in the diagram.

\[\square\]

Up to this lemma, a chain of monomorphisms \(c_L\) with \(\phi_{MN}([\epsilon],c_L) = (c_M,c_N)\) is equivalent to one given by \(B_{c_M,c_N}([\epsilon_0],\ldots,[\epsilon_m])\) with \(([\epsilon_0],\ldots,[\epsilon_m]) \in \text{Ker} \beta_{c_M,c_N}^\ast\).

On the other hand, note that \(\phi_{MN}\) describes the relation between \(\mathcal{F}_L^{\text{mono}}\) and \(\mathcal{F}_M^{\text{mono}}, \mathcal{F}_N^{\text{mono}}\) and hence the relation among characters \(\delta_M, \delta_N\) and \(\delta_L\). In order to describe the structure more clearly, we need to refine this map.

Fix \([\epsilon]\), we define

\[
\phi_{MN,[\epsilon]} := \phi_{MN}([\epsilon], -) : \mathcal{F}_{i,a,L}^{\text{mono}} \to \prod_{a'+a''=a} \mathcal{F}_{i,a',M}^{\text{mono}} \times \mathcal{F}_{i,a'',N}^{\text{mono}}
\]

where \(L = mt\epsilon\) and we write the preimage as

\[
\mathcal{F}_{i,a,L}^{\text{mono}} ([\epsilon], a', a'') = \phi_{MN,[\epsilon]}^{-1}(\mathcal{F}_{i,a',M}^{\text{mono}} \times \mathcal{F}_{i,a'',N}^{\text{mono}}).
\]

Since the coproduct

\[
\prod_{a'+a''=a} \mathcal{F}_{i,a',M}^{\text{mono}} \times \mathcal{F}_{i,a'',N}^{\text{mono}}
\]

is disjoint, we naturally have

\[
\mathcal{F}_{i,a,L}^{\text{mono}} = \prod_{a'+a''=a} \mathcal{F}_{i,a,L}^{\text{mono}}([\epsilon], a', a'').
\]

However, the structure of fiber of

\[
\phi_{MN,[\epsilon]} : \mathcal{F}_{i,a,L}^{\text{mono}} ([\epsilon], a', a'') \to \mathcal{F}_{i,a',M}^{\text{mono}} \times \mathcal{F}_{i,a'',N}^{\text{mono}}
\]

is heavily dependent on the relation between \([\epsilon]\) and specific chains \((c_M, c_N)\).

The following lemma describes the image of \(\phi_{MN,[\epsilon]}\) restricted to \(\mathcal{F}_{i,a,L}^{\text{mono}}([\epsilon], a', a'')\).

**Lemma 3.2.** Given \((c_M, c_N)\) in \(\mathcal{F}_{i,a',M}^{\text{mono}} \times \mathcal{F}_{i,a'',N}^{\text{mono}}\),

\[
(c_M, c_N) \in \phi_{MN,[\epsilon]}(\mathcal{F}_{i,a,L}^{\text{mono}}([\epsilon], a', a''))
\]

if and only if

\[
[\epsilon] \in p_0 \text{Ker} \beta_{c_M,c_N}^\ast
\]

where \(p_0\) is the projection from \(\bigoplus_{j=0}^m \text{Ext}^1_A(M_j, N_j)\) to \(\text{Ext}^1_A(M, N)\).

**Proof.** Notice that whether \((c_M, c_N)\) belongs to \(\phi_{MN,[\epsilon]}(\mathcal{F}_{i,a,L}^{\text{mono}}([\epsilon], a', a''))\) is equivalent to whether the commutative diagram can be completed by adding appropriate chains of monomorphisms end with \(L\) and short exact sequences induced by \([\epsilon]\).
The lemma shows that the existence of appropriate chain of monomorphisms end with $L$ depends on the choice of all short exact sequences. More precisely, the family of short exact sequences should belong to $\text{Ker} \beta_{c_M,c_N}$. However, the top row is given as $[\epsilon_0] = [\epsilon]$ here. So whether the appropriate chain of monomorphisms end with $L$ exists here is equivalent to whether $[\epsilon]$ belong to the 0-component of $\text{Ker} \beta_{c_M,c_N}$. That is to say, we need $[\epsilon] \in p_0 \text{Ker} \beta_{c_M,c_N}$ to ensure that $c_M$ and $c_N$ are induced from some appropriate $c_L$. □

Then, for $[\epsilon] \in p_0 \text{Ker} \beta_{c_M,c_N}$ case, we calculate the fiber $\phi_{MN,[\epsilon]}^{-1}(c_M,c_N)$.

From lemma, we know that the assignment $B_{c_M,c_N}$ of a family of extensions $([\epsilon_0], \ldots, [\epsilon_m])$ to a chain of monomorphisms end with $L = mt\epsilon_0$ is injective. We denote

$$K(c_M,c_N,[\epsilon]) = \{([\epsilon_0], \ldots, [\epsilon_m]) \in \text{Ker} \beta_{c_M,c_N} | [\epsilon_0] = [\epsilon]\}.$$

Then we have

$$\text{Ker} \beta_{c_M,c_N} = \coprod_{[\epsilon] \in p_0 \text{Ker} \beta_{c_M,c_N}} K(c_M,c_N,[\epsilon]).$$

Notice that $\beta_{c_M,c_N}$ is a linear map between linear spaces, so $\text{Ker} \beta_{c_M,c_N}$ is exactly the set of all solutions of a system of linear equations which is homogeneous. Furthermore, fixing $[\epsilon_0] = [\epsilon]$ is an additional linear condition. So $K(c_M,c_N,[\epsilon])$ is also the set of all solutions of a system of linear equations which is homogeneous if and only if $[\epsilon] = 0$. Since different systems of equations which admit a same coefficient matrix also admit the same rank of fundamental system, we can denote the common rank by $k(c_M,c_N)$. Then we have

**Lemma 3.3.** Given $(c_M,c_N)$ in $\mathcal{F}^{\text{mono}}_{1,a',M} \times \mathcal{F}^{\text{mono}}_{1,a'',N}$,

1. If $[\epsilon] \notin p_0 \text{Ker} \beta_{c_M,c_N}$, $\phi_{MN,[\epsilon]}^{-1}(c_M,c_N) = \emptyset$.
2. If $[\epsilon] \in p_0 \text{Ker} \beta_{c_M,c_N}$, $B_{c_M,c_N} : K(c_M,c_N,[\epsilon]) \to \phi_{MN,[\epsilon]}^{-1}(c_M,c_N)$ is bijective.
3.3. Dual case. Recall that the abelian category \( \mathcal{A} \) considered here admits Ext-symmetry. That is to say, for any two objects \( M, N \) in \( \mathcal{A} \), there is a natural isomorphism

\[
E_{M, N} : \operatorname{Ext}^1_\mathcal{A}(M, N) \cong D\operatorname{Ext}^1_\mathcal{A}(N, M)
\]

where \( D \) is the linear dual. Moreover, the linear isomorphism admits the functorial proposition:

**Proposition 3.4.** Given \( \lambda \in \operatorname{Hom}(N, N') \), \( \rho \in \operatorname{Hom}(M', M) \), \( [\epsilon] \in \operatorname{Ext}^1_\mathcal{A}(M, N) \), \( [\eta] \in \operatorname{Ext}^1_\mathcal{A}(N', M') \), we have

\[
E_{M', N'}(\lambda \circ [\epsilon] \circ \rho)([\eta]) = E_{M, N}([\epsilon])(\rho \circ [\eta] \circ \lambda).
\]

So for given \( M \) and \( N \), we can also study the relation between extensions in \( \operatorname{Ext}^1_\mathcal{A}(N, M) \) and characters.

Consider the linear map

\[
\beta_{c_M, c_N} : \bigoplus_{j=0}^{m} \operatorname{Ext}^1(M_j, N_j) \to \bigoplus_{j=0}^{m-1} \operatorname{Ext}^1(M_{j+1}, N_j)
\]

\[
([\epsilon_0], \ldots, [\epsilon_m]) \mapsto ([\epsilon_{j-1}] \circ t_{M,j} - t_{N,j} \circ [\epsilon_j], j = 1, \ldots, m)
\]

Since it is a linear map between finite dimensional spaces, we can calculate the dual of \( \beta_{c_M, c_N} \) explicitly according to the proposition:

\[
\beta'_{c_N, c_M} = D\beta_{c_M, c_N} : \bigoplus_{j=0}^{m} \operatorname{Ext}^1(N_j, M_{j+1}) \to \bigoplus_{j=0}^{m-1} \operatorname{Ext}^1(N_{j+1}, M_j)
\]

\[
([\eta_0], \ldots, [\eta_{m-1}]) \mapsto t_{M,1} \circ [\eta_0] + \sum_{j=1}^{m-1} (t_{M,j+1} \circ [\eta_j] - [\eta_{j-1}] \circ t_{N,j} - [\eta_{m-1}] \circ t_{N,m},
\]

where \( D = \operatorname{Hom}_k(-, k) \) is the linear dual.

Similar to \( \phi_{MN} \), we have the dual version

\[
\phi_{NM} : E\mathcal{F}_{i,a}(N, M) \to \prod_{a'' + a' = a} \mathcal{F}^{\text{mono}}_{i,a'', N} \times \mathcal{F}^{\text{mono}}_{i,a', M}
\]

and consider

\[
\phi_{NM,[\eta]} = \phi_{NM}([\eta], -) : \mathcal{F}^{\text{mono}}_{i,a,L} \to \prod_{a'' + a' = a} \mathcal{F}^{\text{mono}}_{i,a'', N} \times \mathcal{F}^{\text{mono}}_{i,a', M}.
\]

Notice that \( [\eta] \) here is an element in \( \operatorname{Ext}^1_\mathcal{A}(N, M) \).

To decide whether a pair of chains \( (c_N, c_M) \) is located in the image of \( \phi_{NM,[\eta]} \), we need

**Lemma 3.5.** Given \( (c_N, c_M) \) in \( \mathcal{F}^{\text{mono}}_{i,a'', N} \times \mathcal{F}^{\text{mono}}_{i,a', M} \),

\( (c_N, c_M) \in \phi_{NM,[\eta]}(\mathcal{F}^{\text{mono}}_{i,a,L}([\eta], a'', a')) \)
if and only if
\[ [\eta] \in \text{Im}\beta'_{c_N,c_M} \cap \text{Ext}^1_{\mathcal{A}}(N, M) \]
where the intersection is realized through regarding \( \text{Ext}^1_{\mathcal{A}}(N, M) \) as a linear subspace of \( \bigoplus_{j=0}^m \text{Ext}^1_{\mathcal{A}}(N_j, M_j) \).

Proof. By definition of \( \beta'_{c_N,c_M} \), \([\eta] \in \text{Im}\beta'_{c_N,c_M} \cap \text{Ext}^1_{\mathcal{A}}(N, M) \) if and only if there exists a family of extension \(([\eta_0], \ldots, [\eta_{m-1}])\) such that
\[
\begin{align*}
& (1) \quad \iota_{M,1} \circ [\eta_0] = [\eta] \\
& (2) \quad \iota_{M,j+1} \circ [\eta_j] = [\eta_{j-1}] \circ \iota_{N,j} \quad \text{for } j = 1, \ldots, m-1 \\
& (3) \quad [\eta_{m-1}] \circ \iota_{N,m} = 0
\end{align*}
\]
The third condition is always satisfied since \( \text{Ext}^1_{\mathcal{A}}(N_m, M_m) = \text{Ext}^1_{\mathcal{A}}(0, 0) = 0 \).
Since \( a' + a'' = a \) is a 0–1 sequence, either \( \iota_{M,j} \) or \( \iota_{N,j} \) is an isomorphism. In either case, one can check that the first and second condition are equivalent to the condition that the pushout of extension between \( M_j \) and \( N_j \) along \( \iota_{M,j} \) coincide with the pullback of extension between \( M_{j-1} \) and \( N_{j-1} \) along \( \iota_{N,j} \).

According to lemma, the condition that pullback and pushout coincide ensures the preimage \( \phi_{NM,[\eta]}^{-1}(c_N, c_M) \) in nonempty. \( \square \)

Remark 3.6. In fact, we can also define \( B_{c_N,c_M} \) and check that the necessary and sufficient condition of
\[
(c_N, c_M) \in \phi_{NM,[\eta]}^{-1}(\mathcal{X}_{i,a,L}^{\text{mono}}([\eta], a'', a'))
\]
is also \([\eta] \in p_0 \text{Ker} \beta_{c_N,c_M} \) as lemma.

But we introduce the dual linear map \( \beta'_{c_N,c_M} \) here because the necessary and sufficient condition expressed by \( \beta'_{c_N,c_M} \) can be related to the previous one expressed by \( \beta_{c_M,c_N} \) which will be useful latter.

However, if one want to calculate these fibers accurately, using \( p_0 \text{Ker} B_{c_N,c_M} \) is much more easier.
Similar to discussion on $K(c_M, c_N, [\epsilon])$, if $(c_N, c_M) \in \phi^{-1}_{NM,[\eta]}(\mathcal{F}_{1,a,L}^{\text{mono}}([\eta], a'', a'))$, the fiber $\phi^{-1}_{NM,[\eta]}(c_N, c_M)$ is non empty and one-to-one corresponding to a affine subspace which depends on the specific $[\eta]$. However, for any $[\eta]$ such that the fiber is nonempty, the ranks of fundamental systems are the same, denoted by $k(c_N, c_M)$.

Then we have

**Lemma 3.7.** Given $(c_N, c_M)$ in $\mathcal{F}_{1,a',M}^{\text{mono}} \times \mathcal{F}_{1,a'',N}^{\text{mono}}$:

1. If $[\eta] \notin \text{Im}^{\beta}_{c_N,c_M} \cap \text{Ext}^{1}_{A}(N, M)$, $\phi^{-1}_{NM,[\eta]}(c_N, c_M) = \emptyset$.
2. If $[\eta] \in \text{Im}^{\beta}_{c_N,c_M} \cap \text{Ext}^{1}_{A}(N, M)$, $B_{c_N,c_M} : K(c_N, c_M, [\eta]) \to \phi^{-1}_{NM,[\eta]}(c_N, c_M)$ is bijective.

### 3.4. Cardinality.

Based on several lemmas above, we can refine the calculation of $\delta_L$. Recall that all extension groups are finite dimensional over a finite field. Since

$$\mathcal{F}_{1,a,L}^{\text{mono}} = \prod_{a'' + a' = a} \mathcal{F}_{1,a,L}^{\text{mono}}([\epsilon], a', a''),$$

we can write

$$|\mathcal{F}_{1,a,L}^{\text{mono}}| = \int_{a'' + a' = a} |\mathcal{F}_{1,a,L}^{\text{mono}}([\epsilon], a', a'')|$$

Moreover, Lemma 3.3 shows if $[\epsilon] \notin \mathfrak{p}_0 \text{Ker} \beta_{c_M,c_N}$, $|\phi^{-1}_{MN,[\epsilon]}(c_M, c_N)| = 0$, and if $[\epsilon] \in \mathfrak{p}_0 \text{Ker} \beta_{c_M,c_N}$, $|\phi^{-1}_{MN,[\epsilon]}(c_M, c_N)| = |K(c_M, c_N, [\epsilon])| = q^{k(c_M,c_N)}$. So if $\text{mtc} = L$, we have

$$\delta_L(d_{1,a}) = |\mathcal{F}_{1,a,L}^{\text{mono}}|$$

$$= \int_{a'' + a' = a} |\mathcal{F}_{1,a,L}^{\text{mono}}([\epsilon], a', a'')|$$

$$= \int_{a'' + a' = a} \int_{(c_M,c_N) \in \mathcal{F}_{1,a',M}^{\text{mono}} \times \mathcal{F}_{1,a'',N}^{\text{mono}}} |\phi^{-1}_{MN,[\epsilon]}(c_M,c_N)|$$

$$= \int_{a'' + a' = a} \int_{(c_M,c_N) \in \phi_{MN,[\epsilon]}(\mathcal{F}_{1,a,L}^{\text{mono}}([\epsilon], a', a''))} q^{k(c_M,c_N)}$$

where all integrals are exactly finite sum.

**Remark 3.8.** Since different $[\epsilon], [\epsilon']$ in $\text{Ext}^{1}_{A}(M, N)$ may admit the same middle term $\text{mtc} = \text{mtc}' = L$, the refinement of $\delta_L(d_{1,a})$ is not unique. But all refinements are still equal to $|\mathcal{F}_{1,a,L}^{\text{mono}}|$. 

Dually, since

$$\mathcal{F}_{1,a,L}^{\text{mono}} = \prod_{a'' + a' = a} \mathcal{F}_{1,a,L}^{\text{mono}}([\eta], a'', a'),$$

we have

$$|\mathcal{F}_{1,a,L}^{\text{mono}}| = \sum_{a'' + a' = a} |\mathcal{F}_{1,a,L}^{\text{mono}}([\eta], a'', a')|.$$
Moreover, Lemma 3.7 shows if \([\eta] \notin \text{Im} \beta'_{e_N,e_M} \cap \text{Ext}^1_{\mathcal{A}}(N,M), |\phi_{N,M,[\eta]}^{-1}(e_N,e_M)| = 0\) and if \([\eta] \in \text{Im} \beta'_{e_N,e_M} \cap \text{Ext}^1_{\mathcal{A}}(N,M), |\phi_{N,M,[\eta]}^{-1}(e_N,e_M)| = |K(e_N,e_M,[\eta])| = q^{k(e_N,e_M)}\). So if \(m\eta = L\), we have

\[
\delta_L(d_{i,a}) = |\mathcal{F}_{1,a,L}^{\text{mono}}|
\]

\[
= \int_{a''+a'=a} |\mathcal{F}_{1,a,L}^{\text{mono}}([\eta],a'',a')|
\]

\[
= \int_{a''+a'=a} \int_{(e_N,e_M) \in \mathcal{F}_{1,a'',a'}^{\text{mono}} \times \mathcal{F}_{1,a',a''}^{\text{mono}}} |\phi_{N,M,[\eta]}^{-1}(e_N,e_M)|
\]

\[
= \int_{a''+a'=a} \int_{(e_N,e_M) \in \phi_{N,M,[\eta]}(\mathcal{F}_{1,a,L}^{\text{mono}}([\eta],a'',a'))} q^{k(e_N,e_M)}
\]

3.5. **Weight.** Based on the calculation of \(\delta_L\), we introduce weight function and weighted quantum cluster character to reveal the relation between characters more clearly.

We define

\[
\mathcal{F}_M = \{(M,N,c_M,c_N)|M,N \in \mathcal{A}, c_M \in \mathcal{F}_M^{\text{mono}}, c_N \in \mathcal{F}_N^{\text{mono}}\}
\]

and denote the set of all half integer valued functions on \(\mathcal{F}_M\) called weight functions by

\[
\mathbb{Z}_{\mathcal{F}_M} = \{f: \mathcal{F}_M \to \mathbb{Z}\}
\]

where \(\mathbb{Z} = \{\frac{k}{2}|n \in \mathbb{Z}\}\) is the set of all half integers.

A function \(f \in \mathbb{Z}_{\mathcal{F}_M}\) is called supported on \([\epsilon]\) if \(f(M,N,-,-) = 0\) unless \(M = qt\epsilon\) and \(N = st\epsilon\) and

\[
\{(qt\epsilon, st\epsilon, c_1, c_2) \in \mathcal{F}_M|c_1 \in \mathcal{F}_M^{\text{mono}}_\epsilon, c_2 \in \mathcal{F}_M^{\text{mono}}_{\epsilon}\}
\]

is called support area. The set of all functions supported on \([\epsilon]\) is denoted by \(\mathbb{Z}_{\mathcal{F}_M,\epsilon}\).

Moreover, considering that different extensions may admit a same middle term, we define

\[
\mathbb{Z}_{\mathcal{F}_M,L} = \coprod_{m\eta = L} \mathbb{Z}_{\mathcal{F}_M,\epsilon}
\]

Notice that although \(\mathbb{Z}_{\mathcal{F}_M,\epsilon}\) may intersect as subsets of \(\mathbb{Z}_{\mathcal{F}_M}\), we still define \(\mathbb{Z}_{\mathcal{F}_M,L}\) as a disjoint union. For example, even if we take \(m\epsilon = m\epsilon' = L\), the zero function in \(\mathbb{Z}_{\mathcal{F}_M,\epsilon}\) and the one in \(\mathbb{Z}_{\mathcal{F}_M,\epsilon'}\) are two different elements in \(\mathbb{Z}_{\mathcal{F}_M,L}\).

**Definition 3.9** (Weighted quantum cluster character). Given a weight function \(f_{\epsilon,L} \in \mathbb{Z}_{\mathcal{F}_M,L}\), the weighted quantum cluster character \(f_{\epsilon,L} \ast \delta_L\) is a linear function on \(\mathcal{M}_q\) defined as

\[
f_{\epsilon,L} \ast \delta_L(d_{i,a}) = \int_{a''+a'=a} \int_{(e_M,e_N) \in \mathcal{F}_{1,a'',a'}^{\text{mono}} \times \mathcal{F}_{1,a',a''}^{\text{mono}}} |\phi_{N,M,[\epsilon]}^{-1}(e_M,e_N)| \cdot q^{f_{\epsilon,L}(M,N,c_M,c_N)}
\]

\[
= \int_{a''+a'=a} \int_{(e_M,e_N) \in \phi_{N,M,[\epsilon]}(\mathcal{F}_{1,a,L}^{\text{mono}}([\epsilon],a'',a'))} q^{k(e_M,e_N)} \cdot q^{f_{\epsilon,L}(M,N,c_M,c_N)}
\]
where $\epsilon_L$ is a short exact sequence satisfies $mt\epsilon_L = L$, $qt\epsilon_L = M$ and $st\epsilon_L = N$.

Remark 3.10. The short exact sequence $\epsilon_L$ is just a formal notation to mark which component $\mathbb{Z}_{MF,\epsilon}$ the weight function is chosen from. So the definition is without ambiguity.

On the other hand, although the extra term $q_{f,\epsilon_L}(M,N,c_M,c_N)$ compared to non-weighted case just depends on values which the weight function takes at $(M,N,c_M,c_N)$, the domain of integration relies on the specific $\epsilon$. So even if we take some $f \in \mathbb{Z}_{MF,\epsilon} \cap \mathbb{Z}_{MF,\epsilon'}$ with $mt\epsilon = mt\epsilon' = L$, $qt\epsilon = qt\epsilon'$, $st\epsilon = st\epsilon'$, the calculations of $f \ast \delta_L$ regarding $f$ as a function in $\mathbb{Z}_{MF,\epsilon}$ or $\mathbb{Z}_{MF,\epsilon'}$ may derive different results. The subscript $\epsilon_L$ of $f_{\epsilon_L}$ is necessary.

Corollary 3.11. For any zero function $f_{\epsilon_L}$ in $\mathbb{Z}_{MF,L}$, we have $f_{\epsilon_L} \ast \delta_L = \delta_L$.

So weight functions provide $q$-deformations of $\delta_L$.

3.6. Multiplication. Then we introduce the multiplication of weighted quantum cluster characters.

We denote the zero element in $\text{Ext}^1_A(M,N)$ by $0_{MN}$.

Definition 3.12 (Multiplication of quantum cluster characters). Given $M, N$ in $A$, we define the multiplication of quantum cluster characters as

$$\delta_M \ast \delta_N = \delta_{M \oplus N}$$

By definition, we have

Proposition 3.13. $\delta_M \ast \delta_N$ is associative and commutative.

Remark 3.14. From the refinement of quantum cluster character, we have

$$\delta_{M \oplus N}(d_1a) = |F_{i,a,M \oplus N}^{\text{mono}}|$$

$$= \int_{a' + a'' = a} |F_{i,a,M \oplus N}^{\text{mono}}(0_{MN}, a', a'')|$$

$$= \int_{a' + a'' = a} \int_{(c_M,c_N) \in F_{i,a',M}^{\text{mono}} \times F_{i,a'',N}^{\text{mono}}} |\phi_{MN,0_{MN}}^{-1}(c_M,c_N)|$$

$$= \int_{a' + a'' = a} \int_{(c_M,c_N) \in F_{i,a',M}^{\text{mono}} \times F_{i,a'',N}^{\text{mono}}} q^k(c_M,c_N)$$

Notice that the image of $\phi_{MN,0_{MN}}$ is the whole $F_{i,a',M}^{\text{mono}} \times F_{i,a'',N}^{\text{mono}}$ since any two chains $c_M, c_N$ can be assembled into a chain end with $M \oplus N$ through direct sum.
On the other hand, the convolution of two functions \( \delta_M \) and \( \delta_N \) can be formally refined as

\[
\int_{a'+a''=a} \delta_M(d_{a'}) \cdot \delta_N(d_{a''}) = \int_{a'+a''=a} |F_{1a',M}^{\text{mono}}| \cdot |F_{1a'',N}^{\text{mono}}|
\]

\[
= \int_{a'+a''=a} \int_{(c_M,c_N) \in F_{1a',M}^{\text{mono}} \times F_{1a'',N}^{\text{mono}}} 1
\]

So the definition of multiplication is a \( q \)-deformation of conventional convolution.

Such definition provides the domain which we need to define the multiplication of weighted quantum cluster characters.

**Definition 3.15** (Multiplication of weighted quantum cluster character). Given weighted quantum cluster characters \( f_{\varepsilon M} \ast \delta_M \) and \( f_{\varepsilon N} \ast \delta_N \), we define the multiplication as

\[
(f_{\varepsilon M} \ast \delta_M) \ast (f_{\varepsilon N} \ast \delta_N) = f \ast \delta_{M \oplus N}
\]

where \( f \in \mathbb{Z}_{MF,0_{M_0}} \) and

\[
f(M, N, c_M, c_N) = f_{\varepsilon M}(qt_{\varepsilon M}, st_{\varepsilon M}, \phi_{qt_{\varepsilon M}st_{\varepsilon M}}([\varepsilon_M, c_M]))
+ f_{\varepsilon N}(qt_{\varepsilon N}, st_{\varepsilon N}, \phi_{qt_{\varepsilon N}st_{\varepsilon N}}([\varepsilon_N, c_N]))
\]

**Proposition 3.16.** \( (f_{\varepsilon M} \ast \delta_M) \ast (f_{\varepsilon N} \ast \delta_N) \) is associative.

**Proof.** To distinguish, for given \( f_{\varepsilon i} \in \mathbb{Z}_{MF,i} \), \( i = 1, 2, 3 \), we set

\[
((f_{\varepsilon 1} \ast \delta_{M_1}) \ast (f_{\varepsilon 2} \ast \delta_{M_2})) \ast (f_{\varepsilon 3} \ast \delta_{M_3}) = f_{(12)3} \ast \delta_{M_1 \oplus M_2 \oplus M_3}
\]

\[
(f_{\varepsilon 1} \ast \delta_{M_1}) \ast ((f_{\varepsilon 2} \ast \delta_{M_2}) \ast (f_{\varepsilon 3} \ast \delta_{M_3})) = f_{1(23)} \ast \delta_{M_1 \oplus M_2 \oplus M_3}
\]

where \( f_{(12)3} \in \mathbb{Z}_{MF,0_{M_1 \oplus M_2 \oplus M_3}} \) and \( f_{1(23)} \in \mathbb{Z}_{MF,0_{M_1 \oplus M_2 \oplus M_3}} \).

It is obvious that the non-weighted part of two composition methods are the same, we just need to check the relation between \( f_{(12)3} \) and \( f_{1(23)} \).

Direct calculation: \( (f_{\varepsilon 1} \ast \delta_{M_1}) \ast (f_{\varepsilon 2} \ast \delta_{M_2}) = f_{\varepsilon 12} \ast \delta_{M_1 \oplus M_2} \) where

\[
f_{\varepsilon 12}(M_1, M_2, c_{M_1}, c_{M_2}) = f_{\varepsilon 1}(qt_{\varepsilon 1}, st_{\varepsilon 1}, \phi_{qt_{\varepsilon 1}st_{\varepsilon 1}}([\varepsilon_1, c_{M_1}]))
+ f_{\varepsilon 2}(qt_{\varepsilon 2}, st_{\varepsilon 2}, \phi_{qt_{\varepsilon 2}st_{\varepsilon 2}}([\varepsilon_2, c_{M_2}]))
\]

So

\[
f_{(12)3}(M_1 \oplus M_2, M_3, c_{M_1 \oplus M_2}, c_{M_3}) = f_{\varepsilon 12}(M_1, M_2, c_{M_1}, c_{M_2})
+ f_{\varepsilon 3}(qt_{\varepsilon 3}, st_{\varepsilon 3}, \phi_{qt_{\varepsilon 3}st_{\varepsilon 3}}([\varepsilon_3, c_{M_3}]))
\]

\[
= f_{\varepsilon 1}(qt_{\varepsilon 1}, st_{\varepsilon 1}, \phi_{qt_{\varepsilon 1}st_{\varepsilon 1}}([\varepsilon_1, c_{M_1}]))
+ f_{\varepsilon 2}(qt_{\varepsilon 2}, st_{\varepsilon 2}, \phi_{qt_{\varepsilon 2}st_{\varepsilon 2}}([\varepsilon_2, c_{M_2}]))
+ f_{\varepsilon 3}(qt_{\varepsilon 3}, st_{\varepsilon 3}, \phi_{qt_{\varepsilon 3}st_{\varepsilon 3}}([\varepsilon_3, c_{M_3}]))
\]

where \( c_{M_1 \oplus M_2} \cong c_{M_1} \oplus c_{M_2} \).
Similar calculation shows we also have
\[ f_{1(23)}(M_1, M_2 \oplus M_3, c_{M_1}, c_{M_2 \oplus M_3}) = f_{e_1}(qt \epsilon_1, st \epsilon_1, \phi_{qt \epsilon_1 st \epsilon_1}([\epsilon_1], c_{M_1})) + f_{e_2}(qt \epsilon_2, st \epsilon_2, \phi_{qt \epsilon_2 st \epsilon_2}([\epsilon_2], c_{M_2})) + f_{e_3}(qt \epsilon_3, st \epsilon_3, \phi_{qt \epsilon_3 st \epsilon_3}([\epsilon_3], c_{M_3})) \]

where \( c_{M_2 \oplus M_3} \cong c_{M_2} \oplus c_{M_3} \).

Then we have
\[
\begin{align*}
& f_{1(23)} * \delta_{M_1 \oplus M_2 \oplus M_3}(d, a) \\
& = \int_{a'+a''+a'''=a} \int (c_{M_1}, c_{M_2}, c_{M_3}) q^{k_{1(23)}}(c_{M_1}, c_{M_2}, c_{M_3}) \cdot q f_{e_1} + f_{e_2} + f_{e_3}
\end{align*}
\]

and
\[
\begin{align*}
& f_{1(23)} * \delta_{M_1 \oplus M_2 \oplus M_3}(d, a) \\
& = \int_{a'+a''+a'''=a} \int (c_{M_1}, c_{M_2}, c_{M_3}) q^{k_{1(23)}}(c_{M_1}, c_{M_2}, c_{M_3}) \cdot q f_{e_1} + f_{e_2} + f_{e_3}
\end{align*}
\]

where the second integral in both equations runs over \( F_{\text{mono}_{i,a',M_1}} \times F_{\text{mono}_{i,a'',M_2}} \times F_{\text{mono}_{i,a''',M_3}} \) and the function \( f_{e_1} + f_{e_2} + f_{e_3} \) takes value naturally at integral variables. The functions \( k_{1(23)} \) and \( k_{1(23)} \) are dimensions of fibers respectively in following

\[
\begin{array}{c}
\bigoplus F_{\text{mono}_{i,a',M_1}} \times F_{\text{mono}_{i,a'',M_2}} \times F_{\text{mono}_{i,a''',M_3}} \\
\phi_{M_1, M_2 \oplus M_3, 0_{M_1 \oplus M_2 \oplus M_3}} \downarrow k_{1(23)} \\
\bigoplus F_{\text{mono}_{i,a',M_1}} \times F_{\text{mono}_{i,a'',M_2}} \times F_{\text{mono}_{i,a''',M_3}} \\
\phi_{M_1, M_2, 0_{M_1 \oplus M_2}} \times \text{id} \downarrow k_{1(23)}
\end{array}
\]

From the associativity of \( \delta_M * \delta_N \), we know that the diagram commutes. So
\[
k_{1(23)} = k_{1(23)}.
\]

**Remark 3.17.** \( (f_{e_M} * \delta_M) * (f_{e_N} * \delta_N) \) is not necessarily commutative. Recall that the commutativity of \( \delta_M * \delta_N \) provides an identity
\[
\int_{a'+a''=a} \int (c_{M}, c_{N}) \in F_{\text{mono}_{i,a',M}} \times F_{\text{mono}_{i,a'',N}} q^{k(c_M, c_N)}
\]
\[
= \int_{a'+a''=a} \int (c_{M}, c_{N}) \in F_{\text{mono}_{i,a',M}} \times F_{\text{mono}_{i,a'',N}} q^{k(c_N, c_M)}.
\]

The identity is not trivial because \( k(c_M, c_N) \) and \( k(c_N, c_M) \) are deduced from propositions of \( 0_{MN} \) and \( 0_{NM} \) respectively. That is to say, \( k(c_M, c_N) \) and \( k(c_N, c_M) \) may be different. So even if the weight functions \( f_{0_{MN}} \) and \( f_{0_{NM}} \) in
\[
(f_{e_M} * \delta_M) * (f_{e_N} * \delta_N) = f_{0_{MN}} * \delta_{M \oplus N}
\]
\[
(f_{e_N} * \delta_N) * (f_{e_M} * \delta_M) = f_{0_{NM}} * \delta_{M \oplus N}
\]
obviously satisfy
\[ f_{0,M,N}(M, N, c_M, c_N) = f_{0,N,M}(N, M, c_N, c_M) \]
by definition, we still can not deduce that
\[ \int_{\alpha' + \alpha'' = \alpha} \int_{(c_M, c_N) \in F_{I\lambda',M} \times F_{I\lambda'',N}} q^k(c_M, c_N) \cdot q^j f_{0,M,N}(M, N, c_M, c_N) \]
\[ = \int_{\alpha' + \alpha'' = \alpha} \int_{(c_M, c_N) \in F_{I\lambda',M} \times F_{I\lambda'',N}} q^k(c_M, c_N) \cdot q^j f_{0,N,M}(N, M, c_N, c_M). \]

**Definition 3.18.** We denote the \( \mathbb{Q} \)-algebra generated by \( f_{\ell} \ast \delta_L \) by \( A_{\ell}(A) \), where \( L \) runs over \( A \) and \( f_{\ell} \) runs over \( \mathbb{Z}_{MF,L} \).

3.7. **Projectivity of** \( \text{Ext}^1_\mathcal{A}(M, N) \). Since \( \text{Ext}^1_\mathcal{A}(M, N) \) is a finite dimensional space, we can consider \( \mathbb{P}\text{Ext}^1_\mathcal{A}(M, N) \) and we denote the equivalence class of \( \epsilon \) in \( \mathbb{P}\text{Ext}^1_\mathcal{A}(M, N) \) by \( \mathbb{P}[\epsilon] \).

The core aim in this subsection is to check multiplication of weighted quantum cluster character is still well-defined if we replace \( \epsilon \) by \( \mathbb{P}[\epsilon] \).

In this subsection, we always assume the parameter \( \lambda \) is nonzero in \( k \).

Recall the vector bundle
\[ \phi_{M,N} : E\text{Fi}_\mathcal{A}(M, N) \rightarrow \prod_{\alpha' + \alpha'' = \alpha} F_{I\alpha',M} \times F_{I\alpha'',N}. \]

From the linearity of \( \beta_{c_M, c_N} \) \( \epsilon \in p_0 \text{Ker} \beta_{c_M, c_N} \) if and only if \( \lambda[\epsilon] \in p_0 \text{Ker} \beta_{c_M, c_N} \). So in this case,
\[ |\phi_{M,N}^{-1}(c_M, c_N)| = |K(c_M, c_N, [\epsilon])| = |K(c_M, c_N, \lambda[\epsilon])| = |\phi_{M,N,\lambda[\epsilon]}^{-1}(c_M, c_N)| \]

If else, they are both empty. So we have

**Proposition 3.19.** Given \( f_{\ell} \ast \delta_L \), we set \( f_{\lambda,\ell} \in \mathbb{Z}_{MF,\lambda,\ell} \) with
\[ f_{\lambda,\ell}(M, N, c_M, c_N) = f_{\ell}(M, N, c_M, c_N), \]
then
\[ f_{\ell} \ast \delta_L = f_{\lambda,\ell} \ast \delta_L \]

**Proof.**
\[ f_{\ell} \ast \delta_L(d_{1,\alpha}) = \int_{\alpha' + \alpha'' = \alpha} \int_{(c_M, c_N) \in F_{I\alpha',M} \times F_{I\alpha'',N}} |\phi_{M,N,\ell}^{-1}(c_M, c_N)| \cdot q^f_{\ell}(M, N, c_M, c_N) \]
\[ = \int_{\alpha' + \alpha'' = \alpha} \int_{(c_M, c_N) \in F_{I\alpha',M} \times F_{I\alpha'',N}} |\phi_{M,N,\lambda[\ell]}^{-1}(c_M, c_N)| \cdot q^f_{\lambda,\ell}(M, N, c_M, c_N) \]
\[ = f_{\lambda,\ell} \ast \delta_L(d_{1,\alpha}) \]
\[ \square \]
Then we check the multiplication
\[(f_{\epsilon_M} \ast \delta_M) \ast (f_{\epsilon_N} \ast \delta_N) = f \ast \delta_{M \oplus N}\]
where \(f \in \mathbb{Z}_{MF,0_{MN}}\) and
\[
f(M, N, c_M, c_N) = f_{\epsilon_M}(qt_{\epsilon_M}, st_{\epsilon_M}, \phi_{qt_{\epsilon_M} st_{\epsilon_M}}([\epsilon_M], c_M)) + f_{\epsilon_N}(qt_{\epsilon_N}, st_{\epsilon_N}, \phi_{qt_{\epsilon_N} st_{\epsilon_N}}([\epsilon_N], c_N)).
\]

We have already shown that even if we replace \(\epsilon_M, \epsilon_N\) by their scalar multiple, the left hand side remains the same. On the right hand side, the weight function \(f\) is chosen from \(\mathbb{Z}_{MF,0_{MN}}\), so there is no trouble because \(\lambda 0_{MN} = 0_{MN}\).

### 3.8. Multiple weighting.

**Definition 3.20.** Given a weighted quantum cluster character \(f_{\epsilon_L} \ast \delta_L\) and a general weight function \(f\), \((f \ast f_{\epsilon_L}) \ast \delta_L\) is defined to be a weighted quantum cluster character where \(f \ast f_{\epsilon_L} \in \mathbb{Z}_{MF,\epsilon_L}\) satisfying
\[
f \ast f_{\epsilon_L}(qt_{\epsilon_L}, st_{\epsilon_L}, c_{qt_{\epsilon_L} c_{st_{\epsilon_L}}}) = f(qt_{\epsilon_L}, st_{\epsilon_L}, c_{qt_{\epsilon_L} c_{st_{\epsilon_L}}}) + f_{\epsilon_L}(qt_{\epsilon_L}, st_{\epsilon_L}, c_{qt_{\epsilon_L} c_{st_{\epsilon_L}}})
\]
for any \((c_{qt_{\epsilon_L} c_{st_{\epsilon_L}}}) \in \mathcal{F}_{qt_{\epsilon_L}}^{\text{mono}} \times \mathcal{F}_{st_{\epsilon_L}}^{\text{mono}} \) and 0 else. That is to say, \(f \ast f_{\epsilon_L}\) is still supported on \([\epsilon_L]\).

Without ambiguity, we just write \(f \ast f_{\epsilon_L} \ast \delta_L\) because the support area is decide by \(f_{\epsilon_L}\). Of course, we can also define \(f_1 \ast \cdots \ast f_n \ast f_{\epsilon_L} \ast \delta_L\) inductively and the support area is decided by the most right weight function which is at first chosen from a specific \(\mathbb{Z}_{MF,\epsilon_L}\) with \(mt_{\epsilon_L} = L\).

**Definition 3.21.** Given \((f_{\epsilon_M} \ast \delta_M) \ast (f_{\epsilon_N} \ast \delta_N) \ast f_{\epsilon_L} = f \ast \delta_{M \oplus N \oplus L}\) and \([\epsilon]\) \(\in \text{Ext}_{\mathcal{A}}^1(M, N)\), we define \(S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N})\) to be a weight function in \(\mathbb{Z}_{MN, \epsilon}\) with
\[
S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N})(M, N, c_M, c_N) = f(M, N, c_M, c_N) = f_{\epsilon_M}(qt_{\epsilon_M}, st_{\epsilon_M}, \phi_{qt_{\epsilon_M} st_{\epsilon_M}}([\epsilon_M], c_M)) + f_{\epsilon_N}(qt_{\epsilon_N}, st_{\epsilon_N}, \phi_{qt_{\epsilon_N} st_{\epsilon_N}}([\epsilon_N], c_N)).
\]

Notice that although the calculations \(S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N})\) of different \([\epsilon]\) are the same, the adapted \(\delta_L\) are not.

**Corollary 3.22.** Given \(f_{\epsilon_M} \ast \delta_M\) and \(f_{\epsilon_N} \ast \delta_N\), for any \([\epsilon]\) \(\in \text{Ext}_{\mathcal{A}}^1(M, N)\) and \([\eta]\) \(\in \text{Ext}_{\mathcal{A}}^1(N, M)\), we have
\[
S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N})(M, N, c_M, c_N) = S(\eta, f_{\epsilon_N}, f_{\epsilon_M})(N, M, c_N, c_M).
\]

**Proof.** Both sides are equal to
\[
f_{\epsilon_M}(qt_{\epsilon_M}, st_{\epsilon_M}, \phi_{qt_{\epsilon_M} st_{\epsilon_M}}([\epsilon_M], c_M)) + f_{\epsilon_N}(qt_{\epsilon_N}, st_{\epsilon_N}, \phi_{qt_{\epsilon_N} st_{\epsilon_N}}([\epsilon_N], c_N)).
\]
3.9. **Multiplication formula and balanced pair.** Recall that \( \beta_{c_M,c_N}' \) is dual to \( \beta_{c_M,c_N} \). So we have

**Lemma 3.23.** For any chains of morphisms \( c_M, c_N \) end with \( M, N \) respectively, \( \text{Ker} \beta_{c_M,c_N} = (\text{Im} \beta_{c_M,c_N}')^\perp \). In particular,

\[
\dim_k \text{Ker} \beta_{c_M,c_N} + \dim_k (\text{Im} \beta_{c_M,c_N}' \cap \text{Ext}^1_A(N,M)) = \dim_k \text{Ext}^1_A(M,N).
\]

Based on lemma, we introduce several special weight functions.

**Definition 3.24.** There are three weight functions in \( \mathbb{Z}_{MF} \) defined as

1. \( f_{\text{hom}}(N,M,c_N,c_M) = k(c_M,c_N) - k(c_N,c_M) \),
2. \( f_{\text{ext}}^+(M,N,c_M,c_N) = \dim_k (\text{Im} \beta_{c_N,c_M}' \cap \text{Ext}^1_A(N,M)) \),
3. \( f_{\text{ext}}^-(N,M,c_N,c_M) = \dim_k \text{Ker} \beta_{c_M,c_N} \)

for any \( M, N \) in \( A \) and \( (c_M,c_N) \in \mathcal{F}^\text{mono}_M \times \mathcal{F}^\text{mono}_N \).

The three definitions seems not consistent, but it is convenient for latter calculation.

**Definition 3.25.** A pair of weight functions \( (f^+, f^-) \) is called pointwise balanced if

\[
q \frac{\dim_k \text{Ext}^1_A(N,M) - 1}{q - 1} \cdot q^{k(c_M,c_N)}
\]

\[
= \int_{P \in \mathbb{P}_0} q^{k(c_M,c_N) + f^+} \int_{P \in \text{Im} \beta_{c_N,c_M}' \cap \text{Ext}^1_A(N,M)} q^{k(c_N,c_M) + f^-}
\]

holds.

For simplicity, we write the equality in definition as \( \text{lhs} = \sigma_1(f^+) + \sigma_2(f^-) \) for a specific pair \( (f^+, f^-) \).

**Proposition 3.26.** The following two pairs of weighted functions

1. \( (f_{\text{ext}}^+, f_{\text{hom}}) \),
2. \( (0, f_{\text{ext}}^- + f_{\text{hom}}) \)

are pointwise balanced.

**Proof.** We first consider \( \sigma_2(f_{\text{hom}}) \).

\[
\sigma_2(f_{\text{hom}}) = \int_{P \in \text{Im} \beta_{c_N,c_M}' \cap \text{Ext}^1_A(N,M)} q^{k(c_N,c_M) + f_{\text{hom}}(N,M,c_N,c_M)}
\]

\[
= \int_{P \in \text{Im} \beta_{c_N,c_M}' \cap \text{Ext}^1_A(N,M)} q^{k(c_M,c_N)}.
\]
Notice that $k(c_M, c_N)$ is independent of $[\varepsilon]$ or $[\eta]$ as long as they are located in integral domain as follows. So

$$\sigma_1(0) + \sigma_2(f_{\text{hom}})$$

$$= \int_{\mathbb{P}c \in \mathbb{P}p_0 \text{Ker } \beta_{c_M, c_N}} q^{k(c_M, c_N)} + \int_{\mathbb{P}\eta \in \mathbb{P}\text{Im } \beta^\prime_{c_N, c_M} \cap \text{Ext}_{\mathcal{A}}^1(N, M)} q^{k(c_M, c_N)}$$

$$= q^{k(c_M, c_N)} \cdot \left( \frac{\dim_k \text{Ker } \beta_{c_M, c_N} - 1}{q - 1} + \frac{\dim_k \text{Im } \beta^\prime_{c_N, c_M} \cap \text{Ext}_{\mathcal{A}}^1(N, M) - 1}{q - 1} \right).$$

Since

$$\dim_k \text{Ker } \beta_{c_M, c_N} + \dim_k (\text{Im } \beta^\prime_{c_N, c_M} \cap \text{Ext}_{\mathcal{A}}^1(N, M)) = \dim_k \text{Ext}_{\mathcal{A}}^1(M, N),$$

we have two equalities after projection

$$\frac{\dim_k \text{Ext}_{\mathcal{A}}^1(M, N) - 1}{q - 1}$$

$$= q^{\dim_k (\text{Im } \beta^\prime_{c_N, c_M} \cap \text{Ext}_{\mathcal{A}}^1(N, M))} \cdot \frac{\dim_k \text{Ker } \beta_{c_M, c_N} - 1}{q - 1}$$

$$+ q^{\dim_k (\text{Im } \beta^\prime_{c_N, c_M} \cap \text{Ext}_{\mathcal{A}}^1(N, M) - 1)}$$

$$= q^{k(c_M, c_N)} \cdot \frac{\dim_k \text{Ker } \beta_{c_M, c_N} - 1}{q - 1}$$

$$+ q^{\dim_k (\text{Im } \beta^\prime_{c_N, c_M} \cap \text{Ext}_{\mathcal{A}}^1(N, M) - 1)}.$$
and
\[
\sigma_1(0) + \sigma_2(f^\ext + f^\hom) = \int_{\mathcal{P}_e \in \mathcal{P}_0} q^{k(e_M, e_N)} \cdot q^{\dim \ker \beta_{e, e_N} - 1} + \int_{\mathcal{P}_f \in \operatorname{Im} \beta_{e, e_N}} q^{k(e_M, e_N)} \cdot q^{\dim \ker \beta_{e, e_N} - 1} + \frac{q^{\dim \ker \beta_{e, e_N} - 1}}{q - 1} = \text{lhs.}
\]

**Theorem 3.27.** If a pair of weight functions \((f^+, f^-)\) in \(\mathbb{Z}_{MF}\) is pointwise balanced, then for any weighted quantum cluster characters \(f_m^* \delta_M\) and \(f_n^* \delta_N\) satisfying \(\operatorname{Ext}^1_\lambda(M, N) \neq 0\), we have
\[
|\mathcal{P} \operatorname{Ext}^1_\lambda(M, N) |(f_m^* \delta_M) * (f_n^* \delta_N) = \int_{\mathcal{P}_e \in \mathcal{P} \operatorname{Ext}^1_\lambda(M, N)} f^+ * S(\epsilon, f_m^* \delta_M, f_n^* \delta_N) * \delta_{\text{mt} \epsilon} + \int_{\mathcal{P}_f \in \mathcal{P} \operatorname{Ext}^1_\lambda(M, N)} f^- * S(\eta, f_m^* \delta_M, f_n^* \delta_N) * \delta_{\text{mt} \eta}.
\]

**Proof.** We simplify the equality in theorem to \(\text{lhs} = \Sigma_1(f^+) + \Sigma_2(f^-)\).

Just for simplicity, we omit some independent variables of functions which are obvious in following calculation. For example, \(S(\mathbf{0}_{MN}, f_m^* \delta_M, f_n^* \delta_N)(M, N, e_M, e_N)\) is simplified to \(S(\mathbf{0}_{MN}, f_m^*, f_n^*).

Direct calculation:
\[
\text{lhs}(d_{1, a}) = |\mathcal{P} \operatorname{Ext}^1_\lambda(M, N) |(f_m^* \delta_M) * (f_n^* \delta_N)(d_{1, a}) = |\mathcal{P} \operatorname{Ext}^1_\lambda(M, N) |(f_m^* \delta_M, f_n^* \delta_N) d_{1, a} + S(\mathbf{0}_{MN}, f_m^* \delta_M, f_n^* \delta_N) = \int_{a' + a'' = a} \int_{(e_M, e_N) \in \mathcal{F}^{\text{mono}}_{1, a', M} \times \mathcal{F}^{\text{mono}}_{1, a''} N} q^{k(e_M, e_N)} + S(\mathbf{0}_{MN}, f_m^* \delta_M, f_n^* \delta_N) = \int_{a' + a'' = a} \int_{(e_M, e_N) \in \mathcal{F}^{\text{mono}}_{1, a', M} \times \mathcal{F}^{\text{mono}}_{1, a''} N} q^{S(\mathbf{0}_{MN}, f_m^* \delta_M, f_n^* \delta_N)} \cdot q^{\dim \ker \beta_{e, e_N} - 1} \cdot q^{k(e_M, e_N)} = \int_{a' + a'' = a} \int_{(e_M, e_N) \in \mathcal{F}^{\text{mono}}_{1, a', M} \times \mathcal{F}^{\text{mono}}_{1, a''} N} q^{S(\mathbf{0}_{MN}, f_m^* \delta_M, f_n^* \delta_N)} \cdot \text{lhs}.
\]
\[ \Sigma_1(f^+)(d_1, a) \]
\[ = \int_{p \in \mathbb{F} \text{Ext}_A^1(M, N)} f^+ \ast S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) \ast \delta_{\text{mte}}(d_1, a) \]
\[ = \int_{p \in \mathbb{F} \text{Ext}_A^1(M, N)} \int_{a' + a'' = a} \phi_{MN, [\epsilon]}(F_{1_a, [\epsilon]}([\epsilon], a', a'')) q^{k(e_M, e_N) + S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) + f^+} \]
\[ = \int_{a' + a'' = a} \phi_{MN, [\epsilon]}(F_{1_a, [\epsilon]}([\epsilon], a', a'')) q^{S(0_M, f_{\epsilon_M}, f_{\epsilon_N})} \int_{p \in \mathbb{F} \text{Ker} \delta_{e_M, e_N}} q^{k(e_M, e_N)} f^+ \]
\[ = \int_{a' + a'' = a} \phi_{MN, [\epsilon]}(F_{1_a, [\epsilon]}([\epsilon], a', a'')) q^{S(0_M, f_{\epsilon_M}, f_{\epsilon_N})} \cdot \sigma_1(f^+) \]
\[ \Sigma_2(f^-)(d_1, a) \]
\[ = \int_{p \in \mathbb{F} \text{Ext}_A^1(N, M)} f^- \ast S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) \ast \delta_{\text{mte}}(d_1, a) \]
\[ = \int_{p \in \mathbb{F} \text{Ext}_A^1(N, M)} \int_{a' + a'' = a} \phi_{NM, [\eta]}(F_{1_a, [\eta]}([\eta], a', a'')) q^{k(e_N, e_M) + S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) + f^-} \]
\[ = \int_{a' + a'' = a} \phi_{NM, [\eta]}(F_{1_a, [\eta]}([\eta], a', a'')) q^{S(0_M, f_{\epsilon_M}, f_{\epsilon_N})} \int_{p \in \mathbb{F} \text{Im} \phi_{e_N, e_M}} q^{k(e_N, e_M)} f^- \]
\[ = \int_{a' + a'' = a} \phi_{NM, [\eta]}(F_{1_a, [\eta]}([\eta], a', a'')) q^{S(0_M, f_{\epsilon_M}, f_{\epsilon_N})} \cdot \sigma_2(f^-) \]

So lhs = \sigma_1 + \sigma_2 implies LHS = \Sigma_1 + \Sigma_2. \hfill \Box

Remark 3.28. Although the family of equalities in this theorem is indexed by all pairs of weighted quantum cluster characters \((f_{\epsilon_M} \ast \delta_M, f_{\epsilon_N} \ast \delta_N)\), the family of equalities of locally balanced proposition is just indexed by pairs of objects \((M, N)\) and integral variables. This is because all information about weight functions \(f_{\epsilon_M}\) and \(f_{\epsilon_N}\) are contained in \(S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N})\), \(S(\eta, f_{\epsilon_N}, f_{\epsilon_M})\). However, corollary shows all \(S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N})\) and \(S(\eta, f_{\epsilon_N}, f_{\epsilon_M})\) involved in an equality are trivially equal.

From Proposition 3.26 and Theorem 3.27, we have

Theorem 3.29 (Multiplication formula of weighted quantum cluster characters). Let \(A\) be a Hom-finite, Ext-finite abelian category over finite field \(k = \mathbb{F}_q\) with Ext-symmetry and all isoclasses of objects form a set. For any weighted quantum cluster
characters \( f_{\epsilon_M} * \delta_M \) and \( f_{\epsilon_N} * \delta_N \) satisfying \( \text{Ext}_A^1(M, N) \neq 0 \), we have
\[
|\mathbb{P}\text{Ext}_A^1(M, N)|(f_{\epsilon_M} * \delta_M) * (f_{\epsilon_N} * \delta_N)
= \int_{\mathbb{P}\text{Ext}_A^1(M, N)} f^+_\text{ext} * S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) * \delta_{\text{mte}}
+ \int_{\mathbb{P}\text{Ext}_A^1(N, M)} f^-_{\text{hom}} * S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) * \delta_{\text{mtn}}
= \int_{\mathbb{P}\text{Ext}_A^1(M, N)} S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) * \delta_{\text{mte}}
+ \int_{\mathbb{P}\text{Ext}_A^1(N, M)} f^-_{\text{ext}} * f_{\text{hom}} * S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) * \delta_{\text{mtn}}.
\]

Notice that both Proposition 3.28 and Theorem 3.27 are sufficient but not necessary, so we give the definition of balanced pair as

**Definition 3.30.** A pair of weight functions \((f^+, f^-)\) in \( \mathbb{Z}_{MF} \) is called balanced pair if for any weighted quantum cluster characters \( f_{\epsilon_M} * \delta_M \) and \( f_{\epsilon_N} * \delta_N \) satisfying \( \text{Ext}_A^1(M, N) \neq 0 \),
\[
|\mathbb{P}\text{Ext}_A^1(M, N)|(f_{\epsilon_M} * \delta_M) * (f_{\epsilon_N} * \delta_N) = \int_{\mathbb{P}\text{Ext}_A^1(M, N)} f^+_\text{ext} * S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) * \delta_{\text{mte}}
+ \int_{\mathbb{P}\text{Ext}_A^1(N, M)} f^-_{\text{ext}} * f_{\text{hom}} * S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) * \delta_{\text{mtn}}
\]
holds.

Then any balanced pair can induce a multiplication formula similar to Theorem 3.29.

3.10. \( \dim k \text{Ext}_A^1(M, N) = 1 \) case. At last, we simplify the formula in \( \dim k \text{Ext}_A^1(M, N) = 1 \) case.

Assume \( \dim k \text{Ext}_A^1(M, N) = \dim k \text{Ext}_A^1(N, M) = 1 \), then \( \mathbb{P}\text{Ext}_A^1(M, N) \) and \( \mathbb{P}\text{Ext}_A^1(N, M) \) are both single point sets. Moreover, since \( p_0 \text{Ker} \beta_{c_M, c_N} \) and \( \text{Im} \beta_{c_N, c_M} \cap \text{Ext}_A^1(N, M) \) are orthogonal, one of them is of dimension 1 and the other is zero.

**Lemma 3.31.** Assume \( \dim k \text{Ext}_A^1(M, N) = 1 \), \([\epsilon], [\eta]\) are nonzero in \( \text{Ext}_A^1(M, N) \) and \( \text{Ext}_A^1(N, M) \) respectively.

1. If \( (c_M, c_N) \in \phi_{MN,[\epsilon]}(F_{i.a.L}^{\text{mono}}([\epsilon], a', a'')) \), then \( f^+_{\text{ext}}(M, N, c_M, c_N) = 0 \).
2. If \( (c_N, c_M) \in \phi_{NM,[\eta]}(F_{i.a.L}^{\text{mono}}([\eta], a'', a')) \), then \( f^-_{\text{ext}}(N, M, c_N, c_M) = 0 \).

**Proof.** Recall that \( (c_M, c_N) \in \phi_{MN,[\epsilon]}(F_{i.a.L}^{\text{mono}}([\epsilon], a', a'')) \).
if and only if

$$[\epsilon] \in p_0 \text{Ker } \beta_{c_M,c_N}.$$  

In this case, $p_0 \text{Ker } \beta_{c_M,c_N}$ contains a nonzero element, so

$$\dim_k p_0 \text{Ker } \beta_{c_M,c_N} = 1.$$  

By definition, $f^+_\text{ext}(M,N,c_M,c_N) = \dim_k (\text{Im } \beta'_{c_N,c_M} \cap \text{Ext}^1_A(N,M)) = 0.$

Dually,

$$(c_N,c_M) \in \phi_{NM,\eta}(\mathcal{F}^{\text{mono}}_{L,a,L}([\epsilon],a'',a'))$$

if and only if

$$[\eta] \in \text{Im } \beta'_{c_N,c_M} \cap \text{Ext}^1_A(N,M).$$

And in this case,

$$\dim_k p_0 \text{Ker } \beta_{c_M,c_N} = 0.$$  

□

**Corollary 3.32.** Assume $\dim_k \text{Ext}^1_A(M,N) = 1$, $[\epsilon]$, $[\eta]$ are nonzero in $\text{Ext}^1_A(M,N)$ and $\text{Ext}^1_A(N,M)$ respectively. The following are equivalent

1. $(c_M,c_N) \in \phi_{MN,\epsilon}(\mathcal{F}^{\text{mono}}_{L,a,L}([\epsilon],a',a''))$
2. $(c_N,c_M) \notin \phi_{NM,\eta}(\mathcal{F}^{\text{mono}}_{L,a,L}([\eta],a'',a'))$

**Proof.** Since $\dim_k \text{Ext}^1_A(M,N) = 1$, $\dim_k p_0 \text{Ker } \beta_{c_M,c_N}$ is either 0 or 1. Both conditions are equivalent to $\dim_k p_0 \text{Ker } \beta_{c_M,c_N} = 1.$  

□

**Theorem 3.33.** Assume $\dim_k \text{Ext}^1_A(M,N) = 1$ and there are nonsplit short exact sequences

$$\epsilon : 0 \to N \to L \to M \to 0,$$

$$\eta : 0 \to M \to L' \to N \to 0.$$  

Then we have

$$(f_\epsilon * \delta_M) * (f_\epsilon * \delta_N)$$

$$= S(\epsilon, f_\epsilon M, f_\epsilon N) * \delta_L + f_{\text{hom}} * S(\eta, f_\epsilon N, f_\epsilon M) * \delta_{L'}.$$  

In particular,

$$\delta_M * \delta_N = \delta_L + f_{\text{hom}} * f_\eta * \delta_{L'}$$

where $f_\eta$ is zero function in $\mathbb{Z}_{MF,\eta}$.  

Proof. Recall the multiplication formula

\[
|\mathbb{P}\text{Ext}^1_{A}(M, N)|(f_{\epsilon_M} * \delta_M) * (f_{\epsilon_N} * \delta_N)
\]

\[
= \int_{\mathbb{P}e \in \mathbb{P}\text{Ext}^1_{A}(M, N)} f^+_{\text{ext}} * S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) * \delta_{\text{int}}
\]

\[
+ \int_{\mathbb{P}\eta \in \mathbb{P}\text{Ext}^1_{A}(N, M)} f_{\text{hom}} * S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) * \delta_{\text{int}}
\]

\[
= \int_{\mathbb{P}e \in \mathbb{P}\text{Ext}^1_{A}(M, N)} S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) * \delta_{\text{int}}
\]

\[
+ \int_{\mathbb{P}\eta \in \mathbb{P}\text{Ext}^1_{A}(N, M)} f^-_{\text{ext}} * f_{\text{hom}} * S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) * \delta_{\text{int}}
\]

Since \(\dim k \text{Ext}^1_{A}(M, N) = 1\), \(\mathbb{P}\text{Ext}^1_{A}(M, N) = 1\) and both integrals in formula degrade into one term indexed by \([\epsilon]\) and \([\eta]\) respectively. Then we have

\[
(f_{\epsilon_M} * \delta_M) * (f_{\epsilon_N} * \delta_N)
\]

\[
= f^+_{\text{ext}} * S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) * \delta_L + f_{\text{hom}} * S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) * \delta_{L'}
\]

\[
= S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) * \delta_L + f^-_{\text{ext}} * f_{\text{hom}} * S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) * \delta_{L'}.
\]

From Lemma \ref{lem:3.31}

\[
f^+_{\text{ext}} * S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) * \delta_L(d_1,a)
\]

\[
= \int_{a' + a'' = a} \int_{(c_M, c_N) \in \phi_{M,N}[\epsilon]} q^{k(c_M,c_N)+S(f_{\epsilon_M},f_{\epsilon_N})+f^+_{\text{ext}}}
\]

\[
= \int_{a' + a'' = a} \int_{(c_M, c_N) \in \phi_{M,N}[\epsilon]} q^{k(c_M,c_N)+S(f_{\epsilon_M},f_{\epsilon_N})}
\]

\[
= S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) * \delta_L(d_1,a)
\]

and

\[
f^-_{\text{ext}} * f_{\text{hom}} * S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) * \delta_{L'}(d_1,a)
\]

\[
= \int_{a' + a'' = a} \int_{(c_N, c_M) \in \phi_{N,M}[\eta]} q^{k(c_M,c_N)+S(f_{\epsilon_N},f_{\epsilon_M})+f^-_{\text{ext}}+f_{\text{hom}}}
\]

\[
= \int_{a' + a'' = a} \int_{(c_N, c_M) \in \phi_{N,M}[\eta]} q^{k(c_M,c_N)+S(f_{\epsilon_N},f_{\epsilon_M})+f_{\text{hom}}}
\]

\[
= f_{\text{hom}} * S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) * \delta_{L'}(d_1,a).
\]
a finite field $k = \mathbb{F}_q$. The shifting function in $\mathcal{C}$ is denoted by $\Sigma$. Let $B$ be the endomorphism algebra of $T$, then there a functor from $\mathcal{C}$ to abelian category $\text{mod } B$ denoted by $F$

$$F = \text{Hom}(T, -) : \mathcal{C} \rightarrow \text{mod } B$$

$$X \mapsto \text{Hom}(T, X).$$

Let $\{S_1, \ldots, S_n\}$ be a complete set of isomorphism classes of simple objects in $\text{mod } B$. For any two objects $M, N$ in $\text{mod } B$, define

$$\langle M, N \rangle = \dim_k \text{Hom}_B(M, N) - \dim_k \text{Ext}_B^1(M, N),$$

$$\langle M, N \rangle_a = \langle M, N \rangle - \langle N, M \rangle.$$

The form $\langle -, - \rangle_a$ could be reduced to Grothendieck group. For any object $X$ in $\mathcal{C}$, there are two triangles

$$T_2 \rightarrow T_1 \rightarrow X \rightarrow \Sigma T_2$$

and

$$\Sigma T_4 \rightarrow X \rightarrow \Sigma^2 T_3 \rightarrow \Sigma^2 T_4$$

with $T_1, T_2, T_3, T_4$ in $\text{add } T$. So we can define index and coindex of $X$

$$\text{ind}X = [FT_1] - [FT_2]$$

and

$$\text{coind}X = [FT_3] - [FT_4]$$

where $[-]$ represents the equivalence class of an object in Grothendieck group.

4.2. Exact structure. An element $\epsilon \in \text{Hom}_\mathcal{C}(M, \Sigma N)$ could induce a triangle

$$N \xrightarrow{i} L \xrightarrow{p} M \xrightarrow{\epsilon} \Sigma N$$

in $\mathcal{C}$. In this case, we denote $\text{qt} \epsilon = M$, $\text{st} \epsilon = N$ and $\text{mt} \epsilon = L$.

Applying $F$, we can get an short exact sequence in $\text{mod } B$

$$FN \xrightarrow{Fi} FL \xrightarrow{Fp} FM \xrightarrow{F\epsilon} F\Sigma N$$

Assume $M_0 \subseteq FM$ and $N_0 \subseteq FN$ are submodules, consider the diagram

$$FN \longrightarrow FL \longrightarrow FM \longrightarrow F\Sigma N$$

$$\uparrow \quad \uparrow \quad \uparrow$$

$$N_0 \xrightarrow{} L_0 \xrightarrow{} M_0$$

We denote $\text{Gr}^{\epsilon}_{M_0,N_0}(FL) = \{L_0 \subseteq FL|Fi^{-1}(L_0) = N_0, FP(L_0) = M_0\}$.

Then we calculate $|\text{Gr}^{\epsilon}_{M_0,N_0}(FL)|$ specifically.

Recall that $\mathcal{C}$ is 2-Calabi-Yau, so for any two objects $M, N$ in $\mathcal{C}$, there is a natural isomorphism

$$D_{M,N} : \text{Hom}_\mathcal{C}(\Sigma^{-1}M, N) \rightarrow \text{DHom}_\mathcal{C}(M, \Sigma N)$$

which induces a bilinear form

$$\bar{D}_{M,N} : \text{Hom}_\mathcal{C}(\Sigma^{-1}M, N) \times \text{Hom}_\mathcal{C}(M, \Sigma N) \rightarrow k, (a, b) \mapsto D_{M,N}(a)(b).$$
Given submodules $M_0 \subseteq FM$ and $N_0 \subseteq FN$, assume $\tilde{M}_0 \xrightarrow{i_M} M$ and $\tilde{N}_0 \xrightarrow{i_N} N$ lifts to the two including maps respectively. Then we can define two linear maps as

$$\alpha_{M_0,N_0} : \text{Hom}_C(\Sigma^{-1}M, \tilde{N}_0) \oplus \text{Hom}_C(\Sigma^{-1}M, N) \rightarrow \text{Hom}_C(\Sigma^{-1}M, \tilde{N}_0) \oplus \text{Hom}_C(\Sigma^{-1}M, N) \oplus \text{Hom}_C(\Sigma^{-1}M, N)$$

$$(a, b) \mapsto (a \circ \Sigma^{-1}t_M, t_N \circ a \circ \Sigma^{-1}t_M - b \circ \Sigma^{-1}t_M, t_N \circ a - b)$$

and

$$\alpha'_{N_0,M_0} : \text{Hom}_C(\tilde{N}_0, \Sigma \tilde{M}_0) \oplus \text{Hom}_C(N, \Sigma \tilde{M}_0) \oplus \text{Hom}_C(N, \Sigma M) \rightarrow \text{Hom}_C(\tilde{N}_0, \Sigma M) \oplus \text{Hom}_C(N, \Sigma M)$$

$$(a, b, c) \mapsto (\Sigma t_M \circ a + c \circ t_N + \Sigma t_M \circ b \circ t_N, -c - \Sigma t_M \circ b)$$

The following properties of $\alpha_{M_0,N_0}$ and $\alpha'_{N_0,M_0}$ are given in [18].

**Lemma 4.1.** For any $M, N$ in $C$, given $\epsilon \in \text{Hom}_C(M, \Sigma N)$, $\eta \in \text{Hom}_C(N, \Sigma M)$ and submodules $M_0 \subseteq FM$, $N_0 \subseteq FN$.

1. $\text{Gr}^\epsilon_{M_0,N_0}(F(mt\epsilon))$ is nonempty if and only if $\Sigma^{-1}\epsilon \in p\ker \alpha_{M_0,N_0}$ where $p$ is the projection from $\text{Hom}_C(\Sigma^{-1}M, \tilde{N}_0) \oplus \text{Hom}_C(\Sigma^{-1}M, N)$ to $\text{Hom}_C(\Sigma^{-1}M, N)$.

2. $\text{Gr}^\eta_{N_0,M_0}(F(mt\eta))$ is nonempty if and only if $\eta \in \text{Im} \alpha'_{N_0,M_0} \cap \text{Hom}_C(N, \Sigma M)$ where the intersection is realized through regarding $\text{Hom}_C(N, \Sigma M)$ as a linear subspace of $\text{Hom}_C(\tilde{N}_0, \Sigma M) \oplus \text{Hom}_C(N, \Sigma M)$.

Moreover, one can check $\alpha_{M_0,N_0}$ is orthogonal to $\alpha'_{N_0,M_0}$ with respect to the pairing $\tilde{D}_{M,N}$, so

**Lemma 4.2.** For any $M, N$ in $C$ and submodules $M_0 \subseteq FM$, $N_0 \subseteq FN$, we have

$$\ker \alpha_{M_0,N_0} = (\text{Im} \alpha'_{N_0,M_0})^\perp.$$

In particular,

$$\dim_k p\ker \alpha_{M_0,N_0} + \dim_k (\text{Im} \alpha'_{N_0,M_0} \cap \text{Hom}_C(N, \Sigma M)) = \dim_k \text{Hom}_C(M, \Sigma N).$$

Then, to calculate $|\text{Gr}^\epsilon_{M_0,N_0}(F(L))|$ when it is nonzero, we need

**Lemma 4.3.** If $\text{Gr}^\epsilon_{M_0,N_0}(F(mt\epsilon))$ is nonempty, for any $L_0$ in $\text{Gr}^\epsilon_{M_0,N_0}(F(mt\epsilon))$, there is a bijection

$$\text{Gr}^\epsilon_{M_0,N_0,L_0} : \text{Hom}_B(M_0, FN/N_0) \rightarrow \text{Gr}^\epsilon_{M_0,N_0}(F(mt\epsilon)).$$

Moreover, if we set

$$l(M, N, M_0, N_0) = \dim_k \text{Hom}_B(M_0, FN/N_0),$$

then

$$|\text{Gr}^\epsilon_{M_0,N_0}(F(L))| = q^{l(M, N, M_0, N_0)}.$$
Proof. We sketch the proof.
Consider the commutative diagram in mod $B$

$$
\begin{array}{ccc}
FN/N_0 & \xrightarrow{\pi} & FN \\
\uparrow{\pi} & & \uparrow{Fi} \\
FL & \xrightarrow{Fp} & FM \\
\uparrow{i_N} & & \uparrow{i_L} \\
N_0 & \xrightarrow{Fi} & L_0 \\
\uparrow{i_M} & & \uparrow{Fp} \\
& & M_0
\end{array}
$$

where $m_{t\epsilon} = L$ and $M_0, N_0, L_0$ are submodules with $Fi^{-1}(L_0) = N_0, Fp(L_0) = M_0$.

We can define an action of $\text{Hom}_B(M_0, FN/N_0)$ on $\text{Gr}^\epsilon_{M_0,N_0}(FL)$ as:

For any $f \in \text{Hom}_B(M_0, FN/N_0)$ and $L_0 \in \text{Gr}^\epsilon_{M_0,N_0}(FL)$,

$$L_0^f = \{Fi(n) + x | n \in FN, x \in L_0, f(Fp(x)) = \pi(n)\}$$

is a linear subspace of $FL$.

Since $Fi, Fp, f, \pi$ are module homomorphisms,

$$B(Fi(n) + x) = B(Fi(n)) + B(x) = Fi(B(n)) + B(x)$$

and

$$f(Fp(B(x))) = B(f(Fp(x))) = B(\pi(n)) = \pi(B(n)).$$

So $L_0^f$ is a submodule of $FL$.

If $f = 0$, then $f(Fp(x)) = 0$ and $\pi(n) = 0$ implies $n \in N_0$, so $L_0^0 = L_0$. Moreover,

$$(L_0^f)^g = L_0^{f+g}.$$

Since $Fi^{-1}(L_0) = N_0$, $Fi(n) \in L_0$ if and only if $n \in N_0$ and in this case, $\pi(n) = 0$.
So if $L_0^f = L_0$, then $f(Fp(L_0)) = f(M_0) = 0$. That is to say, the action is free.

For any $L_0' \in \text{Gr}^\epsilon_{M_0,N_0}(FL)$, define $f$ as $f(m) = \pi(x' - x)$ where $x \in L_0$ and $x' \in L_0'$
with $Fp(x) = Fp(x') = m$. Then $L_0' = L_0$, so the action is transitive.

So we just need to define $C^\epsilon_{M_0,N_0,L_0}(f) = L_0^f$, then $C_{L_0^f}$ is bijective.

Moreover, according to the proof, we can define linear structure on $\text{Gr}^\epsilon_{M_0,N_0}(FL)$
with respect to a fixed $L_0$ in $\text{Gr}^\epsilon_{M_0,N_0}(FL)$ as:

$$\lambda L_0^f = L_0^{f\lambda}; L_0^f + L_0^g = L_0^{f+g}.$$

Then

$$C^\epsilon_{M_0,N_0,L_0} : \text{Hom}_B(M_0, FN/N_0) \to \text{Gr}^\epsilon_{M_0,N_0}(F(m_{t\epsilon}))$$

is a linear isomorphism.

Remark 4.4. Notice that $\text{Hom}_B(M_0, FN/N_0)$ just depends on $M, N, M_0, N_0$ and is independent of $m_{t\epsilon}$. So as long as $\Sigma^{-1}\epsilon$ is chosen from $p\text{Ker} \alpha_{M_0,N_0}$, the dimension $l(M, N, M_0, N_0)$ is invariant. That is to say, all $\epsilon$ in $\Sigma p\text{Ker} \alpha_{M_0,N_0}$ admit a same $|\text{Gr}^\epsilon_{M_0,N_0}(FL)|$. 
Corollary 4.5. All submodules in $\text{Gr}_{M_0,N_0}^f(F(\text{mt} \varepsilon))$ admit the same dimension vector.

Proof. With the same notations as above, assume $L_0$ and $L_0^f$ are two submodules in $\text{Gr}_{M_0,N_0}^f(FL)$.

Recall that

$$L_0^f = \{Fi(n) + x| n \in FN, x \in L_0, f(Fp(x)) = \pi(n)\},$$

if take $x = 0 \in L_0$, then $\pi(n) = f(Fp(x)) = 0$ implies $n \in N_0$. So any submodule in $\text{Gr}_{M_0,N_0}^f(FL)$ must contains $Fi(N_0)$ as a linear subspace. We consider the commutative diagram modulo $N_0$

\[
\begin{array}{ccc}
FN/N_0 & \xrightarrow{Fi} & FL/Fi(N_0) & \xrightarrow{Fp} & FM \\
\uparrow & & \uparrow & & \uparrow \\
0 & \xrightarrow{Fi} & L_0^f/Fi(N_0) & \xrightarrow{Fp} & M_0
\end{array}
\]

where module monomorphisms retain the same notations and

$$L_0^f/Fi(N_0) = \{Fi(n) + x| n \in FN/N_0, x \in L_0/Fi(N_0), f(Fp(x)) = \pi(\overline{n}) = \overline{x}\}$$

= \{Fi(f(Fp(\overline{x}))) + x| x \in L_0/Fi(N_0)\}

Since the second row is exact and $Fp$ is surjective, we have $L_0^f/Fi(N_0) \cong M_0$. So they must admit the same dimension vector which is independent of $f$. Furthermore, all submodules $L_0^f$ in $\text{Gr}_{M_0,N_0}^f(FL)$ admit the same dimension vector. \qed

Dually, we have

Corollary 4.6. If $\text{Gr}_{N_0,M_0,n}^\eta(F(\text{mt} \eta))$ is nonempty, for any $L_0$ in $\text{Gr}_{N_0,M_0,n}^\eta(F(\text{mt} \eta))$, there is a linear isomorphism

$$C_{N_0,M_0,L_0}^\eta : \text{Hom}_B(N_0, FM/M_0) \rightarrow \text{Gr}_{N_0,M_0,n}^\eta(F(\text{mt} \eta)).$$

Moreover,

$$|\text{Gr}_{N_0,M_0,n}^\eta(F(\text{mt} \eta))| = q^{l(N,M_0,M_0)}.$$

Summarize all analysis in this subsection, we have

Proposition 4.7. For any $M, N$ in $C$, given $\varepsilon \in \text{Hom}_C(M, SN)$, $\eta \in \text{Hom}_C(N, SM)$ and submodules $M_0 \subseteq FM$, $N_0 \subseteq FN$.

1. If $\varepsilon \notin \Sigma p\text{Ker} \alpha_{M_0,M_0}$, $\text{Gr}_{M_0,N_0}^\varepsilon(F(\text{mt} \varepsilon))$ is empty.
2. If $\varepsilon \in \Sigma p\text{Ker} \alpha_{M_0,M_0}$,

$$C_{M_0,N_0,L_0}^\varepsilon : \text{Hom}_B(M_0, FN/N_0) \rightarrow \text{Gr}_{M_0,N_0}^\varepsilon(F(\text{mt} \varepsilon))$$

is linear isomorphism and $|\text{Gr}_{M_0,N_0}^\varepsilon(F(\text{mt} \varepsilon))| = q^{l(M,N,M_0,N_0)}$.
3. If $\eta \notin \text{Im}(\varepsilon)_{M_0,M_0} \cap \text{Hom}_C(N, SM)$, $\text{Gr}_{N_0,M_0}^\varepsilon(F(\text{mt} \eta))$ is empty.
(4) If \( \eta \in \text{Im} \alpha'_{N_0,M_0} \cap \text{Hom}_C(N, \Sigma M) \),
\[
C_{N_0,M_0,L_0}^\eta : \text{Hom}_B(N_0, FM/M_0) \to \text{Gr}_{N_0,M_0}^\eta (F(\text{mt} \eta))
\]
is linear isomorphism and \(|\text{Gr}_{N_0,M_0}^\eta (F(\text{mt} \eta))| = q^{l(N,M,N_0,M_0)}\).

4.3. Character. Let \( A_{n,\lambda} \) be a \( \mathbb{Q} \)-algebra generated by \( x_1^\pm, \ldots, x_n^\pm \) with generating relation: for any \( e = (e_1, \ldots, e_n), f = (f_1, \ldots, f_n) \in \mathbb{Z}^n \),
\[
X^e \cdot X^f = q^{\frac{1}{2} \lambda(e,f)} X^{e+f}
\]
where \( X^e = x_1^{e_1} \cdots x_n^{e_n} \) and \( X^f = x_1^{f_1} \cdots x_n^{f_n} \) are monomials in \( A_{n,\lambda} \) and \( \lambda \) is a skew-symmetric bilinear form. Such \( A_{n,\lambda} \) is called a skew-polynomial algebra and elements in \( A_{n,\lambda} \) are called skew-polynomials.

On the other hand, for any \( L \in \mathcal{C} \) and \( g \in \mathbb{N}^n \), the set of all submodules \( F_0 \) of \( FL \) with dimension vector \( g \) is denoted by \( \text{Gr}_g(FL) \), called Grassmannian.

**Definition 4.8.** For each object \( L \) in \( \mathcal{C} \), we assign a skew-polynomial in \( A_{n,\lambda} \) as
\[
X_L = \int_g |\text{Gr}_g(FL)| \cdot X^{p(L,g)}
\]
where the integral runs over all \( g \) in \( \mathbb{N}^n \) and \( p(L,g) \in \mathbb{N}^n \) with \( p(L,g)_i = -(\text{coind} L)_i + \langle S_i, g \rangle \). The skew-polynomial is called quantum cluster character of \( L \).

Notice that the set of all \( g \) such that \( \text{Gr}_g(FL) \) is nonempty is finite, so the integral is exactly a finite sum.

4.4. Vector bundle. Given \( M, N \in \mathcal{C} \), define
\[
\text{EG}(M,N) = \{(\epsilon, L_0) | \epsilon \in \text{Hom}_C(M, \Sigma N), L = \text{mt} \epsilon, L_0 \in \coprod_g \text{Gr}_g(FL)\}.
\]

Then from \( (\epsilon, L_0) \in \text{EG}(M,N) \), we can induce two submodules \( M_0, N_0 \) of \( FM \) and \( FN \) respectively as \( N_0 = \iota^{-1}(L_0) \) and \( M_0 = p(L_0) \). Then we naturally have the commutative diagram.

\[
\begin{array}{ccc}
FN & \xrightarrow{i} & FL \\
\uparrow & & \uparrow \quad \quad \quad \quad \quad \quad \quad \quad \quad \uparrow \\
N_0 & \xrightarrow{\iota} & L_0 \xrightarrow{p} M_0
\end{array}
\]

We denote such assignment by
\[
\psi_{MN} : \text{EG}(M,N) \to \coprod_{e,f} \text{Gr}_e(FM) \times \text{Gr}_f(FN)
\]
where the coproduct runs over \( \mathbb{N}^n \times \mathbb{N}^n \).

Fix \( \epsilon \), we set
\[
\psi_{MN,\epsilon} = \psi_{MN}(\epsilon, -) : \bigoplus_g \text{Gr}_g(FL) \to \bigoplus_{e,f} \text{Gr}_e(FM) \times \text{Gr}_f(FN).
\]
To separate all pieces indexed by $g$, we set

$$
\psi_{MN,e,g} = \psi_{MN,e}|_{Gr_g(FL)} : Gr_g(FL) \rightarrow \prod_{e,f} Gr_e(FM) \times Gr_f(FN).
$$

Moreover, denote

$$
Gr^e_g(FL, e, f) = \psi_{MN,e,g}^{-1}(Gr_e(FM) \times Gr_f(FN))
$$

and

$$
Gr^e_{e,f}(FM, FN, g) = \psi_{MN,e,g}(Gr^e_g(FL, e, f)).
$$

Notice that $Gr^e_{e,f}(FM, FN, g)$ may not be the whole $Gr_e(FM) \times Gr_f(FN)$ because $\psi_{MN,e,g}$ is not surjective in general.

Rewrite Proposition 4.7 up to notations here, we get

**Lemma 4.9.** Given $(M_0, N_0) \in Gr_e(FM) \times Gr_f(FN)$ and $e \in \text{Hom}_C(M, \Sigma N)$.

1. If $(M_0, N_0) \notin Gr^e_{e,f}(FM, FN, g)$, $\psi_{MN,e,g}^{-1}(M_0, N_0) = \emptyset$;
2. If $(M_0, N_0) \in Gr^e_{e,f}(FM, FN, g)$, for any $L_0$ in $\psi_{MN,e,g}^{-1}(M_0, N_0)$, $C^e_{M_0,N_0,L_0} : \text{Hom}_B(M_0, FN/N_0) \rightarrow \psi_{MN,e,g}^{-1}(M_0, N_0)$ is linear isomorphism.

Dually, we can consider

$$
\psi_{NM} : EG(N, M) \rightarrow \prod_{f,e} Gr_f(FN) \times Gr_e(FM)
$$

and also rewrite last parts of Proposition 4.7 into

**Lemma 4.10.** Given $(N_0, M_0) \in Gr_f(FN) \times Gr_e(FM)$ and $\eta \in \text{Hom}_C(N, \Sigma M)$.

1. If $(N_0, M_0) \notin Gr^e_{e,f}(FM, FN, g)$, $\psi_{NM,e,g}^{-1}(N_0, M_0) = \emptyset$;
2. If $(N_0, M_0) \in Gr^e_{e,f}(FM, FN, g)$, for any $L_0$ in $\psi_{NM,e,g}^{-1}(N_0, M_0)$, $C^e_{N_0,M_0,L_0} : \text{Hom}_B(N_0, FM/M_0) \rightarrow \psi_{NM,e,g}^{-1}(N_0, M_0)$ is linear isomorphism.

### 4.5. Cardinality

In this subsection, we calculate cardinalities of sets involved in several lemmas above and refine the calculation of $X_L$.

Considering $\psi_{MN}$, since $Gr^e_g(FL, e, f) = \psi_{MN,e,g}^{-1}(Gr_e(FM) \times Gr_f(FN))$ and the Grassmannian is a finite set here, we have

$$
|Gr_g(FL)| = \int_{e,f} |Gr^e_g(FL, e, f)|
$$

for any $e \in \text{Hom}_C(M, \Sigma N)$ with $mt_e = L$ and

$$
|Gr^e_g(FL, e, f)| = \int_{(M_0,N_0)\in Gr_e(FM)\times Gr_f(FN)} |\psi_{MN,e,g}^{-1}(M_0, N_0)|.
$$

Moreover, based on Lemma 4.9, we have

**Lemma 4.11.** Given $(M_0, N_0) \in Gr_e(FM) \times Gr_f(FN)$ and $e \in \text{Hom}_C(M, \Sigma N)$.

1. If $(M_0, N_0) \notin Gr^e_{e,f}(FM, FN, g)$, $|\psi_{MN,e,g}^{-1}(M_0, N_0)| = 0$;
(2) If \( (M_0, N_0) \in \text{Gr}^q_{e,f}(FM, FN, g) \), \(|\psi^{-1}_{MN,\epsilon,g}(M_0, N_0)| = |\text{Hom}_B(M_0, FN/N_0)| = q^{l(M,N,M_0,N_0)}.

Up to these calculations, if \( m \epsilon = L \), we can deduce the refinement of \( X_L \) as

\[
X_L = \int g |\text{Gr}_g(FL)| \cdot X^{p(L,g)}
\]

\[
= \int g \int_{e,f} |\text{Gr}_g^e(FL, e, f)| \cdot X^{p(L,g)}
\]

\[
= \int g \int_{e,f} \int_{(M_0, N_0) \in \text{Gr}_e(FM) \times \text{Gr}_f(FN)} |\psi^{-1}_{MN,\epsilon,g}(M_0, N_0)| \cdot X^{p(L,g)}
\]

\[
= \int g \int_{e,f} \int_{(M_0, N_0) \in \text{Gr}^q_{e,f}(FM, FN, g)} q^{l(M,N,M_0,N_0)} \cdot X^{p(L,g)}.
\]

**Remark 4.12.** Similar to the case in section, the refinement of \( X_L \) still depends on choice of \( \epsilon \) which is not unique. But, although different \( \epsilon \) may derives different integrals, the final result is still equal to \( X_L \) itself.

Dually, from Lemma 4.10 we have

**Lemma 4.13.** Given \( (N_0, M_0) \in \text{Gr}_f(FN) \times \text{Gr}_e(FM) \) and \( \eta \in \text{Hom}_C(N, \Sigma M) \).

(1) If \( (N_0, M_0) \notin \text{Gr}^q_{f,e}(FN, FM, g) \), \(|\psi^{-1}_{N,M,\eta,g}(N_0, M_0)| = 0
\]

(2) If \( (N_0, M_0) \in \text{Gr}^q_{f,e}(FN, FM, g) \), \(|\psi^{-1}_{N,M,\eta,g}(N_0, M_0)| = |\text{Hom}_B(N_0, FM/M_0)|
\]

\[
= q^{l(N,M,N_0,M_0)}.
\]

And if \( m \epsilon \eta = L \), we can also refine \( X_L \) as

\[
X_L = \int g |\text{Gr}_g(FL)| \cdot X^{p(L,g)}
\]

\[
= \int g \int_{f,e} |\text{Gr}_g^f(FL, f, e)| \cdot X^{p(L,g)}
\]

\[
= \int g \int_{f,e} \int_{(N_0, M_0) \in \text{Gr}_f(FN) \times \text{Gr}_e(FM)} |\psi^{-1}_{N,M,\eta,g}(N_0, M_0)| \cdot X^{p(L,g)}
\]

\[
= \int g \int_{f,e} \int_{(N_0, M_0) \in \text{Gr}^q_{f,e}(FN, FM, g)} q^{l(N,M,N_0,M_0)} \cdot X^{p(L,g)}.
\]

4.6. **Weight.** Based on the refinements of \( X_L \), we introduce weight function and weighted quantum cluster character.

Define

\[
MG = \{(M, N, M_0, N_0)| M, N \in C, (M_0, N_0) \in \bigoplus_{e,f} \text{Gr}_e(FM) \times \text{Gr}_f(FN)\}
\]

and denote the set of all half integer valued functions on \( MG \) called weight functions by

\[
\mathbb{Z}_{MG} = \{ g : MG \rightarrow \mathbb{Z} \},
\]
where \( Z = \{ \frac{n}{2} | n \in \mathbb{Z} \} \) is the set of half integers.

Given \( \epsilon \in \text{Hom}_C(M, \Sigma N) \), a function \( g \in \mathbb{Z}_{MG} \) is called supported on \( \epsilon \) if
\[
g(M, N, -, -) = 0
\]
unless \( M = q \epsilon \) and \( N = s \epsilon \) and
\[
\{(q \epsilon, s \epsilon, M_0, N_0) \in MG | (M_0, N_0) \in \prod_{e,f} \text{Gr}_e(F(q \epsilon)) \times \text{Gr}_f(F(s \epsilon))\}
\]
is called support area. The set of all functions supported on \( \epsilon \) is denoted by \( \mathbb{Z}_{MG,\epsilon} \).

Moreover, considering that different morphisms may admit a same middle term, we define
\[
\mathbb{Z}_{MG,L} = \bigoplus_{m \epsilon = L} \mathbb{Z}_{MG,\epsilon}
\]
Similar to the case in section, although \( \mathbb{Z}_{MG,\epsilon} \) may intersect as subsets of \( \mathbb{Z}_{MG} \), we still define \( \mathbb{Z}_{MG,L} \) as a disjoint union through which we regard the zero function in different \( \mathbb{Z}_{MG,\epsilon} \) as different elements in \( \mathbb{Z}_{MG,L} \).

**Definition 4.14** (Weighted quantum cluster character). Given a weight function \( g_{\epsilon L} \) in \( \mathbb{Z}_{MG,L} \), the weighted quantum cluster character \( g_{\epsilon L} * X_L \) is a skew-polynomial in \( A_{n,\lambda} \) defined as
\[
g_{\epsilon L} * X_L = \int g \int_{e,f} \int_{(M_0, N_0) \in \text{Gr}_e(FM) \times \text{Gr}_f(FN)} |\psi^{-1}_{MN,\epsilon L, g}(M_0, N_0)| \cdot q^{\theta_{\epsilon L}^{(M,N,M_0,N_0)}} \cdot X_P(L,g)
\]
\[
= \int g \int_{e,f} \int_{(M_0, N_0) \in \text{Gr}_e(FM) \times \text{Gr}_f(FN)} q^{(M,N,M_0,N_0)} \cdot q^{\theta_{\epsilon L}^{(M,N,M_0,N_0)}} \cdot X_P(L,g)
\]
where \( \epsilon_L \) is a morphism in \( \text{Hom}_C(M, \Sigma N) \) with \( q \epsilon_L = M, s \epsilon = N, m \epsilon = L \) and \( \epsilon_L \) marks which component of \( \mathbb{Z}_{MG,L} \) the weight function is chosen from.

**Remark 4.15.** Similar to remark, although the power \( q^{\theta_{\epsilon L}^{(M,N,M_0,N_0)}} \) just depends on values of the weight function, the integral domain depends on specific \( \epsilon_L \). So even if we choose a weight function from \( \mathbb{Z}_{MG,\epsilon} \cap \mathbb{Z}_{MG,\epsilon'} \), regarding the weight function as \( g_\epsilon \) or \( g_{\epsilon'} \) may derives different results. That is why we define \( \mathbb{Z}_{MG,L} \) as a disjoint union.

Similarly, we can take zero function to check such definition is a \( q \)-deformation of quantum cluster character.

**Corollary 4.16.** For any zero function \( g_{\epsilon L} \) in \( \mathbb{Z}_{MG,L} \), \( g_{\epsilon L} * X_L = X_L \).

4.7. Multiplication. We set the zero morphism in \( \text{Hom}_C(M, \Sigma N) \) by \( 0_{MN} \).

First, we consider the multiplication of quantum cluster characters.

Recall that the multiplication of skew-polynomials follows the generating relation
\[
X^e \cdot X^f = q^{\frac{1}{2} \lambda(e,f)} X^{e+f}
\]
So given $M, N$ in $C$, we can multiply the quantum cluster characters as

$$X_M \cdot X_N = \int_e |\text{Gr}_e(FM)| \cdot X^{p(M,e)} \cdot \int_f |\text{Gr}_f(FN)| \cdot X^{p(N,f)}$$

$$= \int_{e,f} |\text{Gr}_e(FM)| \cdot |\text{Gr}_f(FN)| \cdot q^{\frac{1}{2}(p(M,e),p(N,f))} \cdot X^{p(M,e)+p(N,f)}$$

$$= \int_{e,f} \int_{(M_0,N_0) \in \text{Gr}_e(FM) \times \text{Gr}_f(FN)} q^{\frac{1}{2}(p(M,e),p(N,f))} \cdot X^{p(M,e)+p(N,f)}$$

On the other hand, we calculate $X_M^{\oplus N}$ as

$$X_M^{\oplus N} = \int_{g} \int_{e,f} \int_{(M_0,N_0) \in \text{Gr}_e(FM) \times \text{Gr}_f(FN)} |\psi^{-1}_{MN,0}(M_0,N_0)| \cdot X^{p(M^{\oplus N},g)}$$

$$= \int_{g} \int_{e,f} \int_{(M_0,N_0) \in \text{Gr}_e(FM) \times \text{Gr}_f(FN)} q^{p(M,N_0),N_0)} \cdot X^{p(M^{\oplus N},g)}$$

Comparing two equalities, there are three differences: $X$-power, integral domain and $q$-power. We analyse them successively.

Firstly, given $\epsilon \in \text{Hom}_C(M, \Sigma N)$ with $\text{mt}_\epsilon = L$ and submodules as

$$FN \xrightarrow{F_M} FL \xrightarrow{F_P} FM \xrightarrow{F_\epsilon} F\Sigma N$$

where $N_0 = F_i^{-1}(L_0)$, $M_0 = F_p(L_0)$ and dimension vectors of $M_0, N_0, L_0$ are $e, f, g$ respectively. We have

**Lemma 4.17.** \[18\] With the notations above, $p(M, e) + p(N, f) = p(L, g)$.

The lemma makes the $X$-powers in $X_M \cdot X_N$ and $X_M^{\oplus N}$ seems same, but we should be careful to the index $e, f, g$.

Secondly, recall the map

$$\psi_{MN,\epsilon} = \psi_{MN}(\epsilon, -) : \coprod_g \text{Gr}_g(FL) \rightarrow \coprod_{e,f} \text{Gr}_e(FM) \times \text{Gr}_f(FN)$$

and pieces

$$\psi_{MN,\epsilon,g} = \psi_{MN,\epsilon}|_{\text{Gr}_g(FL)} : \text{Gr}_g(FL) \rightarrow \coprod_{e,f} \text{Gr}_e(FM) \times \text{Gr}_f(FN).$$

Although the submodule $L_0$ of $FL$ located in $\text{Gr}_e(FM)$ is not unique, from lemma, the dimension vector of $L_0$ is. So for any integral variable $(e, f, M_0, N_0)$ with respect to integral $\int_{e,f} \int_{(M_0,N_0) \in \text{Gr}_e(FM) \times \text{Gr}_f(FN)}$, the suitable $g$ is uniquely decided. That is to say, for different $g$, $\text{Gr}_{e,f}(FM, FN, g)$ does not intersect. Moreover, for $0_{MN}$,

$$\psi_{MN,0_{MN}} : \coprod_g \text{Gr}_g(FL) \rightarrow \coprod_{e,f} \text{Gr}_e(FM) \times \text{Gr}_f(FN)$$
is surjective because any two submodules of $FM$ and $FN$ could be assembled into a submodule of $F(M \oplus N)$ through direct sum. So in this case, for any $e, f$,$$
abla_e(FM) \times \nabla_f(FN) = \bigoplus g \nabla_{e,f}^0(N)(FM, FN, g).$$Then we have$$X_M \cdot X_N = \int_{e,f} \int_{(M_0, N_0) \in \nabla_e(FM) \times \nabla_f(FN)} q^{\frac{1}{2}(p(M,e)+p(N,f))} \cdot X^{p(M,e)+p(N,f)}$$
At last, we introduce a special family of weight functions.

**Definition 4.18.** For any $M, N$ in $\mathcal{C}$, define weight function $g_{MN}$ as$$g_{MN}(M, N, M_0, N_0) = \frac{1}{2}(p(M,e)+p(N,f)) - l(M, N, M_0, N_0)$$for any $M_0 \in \bigsqcup_e \nabla_e(FM)$, $N_0 \in \bigsqcup_f \nabla_f(FN)$ and zero else.

Then we naturally have

**Proposition 4.19.** For any $M, N$ in $\mathcal{C}$,$$X_M \cdot X_N = g_{MN} \ast X_{M \oplus N}$$in $A_{n,\lambda}$, where $g_{MN} \in \mathbb{Z}_{MG,0_{MN}} \subset \mathbb{Z}_{MG,M@N}$.

To extend the multiplication to weighted quantum cluster characters, we need to define multiple weighting.

**Definition 4.20.** Given weighted quantum cluster character $g_{e_L} \ast X_L$ with $g_{e_L} \in \mathbb{Z}_{MG,e_L}$, $m \in e_L = L$ and a general weight function $g$ in $\mathbb{Z}_{MN}$, $(g \ast g_{e_L}) \ast X_L$ is a weighted quantum cluster character with $g \ast g_{e_L} \in \mathbb{Z}_{MG,e_L}$ defined as$$g \ast g_{e_L}(M, N, M_0, N_0) = g(M, N, M_0, N_0) + g_{e_L}(M, N, M_0, N_0)$$for any $M_0 \in \bigsqcup_e \nabla_e(FM)$, $N_0 \in \bigsqcup_f \nabla_f(FN)$ and zero else.

Since the support domain is decide by $g_{e_L}$, without ambiguity, we just write $g \ast g_{e_L} \ast X_L$. Recursively, we can define $g_1 \ast \cdots \ast g_s \ast g_{e_L} \ast X_L$ whose support domain is decided by the most right weight function.

Then we consider the multiplication $(g_{e_M} \ast X_M) \cdot (g_{e_N} \ast X_N)$. Obviously, the product must contain information of weight functions $g_{e_M}$ and $g_{e_N}$. To record these, we define a corresponding weight function for middle term.

**Definition 4.21.** Given weighted quantum cluster characters $g_{e_M} \ast X_M$, $g_{e_N} \ast X_N$ and a morphism $\epsilon \in \text{Hom}_\mathcal{C}(M, \Sigma N)$, define a weight function $T(\epsilon, g_{e_M}, g_{e_N}) \in \mathbb{Z}_{MG,\epsilon}$ as$$T(\epsilon, g_{e_M}, g_{e_N})(M, N, M_0, N_0) = g_{e_M}(qt\epsilon_M, st\epsilon_M, \psi_{qt\epsilon_M, st\epsilon_M}(\epsilon_M, M_0))$$

$$+ g_{e_N}(qt\epsilon_N, st\epsilon_N, \psi_{qt\epsilon_N, st\epsilon_N}(\epsilon_N, N_0)).$$
Corollary 4.22. Given weighted quantum cluster characters \( g_\epsilon * X_M \) and \( g_\eta * X_N \), for any \( \epsilon \in \text{Hom}_C(M, \Sigma N) \) and \( \eta \in \text{Hom}_C(N, \Sigma M) \), we have

\[
T(\epsilon, g_\epsilon M, g_\eta N)(M, N, M_0, N_0) = T(\eta, g_\epsilon N, g_\eta M)(N, M, N_0, M_0).
\]

Proof. Both sides are by definition equal to

\[
g_\epsilon M(qt \epsilon_M, \text{st} \epsilon_M, \psi qt \epsilon_M \text{st} \epsilon_M(\epsilon_M, M_0)) + g_\eta N(qt \epsilon_N, \text{st} \epsilon_N, \psi qt \epsilon_N \text{st} \epsilon_N(\epsilon_N, N_0)).
\]

\[\square\]

Proposition 4.23. For any weighted quantum cluster characters \( g_\epsilon * X_M \) and \( g_\eta * X_N \),

\[
(g_\epsilon * X_M) \cdot (g_\eta * X_N) = g_{MN} * T(0_{MN}, g_\epsilon M, g_\eta N) * X_{M \oplus N}
\]

in \( A_{n, \lambda} \), where \( g_{MN} \in \mathbb{Z}_{MG, 0_{MN}} \).

Proof. For simplicity, without ambiguity, we omit some variables of weight functions in following calculation. For example, we may write \( T(0_{MN}, g_\epsilon M, g_\eta N) \) for \( T(0_{MN}, g_\epsilon M, g_\eta N)(M, N, M_0, N_0) \).

The key point is to calculate fibers of

\[
\begin{align*}
\prod_{e_1} \text{Gr}_{e_1}(F(qt \epsilon_M)) \\
\prod_{e_2} \text{Gr}_{e_2}(F(\text{st} \epsilon_M)) \\
\prod_{g} \text{Gr}_{g}(F(M \oplus N)) \\
\prod_{f} \text{Gr}_{f}(FN)
\end{align*}
\]

\[
\begin{align*}
p_1 \circ \psi_{MN, 0_{MN}} \circ p_1 &\quad p_2 \circ \psi_{MN, 0_{MN}} \\
p_1 \circ \psi_{MN, 0_{MN}} &\quad p_2 \circ \psi_{MN, 0_{MN}} \\
p_1 \circ \psi_{MN, 0_{MN}} \circ p_1 &\quad p_2 \circ \psi_{MN, 0_{MN}} \circ p_1 \\
p_1 \circ \psi_{MN, 0_{MN}} \circ p_2 &\quad p_2 \circ \psi_{MN, 0_{MN}} \circ p_2
\end{align*}
\]
Notice that $\psi_{M,N,0_{M,N}}$ is surjective, but $\psi_{q_{t_{E,M}},s_{E,M},e_{M}}$ and $\psi_{q_{t_{E,N}},s_{E,N},e_{N}}$ may be not. So

$$\prod_g \text{Gr}_{e,f}^{0_{M,N}}(FM, FN, g) = \text{Gr}_e(FM) \times \text{Gr}_f(FN)$$

$$\prod_e \text{Gr}_{e_1,e_2}^{e_{M}}(F(q_{t_{E,M}}, F(s_{E,N}), e) \subseteq \text{Gr}_{e_1}(F(q_{t_{E,M}})) \times \text{Gr}_{e_2}(F(s_{E,M}))$$

$$\prod_f \text{Gr}_{f_1,f_2}^{e_{N}}(F(q_{t_{E,N}}, F(s_{E,N}), f) \subseteq \text{Gr}_{f_1}(F(q_{t_{E,N}})) \times \text{Gr}_{f_2}(F(s_{E,N}))$$

By definition of weighted quantum cluster character and $g_{M,N}$,

$$g_{M,N} \ast T(0_{M,N}, g_{e_{M}}, g_{e_{N}}) \ast X_{M \oplus N}$$

$$= \int \int \int_{(M_0,N_0) \in \text{Gr}_{e,f}^{0_{M,N}}(FM,FN,g)} q^{l+T(0_{M,N}, g_{e_{M}}, g_{e_{N}})} \cdot X_{p(M \oplus N,g)}$$

$$= \int \int_{(M_0,N_0) \in \text{Gr}_{e}(FM) \times \text{Gr}_{f}(FN)} q^{T(0_{M,N}, g_{e_{M}}, g_{e_{N}})} \cdot X_{p(M,e)} \cdot X_{p(M,f)}$$

$$= \int \int_{M_0 \in \text{Gr}_{e}(FM)} X_{p(M,e)} \int \int_{N_0 \in \text{Gr}_{f}(FN)} X_{p(M,f)} \cdot q^{T(0_{M,N}, g_{e_{M}}, g_{e_{N}})}.$$  

Recall that

$$\text{Gr}_{e}(FM) = \prod_{e_1,e_2} \text{Gr}_{e_1,e_2}^{e_{M}}(FM, e_1, e_2)$$

$$= \prod_{e_1,e_2} \psi_{q_{t_{E,M}},s_{E,M},e_{M}}^{-1}(\text{Gr}_{e_1,e_2}^{e_{M}}(F(q_{t_{E,M}}), F(s_{E,M}), e))$$

with fiber of dimension $l(q_{t_{E,M}}, s_{E,M}, M_1, M_2)$ and

$$\text{Gr}_{f}(FN) = \prod_{f_1,f_2} \text{Gr}_{f_1,f_2}^{e_{N}}(FN, f_1, f_2)$$

$$= \prod_{f_1,f_2} \psi_{q_{t_{E,N}},s_{E,N},f}^{-1}(\text{Gr}_{f_1,f_2}^{e_{N}}(F(q_{t_{E,N}}), F(s_{E,N}), f))$$

with fiber of dimension $l(q_{t_{E,N}}, s_{E,N}, N_1, N_2)$.
Continue calculating
\[ g_{MN} \ast T(0_{MN}, f_M, f_N) \ast X_{M+N} \]
\[ = \int e \int e_{M0} \in \text{Gr}_{e}(FM) \int f \int e_{N0} \in \text{Gr}_{f}(FN) X^{p(M,e)} \cdot q^{T(0_{MN}, f_M, f_N)} \]
\[ = \int e \int e_{1, e_2} \int (M_1, M_2) \in \text{Gr}_{e_{1, e_2}}^{M}(F(qte_M), F(ste_M), e) \]
\[ \cdot \int f \int f_{1, f_2} \int (N_1, N_2) \in \text{Gr}_{f_{1, f_2}}^{N}(F(qte_N), F(ste_N), f) \]
\[ \cdot q^{\beta_M(qte_M, ste_M, \psi_{qte_M st_{qte_M}}(e_M, M_0))} \cdot q^{\beta_N(qte_N, ste_N, \psi_{qte_N st_{qte_N}}(e_N, N_0))} \]
\[ = (g_{eM} \ast X_M) \cdot (g_{eN} \ast X_N) \]

**Definition 4.24.** We denote the \( \mathbb{Q} \)-algebra generated by \( g_{eL} \ast X_L \) by \( \Lambda_q(C) \), where \( L \) runs over \( C \) and \( g_{eL} \) runs over \( Z_{MG, L} \).

4.8. **Projectivity of** \( \text{Hom}_C(M, \Sigma N) \). Since \( \text{Hom}_C(M, \Sigma N) \) is a finite dimensional space, we can consider \( \mathbb{P}\text{Hom}_C(M, \Sigma N) \) and we denote the equivalence class of \( \epsilon \) in \( \mathbb{P}\text{Hom}_C(M, \Sigma N) \) by \( \mathbb{P}\epsilon \).

In this subsection, we shall check multiplication of weighted quantum cluster character is still well-defined if we replace \( \epsilon \) by \( \mathbb{P}\epsilon \).

We always assume the parameter \( \lambda \) is nonzero in \( k \) in this subsection.

Recall the vector bundle
\[ \psi_{MN} : EG(M, N) \to \prod_{e, f} \text{Gr}_e(FM) \times \text{Gr}_f(FN). \]
and lemma.

From the linearity of \( \alpha_{M_0, N_0} \), \( \epsilon \in \Sigma p\text{Ker} \alpha_{M_0, N_0} \) if and only if \( \lambda \epsilon \in \Sigma p\text{Ker} \alpha_{M_0, N_0} \). So in this case,
\[ |\psi_{MN, e, g}^{-1}(M_0, N_0)| = q^{l(M, N, M_0, N_0)} = |\psi_{MN, \lambda e, g}^{-1}(M_0, N_0)| \]
If else, they are both zero. So we have

**Proposition 4.25.** Given \( g_{eL} \ast X_L \), we set \( g_{\lambda eL} \in \mathbb{Z}_{MG, \lambda L} \) with
\[ g_{\lambda eL}(M, N, M_0, N_0) = g_{eL}(M, N, M_0, N_0), \]
then
\[ g_{\epsilon L} \ast X_L = g_{\lambda L} \ast X_L \]

\textbf{Proof.}
\[

g_{\epsilon L} \ast X_L \\
= \int_{g} \int_{e,f} \int_{(M_0,N_0) \in \text{Gr}_e(FM) \times \text{Gr}_f(FN)} \psi_{MN,\lambda L,g}^{-1}(M_0, N_0) \cdot q^{g_{\lambda L}}(M,N,M_0,N_0) \cdot X^p(L,g) \\
= \int_{g} \int_{e,f} \int_{(M_0,N_0) \in \text{Gr}_e(FM) \times \text{Gr}_f(FN)} \psi_{MN,\lambda L,g}^{-1}(M_0, N_0) \cdot q^{g_{\lambda L}}(M,N,M_0,N_0) \cdot X^p(L,g) \\
= g_{\lambda L} \ast X_L
\]

Then we check the multiplication
\[
(g_{\epsilon M} \ast X_M) \cdot (g_{\epsilon N} \ast X_N) = g_{MN} \ast T(0_{MN}, g_{\epsilon M}, g_{\epsilon N}) \ast X_{M \oplus N}
\]
where \(g_{MN} \in \mathbb{Z}_{MN,0_{MN}}\) and
\[
T(0_{MN}, g_{\epsilon M}, g_{\epsilon N})(M, N, M_0, N_0) = g_{\epsilon M}(qt_{\epsilon M}, \text{st}_{\epsilon M}, \psi_{qt_{\epsilon M}, st_{\epsilon M}}(\epsilon_M, M_0)) + g_{\epsilon N}(qt_{\epsilon N}, \text{st}_{\epsilon N}, \psi_{qt_{\epsilon N}, st_{\epsilon N}}(\epsilon_N, N_0)).
\]

We have already shown that even if we replace \(\epsilon_M, \epsilon_N\) by their scalar multiple, the left hand side remains the same. On the right hand side, the weight function \(g_{MN}\) is chosen from \(\mathbb{Z}_{MN,0_{MN}}\), so there is no trouble because \(\lambda 0_{MN} = 0_{MN}\).

\textbf{4.9. Multiplication formula and balanced pair.} Firstly, we introduce several special weight functions and an important property.

\textbf{Definition 4.26.} There are three weight functions in \(\mathbb{Z}_{MG}\) defined as

1. \(g_{skew}(N, M, N_0, M_0) = \lambda(p(M, e), p(N, f))\),
2. \(g^+_{ext}(N, M, N_0, M_0) = \dim_k(\text{Im}(\alpha'_{N_0,M_0}) \cap \text{Hom}_c(N, \Sigma M))\),
3. \(g^-_{ext}(N, M, N_0, M_0) = \dim_k \Sigma p\ker \alpha_{M_0,N_0}\)

for any \(M, N\) in \(\mathcal{C}\) and \((M_0, N_0) \in \coprod_{e,f} \text{Gr}_e(FM) \times \text{Gr}_f(FN)\).

\textbf{Definition 4.27.} A pair of weight functions \((g^+, g^-)\) is called pointwise balanced if for any \(M, N \in \mathcal{C}\) and \((M_0, N_0) \in \coprod_{e,f} \text{Gr}_e(FM) \times \text{Gr}_f(FN),\)
\[
q^{\dim \text{Hom}_c(M, \Sigma N) - 1} - 1 = \int_{P \in \Sigma p\ker \alpha_{M_0,N_0}} q^{g^+} + \int_{P \in \Sigma (\text{Im}(\alpha'_{N_0,M_0}) \cap \text{Hom}_c(N, \Sigma M))} q^{g^-}
\]
holds.

For simplicity, we write the equality in definition as \(\text{lhs} = \sigma_1(g^+) + \sigma_2(g^-)\)

\textbf{Proposition 4.28.} The following two pairs of weight functions
(1) $(g_{ext}^+, g_{skew})$,
(2) $(0, g_{ext}^- + g_{skew})$

are pointwise balanced.

**Proof.** We first consider $(0, g_{skew})$.

Recall Lemma [4.2] for any $M, N \in \mathcal{C}$ and $(M_0, N_0) \in \coprod_{e, f} \text{Gr}_e(FM) \times \text{Gr}_f(FN)$, we have

$$\dim_k \Sigma p \ker \alpha_{M_0, N_0} + \dim_k (\text{Im} \alpha'_{N_0, M_0} \cap \text{Hom}_\mathcal{C}(N, \Sigma M)) = \dim_k \text{Hom}_\mathcal{C}(M, \Sigma N).$$

After projectivity, we have

$$\frac{q \dim_k \text{Hom}_\mathcal{C}(M, \Sigma N) - 1}{q - 1} = q \dim_k (\text{Im} \alpha'_{N_0, M_0} \cap \text{Hom}_\mathcal{C}(N, \Sigma M)) \cdot \frac{q \dim_k \Sigma p \ker \alpha_{M_0, N_0} - 1}{q - 1} + \frac{q \dim_k (\text{Im} \alpha'_{N_0, M_0} \cap \text{Hom}_\mathcal{C}(N, \Sigma M)) - 1}{q - 1} \cdot \frac{q \dim_k \Sigma p \ker \alpha_{M_0, N_0} - 1}{q - 1}.$$

So by definition of $g_{ext}^+$ and $g_{ext}^-$, we have

$$\sigma_1(g_{ext}^+) + \sigma_2(0)$$

$$= \int_{\mathcal{P} \in \Sigma p \ker \alpha_{M_0, N_0}} q^{g_{ext}^+} + \int_{\mathcal{P} \in \text{Im} \alpha'_{N_0, M_0} \cap \text{Hom}_\mathcal{C}(N, \Sigma M)} 1$$

$$= \int_{\mathcal{P} \in \Sigma p \ker \alpha_{M_0, N_0}} q \dim_k (\text{Im} \alpha'_{N_0, M_0} \cap \text{Hom}_\mathcal{C}(N, \Sigma M)) + \int_{\mathcal{P} \in \text{Im} \alpha'_{N_0, M_0} \cap \text{Hom}_\mathcal{C}(N, \Sigma M)} 1$$

$$= q \dim_k (\text{Im} \alpha'_{N_0, M_0} \cap \text{Hom}_\mathcal{C}(N, \Sigma M)) \cdot \frac{q \dim_k \Sigma p \ker \alpha_{M_0, N_0} - 1}{q - 1} + \frac{q \dim_k (\text{Im} \alpha'_{N_0, M_0} \cap \text{Hom}_\mathcal{C}(N, \Sigma M)) - 1}{q - 1} \cdot \frac{q \dim_k \Sigma p \ker \alpha_{M_0, N_0} - 1}{q - 1}.$$
and

$$\sigma_1(0) + \sigma_2(g_{\text{ext}}^-)$$

$$= \int_{P \in \Sigma} \text{Ker} \alpha_{M_0, N_0} 1 + \int_{P \in \Sigma} \text{Hom}_{c}(N, \Sigma M) q^{g_{\text{ext}}^-}$$

$$= \int_{P \in \Sigma} \text{Ker} \alpha_{M_0, N_0} 1 + \int_{P \in \Sigma} \text{Hom}_{c}(N, \Sigma M) q^{\dim \Sigma \text{Ker} \alpha_{M_0, N_0}}$$

$$= \frac{q^{\dim \Sigma \text{Ker} \alpha_{M_0, N_0}} - 1}{q - 1} + q^{\dim \Sigma \text{Ker} \alpha_{M_0, N_0}} \frac{q^{\dim \Sigma \text{Ker} \alpha_{M_0, N_0}} - 1}{q - 1}$$

$$= \frac{q^{\dim \Sigma \text{Ker} \alpha_{M, \Sigma N}} - 1}{q - 1}.$$

Then, with respect to pointwise balanced pair, we have

**Theorem 4.29.** If a pair of weight functions \((g^+, g^-)\) in \(\mathbb{Z}_{MG}\) is pointwise balanced, then for any weighted quantum cluster characters \(g_{\epsilon M} \ast M \ast X_N\) and \(g_{\epsilon N} \ast X_N\) satisfying \(\text{Hom}_c(M, \Sigma N) \neq 0\),

$$|\text{PHom}_{c}(M, \Sigma N)|(g_{\epsilon M} \ast X_M) \cdot (g_{\epsilon N} \ast X_N)$$

$$= \int_{P \in \text{PHom}_{c}(M, \Sigma N)} g^+ \ast g_{MN} \ast T(\epsilon, g_{\epsilon M}, g_{\epsilon N}) \ast X_{m_t \epsilon}$$

$$+ \int_{P \in \text{PHom}_{c}(N, \Sigma M)} g^- \ast g_{NM} \ast T(\eta, g_{\epsilon N}, g_{\epsilon M}) \ast X_{m_t \eta}$$

holds.

**Proof.** We simplify the equality in theorem to LHS = \(\Sigma_1(g^+) + \Sigma_2(g^-)\) and omit some independent variables without ambiguity in following proof. For example, we just write \(T(0_{MN}, g_{\epsilon M}, g_{\epsilon N})(M, N, M_0, N_0)\) into \(T(0_{MN}, g_{\epsilon M}, g_{\epsilon N})\).

Direct calculation:

LHS

$$= |\text{PHom}_{c}(M, \Sigma N)|(g_{\epsilon M} \ast X_M) \cdot (g_{\epsilon N} \ast X_N)$$

$$= |\text{PHom}_{c}(M, \Sigma N)|g_{MN} \ast T(0_{MN}, g_{\epsilon M}, g_{\epsilon N}) \ast X_{M_{\oplus N}}$$

$$= |\text{PHom}_{c}(M, \Sigma N)|\int_{g} \int_{e, f} \int_{(M_0, N_0) \in \text{Gr}_{e, f}^{g_{MN}}(F M, F N, g)} q^{l + T(0_{MN}, g_{\epsilon M}, g_{\epsilon N}) + g_{MN}} \cdot X^{p(M \oplus N, g)}$$

$$= |\text{PHom}_{c}(M, \Sigma N)|\int_{e, f} \int_{(M_0, N_0) \in \text{Gr}_{e}(F M) \times \text{Gr}_{f}(F N)} q^{T(0_{MN}, g_{\epsilon M}, g_{\epsilon N})} \cdot X^{p(M, e)} \cdot X^{p(N, f)}$$

$$= \int_{e, f} \int_{(M_0, N_0) \in \text{Gr}_{e}(F M) \times \text{Gr}_{f}(F N)} q^{T(0_{MN}, g_{\epsilon M}, g_{\epsilon N})} \cdot X^{p(M, e)} \cdot X^{p(N, f)} \cdot \text{lhs}$$
Recall that the fourth equal sign is based on the fact

\[ \prod_{g} \text{Gr}^0_{e,f}(FM, FN, g) = \text{Gr}_e(FM) \times \text{Gr}_f(FN). \]

For general \( \epsilon \in \text{Hom}_C(M, \Sigma N) \) and \( \eta \in \text{Hom}_C(N, \Sigma M) \), we only have

\[ \prod_{g} \text{Gr}^\epsilon_{e,f}(FM, FN, g) \subseteq \text{Gr}_e(FM) \times \text{Gr}_f(FN), \]

\[ \prod_{g} \text{Gr}^\eta_{f,e}(FN, FM, g) \subseteq \text{Gr}_f(FN) \times \text{Gr}_e(FM), \]

and whether a pair \((M_0, N_0) \in \text{Gr}_e(FM) \times \text{Gr}_f(FN)\) is located in \(\text{Gr}^\epsilon_{e,f}(FM, FN, g)\) or \(\text{Gr}^\eta_{f,e}(FN, FM, g)\) is determined in Proposition 4.7.

So we can calculate right hand side as

\[ \Sigma_1(g^+) \]
\[ = \int_{P \in \mathsf{P}_{0}} \int_{g} \int_{e,f} \int_{(M_0, N_0) \in \text{Gr}^e_{e,f}(FM, FN, g)} q^{r+T(\epsilon, g_{eM}, g_{eN}) + g_{MN} \cdot X_p(L, g)} \]
\[ = \int_{P \in \mathsf{P}_{0}} \int_{e,f} \int_{(M_0, N_0) \in \prod_{g} \text{Gr}^e_{e,f}(FM, FN, g)} q^{g^+ + T(\epsilon, g_{eM}, g_{eN}) \cdot X_p(M, e) \cdot X_p(N, f)} \]
\[ = \int_{e,f} \int_{(M_0, N_0) \in \text{Gr}_e(FM) \times \text{Gr}_f(FN)} \int_{P \in \mathsf{P}_{\Sigma p} \text{Ker}_{\alpha_{M_0, N_0}}} q^{T(\epsilon, g_{eM}, g_{eN}) \cdot X_p(M, e) \cdot X_p(N, f) \cdot \sigma_1(g^+)} \]
Notice that in calculation of $\Sigma_2(g^-)$, we denote $l = l(N, M, N_0, M_0)$.

\[
\Sigma_2(g^-)
= \int_{\mathcal{P} Hom\Sigma \mathcal{N}(M, \Sigma N)} \int_{\mathcal{P} Hom\Sigma \mathcal{N}(M, \Sigma N)} \int_{\mathcal{P} Hom\Sigma \mathcal{N}(M, \Sigma N)} T(\eta, g_{\epsilon_n}, g_{\epsilon_m}) \cdot X_{mt\eta}
\]

Moreover, we can define balanced pair as

**Definition 4.31.** A pair of weight functions $(g^+, g^-)$ is called balanced if for any weighted quantum cluster characters $g_{\epsilon_m} \cdot X_M$, $g_{\epsilon_n} \cdot X_N$ satisfying $\text{Hom}_C(M, \Sigma N) \neq 0$, we have

\[
\left|\mathcal{P} Hom\Sigma \mathcal{N}(M, \Sigma N)\right| (g_{\epsilon_m} \cdot X_M) \cdot (g_{\epsilon_n} \cdot X_N)
\]

From Proposition 4.28 and Theorem 4.29, we have

**Theorem 4.30 (Multiplication formula of weighted quantum cluster characters).** Let $C$ be a Hom-finite, 2-Calabi-Yau, Krull-Schmidt triangulated category over finite field $k = \mathbb{F}_q$ with a cluster tilting object $T$. For any weighted quantum cluster characters $g_{\epsilon_m} \cdot X_M$ and $g_{\epsilon_n} \cdot X_N$ satisfying $\text{Hom}_C(M, \Sigma N) \neq 0$, we have

\[
|\mathcal{P} Hom\Sigma \mathcal{N}(M, \Sigma N)| (g_{\epsilon_m} \cdot X_M) \cdot (g_{\epsilon_n} \cdot X_N)
\]
\[ \text{dim}_k \operatorname{Hom}_C(M, \Sigma N) = 1 \text{ case.} \]

In this subsection, we always assume
\[ \dim_k \operatorname{Hom}_C(M, \Sigma N) = \dim_k \operatorname{Hom}_C(N, \Sigma M) = 1 \]
and there are non-split triangles
\[
N \to L \to M \xrightarrow{\epsilon} \Sigma N;
\]
\[
M \to L' \to N \xrightarrow{\eta} \Sigma M.
\]

In this case, \( \mathcal{P} \operatorname{Hom}_C(M, \Sigma N) \) and \( \mathcal{P} \operatorname{Hom}_C(N, \Sigma M) \) are both single point sets represented by \( \mathcal{P} \epsilon \) and \( \mathcal{P} \eta \) respectively. Since \( \Sigma p \operatorname{Ker} \alpha_{M_0, N_0} \) and \( \Im \alpha'_{N_0, M_0} \cap \operatorname{Hom}_C(N, \Sigma M) \) are orthogonal mutually in a one-dimensional space, one of \( \dim_k \Sigma p \operatorname{Ker} \alpha_{M_0, N_0} \) and \( \dim_k (\Im \alpha'_N, M_0 \cap \operatorname{Hom}_C(N, \Sigma M)) \) is one and the other is zero.

**Lemma 4.32.** With assumptions above,
\[
(1) \text{ If } (M_0, N_0) \in \Im \psi_{MN, \epsilon}, \ g^+_{ext}(M, N, M_0, N_0) = 0;
\]
\[
(2) \text{ If } (N_0, M_0) \in \Im \psi_{NM, \eta}, \ g^-_{ext}(N, M, N_0, M_0) = 0.
\]

**Proof.** If \((M_0, N_0) \in \Im \psi_{MN, \epsilon}, \epsilon \in \Sigma p \operatorname{Ker} \alpha_{M_0, N_0}. \) Since \( \epsilon \) is nonzero, \( \Sigma p \operatorname{Ker} \alpha_{M_0, N_0} \) is one-dimensional and so
\[ g^+_{ext}(M, N, M_0, N_0) = \dim_k (\Im \alpha'_{N_0, M_0} \cap \operatorname{Hom}_C(N, \Sigma M)) = 0. \]
On the other hand, if \((N_0, M_0) \in \Im \psi_{NM, \eta}, \eta \in \Im \alpha'_N, M_0 \cap \operatorname{Hom}_C(N, \Sigma M). \) Since \( \eta \) is nonzero, similarly we have
\[ g^-_{ext}(N, M, N_0, M_0) = \dim_k \Sigma p \operatorname{Ker} \alpha_{M_0, N_0} = 0. \]

**Corollary 4.33.** With assumptions above, the following are equivalent
\[
(1) \ (M_0, N_0) \in \Im \psi_{MN, \epsilon};
\]
\[
(2) \ (N_0, M_0) \notin \Im \psi_{NM, \eta}.
\]

**Proof.** Both conditions are equivalent to
\[ \dim_k \Sigma p \operatorname{Ker} \alpha_{M_0, N_0} = 1. \]
So in this case, in respective integral domain, $g_{ext}^+$ and $g_{ext}^-$ are zero. The two balanced pairs given in Proposition 4.28 both degenerate to $(0, g_{skew})$.

**Theorem 4.34.** Assume $\dim_k \text{Hom}_C(M, \Sigma N) = 1$ and there are non-split triangles

$$N \to L \to M \overset{\xi}{\to} \Sigma N;$$
$$M \to L' \to N \overset{\eta}{\to} \Sigma M.$$ 

Then we have

$$(g_{\xi M} * X_M) \cdot (g_{\xi N} * X_N)$$

$$= g_{MN} * T(\epsilon, g_{\xi M}, g_{\xi N}) * X_L + g_{skew} * g_{NM} * T(\eta, g_{\xi N}, g_{\xi M}) * X_{L'}.$$ 

5. **Connection on $C_\omega$**

5.1. **Preprojective algebra and nilpotent modules.** Let $k$ be a finite field and $Q = (Q_0, Q_1, s, t)$ be a finite quiver where $Q_0 = \{1, \ldots, n\}$ is vertex set, and for an arrow $\alpha : i \to j$ in $Q_1$, set $s(\alpha) = i, t(\alpha) = j$. We can obtain a new quiver $\tilde{Q}$ from $Q$ by adding a new arrow $\bar{\alpha} : j \to i$ for each arrow $\alpha : i \to j$ in $Q_1$. Define

$$c = \sum_{\alpha \in Q_1} \alpha \bar{\alpha} - \bar{\alpha} \alpha$$

and $\Lambda = k\tilde{Q}/\langle c \rangle$ be the preprojective algebra of $Q$. Let $S_1, \ldots, S_n$ be simple $\Lambda$-modules associated to vertexes $1, \ldots, n$ respectively. An $\Lambda$-module is called nilpotent if it admits a composition series consists of $S_1, \ldots, S_n$ and we denote the category of all nilpotent $\Lambda$-modules by nil$\Lambda$. Let $\hat{I}_1, \ldots, \hat{I}_n$ be injective envelopes of $S_1, \ldots, S_n$ respectively. Given an element $\omega$ in Weyl group, we can define a subcategory $C_{\omega} \subset$ nil$\Lambda$. In following discussion of this section, we fix the element $\omega$ and a reduced expression $i$.

In nil$\Lambda$, there is a classical definition of flag.

**Definition 5.1.** A flag $L_\bullet$ of $L$ in nil$\Lambda$ is a series of submodules

$$0 = L_m \subseteq L_{m-1} \subseteq \cdots \subseteq L_1 \subseteq L_0 = L.$$ 

Moreover, a flag is called of type $(i, a)$ if for $j = 1, \ldots, m$, $L_{j-1}/L_j$ is isomorphic to $S_{i_j}^\otimes a_j$. We denote $\Phi_{i, a, L}$ the set of all flags of $L$ of type $(i, a)$.

Given a flag of $L$, the submodules and natural embedding morphisms provide necessary datum of a chain of monomorphisms. Conversely, given a chain of monomorphisms end with $L$, taking image $\text{Im} \iota_{L,0} \circ \cdots \circ \iota_{L,j}$ provides the $j$-th submodule. Thus we construct two maps between $\mathcal{F}_{i, a, L}^{\text{mono}}$ and $\Phi_{i, a, L}$. One can easily check they are reciprocal. So in nil$\Lambda$, we do not distinguish two concepts.

Geiss, Leclerc and Schröer[16] proved an isomorphism of algebraic varieties from $\Phi_{i, a, L}$ to a certain quiver Grassmannian over complex field $\mathbb{C}$. We claim that the result degenerates to bijection between finite sets on finite field $k$ under some assumptions and sketch some constructions and steps.
Theorem 5.2. [16] For any $L \in \mathcal{C}_\omega$ and $a \in \mathbb{N}^n$, there exists an isomorphism of algebraic varieties

$$FG_{i,a,L} : \Phi_{i,a,L} \rightarrow G_{i,a,L}^F(a)(FL)$$

where $FL = D\text{Hom}_\Lambda(L,V_i) \cong \text{Ext}_\Lambda^1(W_i,L)$.

5.2. Refined socle and top series. In this subsection, we introduce two special flags of each module $L$ which are to some extent minimal and maximal.

Let $L$ be an $\Lambda$-module and $S$ be a simple $\Lambda$-module. Let $\text{soc}_S L$ be the sum of all submodules $U \cong S$ of $L$. If there is no such $U$, $\text{soc}_S L = 0$. Similarly, let $\text{top}_S L = L/V$ where $V$ is the intersection of all submodules $U$ of $L$ such that $L/U \cong S$. If there is no such $U$, $V = L$ and $\text{top}_S L = 0$. Moreover, $\text{top}_S L := V$.

For $i = (i_1, \ldots, i_m)$, there exists a unique chain of submodules

$$0 = L_m \subseteq L_{m-1} \subseteq \cdots \subseteq L_1 \subseteq L_0 \subseteq L$$

such that $L_{j-1}/L_j = \text{soc}_{S_{i_j}} L/L_j$. We define $\text{soc}_i L = L_0$ and

$$L_j^+ = L_{j+1}^+ = L_j.$$ 

Moreover, the chain is denoted by

$$L^+ = (L_0^+ \subseteq \cdots \subseteq L_m^+).$$

In particular, if $\text{soc}_i L = L$, $L^+_i$ is called the refined socle series of type $i$ of $L$.

Similarly, there exists a unique chain of submodules

$$0 \subseteq L_m \subseteq L_{m-1} \subseteq \cdots \subseteq L_1 \subseteq L_0 = L$$

such that $L_{j-1}/L_j = \text{top}_{S_{i_j}} L_{j-1}$. We define $\text{top}_i L = L/L_m$, $\text{rad}_i L = L_m$ and

$$L_j^- = L_{j-1}^- = L_j.$$ 

Moreover, the chain is denoted by

$$L^- = (L_0^- \subseteq \cdots \subseteq L_m^-).$$

In particular, if $\text{rad}_i L = 0$, $L^-_i$ is called the refined top series of type $i$ of $L$.

Lemma 5.3. For any $L \in \mathcal{C}_\omega$ and reduced expression $i$ of $\omega$, the following hold:

1. $\text{soc}_i L = L$;
2. $\text{rad}_i L = 0$.

The following lemma implies that the refined socle series and refined top series are maximal and minimal flags respectively.

Lemma 5.4. For any $L \in \mathcal{C}_\omega$ and any flag $L^+_i = (0 = L_m \subseteq \cdots \subseteq L_0 = L) \in \Phi_{i,a,L}$, we have

$$L_j^- \subseteq L_j \subseteq L_j^+$$

for $j = 0, \ldots, m$. 
5.3. Construction of cluster tilting object. We first introduce some notations about subscript $j$. We assume for each $i \in \{1, \ldots, n\}$, there exists a $j \in \{1, \ldots, m\}$, such that $i = i_j$. For $j \in \{1, \ldots, m\}$ and $i \in \{1, \ldots, n\}$, define
\[
\begin{align*}
    j^- &= \max \{0, 1 \leq s \leq j - 1 | i_s = i_j\} \\
    j^+ &= \min \{j + 1 \leq s \leq m, m + 1 | i_s = i_j\} \\
    j_{\max} &= \max \{1 \leq s \leq r | i_s = i_j\} \\
    j_{\min} &= \min \{1 \leq s \leq r | i_s = i_j\} \\
    j_i &= \max \{1 \leq s \leq m | i_s = i\}
\end{align*}
\]
We define $V_0 = 0$ and $V_j = \soc_{(i_1, \ldots, i_j)} \hat{I}_{ij}$ for $1 \leq j \leq m$. Moreover, let $V_i = V_1 \oplus \cdots \oplus V_m$. For $1 \leq i \leq n$, let $I_{i,i} = V_j$ and $I_i = I_{i,1} \oplus \cdots \oplus I_{i,n}$.

Remark 5.5. The module $V_i$ is a cluster tilting object in $\mathcal{C}_\omega$.

Since nil$\mathcal{A}$ is a Frobenius category, we can consider the stabilization. Let $\mathcal{I}(M, N)$ be the subspace of $\Hom_{\mathcal{A}}(M, N)$ consist of all morphisms factor through objects in $\add I_i$ and define
\[
\overline{\Hom}_{\mathcal{A}}(M, N) = \Hom_{\mathcal{A}}(M, N)/\mathcal{I}(M, N).
\]
Then we have

Proposition 5.6. For any $L \in \mathcal{C}_\omega$ and $1 \leq j \leq m$, we have
\[
D\overline{\Hom}_{\mathcal{A}}(L, V_j) \cong e_i(X_j^+/X_j^-)
\]
where $e_i$ is the primitive idempotent in $\Lambda$ associated to vertex $i$.

5.4. Quiver Grassmannian. Define $E_i = \End_{\mathcal{A}}(V_i)^{\text{op}}$ and $E_i = \End_{\mathcal{A}_i}(V_i)^{\text{op}}$. If $k$ is algebraically closed, $E_i$ is a finite-dimensional basic algebra and the corresponding quiver could be constructed explicitly. However, over finite field, it is not always true. In following discussion of this section, we always assume that over the fixed finite field $k$, $E_i$ is still a finite-dimensional basic algebra and the corresponding quiver could be constructed in the same way.

Define a quiver $Q_1$ as:
- The vertex set is $\{1, \ldots, m\}$.
- For each pair of subscripts $1 \leq k, j \leq m$ satisfying $k^+ \geq j^+ \geq k > j$ and each arrow $\alpha : i_j \to i_k$, there is an arrow $\gamma^{k,j}_\alpha : j \to k$ called ordinary arrow.
- For each $1 \leq j \leq m$, there is an arrow $\gamma_j : j \to j^-$ if $j^- \neq 0$ called horizontal arrow.

Proposition 5.7. There is a quiver isomorphism $Q_1 \to Q_{E_i}$ which maps $j$ to $V_j$.

Moreover, for $L \in \mathcal{C}_\omega$, the $E_i$-module $D\overline{\Hom}_{\mathcal{A}}(L, V_i)$ could be realized as:
- The vector space at vertex $j$ is $D\overline{\Hom}_{\mathcal{A}}(L, V_j) = e_{ij}(L_j^+/L_j^-)$.
- For ordinary arrow $\gamma^{k,j}_\alpha : j \to k$, the linear map is given by
  \[
e_{ij}(L_j^+/L_j^-) \xrightarrow{\alpha} e_{ik}(L_k^+/L_k^-).\]
5.5. Bijection. Let $L \in \mathcal{C}_\omega$, we can define a map

$$d_{i,L} : \mathbb{N}^m \to \mathbb{Z}^m$$

$$(a_1, \ldots, a_m) \mapsto (g_1, \ldots, g_m)$$

where $g_j = (a_j - a_j + (a_j - a_j) + \cdots + (a_j - a_j)$.

Lemma 5.8. The map

$$d_{i,L} : \{a \in \mathbb{N}^n | \Phi_{i,a,L} \neq \emptyset \} \to \{g \in \mathbb{N}^n | \text{Gr}_E^g(FL) \neq \emptyset \}$$

is a bijection.

Then we have

Theorem 5.9. For any $L \in \mathcal{C}_\omega$ and $a \in \mathbb{N}^n$ such that $\Phi_{i,a,L} \neq \emptyset$, there is a bijection between finite sets

$$FG_{i,a,L} : \Phi_{i,a,L} \to \text{Gr}_{d_{i,L}(a)}^i(FL)$$

where $FL = D\text{Hom}_A(L, V_i) \cong \text{Ext}_A^1(W_i, L)$. For given $L_* = (0 = L_m \subseteq \cdots \subseteq L_0 = L) \in \Phi_{i,a,L}$, the image $FG_{i,a,L}(L_*)$ is a submodule of $FL$ which is realized as:

The vector space at vertex $j$ is $e_{ij}(L_j/L_j)$.

For ordinary arrow $\gamma^i_{k,j} : j \to k$, the linear map is given by

$$e_{ij}(L_j/L_j) \xrightarrow{a} e_{ik}(L_k/L_k).$$

For horizontal arrow $\gamma^j_j : j \to j^-$, the linear map is given by

$$e_{ij}(L_j/L_j) \xrightarrow{a} e_{ij}(L_j^-/L_j^-).$$

Theorem gives the relation between flags and Grassmannians. Furthermore, to discover relations between multiplication formulas, we need the following commutative diagram.

Theorem 5.10. Let $M, N, L \in \mathcal{C}_\omega$ where $L = m\epsilon$ for some $[\epsilon] \in \text{Ext}_A^1(M, N)$. The short exact sequence provides a triangle $N \to L \to M \xrightarrow{\epsilon} \Sigma N$ after stabilization which we still denote by $\epsilon$. Then there is a commutative diagram

$$\begin{array}{ccc}
\Phi_{i,a,L} & \xrightarrow{FG_{i,a,L}} & \text{Gr}_{d_{i,L}(a)}^i(FL) \\
\downarrow \phi_{\text{MN},[\epsilon]} & & \downarrow \psi_{\text{MN},[\epsilon]} \\
\prod_{a' + a'' = a} \Phi_{i,a',M} \times \Phi_{i,a'',N} & \xrightarrow{\prod FG_{i,a',M} \times FG_{i,a'',N}} & \prod_{a' + a'' = a} \text{Gr}_{d_{i,L}(a')}^i(FM) \times \text{Gr}_{d_{i,N}(a'')}^i(FN)
\end{array}$$
We should be careful of the coproduct at lower right corner. Notice that \( \text{Im} \psi_{MN, \varepsilon} \) should be contained in \( \coprod_{e,f} \text{Gr}^{\xi_i}_{d_i} \mathcal{M}(FM) \times \text{Gr}^{\xi_i}_{d_i} \mathcal{N}(FN) \) where \( e, f \) runs over all dimension vectors such that corresponding Grassmannians are non-empty. Lemma ensures such coproduct is equivalent to \( \coprod_{a', a''} \text{Gr}^{\xi_i}_{d_i} \mathcal{M}(FM) \times \text{Gr}^{\xi_i}_{d_i} \mathcal{N}(FN) \) where \( a', a'' \) runs over all vectors such that corresponding flag varieties are non-empty. However, according to lower row, the image \( \text{Im} (\coprod FG_{1, a', M} \times FG_{1, a'', N}) \) just runs over all \( a', a'' \) satisfying \( a' + a'' = a \). Latter, we shall show such coproduct is enough.

**Proof.** Fix a flag \( L_\bullet = (0 = L_m \subseteq L_{m-1} \subseteq \cdots \subseteq L_1 \subseteq L_0 = L) \).

By definition of \( FL \), the vector space at vertex \( j \) is \( e_i (L_j^+ / L_j^-) \) and the vector space of \( FG_{1, a, L}(L_\bullet) \) at vertex \( k \) is \( e_j (L_j / L_j^-) \) which is regarded as a subspace through modulo \( L_j^- \) from

\[
L_j^- \subseteq L_j \subseteq L_j^+.
\]

From short exact sequence \( \varepsilon \), we can induce the \( k \)-th level

\[
\varepsilon : \quad 0 \longrightarrow N \xrightarrow{i} L \xrightarrow{p} M \longrightarrow 0
\]

\[
\varepsilon_j : \quad 0 \longrightarrow N_j \xrightarrow{i_j} L_j \xrightarrow{p_j} M_j \longrightarrow 0
\]

We assume \( i \) is the natural embedding, \( i_j \) is the restriction of \( i \) on \( N_j \) and \( p_j \) is realized as

\[
L_j \rightarrow L \xrightarrow{p} M = L/N \supseteq (L_j + N)/N \cong L_j / L_j \cap N = L_j / N_j = M_j.
\]

Furthermore, we consider the refined socle and top series.

\[
\varepsilon : \quad 0 \longrightarrow N \xrightarrow{i} L \xrightarrow{p} M \longrightarrow 0
\]

\[
\varepsilon_j : \quad 0 \longrightarrow N_j \xrightarrow{i_j} L_j \xrightarrow{p_j} M_j \longrightarrow 0
\]

Set \( p_M, p_N \) the projection from \( \coprod_{a', a'' = a} \text{Gr}^{\xi_i}_{d_i} \mathcal{M}(FM) \times \text{Gr}^{\xi_i}_{d_i} \mathcal{N}(FN) \) to first and second components respectively.

We first consider \( p_N \circ \coprod FG_{1, a', M} \times FG_{1, a'', N} \circ \phi_{MN, [\varepsilon]}(L_\bullet) \). The vector space at vertex \( j \) of the image is \( e_j (N_j / N_j^-) \). Since

\[
N_j / N_j^- = N_j / N_j \cap L_j^- = (N_j + L_j^-) / L_j^- \subseteq L_j / L_j^-,
\]
we have
\[ e_{ij}(N_j/N_j^-) = e_{ij}((N_j + L_j^-)/L_j^-) \subseteq e_{ij}(L_j/L_j^-) \]
which is exactly the subspace of $FG_{i,a,L}(L_\bullet)$ at vertex $j$.

Similarly, the vector space of $\coprod FG_{i,a',M} \times FG_{i,a'',N} \circ \phi_{MN,[i]}(L_\bullet)$ at vertex $j$ is $e_{ij}(M_j/M_j^-)$. Since
\[ L_j^-/N_j^- = L_j^-/N_j \cap L_j^-= (L_j^- + N_j)/N_j, \]
we have
\[ M_j/M_j^- = (L_j/N_j)/(L_j^-/N_j^-) \]
\[ = (L_j/N_j)/(L_j^- + N_j)/N_j \]
\[ = L_j/(L_j^- + N_j) \]
\[ = (L_j/L_j^-)/(L_j^- + N_j)/N_j \]
\[ = (L_j/L_j^-)/(N_j/N_j \cap L_j^-) \]
\[ = (L_j/L_j^-)/(N_j^-). \]

So $e_{ij}(M_j/M_j^-) = e_{ij}((L_j/L_j^-)/(N_j/N_j^-))$ is exactly the quotient space of $FG_{i,a,L}(L_\bullet)$ modulo $N_j/N_j^-$ at vertex $j$.

Now we have checked the spaces of images at each vertex $j$ are coincide through two compositions $\coprod FG_{i,a',M} \times FG_{i,a'',N} \circ \phi_{MN,[i]}$ and $\psi_{MN,[i]} \circ FG_{i,a,L}$. Notice that all propositions used here are module homomorphism theorems. So the images are naturally submodules and quotient modules. That is to say, the subspaces and quotients spaces are closed under linear maps corresponding to both ordinary arrows and horizontal arrows. \hfill \Box

**Remark 5.11.** Since the images of $\coprod FG_{i,a',M} \times FG_{i,a'',N} \circ \phi_{MN,[i]}$ and $\psi_{MN,[i]} \circ FG_{i,a,L}$ coincide, so is the dimension vectors. Through $\coprod FG_{i,a',M} \times FG_{i,a'',N} \circ \phi_{MN,[i]}$, we know that any pair of submodules in image of both compositions satisfies $a'+a'' = a$. That is to say, the coproduct $\coprod_{a'+a''=a}$ at lower right corner is enough.

From Theorem 5.10 we have

**Corollary 5.12.** Under the same assumption as Theorem 5.10, for any $(M_\bullet, N_\bullet) \in \coprod_{a'+a''=a} \Phi_{i,a',M} \times \Phi_{i,a'',N}$, the map
\[ FG_{i,a,L} : \phi_{MN,[i]}^{-1}(M_\bullet, N_\bullet) \rightarrow \psi_{MN,[i]}^{-1}(FG_{i,a',M}(M_\bullet), FG_{i,a'',N}(N_\bullet)). \]
is a bijection. In particular,
\[ |\phi_{MN,[i]}^{-1}(M_\bullet, N_\bullet)| = |\psi_{MN,[i]}^{-1}(FG_{i,a',M}(M_\bullet), FG_{i,a'',N}(N_\bullet))| \]

5.6. **Skew-polynomial corresponding to $\delta_L$.** Notice that $C_\omega$ is an abelian category of Ext-symmetry which satisfies conditions in Section 3. So we can introduce $\delta_L$ here which is a linear function. On the other hand, after stabilization, $C_\omega$ is a 2-Calabi-Yau triangulated category. So for object $L$ in $C_\omega$, we can introduce $X_L$
which is a skew-polynomial. To compare these two characters, we should define the skew-polynomial corresponding to \( \delta_L \).

Recall the weighted quantum cluster character \( f_{\epsilon L} \ast \delta_L \) which is defined as a linear function on \( \mathcal{M}_q \)

\[
f_{\epsilon L} \ast \delta_L(d_{i,a}) = \int_{a'+a''=a} \int_{(e_M,e_N)\in\Phi_{M,N,S_L}(F_{i,a,L}([\epsilon_L],[a',a'']))} q^{k(e_M,e_N)} \cdot q^{f_{\epsilon L}(M,N,e_M,e_N)}.
\]

**Definition 5.13.** For fixed \( i \), \( f_{\epsilon L} \ast \Delta_{i,L} \) is a skew-polynomial in \( A_{m,\lambda} \) defined as

\[
f_{\epsilon L} \ast \Delta_{i,L} = \int_a f_{\epsilon L} \ast \delta_L(d_{i,a}) \cdot \chi_p(L,d_{i,L}(a))
\]

Notice that \( A_{m,\lambda} \) is defined in Section \( 4.3 \) and we take the same skew polynomial algebra for \( f_{\epsilon L} \ast \Delta_{i,L} \) as the one where \( g_{\epsilon L} \ast X_L \) located. The skew-polynomial \( f_{\epsilon L} \ast \Delta_{i,L} \) is also called weighted quantum cluster character of \( L \) here.

To state the corresponding multiplication and multiplication formula of \( f_{\epsilon L} \ast \Delta_{i,L} \), we need two specific weight functions.

**Definition 5.14.** For any objects \( M,N \) in \( C_\omega \), define weight function \( f_{MN} \) as

\[
f_{MN}(M, N, M_*, N_*) = \frac{1}{2} \lambda(p(M,d_{i,M}(a'), p(N,d_{i,N}(a''))) - k(M_*, N_*)
\]

for any \( M_* \in \bigcap_{a'} \Phi_{i,a',M}, N_* \in \bigcap_{a'} \Phi_{i,a',N} \) and zero else.

**Definition 5.15.** For any objects \( M,N \) in \( C_\omega \), define weight function \( f_{\text{skew}} \) as

\[
f_{\text{skew}}(M, N, M_*, N_*) = \lambda(p(M,d_{i,M}(a'), p(N,d_{i,N}(a'')))
\]

for any \( M_* \in \bigcap_{a'} \Phi_{i,a',M}, N_* \in \bigcap_{a'} \Phi_{i,a',N} \) and zero else.

Then we have

**Proposition 5.16.** For any objects \( M,N \in C_\omega \) and any weighted quantum cluster characters \( f_{\epsilon M} \ast \Delta_{i,M} \) and \( f_{\epsilon N} \ast \Delta_{i,N} \),

\[
(f_{\epsilon M} \ast \Delta_{i,M}) \cdot (f_{\epsilon N} \ast \Delta_{i,N}) = f_{MN} \ast S(0_{MN}, f_{\epsilon M}, f_{\epsilon N}) \ast \Delta_{i,M_N}
\]

in \( A_{m,\lambda} \).

**Proof.** Direct calculation

\[
(f_{\epsilon M} \ast \Delta_{i,M}) \cdot (f_{\epsilon N} \ast \Delta_{i,N})
\]

\[
= \int_{a'+a''=a} f_{\epsilon M} \ast \delta_M(d_{i,a'}) \cdot f_{\epsilon N} \ast \delta_N(d_{i,a''}) \cdot \chi_p(M,d_{i,M}(a')) \cdot \chi_p(N,d_{i,N}(a''))
\]

\[
= \int_a \int_{a'+a''=a} f_{\epsilon M} \ast \delta_M(d_{i,a'}) \cdot f_{\epsilon N} \ast \delta_N(d_{i,a''}) \cdot q^{\frac{1}{2} \lambda(p(M,d_{i,M}(a'), p(N,d_{i,N}(a'')))}
\]

\[
\cdot \chi_p(M,d_{i,M}(a')) \cdot p(N,d_{i,N}(a''))
\]

\[
= \int_a \int_{a'+a''=a} f_{\epsilon M} \ast \delta_M(d_{i,a'}) \cdot f_{\epsilon N} \ast \delta_N(d_{i,a''}) \cdot q^{\frac{1}{2} \lambda(p(M,d_{i,M}(a'), p(N,d_{i,N}(a'')))}
\]

\[
\cdot \chi_p(M \oplus N,d_{i,M \oplus N}(a')
\]

On the other hand,
\[ f_{MN} \ast S(0_{MN}, f_{\epsilon_M}, f_{\epsilon_N}) \ast \Delta_{1,M} \ast \Delta_N = \int_a f_{MN} \ast S(0_{MN}, f_{\epsilon_M}, f_{\epsilon_N}) \ast \delta_{M} \ast \delta_N (d_1, a) \cdot X^{p(M \ast N, d_1, M \ast N)}(a) \]
\[ = \int_a \int_{a' + a'' = a} \int_{(M, N) \in \Phi_{1,a',M} \times \Phi_{1,a'',N}} q^{k(M, N)} \cdot q^{f_{SM} + f_{N} + f_{MN}} \cdot X^{p(M \ast N, d_1, M \ast N)}(a) \]
\[ = \int_a \int_{a' + a'' = a} \int_{(M, N) \in \Phi_{1,a',M} \times \Phi_{1,a'',N}} q^{f_{SM} + f_{N} + f_{MN}} q^{\frac{1}{2} \lambda(p(M, d_1, M(a')), p(N, d_1, N(a'')))} \cdot X^{p(M \ast N, d_1, M \ast N)}(a). \]

The following can be deduced from definition of \( f_{\epsilon_M} \ast \delta_M \) and \( f_{\epsilon_N} \ast \delta_N. \)

Moreover, we have the multiplication formula with respect to \( f_{\epsilon_L} \ast \Delta_{1,L}. \)

**Theorem 5.17.** For any weighted quantum cluster characters \( f_{\epsilon_M} \ast \Delta_{1,M} \) and \( f_{\epsilon_N} \ast \Delta_{1,N} \) satisfying \( \text{Ext}^1_{\mathcal{C}_\omega}(M, N) \neq 0, \) we have

\[ |\text{PExt}^1_{\mathcal{C}_\omega}(M, N)| (f_{\epsilon_M} \ast \Delta_{1,M}) \cdot (f_{\epsilon_N} \ast \Delta_{1,N}) \]
\[ = \int_{P \in \text{PExt}^1_{\mathcal{C}_\omega}(M, N)} f^{+}_{\epsilon_M} \ast f_{MN} \ast S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) \ast \Delta_{1,m}\text{te} \]
\[ + \int_{P \in \text{PExt}^1_{\mathcal{C}_\omega}(N, M)} f_{skew} \ast f_{NM} \ast S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) \ast \Delta_{1,m\text{te}} \]
\[ = \int_{P \in \text{PExt}^1_{\mathcal{C}_\omega}(M, N)} f^{+}_{MN} \ast S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) \ast \Delta_{1,m\text{te}} \]
\[ + \int_{P \in \text{PExt}^1_{\mathcal{C}_\omega}(N, M)} f^{-}_{\epsilon_N} \ast f_{skew} \ast f_{NM} \ast S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) \ast \Delta_{1,m\text{te}} \]

in \( A_{m,\lambda}. \)

**Proof.** We just prove the first equality. The calculation for the second one is similar.

Recall that
\[ f_{MN}(M, N, M_\bullet, N_\bullet) = \frac{1}{2} \lambda(p(M, d_1, M(a')), p(N, d_1, N(a''))) - k(M_\bullet, N_\bullet); \]
\[ f_{NM}(M, N, N_\bullet, M_\bullet) = \frac{1}{2} \lambda(p(N, d_1, N(a'')), p(M, d_1, M(a'))) - k(N_\bullet, M_\bullet); \]
\[ f_{skew}(N, M, N_\bullet, M_\bullet) = \lambda(p(M, d_1, M(a'), p(N, d_1, N(a''))); \]
\[ f_{hom}(N, M, N_\bullet, M_\bullet) = k(M_\bullet, N_\bullet) - k(N_\bullet, M_\bullet). \]

So we have
\[ f_{skew}(N, M, N_\bullet, M_\bullet) + f_{NM}(N, M, N_\bullet, M_\bullet) \]
\[ = f_{hom}(N, M, N_\bullet, M_\bullet) + f_{MN}(M, N, M_\bullet, N_\bullet). \]
Then we have
\[ |\mathbb{P}\text{Ext}^{1}_{C_{\omega}}(M, N)| (f_{\epsilon_M} \ast \Delta_{i,M}) \cdot (f_{\epsilon_N} \ast \Delta_{i,N}) \]
\[ = |\mathbb{P}\text{Ext}^{1}_{C_{\omega}}(M, N)| f_{MN} \ast S(0_{MN}, f_{\epsilon_M}, f_{\epsilon_N}) \ast \Delta_{i,M \oplus N} \]
\[ = \int_a |\mathbb{P}\text{Ext}^{1}_{C_{\omega}}(M, N)| f_{MN} \ast S(0_{MN}, f_{\epsilon_M}, f_{\epsilon_N}) \ast \delta_{M \oplus N}(d_{i,a}) \cdot X^{p(M \oplus N, d_{i,M \oplus N}(a))} ; \]
and
\[ \int_{P \in \mathbb{P}\text{Ext}^{1}_{C_{\omega}}(M, N)} f_{\text{ext}}^+ \ast f_{MN} \ast S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) \ast \Delta_{i,m\epsilon} \]
\[ = \int \int_{P \in \mathbb{P}\text{Ext}^{1}_{C_{\omega}}(M, N)} f_{\text{ext}}^+ \ast f_{MN} \ast S(\epsilon, f_{\epsilon_M}, f_{\epsilon_N}) \ast \delta_{m\epsilon}(d_{i,a}) \cdot X^{p(m\epsilon,d_{i,m\epsilon}(a))} ; \]
and
\[ \int_{P \in \mathbb{P}\text{Ext}^{1}_{C_{\omega}}(N,M)} f_{\text{skew}} \ast f_{NM} \ast S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) \ast \Delta_{i,m\eta} \]
\[ = \int \int_{P \in \mathbb{P}\text{Ext}^{1}_{C_{\omega}}(N,M)} f_{\text{skew}} \ast f_{NM} \ast S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) \ast \delta_{m\eta}(d_{i,a}) \cdot X^{p(m\eta,d_{i,m\eta}(a))} . \]

Due to support area, we can't rewrite
\[ \int \int_{P \in \mathbb{P}\text{Ext}^{1}_{C_{\omega}}(N,M)} f_{\text{hom}} \ast f_{NM} \ast S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) \ast \delta_{m\eta}(d_{i,a}) \cdot X^{p(m\eta,d_{i,m\eta}(a))} . \]

But in calculation of \( q \)-powers, we can replace \( q^{f_{\text{skew}} \ast S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) \ast f_{NM}} \) by
\[ q^{f_{\text{hom}} \ast S(\eta, f_{\epsilon_N}, f_{\epsilon_M}) \ast f_{NM}} . \]

Then the desired equality is a direct corollary of Theorem \[4.30\].

**Definition 5.18.** We set the \( \mathbb{Q} \)-algebra generated by all weighted quantum cluster characters \( f_{\epsilon_L} \ast \Delta_{i,L} \) where \( L \) runs over \( C_{\omega} \) and \( f_{\epsilon_L} \) runs over \( \mathbb{Z}_{M_F,L} \) by \( A_{\eta}(C_{\omega}) \).

**5.7. Connection between two multiplication formulas.** Now we have introduced multiplication rule and proved multiplication formula for both \( f_{\epsilon_L} \ast \Delta_{i,L} \) and \( g_{\epsilon_L} \ast X_{L} \). At last, we give the relations between weight functions.

We denote both the short exact sequence
\[ 0 \to N \to L \to M \to 0 \]
in \( C_{\omega} \) and the triangle
\[ N \to L \to M \to \Sigma N \]
in \( C_{\omega} \) by \( \epsilon_L \).
Definition 5.19. A pair of weight functions \((f_{\epsilon_L}, g_{\epsilon_L}) \in \mathbb{Z}_{MF, \epsilon_L} \times \mathbb{Z}_{MG, \epsilon_L}\) is called \(i\)-compatible if for any \((M_*, N_*) \in \prod_{a', a''} \Phi_{1,a',M} \times \Phi_{1,a'',N}\),
\[f_{\epsilon_L}(M, N, M_*, N_*) = g_{\epsilon_L}(M, N, FG_{i,a',M}(M_*), FG_{i,a'',N}(N_*))\]
holds.

Notice that by definition, weight functions \(f_{\epsilon_L}\) and \(g_{\epsilon_L}\) in a \(i\)-compatible pair are uniquely determined mutually. Given \(f_{\epsilon_L}\), we denote \(FG_{i}(f_{\epsilon_L})\) the unique weight function such that \((f_{\epsilon_L}, FG(f_{\epsilon_L}))\) is \(i\)-compatible. We set the inverse of \(FG\) by \(GF\).

Moreover, we can extend definition of \(FG\) and \(GF\) to quantum cluster algebras.

Definition 5.20. Define \(FG\) as a map from \(A_{q}\) to \(A_{q}\) by
\[FG(f_{\epsilon_L} \Delta_{i,L}) = FG(f_{\epsilon_L}) \cdots X_L\]
and \(GF\) as a map from \(A_{q}\) to \(A_{q}\) by
\[GF(g_{\epsilon_L} \cdots X_L) = GF(g_{\epsilon_L}) \Delta_{i,L}.\]

Theorem 5.21. The map \(FG\) is an algebraic isomorphism with inverse \(GF\).

Proof. In fact, if we regard \(A_{q}\) and \(A_{q}\) as subalgebras of a fixed \(A_{m, \lambda}\), \(FG\) and \(GF\) are identities. Set
\[FG(f_{\epsilon_L} \Delta_{i,L}) = g_{\epsilon_L} \cdots X_L\]

By definition,
\[f_{\epsilon_L} \cdots \Delta_{i,L} = \int_a f_{\epsilon_L} \cdots \delta_L(d_i,a) \cdots X_p(L, d_i L(a))\]
\[= \int_a \int_{a'+a''=a} \int (M_*, N_* \in \Phi_{M,N, \epsilon}(F_{L}(M_*, N_*))) \cdots q^{k(M_*, N_*)} \cdots q^{f_{\epsilon_L}(M, N, M_*, N_*)} \cdots X_p(L, d_i L(a))\]

and
\[g_{\epsilon_L} \cdots X_L\]
\[= \int_g \int_{e,f} \int (M_0, N_0 \in G_{L}(F_{L}, F_{N}, g)) \cdots q^{l(M, N, M_0, N_0)} \cdots q^{g_{\epsilon_L}(M, N, M_0, N_0)} \cdots X_p(L, g)\]

From Theorem 5.10 and Definition 5.20, \(f_{\epsilon_L} \cdots \Delta_{i,L} = g_{\epsilon_L} \cdots X_L.\) □

6. Special version in hereditary case

In this section, we consider cluster category from hereditary algebra and corresponding multiplication formula.
6.1. Cluster category from hereditary algebra. Let \( n \) be a positive integer and \( A \) be a finite-dimensional hereditary algebra over a finite field \( k \) with a complete set of simple objects \( \{S_1, \ldots, S_n\} \). Let \( \mathcal{A} \) be the category of finite-dimensional (left) \( A \)-modules. Then the cluster category from hereditary algebra is defined as \( \mathcal{C} = \mathcal{C}_A = D^b(\mathcal{A})/\tau^{-1}\Sigma \) where \( D^b(\mathcal{A}) \) is the bounded derived category of \( \mathcal{A} \), \( \tau \) is the Auslander-Reiten functor and \( \Sigma \) is the shifting functor.

Let \( \tilde{B} = (b_{ij}) \) be a \( n \times n \)-matrix where
\[
b_{ij} = \dim_k \text{Ext}^1_A(S_i, S_j) - \dim_k \text{Ext}^1_A(S_j, S_i).
\]
We assume there is skew-symmetric \( n \times n \)-matrix \( \Lambda \) such that
\[
\Lambda(\tilde{B}) = \text{diag}\{d_1, \ldots, d_n\}.
\]
where \( d_j = \dim_k \text{End}(S_j) \).

In following discussion, the bilinear form \( \lambda \) is always given by
\[
\lambda(e, f) = e^T \Lambda f.
\]

As well known, \( \mathcal{C} \) is a 2-Calabi-Yau triangulated category with a cluster tilting object \( T = \Sigma P \), where \( P = \oplus_{j=1}^n P_j \) is the direct sum of all non-isomorphic indecomposable projective modules of \( A \). Moreover, all isoclasses of indecomposable objects in \( \mathcal{C} \) could be represented by
\[
\text{indC} = \text{indA} \cup \{\Sigma P_1, \ldots, \Sigma P_n\}.
\]
where \( \text{indA} \) is the isoclasses of all indecomposable objects in \( \mathcal{A} \). An object \( L \) in \( \mathcal{C} \) is called located in fundamental domain if \( L \in \text{indA} \).

In particular, if \( \dim \text{Hom}_\mathcal{C}(M, \Sigma N) = 1 \) and there are non-split triangles
\[
N \to L \to M \to \Sigma N;
\]
\[
M \to L' \to N \to \Sigma M,
\]
one of \( L \) and \( L' \) is located in fundamental domain and the other is not. In following discussion, we always assume \( L' \) is.

Now we can introduce weighted quantum cluster characters and corresponding multiplication formulas given in Section 4 to cluster category \( \mathcal{C} \) from hereditary algebra here.

6.2. A special weighted quantum cluster character. For any object \( L \) with \( \dim_k FL = l \) in \( \mathcal{C} \) and the trivial triangle
\[
L = L \to 0 \xrightarrow{\sigma_L} \Sigma L
\]
with respect to \( L \), we introduce a special weight function \( g_{\sigma L} \) as

**Definition 6.1.** Define
\[
g_{\sigma L}(0, L, 0, L_0) = -\frac{1}{2} \langle \dim_k L_0, l - \dim_k L_0 \rangle
\]
for any \( L_0 \in \coprod_g \text{GrgFL} \) and zero else.
Moreover, with respect to this weight function, we can define the corresponding weighted quantum cluster character as

**Definition 6.2.**

\[ \tilde{X}_L = g_{\sigma_L} \ast X_L. \]

Notice that, for given dimension vector \( g \) of submodule of \( FL \), the appropriate dimension vectors of \( qt_{\sigma_L} \) and \( st_{\sigma_L} \) are unique and obviously 0 and \( g \). So we can simplify the calculation of \( \tilde{X}_L \) as

\[
\tilde{X}_L = \int g \int (0,g) \int (0,L_0) q^{g_{\sigma_L}} \cdot X^{p(L,g)} \]

**Remark 6.3.** For convenience, the weight function \( g_{\sigma_L} \) is just used for calculation, but not for decision of support area. That is to say, even if \( g_{\epsilon_L} \ast X_L = g_{\epsilon_L} \ast g_{\sigma_L} \ast X_L \), the support area is still decided by \( \epsilon_L \) instead of \( \sigma_L \).

Recall the multiplication of weighted quantum cluster characters, we have the multiplication rule of \( \tilde{X}_L \).

**Lemma 6.4.** For any \( M, N \in \mathcal{C} \),

\[ \tilde{X}_M \cdot \tilde{X}_N = \tilde{g}_{MN} \ast \tilde{X}_{M \oplus N} \]

in \( A_{n,\lambda} \) where \( \tilde{g}_{MN} \in \mathbb{Z}_{MG,0_{MN}} \) is defined as

\[
\tilde{g}_{MN}(M,N,M_0,N_0) = \frac{1}{2} \lambda(p(M,e),p(N,f)) - l(M,N,M_0,N_0) + g_{\sigma_M}(0,M,0,M_0) + g_{\sigma_N}(0,N,0,N_0) - g_{\sigma_{M\oplus N}}(0,M \oplus N,0,M_0 \oplus N_0)
\]

for any \( M_0 \in \bigsqcup_e \text{Gr}_e(FM), N_0 \in \bigsqcup_f \text{Gr}_f(FN) \) and zero else.

**Proof.** We can calculate both sides as

\[
\tilde{X}_M \cdot \tilde{X}_N = \int e |\text{Gr}_e(FM)| \cdot q^{g_{\sigma_M}} \cdot X^{p(M,e)} \cdot \int f |\text{Gr}_f(FN)| \cdot q^{g_{\sigma_N}} \cdot X^{p(N,f)}
\]

\[
= \int e,f |\text{Gr}_e(FM)| \cdot |\text{Gr}_f(FN)| \cdot q^{\frac{1}{2} \lambda(p(M,e),p(N,f)) + g_{\sigma_M} + g_{\sigma_N}} \cdot X^{p(M,e)+p(N,f)}
\]

\[
= \int e,f \int (M_0,N_0) \in \text{Gr}_e(FM) \times \text{Gr}_f(FN) q^{\frac{1}{2} \lambda(p(M,e),p(N,f)) + g_{\sigma_M} + g_{\sigma_N}} \cdot X^{p(M,e)+p(N,f)}
\]
and

\[ \tilde{\chi}_{M \oplus N} = \int g \int e, f \int \psi_{M_N, N_0} \in \text{Gr}_e(FM) \times \text{Gr}_f(FN) \left| \psi_{M_N, N_0}(M_0, N_0) \right| \cdot q^{g_{M \oplus N}} \cdot X^{p(M \oplus N, g)} \]

Then by definition of weighted quantum cluster characters, one can easily check such defined \( \tilde{g}_{MN} \) is the appropriate weight function to satisfy the lemma. \( \square \)

Moreover, if we set \( \dim_k FM = m, \dim_k FN = n \), then

**Lemma 6.5. [20]** With the notations above, we have

\[
\frac{1}{2} \lambda(p(M, e), p(N, f)) + \frac{1}{2} \lambda(\text{ind} M, \text{ind} N) + \frac{1}{2} f m - \frac{1}{2} e n + \frac{1}{2} e f - \frac{1}{2} f e - l(M, N, M_0, N_0).
\]

Up to this lemma, we can simplify the calculation of \( \tilde{g}_{MN} \) as

\[
\tilde{g}_{MN}(M, N, M_0, N_0) = \frac{1}{2} \lambda(p(M, e), p(N, f)) - l(M, N, M_0, N_0)
+ g_{\sigma_M}(0, M, 0, M_0) + g_{\sigma_N}(0, N, 0, N_0) - g_{\sigma_{M \oplus N}}(0, M \oplus N, 0, M_0 \oplus N_0)
= \frac{1}{2} \lambda(\text{ind} M, \text{ind} N) + \frac{1}{2} f m - \frac{1}{2} e n + \frac{1}{2} e f - \frac{1}{2} f e - l(M, N, M_0, N_0)
- \frac{1}{2} e m - \frac{1}{2} f n + \frac{1}{2} e f + m + n - e - f
= \frac{1}{2} \lambda(\text{ind} M, \text{ind} N) + (f, m - e) - l(M, N, M_0, N_0).
\]

### 6.3. Special version of multiplication formula.

Recall that given any balanced pair of weight functions \( (g^+, g^-) \) and weighted quantum cluster characters \( g_{\epsilon M} \cdot X_M, g_{\epsilon N} \cdot X_N \) satisfying \( \text{Hom}_C(M, \Sigma N) \neq 0 \), we have the multiplication formula

\[
|\text{Phom}_C(M, \Sigma N)| (g_{\epsilon M} \cdot X_M) \cdot (g_{\epsilon N} \cdot X_N)
= \int_{F \in \text{Phom}_C(M, \Sigma N)} g^+ \cdot g_{MN} \cdot T(\epsilon, g_{\epsilon M}, g_{\epsilon N}) \cdot X_{\text{mte}}
+ \int_{F \eta \in \text{Phom}_C(N, \Sigma M)} g^- \cdot g_{NM} \cdot T(\eta, g_{\epsilon N}, g_{\epsilon M}) \cdot X_{\text{mte}}.
\]
In particular, we can take $g_{\epsilon M} = g_{\sigma M}, g_{\epsilon N} = g_{\sigma N}$, then we have
\[
|\mathbb{P}\text{Hom}_C(M, \Sigma N)|X_M \cdot X_N
= \int_{\mathbb{P}\text{Hom}_C(M, \Sigma N)} g^+ * g_{MN} * T(\epsilon, g_{\sigma M}, g_{\sigma N}) * X_{\text{mte}}
+ \int_{\mathbb{P}\text{Hom}_C(N, \Sigma M)} g^- * g_{NM} * T(\eta, g_{\sigma N}, g_{\sigma M}) * X_{\text{mte}}.
\]

To rewrite the right hand side into tilde version, we need extend $\tilde{g}_{MN}$ to non-split case.

**Definition 6.6.** Given $M, N \in \mathcal{C}$ and $\epsilon \in \text{Hom}_C(M, \Sigma N)$ with $\text{mte} = L$, define $\tilde{g}_{MN, \epsilon} \in \mathbb{Z}_{MG, \epsilon}$ as
\[
\tilde{g}_{MN, \epsilon}(M, N, M_0, N_0) = \frac{1}{2} \lambda(p(M, \epsilon), p(N, f)) - l(M, N, M_0, N_0)
+ g_{\sigma M}(0, M, 0, M_0) + g_{\sigma N}(0, N, 0, N_0)
- g_{\sigma L}(0, L, 0, L_0)
\]
for $(M_0, N_0) \in \text{Im} \psi_{MN, \epsilon}$ where $L_0$ satisfies $\psi_{MN}(\epsilon, L_0) = (M_0, N_0)$ and zero else.

**Remark 6.7.**
(1) Although the submodule $L_0$ satisfying $\psi_{MN}(\epsilon, L_0) = (M_0, N_0)$ is not unique, according to Corollary 4.5, the dimension vector of $L_0$ is. So $\tilde{g}_{MN, \epsilon}$ is well-defined.

(2) By definition, $\tilde{g}_{MN,0_{MN}} = \tilde{g}_{MN}$.

(3) If the triangle induced by $\epsilon$ is mapped to a short exact sequence
\[0 \to FN \to FL \to FM \to 0\]
by $F$, then for any $(M_0, N_0) \in \text{Im} \psi_{MN, \epsilon}$,
\[\tilde{g}_{MN, \epsilon}(M, N, M_0, N_0) = \tilde{g}_{MN}(M, N, M_0, N_0).
\]

Then we have

**Lemma 6.8.** For any balanced pair $(g^+, g^-)$ and morphisms $\epsilon \in \text{Hom}_C(M, \Sigma N), \eta \in \text{Hom}_C(N, \Sigma M)$ with $\text{mte} = L, \text{mt}\eta = L'$,
\[
g^+ * g_{MN} * T(\epsilon, g_{\sigma M}, g_{\sigma N}) * X_L = g^+ * \tilde{g}_{MN, \epsilon} * \tilde{X}_L,
\]
\[
g^- * g_{NM} * T(\eta, g_{\sigma N}, g_{\sigma M}) * X_{L'} = g^- * \tilde{g}_{NM, \eta} * \tilde{X}_{L'}
\]
hold.

**Proof.** We just prove the first equality. By definition, the right hand side is equal to $g^+ * \tilde{g}_{MN, \epsilon} * g_{\sigma L} * X_L$. We just need to compare the values both weight functions take
at any \((M, N, M_0, N_0)\) satisfying \((M_0, N_0) \in \text{Im} \psi_{MN, \epsilon}\).

\[
g^+ * g_{MN} * T(\epsilon, g_{\sigma_M}, g_{\sigma_N})(M, N, M_0, N_0) = g^+(M, N, M_0, N_0) + g_{\sigma_M}(0, M, 0, M_0) + g_{\sigma_N}(0, N, 0, N_0) + \frac{1}{2}(p(M, e), p(N, f)) - l(M, N, M_0, N_0).
\]

On the other hand,

\[
g^+ * \tilde{g}_{MN, \epsilon} * g_{\sigma_L}(M, N, M_0, N_0) = g^+(M, N, M_0, N_0) + \frac{1}{2}\lambda(p(M, e), p(N, f)) - l(M, N, M_0, N_0) + g_{\sigma_M}(0, M, 0, M_0) + g_{\sigma_N}(0, N, 0, N_0).
\]

Recall the definition of weighted quantum cluster character

\[
g_{\epsilon} * X_L = \int \int g \int_{(M_0, N_0)} q^{\lambda(M, N, M_0, N_0)} \cdot q^{g_{\epsilon_L}(M, N, M_0, N_0)} \cdot X_{p(L, g)}
\]

Since \(\text{Im} \psi_{MN, \epsilon} = \bigcup g \bigcup e, f \text{Gr}_{e, f}(FM, FN, g)\), the weight functions

\[
g^+ * g_{MN} * T(\epsilon, g_{\sigma_M}, g_{\sigma_N}), g^+ * \tilde{g}_{MN, \epsilon} * g_{\sigma_L}
\]

are the same on whole integral domain. So hence the weighted quantum cluster characters.

Then we can rewrite the multiplication formula into the special tilde version.

**Theorem 6.9.** Given a balanced pair of weight functions \((g^+, g^-)\) and two objects \(M, N \in \mathcal{C}\) satisfying \(\text{Hom}_\mathcal{C}(M, \Sigma N) \neq 0\), we have

\[
|\mathcal{P}\text{Hom}_\mathcal{C}(M, \Sigma N)| \tilde{X}_M \cdot \tilde{X}_N
\]

\[
= \int_{\mathcal{P} \text{Hom}_\mathcal{C}(M, \Sigma N)} g^+ * \tilde{g}_{MN, \epsilon} * \tilde{X}_{\mu \tau} + \int_{\mathcal{P} \eta \text{Hom}_\mathcal{C}(N, \Sigma M)} g^- * \tilde{g}_{NM, \eta} * \tilde{X}_{\mu \eta}.
\]

Recall that Proposition 4.28 provides two pointwise balanced pairs of weight functions.
Corollary 6.10. Given two objects $M, N$ in $\mathcal{C}$ satisfying $\text{Hom}_\mathcal{C}(M, \Sigma N) \neq 0$, we have

$$|\mathbb{P}\text{Hom}_\mathcal{C}(M, \Sigma N)| \tilde{X}_M \ast \tilde{X}_N$$

$$= \int_{\mathbb{P} \in \mathbb{P}\text{Hom}_\mathcal{C}(M, \Sigma N)} g^+_{\text{ext}} \ast \tilde{g}_{MN, \epsilon} \ast \tilde{X}_{M^\ast \eta} + \int_{\mathbb{P} \in \mathbb{P}\text{Hom}_\mathcal{C}(N, \Sigma M)} g_{\text{skew}} \ast \tilde{g}_{NM, \eta} \ast \tilde{X}_{M^\ast \eta}$$

$$= \int_{\mathbb{P} \in \mathbb{P}\text{Hom}_\mathcal{C}(M, \Sigma N)} \tilde{g}_{MN, \epsilon} \ast \tilde{X}_{M^\ast \eta} + \int_{\mathbb{P} \in \mathbb{P}\text{Hom}_\mathcal{C}(N, \Sigma M)} g^+_{\text{ext}} \ast g_{\text{skew}} \ast \tilde{g}_{NM, \eta} \ast \tilde{X}_{M^\ast \eta}.$$

Remark 6.11. When this work is closed to finish, we know there is a similar result given by Chen, Ding and Zhang [9] in hereditary category, exact relation between these two results will be discovered in near future.

In particular, if $\dim_k \text{Hom}_\mathcal{C}(M, \Sigma N) = 1$, both pairs degenerate to $(0, g_{\text{skew}})$. So we have

Theorem 6.12. Given two objects $M, N \in \mathcal{C}$ with $\dim_k \text{Hom}_\mathcal{C}(M, \Sigma N) = 1$ and two non-split triangles in $\mathcal{C}$ as

$$N \rightarrow L \rightarrow M \xrightarrow{\epsilon} \Sigma N$$

$$M \rightarrow L' \rightarrow N \xrightarrow{\eta} \Sigma M$$

then we have

$$\tilde{X}_M \cdot \tilde{X}_N = \tilde{g}_{MN, \epsilon} \ast \tilde{X}_L + g_{\text{skew}} \ast \tilde{g}_{NM, \eta} \ast \tilde{X}_{L'}$$

6.4. Recalculation and simplification. Theorem 6.12 is a special version of Theorem 4.34 which was proved generally in Section 4.10. But in this subsection, we calculate the right hand side again to show a more simple expression.

In this subsection, we always assume $M, N$ are two indecomposable coefficient-free rigid objects with $\dim_k \text{Hom}_\mathcal{C}(M, \Sigma N) = 1$ and there are two non-split triangles in $\mathcal{C}$ as

$$N \rightarrow L \rightarrow M \xrightarrow{\epsilon} \Sigma N$$

$$M \rightarrow L' \rightarrow N \xrightarrow{\eta} \Sigma M$$

where $L'$ is located in fundamental domain.

By definition of weighted quantum cluster characters and Lemma 6.5:

$$\tilde{g}_{MN, \epsilon} \ast \tilde{X}_L$$

$$= \int g \cdot e, f \int (M_0, N_0) \in \text{Gr}^e_{\epsilon, f}(FM, FN, g) q^{\frac{1}{2}(\lambda(p(M, e), p(N, f)) + g_{\sigma M} + g_{\sigma N})} \cdot X^{p(L, g)}$$

$$= \int g \cdot e, f \int (M_0, N_0) \in \text{Gr}^e_{\epsilon, f}(FM, FN, g) q^{\frac{1}{2}(\lambda(\text{ind } M, \text{ind } N) + (f, m - e) + g_{\sigma M \oplus N})} \cdot X^{p(L, g)}.$$
On the other hand,
\[ g_{\text{skew}} * \tilde{g}_{NM, \eta} * \tilde{X}_{L'} = \int_g \int_{f,e} \int_{(N_0, M_0) \in \text{Gr}_{f,e}^\eta(FN,FM,g)} q^{\frac{1}{2} \lambda(p(M,e),p(N,f)) + g_{\sigma M} + g_{\sigma N}} \cdot \chi^{p(L',g)} \]
\[ = \int_g \int_{f,e} \int_{(N_0, M_0) \in \text{Gr}_{f,e}^\eta(FN,FM,g)} q^{\frac{1}{2} \lambda(\text{ind} M, \text{ind} N) + (f,m-e) + g_{\sigma M \oplus M}} \cdot \chi^{p(L',g)}. \]

Remark 6.13. One can check the left hand side in Theorem 6.12 is
\[ \tilde{X}_M \cdot \tilde{X}_N \]
\[ = \int_{e,f} \int_{(M_0, N_0) \in \text{Gr}_e FM \times \text{Gr}_f FN} q^{\frac{1}{2} \lambda(p(M,e),p(N,f)) + g_{\sigma M} + g_{\sigma N}} \cdot \chi^{p(M,e) + p(N,f)} \]
\[ = \int_{e,f} \int_{(M_0, N_0) \in \text{Gr}_e FM \times \text{Gr}_f FN} q^{\frac{1}{2} \lambda(\text{ind} M, \text{ind} N) + (f,m-e) + g_{\sigma M \oplus M}} \cdot \chi^{p(M,e) + p(N,f)}. \]

Notice that in \( \dim_k \text{Hom}_C(M, \Sigma N) = 1 \) case, \( \text{Gr}_{e,f}^\epsilon(FM, FN, g) \) is complementary to \( \text{Gr}_{f,e}^\eta(FN, FM, g) \). That is to say,
\[ \text{Gr}_e FM \times \text{Gr}_f FN = \bigsqcup_g (\text{Gr}_{e,f}^\epsilon(FM, FN, g) \cup \text{Gr}_{f,e}^\eta(FN, FM, g)). \]

So this calculation also gives a direct proof of Theorem 6.12.

Now we focus on
\[ g_{\text{skew}} * \tilde{g}_{NM, \eta} * \tilde{X}_{L'} \]
\[ = \int_g \int_{f,e} \int_{(N_0, M_0) \in \text{Gr}_{f,e}^\eta(FN,FM,g)} q^{\frac{1}{2} \lambda(\text{ind} M, \text{ind} N) + (f,m-e) + g_{\sigma N \oplus M}} \cdot \chi^{p(L',g)}. \]

Recall the assumption that \( L' \) is located in fundamental domain, so
\[ 0 \to FM \to FL' \to FN \to 0 \]
is a short exact sequence.

Lemma 6.14. With the assumptions above, if \( \psi_{NM}(\eta, L'_0) = (N_0, M_0) \) which are given as

\[
\begin{array}{c|cc}
& FM/M_0 & FN/N_0 \\
\hline
p_M & \uparrow & p_N \\
\hline
\epsilon & FM & \longrightarrow & FL' & \longrightarrow & FN \\
i_M & \\
\hline
\epsilon_0 & M_0 & \longrightarrow & L'_0 & \longrightarrow & N_0 \\
i_N & 
\end{array}
\]

then \( \dim_k \text{Ext}^1_{A}(N_0, FM/M_0) = 0. \)
Proof. Notice that $A$ is hereditary, so $\Ext^2_A(-,-) = 0$.

Applying $\Hom_A(N_0,-)$ on

$$0 \to M_0 \to FM \to FM/M_0 \to 0,$$

we get

$$\Ext^1_A(N_0, M_0) \xrightarrow{\Ext^1_A(N_0,M_0)} \Ext^1_A(N_0,FM) \xrightarrow{\Ext^1_A(\iota_M,FM)} \Ext^1_A(N_0,FM/M_0) \to 0.$$

Similarly, applying $\Hom_A(-,FM)$ on

$$0 \to N_0 \to FN \to FN/N_0 \to 0,$$

we get

$$\Ext^1_A(FN/N_0,FM) \xrightarrow{\Ext^1_A(FN,N_0,FM)} \Ext^1_A(N_0,FM) \to 0.$$

Since $\dim_k \Ext^1_A(FN,FM) = 1$, $\dim_k \Ext^1_A(N_0,FM/M_0)$ is at most one. Assume $\dim_k \Ext^1_A(N_0,FM/M_0) = 1$, then $\dim_k \Ext^1_A(N_0,FM) = 1$, $\Ext^1_A(N_0,i_M)$ is zero map and $\Ext^1(i_M,FM)$ is linear isomorphism between one dimensional spaces. However, by construction of $\alpha'_{N_0,M_0}$, such commutative diagram implies that $\Ext^1_A(N_0,i_M) (\epsilon_0)$ and $\Ext^1_A(i_M,FM) (\epsilon)$ should coincide where $\epsilon$ is by assumption nonzero. This is a contradiction. \qed

Recall Remark 6.7 for short exact sequence

$$0 \to FM \to FL' \to FN \to 0$$

and $(N_0, M_0) \in \text{Im} \psi_{N,M,N}$, we have

$$g_{\sigma_{N \oplus M}}(N,M,N_0,M_0) = g_{\sigma_{L'}}(N,M,N_0,M_0).$$

Finally we can simplify the calculation of $g_{skew} \cdot \tilde{g}_{NM,\eta} \cdot \tilde{X}_{L'}$.

Lemma 6.15. We have

$$g_{skew} \cdot \tilde{g}_{NM,\eta} \cdot \tilde{X}_{L'} = q^{\frac{1}{2}(\text{ind}_M, \text{ind}_N)} \cdot \tilde{X}_{L'}.$$

Proof. Direct calculation,

$$g_{skew} \cdot \tilde{g}_{NM,\eta} \cdot \tilde{X}_{L'}$$

$$= \int_g \int_{f,e} \int_{(N_0,M_0) \in \text{Gr}_{f,e}^p(FN,FM,g)} q^{\frac{1}{2}(\text{ind}_M, \text{ind}_N) + (f,m-c) + g_{N \oplus M}} \cdot X_{p(L',g)}$$

$$= \int_g \int_{f,e} \int_{(N_0,M_0) \in \text{Gr}_{f,e}^p(FN,FM,g)} q^{\frac{1}{2}(\text{ind}_M, \text{ind}_N) + g_{L',\eta}} \cdot X_{p(L',g)}$$

$$= q^{\frac{1}{2}(\text{ind}_M, \text{ind}_N)} \cdot g_{X_{L'}} = q^{\frac{1}{2}(\text{ind}_M, \text{ind}_N)} \cdot \tilde{X}_{L'}.$$
Notice that in final expression, the $q$–power is independent of specific choice of submodules, but a constant just depending on product items $M$ and $N$.

Then we analyze

$$
\tilde{g}_{MN,\epsilon} \ast \tilde{X}_L = \int g \int e,f \int (M_0,N_0) \in \text{Gr}^*_{\epsilon,f}(FM, FN, g) \int \frac{1}{2}(\text{ind} M, \text{ind} N) + (f, m - \epsilon) + \sigma_{M \oplus N} . X^{p(L, g)}
$$

where $N \to L \to M \xrightarrow{F_\epsilon} \Sigma N$ is not located in fundamental domain. In this case, there is a explicit construction of $FL$ given as

$$
FN \xrightarrow{F_i} W \oplus V \xrightarrow{F_p} FM \xrightarrow{F_\epsilon} F\Sigma N
$$

where

$$
U = \text{Im} F_\epsilon
$$

$$
0 \to V \to FM \xrightarrow{F_\epsilon} U \to 0
$$

$$
0 \to U \to F\Sigma N \to \tau W' \oplus I \to 0
$$

$$
W = W' \oplus P
$$

$$
FL = W \oplus V.
$$

Based on $FN \to FL \to FM \xrightarrow{F_\epsilon} F\Sigma N$, we can complete the long exact sequence as

$$
\begin{array}{cccc}
0 & 0 & 0 & 0 \\
\uparrow & \uparrow & \uparrow & \uparrow \\
FN/N_0 & FL/L_0 & FM/M_0 & \text{Coker} Fp \\
\uparrow & \uparrow & \uparrow & \uparrow \\
FN & FL & FM & F\Sigma N \\
\uparrow & \uparrow & \uparrow & \uparrow \\
\text{Ker} F_i & N_0 & L_0 & M_0 \\
\uparrow & \uparrow & \uparrow & \uparrow \\
0 & 0 & 0 & 0
\end{array}
$$

By construction $FL = W \oplus V$, we can also complete the short exact sequence $0 \to V \to W \oplus V \to W \to 0$ as
where notations in brackets represent dimension vectors of corresponding objects. Moreover, we can construct a correspondence

\[
\phi : \prod_{g} \prod_{k,j} \text{Gr}_{k,j}^{0w}(W, V, g) \to \prod_{g} \prod_{e,f} \text{Gr}_{e,f}^{e,f}(FM, FN, g)
\]

\[(K, J) \mapsto (M_0, N_0)\]

between two diagrams.

Considering \(J\) as a submodule of \(V\), we have commutative diagram.

\[
\begin{array}{c}
0 \quad 0 \\
\downarrow & \downarrow \\
J = \quad J \\
\downarrow & \downarrow \\
0 \quad \to \quad V \quad \to \quad FM \quad \longrightarrow \quad U \\
\downarrow & \downarrow & \quad \parallel \\
0 \quad \to \quad V/J \quad \to \quad FM/J \quad \longrightarrow \quad U \\
\downarrow & \downarrow & \downarrow \\
0 & 0 & 0
\end{array}
\]

On the other hand, given submodule \(K\) of \(W\), we may deduce an injection \(\tau K \to \tau W' \oplus I\) by taking \(\tau\) and a commutative diagram.
where $\tau N_0$ is given by pullback, so is unique up to isomorphism. As known, the composition of morphisms
\[ FM \longrightarrow U \longrightarrow F\Sigma N \]
is exactly $F\epsilon$. So we define the composition of morphisms
\[ FM/J \longrightarrow U \longrightarrow \tau N_0 \]
as $\bar{F}\epsilon$ where $\bar{F}\epsilon(\bar{m}) = F\epsilon(m)$.

**Lemma 6.16.** $F\epsilon$ is well-defined and there is a commutative diagram.

\[ \begin{array}{ccc}
J & \longrightarrow & J \\
\downarrow & & \downarrow \\
0 & \longrightarrow & V \longrightarrow FM \text{ } F\epsilon \text{ } F\Sigma N \longrightarrow \tau W' \oplus I \longrightarrow 0 \\
\downarrow & & \downarrow & & \uparrow \\
0 & \longrightarrow & V/J \longrightarrow FM/J \text{ } F\epsilon \text{ } \tau N_0 \longrightarrow \tau K \longrightarrow 0 \\
\uparrow & & \uparrow & & \uparrow \\
0 & = & 0 & = & 0
\end{array} \]

**Proof.** Since $J \subseteq V = \text{Ker } F\epsilon$, $F\epsilon(J) = 0$ and $\bar{F}\epsilon(FM/J) = F\epsilon(FM) = U \subseteq \tau N_0$. So $\bar{F}\epsilon$ is well-defined and
\[ \begin{array}{ccc}
FM & \xrightarrow{F\epsilon} & F\Sigma N \\
\downarrow & & \uparrow \\
FM/J & \xrightarrow{\bar{F}\epsilon} & \tau N_0
\end{array} \]
commutes. Moreover,
\[ \text{Ker } \bar{F}\epsilon = \text{Ker } F\epsilon/J = V/J; \]
\[ \text{Im } \bar{F}\epsilon = \text{Im } F\epsilon = U. \]
So the second row is long exact sequence. $\square$
Then given \((K, J) \in \coprod_g \coprod_{k,j} \text{Gr}^{\partial W V}_{k,j}(W, V, g)\), we can define
\[
\phi(K, J) = (M_0, N_0) \in \coprod_g \coprod_{e,f} \text{Gr}^e \text{Gr}_e,f(FM, FN, g)
\]
where \(M_0 = J\) and \(N_0\) is determined by \(\tau N_0\) in the second row.

**Lemma 6.17.** Such defined
\[
\phi : \coprod_g \coprod_{k,j} \text{Gr}^{\partial W V}_{k,j}(W, V, g) \rightarrow \coprod_g \coprod_{e,f} \text{Gr}^e \text{Gr}_e,f(FM, FN, g)
\]
\((K, J) \mapsto (M_0, N_0)\)
is a bijection.

**Proof.** First consider surjectivity. Given any \((M_0, N_0)\), since
\[
\begin{align*}
FM & \xrightarrow{F\epsilon} F\Sigma N \\
M_0 & \rightarrow 0
\end{align*}
\]
\(M_0 \subseteq \text{Ker} F\epsilon = V\). So any \(M_0\) could be realized by submodule \(J = M_0\) of \(V\). To realize \(N_0\), we should consider
\[
\begin{array}{ccccccc}
FN/N_0 & FM/M_0 & \rightarrow & \tau N_0 \\
\uparrow & & \uparrow & \downarrow \tau i_N \\
FN & FL & \rightarrow & FM & \rightarrow & F\Sigma N \\
\uparrow i_N & \uparrow & \uparrow & \uparrow & \\
N_0 & \rightarrow L_0 & \rightarrow & M_0
\end{array}
\]
Notice that there is an isomorphism
\[
D\text{Hom}_A(FM/M_0, \tau N_0) \cong \text{Ext}^1_A(N_0, FM/M_0)
\]
which could be realized in this commutative diagram as:
Given \(f \in \text{Hom}_A(FM/M_0, \tau N_0)\), the composition
\[
FM \xrightarrow{p_M} FM/M_0 \xrightarrow{f} \tau N_0 \xrightarrow{\tau i_N} F\Sigma N
\]
is exactly the image \(F\circ \text{Ext}^1_A(p_M, FN)\circ \text{Ext}^1_A(FM, i_N)(\epsilon_0) \in \text{Ext}^1_A(FM, FN)\) where \(\epsilon_0 \in \text{Ext}^1_A(N_0, FM/M_0)\) is dual to \(f\).
In particular, with given \(F\epsilon\) and \(N_0\),
\[
\text{Im}(f \circ p_M) = \text{Im} F\epsilon = U \subseteq \tau N_0.
\]
So taking cokernal \(\tau K\) of \(U \rightarrow \tau N_0\) gives the \(K\) which satisfies \(\phi(K, M_0) = (M_0, N_0)\).
That is to say, \(\phi\) is surjective.
Then consider injectivity. Given \((M_0, N_0)\), the preimage \(\phi^{-1}(M_0, N_0)\) admits a unique \(J = M_0\). Moreover, the cokernal \(U \rightarrow \tau N_0\) is also unique up to isomorphism, so \(K\) is uniquely determined by \(\tau K\).

Based on bijection \(\phi\) between objects, we then discuss dimension vector.

**Lemma 6.18.** The bijection \(\phi\) could be reduced to dimension vector and

\[
\phi(k, j) = (j, n - (w - k)).
\]

**Proof.** Given \((K, J)\) with dimension vector \((k, j)\). Obviously, \(\dim_k M_0 = \dim_k J = j\). On the other hand, considering the commutative diagram

\[
0 \longrightarrow U \longrightarrow F\Sigma N \longrightarrow \tau W' \oplus I \longrightarrow 0
\]

\[
0 \longrightarrow U \longrightarrow \tau N_0 \longrightarrow \tau K \longrightarrow 0
\]

Since both rows are short exact sequences, we can compute dimension vector after taking \(\tau^{-1}\) as

\[
\dim_k N_0 = \dim_k FN + \dim_k K - \dim_k W = n - (w - k).
\]

To complete the final calculation, we also need an identity given in [20] as

**Lemma 6.19.** [20] With notations above, we have

\[
\langle n - (w - k), m - j \rangle - \frac{1}{2}\langle e + f, m + n - e - f \rangle
\]

\[
= \langle k, v - j \rangle - \frac{1}{2}\langle j + k, w + v - j - k \rangle - \frac{1}{2}.
\]

**Remark 6.20.** Recall the definitions of \(g_{\sigma M \oplus N}\) and \(g_{\sigma L}\), we can rewrite the identity as

\[
\langle n - (w - k), m - j \rangle + g_{\sigma M \oplus N}(0, FM \oplus FN, 0, M_0 \oplus N_0)
\]

\[
= \langle k, v - j \rangle + g_{\sigma L}(0, FL, 0, L_0) - \frac{1}{2}.
\]

Finally we can simplify the calculation of \(\tilde{g}_{MN, \epsilon} \ast \tilde{X}_L\).

**Lemma 6.21.** We have

\[
\tilde{g}_{MN, \epsilon} \ast \tilde{X}_L = q^\frac{1}{2}(\ind M, \ind N) - \frac{1}{2} \cdot \tilde{X}_L.
\]
Proof. Direct calculation,
\[
\tilde{g}_{MN, \varepsilon} \ast \tilde{X}_L = q^{\binom{1}{2} \lambda_{\text{ind } M, \text{ind } N} + \langle f, m - e \rangle + g_{\sigma M \oplus N} \cdot X^{p(L,g)}}
\]
\[
= q^{\binom{1}{2} \lambda_{\text{ind } M, \text{ind } N}} \cdot \int_{g} \int_{e, f} \int_{(M_0, N_0) \in \text{Gr}_{e,f}(FM, FN, g)} q^{\langle f, m - e \rangle + g_{\sigma M \oplus N} \cdot X^{p(L,g)}}
\]
\[
= q^{\binom{1}{2} \lambda_{\text{ind } M, \text{ind } N}} \cdot \int_{g} \int_{j} \int_{(K, J) \in \text{Gr}_{k,j}^0(W, V)} q^{\langle n - (w - k), m - j \rangle + g_{\sigma L} \cdot X^{p(L,g)}}
\]
Now we focus on the exponent \(\langle k, v - j \rangle\) of \(q\) in integral. Since \(M, N\) are rigid, \(W \oplus V \oplus \Sigma^{-1} I\) is also rigid. Notice that \(0 \to V \to W \oplus V \to W \to 0\) is a split short exact sequence here. So in this case, we also have
\[
\dim_k \text{Ext}^1_A(K, V/J) = 0
\]
for any \((K, J) \in \text{Gr}_k W \times \text{Gr}_j V\) and hence
\[
\langle k, v - j \rangle = \dim_k \text{Hom}_A(K, V/J).
\]
On the other hand, we can consider the vector bundle
\[
\coprod_g \text{Gr}_g FL \to \coprod_{k,j} \text{Gr}_k W \times \text{Gr}_j V
\]
induced by split case and \(\dim_k \text{Hom}_A(K, V/J)\) is exactly the dimension of fiber at \((K, J)\). So we have
\[
\tilde{g}_{MN, \varepsilon} \ast \tilde{X}_L = q^{\binom{1}{2} \lambda_{\text{ind } M, \text{ind } N} - \binom{1}{2} \lambda_{\text{ind } M, \text{ind } N} - \binom{1}{2} \int_{L_0 \in \text{Gr}_g FL} q^{g_{\sigma L} \cdot X^{p(L,g)}}}
\]
\[
= q^{\binom{1}{2} \lambda_{\text{ind } M, \text{ind } N} - \binom{1}{2} \int_{L_0 \in \text{Gr}_g FL} q^{g_{\sigma L} \cdot X^{p(L,g)}}}
\]
\[
= q^{\binom{1}{2} \lambda_{\text{ind } M, \text{ind } N} - \binom{1}{2} \int_{\text{Gr}_g FL} q^{\langle g, j-g \rangle \cdot X^{p(L,g)}}}
\]
\[
= q^{\binom{1}{2} \lambda_{\text{ind } M, \text{ind } N} - \binom{1}{2} \cdot \tilde{X}_L.
\]
Combining Theorem 6.12, Lemma 6.15 and Lemma 6.21, we have

**Theorem 6.22.** In cluster category $\mathcal{C} = \mathcal{D}^b(A)/\tau^{-1}\Sigma$ from hereditary algebra $A$, given two indecomposable coefficient-free rigid objects $M, N$ with $\dim_k \text{Hom}_\mathcal{C}(M, \Sigma N) = 1$ and two non-split triangles in $\mathcal{C}$ as

$$N \to L \to M \xrightarrow{\delta} \Sigma N$$
$$M \to L' \to N \xrightarrow{\eta} \Sigma M$$

where $L'$ is located in fundamental domain, then we have

$$\tilde{X}_M \cdot \tilde{X}_N = q^{\frac{1}{2}(\text{ind} M, \text{ind} N) - \frac{1}{2}} \cdot \tilde{X}_L + q^{\frac{1}{2}(\text{ind} M, \text{ind} N)} \cdot \tilde{X}_{L'}.$$
