On perturbations of Ising models

Shunsuke Usuki

Abstract
We prove that, for \( d \geq 2 \), the uniqueness of the equilibrium state of \( d \)-dimensional Ising models for sufficiently high temperature persists under small perturbations of the interaction and the non-uniqueness for sufficiently low temperature also persists under small perturbations of interactions preserving symmetricity.

1 Introduction
We consider a \( \mathbb{Z}^d \) symbolic dynamical system \( \Omega = \mathbb{F}^{\mathbb{Z}^d} \) with a finite symbol set \( \mathbb{F} \). \( \Omega \) is a compact metrizable space with respect to the product topology. For each \( a \in \mathbb{Z}^d \) and \( S \subset \mathbb{Z}^d \), the translation on \( \Omega \) by \( a \) is a map \( \tau^a : \Omega \to \Omega_{S-a} \) defined by
\[
(\tau^a \xi)(x) = \xi(x + a), \quad x \in S - a.
\]
These define the \( \mathbb{Z}^d \)-action on \( \Omega \). An interaction on \( \Omega \) is \( \Phi = \{ \Phi_\Lambda \}_{\Lambda \subset \mathbb{Z}^d : \text{finite}} \), where \( \Phi_\Lambda \) is a real valued function on \( \Omega_\Lambda \). Then \( \Phi \) defines a potential on \( \Omega \) and \( \Omega \) is interpreted as the configuration space. In this paper, we always assume that an interaction \( \Phi \) is translation invariant, that is, for any \( a \in \mathbb{Z}^d \) and finite \( \Lambda \subset \mathbb{Z}^d \),
\[
\Phi_\Lambda(\xi) = \Phi_{\Lambda-a}(\tau^a \xi).
\]
For such an interaction \( \Phi \), we consider the norm of \( \Phi \) defined by
\[
\| \Phi \| = \sum_{0 \in \Lambda \subset \mathbb{Z}^d : \text{finite}} \sup_{\xi \in \Omega_\Lambda} |\Phi_\Lambda(\xi)|
\]
and we also assume \( \| \Phi \| < \infty \) in this paper. For two interactions \( \Phi \) and \( \Psi \) on \( \Omega \), we define the sum \( \Phi + \Psi \) as the interaction on \( \Omega \) defined by
\[
(\Phi + \Psi)_\Lambda = \Phi_\Lambda + \Psi_\Lambda
\]
for each \( \Lambda \subset \mathbb{Z}^d \).

Let \( C(\Omega) \) be the real Banach space of continuous real-valued functions on \( \Omega \) with the supremum norm and \( \mathcal{M}(\Omega) \) be the set of Borel probability measures on \( \Omega \). \( \mathcal{M}(\Omega) \) can be viewed as a subset of \( C(\Omega)^* \); the dual space of the Banach space \( C(\Omega) \). Then \( \mathcal{M}(\Omega) \) is a compact, convex and metrizable space with respect to the weak*-topology. An element of \( \mathcal{M}(\Omega) \) is called a state.

Definition 1.1. \( \sigma \in \mathcal{M}(\Omega) \) is a Gibbs state for the interaction \( \Phi \) if for each finite \( \Lambda \subset \mathbb{Z}^d \), there exists a Borel probability measure \( \sigma_{\mathbb{Z}^d \setminus \Lambda} \) on \( \Omega_{\mathbb{Z}^d \setminus \Lambda} \) such that for any \( \xi_\Lambda \in \Omega_\Lambda \),
\[
\sigma(\{ \xi \in \Omega \mid \xi|_\Lambda = \xi_\Lambda \}) = \int_{\Omega_{\mathbb{Z}^d \setminus \Lambda}} \mu(\Lambda)_\eta(\xi_\Lambda) d\sigma_{\mathbb{Z}^d \setminus \Lambda}(\eta),
\]
where \( \mu(\Lambda)_\eta \) is a Borel probability measure on \( \Omega_{\mathbb{Z}^d \setminus \Lambda} \) defined by
\[
\mu(\Lambda)_\eta(\xi_\Lambda) = \sigma_{\mathbb{Z}^d \setminus \Lambda}(\eta) = \int_{\Omega_{\mathbb{Z}^d \setminus \Lambda}} \sigma_{\mathbb{Z}^d \setminus \Lambda}(\eta) d\sigma_{\mathbb{Z}^d \setminus \Lambda}(\eta).
\]
where
\[
\mu(\Lambda)\eta\{\xi\Lambda\} = \frac{\exp \left( - \sum_{M \in {\mathcal{F}}_\Lambda} \Phi_M(\xi \Lambda \vee \eta | M) \right)}{\sum_{\zeta \Lambda \in \Omega_\Lambda} \exp \left( - \sum_{M \in {\mathcal{F}}_\Lambda} \Phi_M(\zeta \Lambda \vee \eta | M) \right)},
\]
(1.1)

\[\mathcal{F}_\Lambda = \{ M \subset \mathbb{Z}^d \mid M \text{ is finite and } M \cap A \neq \emptyset \},\]
and for \( \zeta \Lambda \in \Omega_\Lambda \) and \( \eta \in \Omega_{\mathbb{Z}^d \setminus A} \), \( \zeta \Lambda \vee \eta \in \Omega \) is defined by \( \zeta \Lambda \vee \eta | \Lambda = \zeta \Lambda \) and \( \zeta \Lambda \vee \eta | \mathbb{Z}^d \setminus A = \eta \).

Definition 1.3. is equivalent to the following: for each finite \( A \subset \mathbb{Z}^d \) and \( \eta \in \Omega_{\mathbb{Z}^d \setminus A} \), the conditional probability that \( \xi | A = \xi \Lambda \) under \( \xi | \mathbb{Z}^d \setminus A = \eta \) is \( \mu(\Lambda)\eta \{\xi\Lambda\} \). Physically, the definition means statistical stability under the potential. We notice that if \( \Psi \) is an interaction such that \( \Psi \Lambda \) is constant for each finite \( \Lambda \subset \mathbb{Z}^d \), then the interaction \( \Phi + \Psi \) defines the same Gibbs states as \( \Phi \). Let \( K_\Phi \) be the set of Gibbs states for \( \Phi \). This is a nonempty, compact and convex subset of \( \mathcal{M}(\Omega) \) (see [7, Chapter 1]).

The next definitions give quantities which are very important in the theory of dynamical systems. Let \( I \) be the set of Borel probability measures on \( \Omega \) which are translation invariant. This is a nonempty, compact and convex subset of \( \mathcal{M}(\Omega) \). For a sequence \( \{\Lambda_n\}_{n=1}^{\infty} \) of finite subsets of \( \mathbb{Z}^d \), we write \( \Lambda_n \not\nearrow \infty \) when \( |\Lambda_n| \to \infty \) and, for any \( a \in \mathbb{Z}^d \), \( |(\Lambda_n + a) \setminus \Lambda_n|/|\Lambda_n| \to 0 \). An example of such a sequence is \( \{[-n, n]^d \cap \mathbb{Z}^d\}_{n=1}^{\infty} \).

Definition 1.2. For each \( \mu \in I \), the limit
\[
h(\mu) = \lim_{n \to \infty} -\frac{1}{|\Lambda_n|} \sum_{\xi \in \Omega_{\Lambda_n}} \mu_{\Lambda_n} \{\xi\} \log \mu_{\Lambda_n} \{\xi\},
\]
where \( \mu_{\Lambda_n} \{\xi\} = \mu(\eta \in \Omega \mid \eta | \Lambda_n = \xi \}) \), exists and is independent of a sequence \( \{\Lambda_n\}_{n=1}^{\infty} \) such that \( \Lambda_n \not\nearrow \infty \) (see [7, Chapter 3]). \( h(\mu) \) is called the measure-theoretic entropy of \( \mu \).

For an interaction \( \Phi \), we define \( A_\Phi \in C(\Omega) \) by
\[
A_\Phi(\xi) = -\sum_X \Phi_X(\xi | X),
\]
where the sum runs over those finite \( X \subset \mathbb{Z}^d \) such that \( 0 \in X \) and \( 0 \) is the middle element of \( X \) (that is, the \([|X|+1]/2\) element) with respect to the lexicographic order on \( X \). \(-A_\Phi(\xi)\) physically represents the contribution of \( 0 \in \mathbb{Z}^d \) to the energy in the configuration \( \xi \).

Definition 1.3. For each \( A \in C(\Omega) \), the limit
\[
P(A) = \lim_{n \to \infty} \frac{1}{|\Lambda_n|} \log \sum_{\xi \in \Omega_{\Lambda_n}} \exp \left( \sup_{\xi^* \in \Omega, \xi^* | \Lambda_n = \xi} \sum_{x \in \Lambda_n} A(\tau^x \xi^*) \right)
\]
\footnote{For \( a \in \mathbb{R} \), \([a]\) denotes the largest integer that is not larger than \( a \).}
exists and is independent of a sequence \( \{\Lambda_n\}_{n=1}^{\infty} \) such that \( \Lambda_n \not\to \infty \) (see [7, Chapter 3]).

\( P(A) \) is called the pressure of \( A \). For each interaction \( \Phi \), the limit

\[
P^\Phi = \lim_{n \to \infty} \frac{1}{|\Lambda_n|} \log \sum_{\xi \in \Omega_{\Lambda_n}} \exp \left( -\sum_{X \subset \Lambda_n} \Phi_X(\xi|_X) \right)
\]

exists and is independent of a sequence \( \{\Lambda_n\}_{n=1}^{\infty} \) such that \( \Lambda_n \not\to \infty \). Moreover, \( P^\Phi = P(A_\Phi) \) (see [7, Chapter 3]). \( P^\Phi \) is called the pressure of \( \Phi \).

The following important theorem, called the variational principle, connects the entropy and the pressure (see [7, Theorem 3.12] for the proof).

**Proposition 1.1** (Variational Principle). For each \( A \in C(\Omega) \),

\[
P(A) = \sup_{\mu \in I} \left( h(\mu) + \int_{\Omega} A \, d\mu \right).
\]

In particular, for each interaction \( \Phi \),

\[
P^\Phi = \sup_{\mu \in I} \left( h(\mu) + \int_{\Omega} A_\Phi \, d\mu \right).
\]

Moreover, there exists some \( \mu \in I \) such that \( \mu \) achieves the supremum.

For an interaction \( \Phi \) (resp. \( A \in C(\Omega) \)), an element \( \mu \in I \) which achieves the supremum is called an equilibrium state for \( \Phi \) (resp. \( A \)). Let \( I_\Phi \) be the set of the equilibrium states for \( \Phi \). This is a nonempty, compact and convex subset of \( M(\Omega) \). The following proposition is established (see [7, Theorem 4.2]).

**Proposition 1.2.** For each interaction \( \Phi \),

\[I_\Phi = K_\Phi \cap I.\]

From Proposition 1.2, equilibrium states are physically interpreted as translation invariant and statistically stable states of the system under the potential. For each interaction \( \Phi \), it is a meaningful problem whether there are more than one equilibrium states for \( \Phi \) or not. For the case of \( d = 1 \), it is known that there exists only one equilibrium state for any interaction under mild conditions (see [7, Chapter 5]). On the other hand, the system might have more than one equilibrium states when \( d \geq 2 \). One of the most famous such systems is the Ising model.

**Definition 1.4** (Ising Model). Let \( d \) be a positive integer and \( L > 0 \). The \( d \)-dimensional Ising model with the inverse temperature parameter \( L \) is a symbolic dynamical system \( \Omega = \{1, -1\}^{Z^d} \) with an interaction \( \Phi^L \) defined as

\[
\Phi^L_{\Lambda}(\xi) = \begin{cases} 
-L\xi(x)\xi(y), & \text{if } \Lambda = \{x, y\} \text{ with } ||x - y||_1 = 1 \\
0, & \text{otherwise},
\end{cases}
\]

for each finite \( \Lambda \subset \mathbb{Z}^d \) and \( \xi \in \Omega_\Lambda = \{1, -1\}^\Lambda \), where \( ||x||_1 = \sum_{i=1}^{d} |x_i| \) for \( x = (x_1, \ldots, x_d) \in \mathbb{Z}^d \).
When $d \geq 2$, it is known that phase transition occurs on the Ising model, that is, there exists $L_c > 0$ such that the $d$-dimensional Ising model with the parameter $L$ has a unique equilibrium state for $L < L_c$, and has more than one equilibrium states for $L_c < L$ (for example, see [6], [3]).

This paper is concerned with the question that, for a symbolic dynamical system on $\mathbb{Z}^d$ with an interaction $\Phi$, whether the uniqueness or non-uniqueness of the equilibrium state is preserved if we perturb the interaction within an appropriate range. A perturbation of $\Phi$ means considering an interaction $\Phi + \Psi$ for a small interaction $\Psi$. A perturbation of the interaction corresponds to some influence from the surroundings to the system or some noise in the potential. Hence it is interesting to study what happens under a perturbation of the interaction. In particular, we discuss in this paper the case when $\Omega = \{1, -1\}^{\mathbb{Z}^d}$ and the system is the $d$-dimensional Ising model. We show that the uniqueness or non-uniqueness of $\Phi^L$ for sufficiently small $L$ or sufficiently large $L$ is preserved under perturbations in some class of interactions about some norm.

**Definition 1.5.** An interaction $\Psi$ on $\Omega = \{1, -1\}^{\mathbb{Z}^d}$ is symmetric if

$$\Psi_A(\xi) = \Psi_A(-\xi)$$

for any finite $\Lambda \subset \mathbb{Z}^d$ and $\xi \in \Omega_\Lambda$.

It is obvious that the interaction $\Phi^L$ defining the Ising model is symmetric.

For $\Lambda \subset \mathbb{Z}^d$, we write $\text{diam}(\Lambda)$ as the diameter of $\Lambda$, that is,

$$\text{diam}(\Lambda) = \sup \{ \|x - y\|_\infty | x, y \in \Lambda \},$$

where $\|x\|_\infty = \max \{|x_1|, \ldots, |x_d|\}$ for $x = (x_1, \ldots, x_d) \in \mathbb{Z}^d$.

**Definition 1.6.** An interaction $\Psi$ on $\Omega$ is $d$-th order decreasing if

$$\|\Psi\| = \sum_{0 \in \Lambda \subset \mathbb{Z}^d: \text{finite}} (\text{diam}(\Lambda) + 1)^d \sup_{\xi \in \Omega_\Lambda} |\Psi_A(\xi)| < \infty.$$

It is obvious that

$$\|\Psi\| \leq \|\Psi\|$$

for any $d$-th order decreasing interaction $\Psi$ on $\Omega$.

**Example 1.1** (Finite Range Interactions). Let $\Psi$ be a translation invariant interaction on $\Omega$ which satisfies that the number of finite subsets $\Lambda \subset \mathbb{Z}^d$ such that $0 \in \Lambda$ and $\Psi_A \neq 0$ is finite. We call such an interaction $\Psi$ a finite range interaction. It is clear that $\|\Psi\| < \infty$. Hence $\Psi$ is $d$-th order decreasing.

**Example 1.2** ((2$d$ + $\varepsilon$)-th Order Decreasing Interactions Between Two Sites). Let $\Psi$ be a translation invariant interaction on $\Omega$ which satisfies

$$\Psi_A = 0$$

unless $\Lambda$ consists of distinct two points. We assume that $\Psi$ is (2$d$ + $\varepsilon$)-th order decreasing, that is, there exists $\varepsilon > 0$ such that

$$\|\Psi\|_\varepsilon = \sup \left\{ \|x - y\|^{2d + \varepsilon}_\infty |\Psi_{\{x,y\}}(\xi)| \mid x, y \in \mathbb{Z}^d, x \neq y, \xi \in \Omega_{\{x,y\}} \right\} < \infty.$$
We have
\[
\|\Psi\| = \sum_{x \in \mathbb{Z}^d \setminus \{0\}} (\|x\|_\infty + 1)^d \sup_{\xi \in \Omega(0,x)} |\Psi_{\{0,x\}}(\xi)| \\
\leq \sum_{x \in \mathbb{Z}^d \setminus \{0\}} (\|x\|_\infty + 1)^d \|x\|_\infty^{-d-\varepsilon} \|\xi\|_\varepsilon \\
= M_\varepsilon \|\Psi\|_\varepsilon,
\]
where \(M_\varepsilon = \sum_{n=1}^{\infty} ((2n+1)^d - (2n-1)^d)(n+1)^d n^{-(2d+\varepsilon)} < \infty\). Hence \(\Psi\) is \(d\)-th order decreasing.

In this paper, we show that the uniqueness of the equilibrium state for \(\Phi_L\) for sufficiently small \(L\) is preserved under perturbations of \(d\)-th order decreasing interactions and the non-uniqueness for sufficiently large \(L\) is preserved under perturbations of symmetric and \(d\)-th order decreasing interactions about the norm \(||\cdot||\). The following is the main theorem of this paper.

**Theorem 1.3.** Let \(d \geq 2\) and, for \(L > 0\), \(\Phi^L\) be the interaction which defines the \(d\)-dimensional Ising model with the parameter \(L\).

1. For sufficiently small \(L > 0\), there exists \(\varepsilon > 0\) such that for any \(d\)-th order decreasing interaction \(\Psi\) on \(\Omega\), which satisfies \(||\Psi|| < \varepsilon\), the interaction \(\Phi = \Phi^L + \Psi\) has a unique equilibrium state.

2. For sufficiently large \(L > 0\), there exists \(\varepsilon > 0\) such that for any \(d\)-th order decreasing interaction \(\Psi\) on \(\Omega\) which satisfies \(||\Psi|| < \varepsilon\), if \(\Psi\) is symmetric, then \(\Phi = \Phi^L + \Psi\) has more than one equilibrium states.

Theorem 1.3 (1) follows from Dobrushin’s criterion, which gives a sufficient condition for an interaction to have a unique Gibbs state. We will see a more general result in Section 2. To prove Theorem 1.3 (2), we must see how the perturbative part of the interaction affects arguments in the case of the non-perturbed Ising model. In Section 2, we will see the effect of the symmetric perturbative part is canceled by the Ising model when \(L\) is sufficiently large.

## 2 Dobrushin’s criterion and the case of small \(L\)

In this section, we introduce Dobrushin’s criterion and derive Theorem 1.3 (1) from it.

Let \(\Omega = \{1, -1\}^{\mathbb{Z}^d}\) and \(\Phi\) be an interaction on \(\Omega\). For any finite subset \(\Lambda \subset \mathbb{Z}^d\) and \(\eta \in \Omega_{\mathbb{Z}^d \setminus \Lambda}\), let \(\mu(\Lambda)\eta\) be the probability measure on \(\Omega_{\Lambda}\) which is defined in Definition 1.1.

For any \(x \in \mathbb{Z}^d \setminus \{0\}\), we define
\[
\rho(x) = \sup \{ |\mu(\{0\})\eta(1) - \mu(\{0\})\zeta(1)| \mid \eta, \zeta \in \Omega_{\mathbb{Z}^d \setminus \{0\}}, \eta|z^d \setminus \{0,x\} = \zeta|z^d \setminus \{0,x\} \}
\]
(where we identify \(\{1, -1\}\) with \(\{1, -1\}^{\{0\}}\)). Then we have Dobrushin’s criterion (see 3 or 4 for the proof and more details).
Proposition 2.1 (Dobrushin’s Criterion). If
\[ \sum_{x \in \mathbb{Z}^d \setminus \{0\}} \rho_x(x) < 1, \]
then \( \Phi \) has a unique Gibbs state and, by Proposition 1.2, a unique equilibrium state.

When \( \Phi = 0 \), that is, there are no interactions on the configuration space, the equilibrium state means the measure of maximal entropy, and is unique (the direct product of the measure \( m \) on \( \{1, -1\} \) defined by \( m\{1\} = m\{-1\} = 2^{-1} \)). Using Proposition 2.1, we want to show that an interaction \( \Phi \) has a unique equilibrium state if \( \Phi \) is small with respect to the norm. However, it seems difficult to do this about the norm \( \| \cdot \| \) defined in Section 1. We define a new norm and see the statement holds about it.

Let \( \Phi \) be an interaction on \( \Omega \). For each finite \( \Lambda \subset \mathbb{Z}^d \), we define
\[ \text{var}_\Lambda \Phi = \sup_{\xi, \xi' \in \Omega^\Lambda} |\Phi^\Lambda(\xi) - \Phi^\Lambda(\xi')|. \]

We define the \textbf{variational norm} of \( \Phi \) as
\[ \| \Phi \|_{\text{var}} = \sum_{0 \in \Lambda \subset \mathbb{Z}_d: \text{finite}} (|\Lambda| - 1) \text{var}_\Lambda \Phi \in [0, \infty]. \]

It is obvious that
\[ \| \Phi \|_{\text{var}} \leq 2\| \Phi \| \tag{2.1} \]
for any \( d \)-th order decreasing interaction \( \Phi \) on \( \Omega \).

The following theorem is in [3, (8.8) Proposition], but we give a proof for the case of \( \Omega = \{1, -1\}^{\mathbb{Z}^d} \).

**Theorem 2.2.** If
\[ \| \Phi \|_{\text{var}} < 2, \]
then \( \Phi \) satisfies Dobrushin’s criterion and hence has a unique Gibbs state.

**Proof.** Put
\[ f(t) = \frac{1}{1 + e^t} \]
for any \( t \in \mathbb{R} \). Then, for any \( \eta \in \Omega^{\mathbb{Z}^d \setminus \{0\}} \),
\[ \mu_{\{0\}}(\eta) \{1\} \]
\[ = \frac{\exp \left( - \sum_{0 \in \Lambda \subset \mathbb{Z}_d: \text{finite}} \Phi^\Lambda(\eta \lor \{1\}|_\Lambda) \right)}{\exp \left( - \sum_{0 \in \Lambda \subset \mathbb{Z}_d: \text{finite}} \Phi^\Lambda(\eta \lor \{1\}|_\Lambda) \right) + \exp \left( - \sum_{0 \in \Lambda \subset \mathbb{Z}_d: \text{finite}} \Phi^\Lambda(\eta \lor \{-1\}|_\Lambda) \right)} \]
\[ = \left( 1 + \exp \left( \sum_{0 \in \Lambda \subset \mathbb{Z}_d: \text{finite}} (\Phi^\Lambda(\eta \lor \{1\}|_\Lambda) - \Phi^\Lambda(\eta \lor \{-1\}|_\Lambda)) \right) \right)^{-1} \]
\[ = f \left( \sum_{0 \in \Lambda \subset \mathbb{Z}_d: \text{finite}} (\Phi^\Lambda(\eta \lor \{1\}|_\Lambda) - \Phi^\Lambda(\eta \lor \{-1\}|_\Lambda)) \right) . \]
Let \( x \in \mathbb{Z}^d \setminus \{0\} \) and \( \eta, \zeta \in \Omega_{\mathbb{Z}^d \setminus \{0\}} \) with \( \eta|_{\mathbb{Z}^d \setminus \{0, x\}} = \zeta|_{\mathbb{Z}^d \setminus \{0, x\}} \). Since
\[
f'(t) = -\frac{1}{(e^t + e^{-t})^2} \in \left[-\frac{1}{4}, 0\right)
\]
for any \( t \in \mathbb{R} \), by the mean-value theorem,
\[
\left| \mu(\{0\}) \eta(1) - \mu(\{0\}) \zeta(1) \right|
= \left| f \left( \sum_{\Lambda \subset \mathbb{Z}^d: \text{finite}} (\Phi_\Lambda(\eta \vee \{1\}|_\Lambda) - \Phi_\Lambda(\eta \vee \{-1\}|_\Lambda)) \right) \right|
- \left| f \left( \sum_{\Lambda \subset \mathbb{Z}^d: \text{finite}} (\Phi_\Lambda(\zeta \vee \{1\}|_\Lambda) - \Phi_\Lambda(\zeta \vee \{-1\}|_\Lambda)) \right) \right|
\leq \frac{1}{4} \left| \sum_{\Lambda \subset \mathbb{Z}^d: \text{finite}} (\Phi_\Lambda(\eta \vee \{1\}|_\Lambda) - \Phi_\Lambda(\eta \vee \{-1\}|_\Lambda)) \right|
- \sum_{\Lambda \subset \mathbb{Z}^d: \text{finite}} (\Phi_\Lambda(\zeta \vee \{1\}|_\Lambda) - \Phi_\Lambda(\zeta \vee \{-1\}|_\Lambda))
\leq \frac{1}{4} \left| \sum_{\Lambda \subset \mathbb{Z}^d: \text{finite}} (\Phi_\Lambda(\eta \vee \{1\}|_\Lambda) - \Phi_\Lambda(\zeta \vee \{1\}|_\Lambda)) \right|
- \sum_{\Lambda \subset \mathbb{Z}^d: \text{finite}} (\Phi_\Lambda(\eta \vee \{-1\}|_\Lambda) - \Phi_\Lambda(\zeta \vee \{-1\}|_\Lambda))
\leq \frac{1}{4} \left\{ \sum_{\Lambda \subset \mathbb{Z}^d: \text{finite}} |\Phi_\Lambda(\eta \vee \{1\}|_\Lambda) - \Phi_\Lambda(\zeta \vee \{1\}|_\Lambda)| \right. \\
+ \left. \sum_{\Lambda \subset \mathbb{Z}^d: \text{finite}} |\Phi_\Lambda(\eta \vee \{-1\}|_\Lambda) - \Phi_\Lambda(\zeta \vee \{-1\}|_\Lambda)| \right\}
\leq \frac{1}{2} \sum_{\Lambda \subset \mathbb{Z}^d: \text{finite}} \text{var}_\Lambda \Phi
\]
On the second equation, we recall that \( \eta|_{\mathbb{Z}^d \setminus \{0, x\}} = \zeta|_{\mathbb{Z}^d \setminus \{0, x\}} \). Hence we have
\[
\rho_\Phi(x) \leq \frac{1}{2} \sum_{\Lambda \subset \mathbb{Z}^d: \text{finite}} \text{var}_\Lambda \Phi
\]
for $x \in \mathbb{Z}^d \setminus \{0\}$. Then

$$\sum_{x \in \mathbb{Z}^d \setminus \{0\}} \rho \Phi (x) \leq \frac{1}{2} \sum_{x \in \mathbb{Z}^d \setminus \{0\}} \sum_{0 \leq |\Lambda| - 1} \var_\Lambda \Phi$$

$$= \frac{1}{2} \sum_{0 \leq |\Lambda|} (|\Lambda| - 1) \var_\Lambda \Phi$$

$$= \frac{1}{2} \Vert \Phi \Vert_{\text{var}}$$

$$< 1,$$

and this means that $\Phi$ satisfies Dobrushin’s criterion. $\square$

For $L > 0$,

$$\Vert \Phi^L \Vert_{\text{var}} = 4dL.$$

Hence, by Theorem 2.2 we have the following result about a perturbation of the Ising model for small $L$.

**Corollary 2.3.** Let $0 < L < \frac{1}{2d}$. Then for any interaction $\Psi$ with

$$\Vert \Psi \Vert_{\text{var}} < 2 - 4dL,$$

the interaction $\Phi^L + \Psi$ has a unique Gibbs state and a unique equilibrium state. Hence, by (2.1), for any $d$-th order decreasing interaction $\Psi$ with

$$\Vert \Psi \Vert < 2^{-1}(2 - 4dL),$$

the interaction $\Phi^L + \Psi$ has a unique equilibrium state.

The latter statement in Corollary 2.3 is nothing else but Theorem 1.3 (1).

3 The case of large $L$

In this section, we give a proof of Theorem 1.3 (2). We first give Theorem 3.1 and see Theorem 1.3 (2) follows from it.

For $\Lambda \subset \mathbb{Z}^d$, we say $\Lambda$ is path-connected if for any $x$ and $y \in \Lambda$ there exist finite points $x_0, x_1, \ldots, x_{n-1}, x_n \in \Lambda$ such that

$$x_0 = x, \quad x_n = y, \quad \|x_{i+1} - x_i\|_1 = 1 \text{ for } i = 0, \ldots, n - 1.$$

We call such a finite sequence $x_0, x_1, \ldots, x_{n-1}, x_n$ a path from $x$ to $y$.

**Definition 3.1.** An interaction $\Psi$ is zero on non-path-connected sets if

$$\Psi_\Lambda = 0$$

unless $\Lambda$ is path-connected.

Then the following Theorem 3.1 is established:
Theorem 3.1. For sufficiently large \( L > 0 \), there exists \( \varepsilon > 0 \), such that for any interaction \( \Psi \) on \( \Omega \) which satisfies \( \| \Psi \| < \varepsilon \), if \( \Psi \) is symmetric and zero on non-path-connected sets, then there exist more than one equilibrium states for the interaction \( \Phi^L + \Psi \).

We see that Theorem 1.3 (2) follows from Theorem 3.1. For \( R \subset \mathbb{Z}^d \), we say \( R \) is a rectangle if \( R = [a_1, b_1] \times \cdots \times [a_d, b_d] \cap \mathbb{Z}^d \) for some \( a_1, b_1, \ldots, a_d, b_d \in \mathbb{Z} \).

For each finite \( \Lambda \subset \mathbb{Z}^d \), we write \( R(\Lambda) \) as the minimal rectangle which contains \( \Lambda \). We notice that \( \text{diam}(\Lambda) = \text{diam}(R(\Lambda)) \). For each rectangle \( R \), we define \( S(R) = \{ \Lambda \subset \mathbb{Z}^d : \text{finite} \mid R(\Lambda) = R \} \).

Let \( \Psi \) be a \( d \)-th order decreasing interaction. We assume that \( \Psi \) is symmetric. We define an interaction \( \tilde{\Psi} \) on \( \Omega \) as

\[
\tilde{\Psi}_R(\xi) = \sum_{\Lambda \in S(R)} \Psi_{\Lambda}(\xi|_{\Lambda})
\]

for any rectangle \( R \subset \mathbb{Z}^d \) and \( \xi \in \Omega_R \). This interaction \( \tilde{\Psi} \) is made by putting interactions \( \Psi_\Lambda \) on \( \Lambda \in S(R) \) together into the rectangle \( R \). \( \tilde{\Psi} \) is obviously translation invariant and symmetric interaction which is zero on non-path-connected sets. We write \( X \) as the set of finite subsets \( \Lambda \subset \mathbb{Z}^d \) such that \( 0 \in \Lambda \) and \( 0 \) is the middle element of \( \Lambda \) (that is, the \( \lfloor (|\Lambda|+1)/2 \rfloor \)-th element) when \( \Lambda \) is lexicographically ordered. Then, by the translation-invariance of \( \tilde{\Psi} \), we have

\[
\| \tilde{\Psi} \| = \sum_{0 \in R \subset \mathbb{Z}^d : \text{rectangle}} \sup_{\xi \in \Omega_R} |\tilde{\Psi}_R(\xi)|
\]

\[
= \sum_{0 \in R \subset \mathbb{Z}^d : \text{rectangle}, R \in X} |R| \sup_{\xi \in \Omega_R} |\tilde{\Psi}_R(\xi)|
\]

\[
\leq \sum_{0 \in R \subset \mathbb{Z}^d : \text{rectangle}, R \in X} |R| \sum_{\Lambda \in S(R)} \sup_{\xi \in \Omega_\Lambda} |\Psi_\Lambda(\xi)|
\]

\[
= \sum_{\Lambda \subset \mathbb{Z}^d : \text{finite}, R(\Lambda) \in X} |R(\Lambda)| \sup_{\xi \in \Omega_\Lambda} |\Psi_\Lambda(\xi)|
\]

\[
\overset{(*)}{=} \sum_{0 \in \Lambda \subset \mathbb{Z}^d : \text{finite}} |\Lambda|^{-1} |R(\Lambda)| \sup_{\xi \in \Omega_\Lambda} |\Psi_\Lambda(\xi)|
\]

\[
\leq \sum_{0 \in \Lambda \subset \mathbb{Z}^d : \text{finite}} |\Lambda|^{-1} \left( \text{diam}(\Lambda) + 1 \right)^d \sup_{\xi \in \Omega_\Lambda} |\Psi_\Lambda(\xi)|
\]

\[
\leq \|\Psi\|. \tag{3.1}
\]

Here the equation (*) holds since \( \Psi \) is translation invariant and, for each finite \( \Lambda \subset \mathbb{Z}^d \), translations of \( \Lambda \) appear only once in the sum \( \sum_{\Lambda \subset \mathbb{Z}^d : \text{finite}, R(\Lambda) \in X} \). The following means that we can identify \( \tilde{\Psi} \) with \( \Psi \) as statistical systems.

Proposition 3.2. For any interaction \( \Phi \) on \( \Omega \), interactions \( \Phi + \Psi \) and \( \Phi + \tilde{\Psi} \) define the same Gibbs states and, by Proposition 1.2 equilibrium states.
Proof. For any finite $\Lambda \subset \mathbb{Z}^d$ and any $\eta \in \Omega_{\mathbb{Z}^d \setminus \Lambda}$, let $\mu_{(\Lambda)\eta}$ and $\tilde{\mu}_{(\Lambda)\eta}$ be the measures on $\Omega_\Lambda$ which are defined in (1.1) for $\Phi + \Psi$ and $\Phi + \tilde{\Psi}$, respectively. For any $\xi_\Lambda \in \Omega_\Lambda$, we have

$$
\tilde{\mu}_{(\Lambda)\eta}\{\xi_\Lambda\} = \exp\left(- \sum_{M \in F_\Lambda} \left( \Phi_M(\xi_\Lambda \vee \eta|_M) + \tilde{\Psi}_M(\xi_\Lambda \vee \eta|_M) \right) \right) = \sum_{\zeta_\Lambda \in \Omega_\Lambda} \frac{\exp\left(- \sum_{M \in F_\Lambda} \left( \Phi_M(\zeta_\Lambda \vee \eta|_M) + \tilde{\Psi}_M(\zeta_\Lambda \vee \eta|_M) \right) \right) \exp\left(- \sum_{R \in R_\Lambda} \sum_{S \in S(R)} \Psi_S(\zeta_\Lambda \vee \eta|_S) \right)}{\sum_{\zeta_\Lambda \in \Omega_\Lambda} \exp\left(- \sum_{M \in F_\Lambda} \left( \Phi_M(\zeta_\Lambda \vee \eta|_M) - \sum_{R \in R_\Lambda} \sum_{S \in S(R)} \Psi_S(\zeta_\Lambda \vee \eta|_S) \right) \right)}
$$

where $R_\Lambda = \{ R \subset \mathbb{Z}^d | R \text{ is a rectangle and } R \cap \Lambda \neq \emptyset \}$. Here, for any $\zeta_\Lambda \in \Omega_\Lambda$,

$$
\sum_{R \in R_\Lambda} \sum_{S \in S(R)} \Psi_S(\zeta_\Lambda \vee \eta|_S) = \sum_{R \in R_\Lambda} \sum_{S \in S(R) \cap F_\Lambda} \Psi_S(\zeta_\Lambda \vee \eta|_S) + \sum_{R \in R_\Lambda} \sum_{S \in S(R) \setminus F_\Lambda} \Psi_S(\zeta_\Lambda \vee \eta|_S) = \sum_{S \in F_\Lambda} \Psi_S(\zeta_\Lambda \vee \eta|_S) + \sum_{R \in R_\Lambda} \sum_{S \in S(R) \setminus F_\Lambda} \Psi_S(\zeta_\Lambda \vee \eta|_S)
$$

and the second term is independent of $\zeta_\Lambda$. Hence we have

$$
\tilde{\mu}_{(\Lambda)\eta}\{\xi_\Lambda\} = \exp\left(- \sum_{M \in F_\Lambda} \left( \Phi_M(\xi_\Lambda \vee \eta|_M) - \sum_{S \in F_\Lambda} \Psi_S(\zeta_\Lambda \vee \eta|_S) \right) \right) = \mu_{(\Lambda)\eta}\{\xi_\Lambda\}
$$

and this implies the statement holds.

If $L > 0$ is sufficiently large and $||\Psi||$ is sufficiently small, by (3.1), we can apply Theorem 3.1 to $\tilde{\Psi}$ and see that the interaction $\Phi^L + \tilde{\Psi}$ has more than one equilibrium.
states and, by Proposition 3.2, $\Phi^L + \Psi$ also does. Hence we showed that Theorem 1.3 (2) follows from Theorem 3.1.

We prove Theorem 3.1. To do this, we must see how the symmetric perturbative part of the interaction affects arguments in [6], [3] or [1] in the case of the non-perturbed Ising model. We see the effect of the symmetric perturbative part is canceled by the Ising model and the evaluation similar to that in the case of non-perturbed Ising model holds when $L$ is sufficiently large.

Let $L > 0$ and $\Psi$ be an interaction on $\Omega = \{1, -1\}^{\mathbb{Z}^d}$ which is symmetric and zero on non-path-connected sets. We write $\Phi = \Phi^L + \Psi$. For each positive integer $n$, we write $\Lambda_n = [-n, n]^d \cap \mathbb{Z}^d \subset \mathbb{Z}^d$ and define $\xi_n \in \Omega_{\mathbb{Z}^d \setminus \Lambda_n}$ by

$$\xi_n^+(x) = 1$$

for any $x \in \mathbb{Z}^d \setminus \Lambda_n$. We define $\mu_n^+ \in \mathcal{M}(\Omega)$ by

$$\mu_n^+ (\{\xi \in \Omega | \xi|_{\mathbb{Z}^d \setminus \Lambda_n} = \xi_n^+ \}) = 1$$

and, for each $\xi \in \Omega_{\Lambda_n}$,

$$\mu_n^+ (\xi \vee \xi_n^+) = Z_n^+ \exp \left( - \sum_{\Lambda \in \mathcal{F}_{\Lambda_n}} \Phi_{\Lambda} (\xi \vee \xi_n^+) \right),$$

where

$$Z_n^+ = \sum_{\xi \in \Omega_{\Lambda_n}} \exp \left( - \sum_{\Lambda \in \mathcal{F}_{\Lambda_n}} \Phi_{\Lambda} (\xi \vee \xi_n^+) \right).$$

Since $\mathcal{M}(\Omega)$ is a compact metric space, $\{\mu_n\}_{n=1}^\infty \subset \mathcal{M}(\Omega)$ has an accumulation point $\mu^+$ in $\mathcal{M}(\Omega)$. It is known that $\mu^+$ is a Gibbs state for $\Phi$ (see [2] Chapter 1).

For $x \in \mathbb{Z}^d$, we define $f_x \in C(\Omega)$ as

$$f_x (\xi) = \xi(x) \in \{1, -1\}$$

for any $\xi \in \Omega$. We will prove the following proposition.

**Proposition 3.3.** For sufficiently large $L > 0$, there exists $\varepsilon > 0$ satisfying the following: if $\Psi$ is an interaction on $\Omega$ which is symmetric, zero on non-path-connected sets and $\|\Psi\| < \varepsilon$, then for a Gibbs state $\mu^+$ for $\Phi^L + \Psi$ defined as above, there exists $a > 0$ such that

$$\int_{\Omega} f_x \, d\mu^+ > a$$

for any $x \in \mathbb{Z}^d$.

This proposition means that, with respect to $\mu^+$, the expected value of the ‘spin’ at the site $x$ is magnetized for each $x \in \mathbb{Z}^d$. As we will see later, we can construct two distinct equilibrium states for $\Phi$ by Proposition 3.3 and show that Theorem 3.1 is established.

We give the outline of the proof of Proposition 3.3. We prove Proposition 3.3 by showing that, for each $x \in \mathbb{Z}^d$ and large positive integer $n$, the contribution of configurations which take 1 on $x$ to the ‘finite Gibbs state’ $\mu_n^+$ is greater than that of configurations.
which take \(-1\) on \(x\) in the ratio which is independent of \(x\) and \(n\). To do this, we appropriately define the operation \(\delta\) that constructs the configuration \(\delta \xi\) which takes 1 on \(x\) from each configuration \(\xi\) which takes \(-1\) on \(x\) by flipping the sign of \(\xi\) on some domain containing \(x\) such that \(\delta\) derives that the sum of the weight (with respect to \(\mu^+_n\)) of each configuration which take \(-1\) on \(x\) is bounded by \(b\) times the sum of the weight of each configuration which take 1 on \(x\), where \(b < 1\) and \(b\) is independent of \(x\) and \(n\). This turns out to be possible under the condition of a perturbed part \(\Psi\).

Now we prove Proposition 3.3. Let \(L > 0\) be large and \(\varepsilon > 0\) be small. We take any interaction \(\Psi\) which is symmetric, zero on non-path-connected sets and \(\|\Psi\| < \varepsilon\) and write \(\Phi = \Phi^L + \Psi\). Let \(x \in \mathbb{Z}^d\) and

\[
P_{x,n}^+ = \mu_n^+ (\{\xi \in \Omega \mid \xi(x) = 1\})
\]

\[
P_{x,n}^- = \mu_n^+ (\{\xi \in \Omega \mid \xi(x) = -1\})
\]

for each a positive integer \(n\). Since

\[
\int_\Omega f_x \, d\mu_n^+ = P_{x,n}^+ - P_{x,n}^-,
\]

\[
P_{x,n}^+ + P_{x,n}^- = 1
\]

for each \(n\) and, if \(\{\mu_{n_k}\}_{k=1}^\infty\) is a subsequence of \(\{\mu_n\}_{n=1}^\infty\) which converges to \(\mu^+\) in \(M(\Omega)\) as \(k \to \infty\), then

\[
\lim_{k \to \infty} \int_\Omega f_x \, d\mu_{n_k}^+ = \int_\Omega f_x \, d\mu^+,
\]

it is sufficient to prove the following lemma:

**Lemma 3.4.** If \(L\) is sufficiently large and \(\varepsilon\) is sufficiently small, there exists \(0 < b < 1\) such that for each \(x_0 \in \mathbb{Z}^d\), if \(n\) is sufficiently large,

\[
P_{x_0,n}^- \leq b P_{x_0,n}^+.
\]

In fact, from Lemma 3.4, we have Proposition 3.3 with \(a = (1 - b)/(1 + b)\). Then we prove Lemma 3.3. The following Definition 3.2 and Lemma 3.5 are essential in the proof.

**Definition 3.2.** Let \(x \in \mathbb{Z}^d\). We say \(G \subset \mathbb{Z}^d\) is an \(x\)-enclosing set if

(i) \(x \in G\)

(ii) \(G\) is finite

(iii) \(G\) and \(\mathbb{Z}^d \setminus G\) are each path-connected.

For \(G \subset \mathbb{Z}^d\), we write \(\partial G = \{x \in G \mid \|x - y\|_1 = 1\ \text{for some} \ y \in \mathbb{Z}^d \setminus G\}\).

**Lemma 3.5.** Let \(x \in \mathbb{Z}^d\), \(l\) be a positive integer, and \(N_{x,l}\) be the number of \(x\)-enclosing sets \(G\) with \(|\partial G| = l\). Then

\[
N_{x,l} \leq \frac{(l + 2d - 4) (e \cdot 7^d)^l}{2d - 2}.
\]

See [2] Lemma 3.6 for a proof.
Proof of Lemma 3.3. Let \( n \) be a large positive integer such that \( x_0 \in \Lambda_n \). For each \( \xi \in \Omega_{\Lambda_n} \), we write

\[
\Gamma_\xi = \left\{ \{x, y\} \subset \mathbb{Z}^d \mid \|x - y\|_1 = 1, \ \xi \vee \xi_n^+(x) \neq \xi \vee \xi_n^+(y) \right\}.
\]

In addition, we write

\[
M_n = L \cdot \left| \left\{ \{x, y\} \subset \mathbb{Z}^d \mid \|x - y\|_1 = 1, \ x \in \Lambda_n \text{ or } y \in \Lambda_n \right\} \right|.
\]

For each \( \xi \in \Omega_{\Lambda_n} \), we have

\[
\mu_n^+ \{ \xi \vee \xi_n^+ \} = Z_n^{-1} \exp \left( - \sum_{\Lambda \in \mathcal{F}_{\Lambda_n}} \left( \Phi^*_\Lambda(\xi \vee \xi_n^+|\Lambda) + \Psi_\Lambda(\xi \vee \xi_n^+|\Lambda) \right) \right)
\]

\[
= Z_n^{-1} e^{M_n} \exp \left( -2L |\Gamma_\xi| - \sum_{\Lambda \in \mathcal{F}_{\Lambda_n}} \Psi_\Lambda(\xi \vee \xi_n^+|\Lambda) \right).
\]

Let

\[
\Omega^+_{\Lambda_n, x_0} = \{ \xi \in \Omega_{\Lambda_n} \mid \xi(x_0) = 1 \}
\]

\[
\Omega^-_{\Lambda_n, x_0} = \{ \xi \in \Omega_{\Lambda_n} \mid \xi(x_0) = -1 \}.
\]

Then we have

\[
P^+_{x_0, n} = Z_n^{-1} e^{M_n} \sum_{\xi \in \Omega^+_{\Lambda_n, x_0}} \exp \left( -2L |\Gamma_\xi| - \sum_{\Lambda \in \mathcal{F}_{\Lambda_n}} \Psi_\Lambda(\xi \vee \xi_n^+|\Lambda) \right)
\]

\[
P^-_{x_0, n} = Z_n^{-1} e^{M_n} \sum_{\xi \in \Omega^-_{\Lambda_n, x_0}} \exp \left( -2L |\Gamma_\xi| - \sum_{\Lambda \in \mathcal{F}_{\Lambda_n}} \Psi_\Lambda(\xi \vee \xi_n^+|\Lambda) \right).
\]

(3.2)

For each \( \xi \in \Omega_{\Lambda_n} \), we define equivalent relation \( \sim_\xi \) as follows: for \( x, y \in \mathbb{Z}^d \), \( x \sim_\xi y \) if there is a path \( \gamma \) on \( \mathbb{Z}^d \) from \( x \) to \( y \) such that \( \xi \vee \xi_n^+ \) is constant on \( \gamma \). Since \( \xi \vee \xi_n^+ \) is constant on \( \gamma \), we define \( \delta \xi \in \Omega_{\Lambda_n} \) as

\[
(\delta \xi)(x) = \begin{cases} 
-\xi(x), & x \in S_{\xi, x_0} \\
\xi(x), & x \notin S_{\xi, x_0}
\end{cases}
\]

for each \( x \in \Lambda_n \). For \( x, y \in \mathbb{Z}^d \) with \( \|x - y\|_1 = 1 \) and \( \xi \vee \xi_n^+(x) = \xi \vee \xi_n^+(y) \), if \( x \in S_{\xi, x_0} \), then \( y \in S_{\xi, x_0} \). From this, it is easily seen that

\[
\Gamma_{\delta \xi} = \left\{ \{x, y\} \in \Gamma_\xi \mid \text{ both } x \text{ and } y \text{ are in } S_{\xi, x_0} \text{ or neither } x \text{ nor } y \text{ is in } S_{\xi, x_0} \right\}.
\]

Hence, if we write

\[
\beta_{\xi, x_0} = \{ \{x, y\} \subset \mathbb{Z}^d \mid \|x - y\|_1 = 1, \text{ one of } \{x, y\} \text{ is in } S_{\xi, x_0} \text{ and the other not in } S_{\xi, x_0} \},
\]

\[
\Gamma_{\beta_{\xi, x_0}} = \left\{ \{x, y\} \in \Gamma_{\delta \xi} \right\}.
\]

13
we have $\beta_{\xi,x_0} = \Gamma_\xi \setminus \Gamma_\delta \xi$ and \[|\Gamma_\xi| = |\Gamma_\delta \xi| + |\beta_{\xi,x_0}|.\]

Hence
\[
P_{x_0,n}^-
= Z_n^{-1} e^{M_n} \sum_{\xi \in \Omega_{\Lambda_n,x_0}} \exp \left( -2L |\Gamma_\xi| - \sum_{\Lambda \in \mathcal{P}_\Lambda_n} \Psi_\Lambda(\xi \lor \xi^+_n|_\Lambda) \right)
= Z_n^{-1} e^{M_n} \sum_{\eta \in \Omega_{\Lambda_n,x_0}^+} \sum_{\xi \in \Omega_{\Lambda_n,x_0}^-} \exp \left( -2L |\Gamma_\eta| - \sum_{\Lambda \in \mathcal{P}_\Lambda_n} \Psi_\Lambda(\eta \lor \xi^+_n|_\Lambda) \right)
= Z_n^{-1} e^{M_n} \sum_{\eta \in \Omega_{\Lambda_n,x_0}^+} \exp \left( -2L |\Gamma_\eta| - \sum_{\Lambda \in \mathcal{P}_\Lambda_n} \Psi_\Lambda(\eta \lor \xi^+_n|_\Lambda) \right)
\]
\[
\sum_{\xi \in \Omega_{\Lambda_n,x_0}^-} \sum_{\delta \xi = \eta} \exp \left( \sum_{\Lambda \in \mathcal{P}_\Lambda_n} \left( \Psi_\Lambda(\eta \lor \xi^+_n|_\Lambda) - \Psi_\Lambda(\xi \lor \xi^+_n|_\Lambda) \right) \right)
\]
where $\mathcal{P}_\Lambda_n = \{ \Lambda \subset \mathbb{Z}^d \mid \Lambda \text{ is finite, path-connected and } \Lambda \cap \Lambda_n \neq \emptyset \}$. We recall that $\Psi$ is zero on non-path-connected sets.

If we show that for each $\eta \in \Omega_{\Lambda_n,x_0}^+$
\[
\sum_{\xi \in \Omega_{\Lambda_n,x_0}^-} \sum_{\delta \xi = \eta} \exp \left( \sum_{\Lambda \in \mathcal{P}_\Lambda_n} \left( \Psi_\Lambda(\eta \lor \xi^+_n|_\Lambda) - \Psi_\Lambda(\xi \lor \xi^+_n|_\Lambda) \right) \right) \leq b \quad (3.3)
\]
for some $0 < b < 1$ which is independent $x_0$, $n$ and $\eta$, then, by the equation above and \[3.2\], we have
\[
P_{x_0,n}^- \leq b Z_n^{-1} e^{M_n} \sum_{\eta \in \Omega_{\Lambda_n,x_0}^+} \exp \left( -2L |\Gamma_\eta| - \sum_{\Lambda \in \mathcal{P}_\Lambda_n} \Psi_\Lambda(\eta \lor \xi^+_n|_\Lambda) \right)
= b P_{x_0,n}^+,
\]
and hence Lemma \[3.4\] is proved.

We prove \[3.3\]. Let $\eta \in \Omega_{\Lambda_n,x_0}^+$. For each $\xi \in \Omega_{\Lambda_n,x_0}^-$ with $\delta \xi = \eta$, we have
\[
|\partial S_\xi,x_0| \leq |\beta_{\xi,x_0}|. \quad (3.4)
\]
Let $\Lambda \in \mathcal{P}_\Lambda_n$. If $\Lambda \cap \partial S_\xi,x_0 = \emptyset$, then $\Lambda \subset S_\xi,x_0$ or $\Lambda \cap S_\xi,x_0 = \emptyset$, since $\Lambda$ is path-connected.

Hence $\xi \lor \xi^+_n|_\Lambda = \xi|_\Lambda = -\delta \xi|_\Lambda = -\eta \lor \xi^+_n|_\Lambda$ or $\xi \lor \xi^+_n|_\Lambda = \delta \xi \lor \xi^+_n|_\Lambda = \eta \lor \xi^+_n|_\Lambda$ and, by the symmetricity of $\Psi$,
\[
\Psi_\Lambda(\xi \lor \xi^+_n|_\Lambda) = \Psi_\Lambda(\eta \lor \xi^+_n|_\Lambda).
\]
From this, the translation invariance of \( \Psi \) and (3.4), it follows that
\[
\sum_{\Lambda \in P_n} (\Psi_{\Lambda}(\eta \lor \xi | \Lambda) - \Psi_{\Lambda}(\xi \lor \xi^+ | \Lambda)) = 2 \sum_{\Lambda \in P_n, \Lambda \cap \partial S_{\xi, x_0} \neq \emptyset} \sup_{\zeta \in \Gamma_{\Lambda}} |\Psi(\zeta)| 
\leq 2 |\partial S_{\xi, x_0}| \|\Psi\| 
< 2 |\partial S_{\xi, x_0}| \varepsilon.
\]

Then, by (3.4),
\[
\sum_{\xi \in \Omega_{\Lambda_n, x_0}, \delta \xi = \eta} e^{-2L|\partial S_{\xi, x_0}|} \exp \left( \sum_{\Lambda \in P_n} (\Psi_{\Lambda}(\eta \lor \xi^+ | \Lambda) - \Psi_{\Lambda}(\xi \lor \xi^+ | \Lambda)) \right) 
\leq 2 \sum_{\xi \in \Omega_{\Lambda_n, x_0}, \delta \xi = \eta} e^{-2(L-\varepsilon)|\partial S_{\xi, x_0}|} 
\leq 2 \sum_{\xi \in \Omega_{\Lambda_n, x_0}, \delta \xi = \eta} e^{-2(L-\varepsilon)|\partial S_{\xi, x_0}|} 
= 2 \sum_{\xi \in \Omega_{\Lambda_n, x_0}, \delta \xi = \eta} e^{-2(L-\varepsilon)|\partial S_{\xi, x_0}|} \}
\leq \frac{(l + 2d - 4)(e \cdot 7^d)}{2d - 2}.
\]

For each positive integer \( l \), the map which sends \( \xi \in \{\xi \in \Omega_{\Lambda_n, x_0} : |\partial \xi_0| = l \} \) to \( S_{\xi, x_0} \in \{ G \subset \mathbb{Z}^d : x_0-\text{enclosing set} | |\partial G| = l \} \) is obviously injective. Then, by Lemma 3.5
\[
|\{\xi \in \Omega_{\Lambda_n, x_0} : |\partial \xi_0| = l \}| \leq \frac{(l + 2d - 4)(e \cdot 7^d)}{2d - 2}.
\]

Hence
\[
\sum_{l=1}^{\infty} e^{-2(L-\varepsilon)l} \left( \{\xi \in \Omega_{\Lambda_n, x_0} : |\partial \xi_0| = l \} \right) \leq \frac{(l + 2d - 4)(e \cdot 7^d)}{2d - 2} \leq \frac{1}{2d - 2} \sum_{l=1}^{\infty} (l + 2d - 4)(r_{L, \varepsilon})^l
\]
where \( r_{L, \varepsilon} = \varepsilon^d e^{1-2L-\varepsilon} \). If \( L \) is sufficiently large and \( \varepsilon \) is sufficiently small such that
\( r_{L,\varepsilon} \) is sufficiently small, then

\[
b = \frac{1}{2d - 2} \sum_{l=1}^{\infty} (l + 2d - 4)(r_{L,\varepsilon})^l
= \frac{r_{L,\varepsilon}}{(2d - 2)(1 - r_{L,\varepsilon})} \left( \frac{r_{L,\varepsilon}}{1 - r_{L,\varepsilon}} + 2d - 3 \right)
< 1
\]

and \( b \) depends only on \( L \) and \( \varepsilon \) and does not on \( x_0, n \) and \( \eta \). Hence we complete the proof of Lemma 3.4. Then we finished the proof of Proposition 3.3.

\[\square\]

**Proof of Theorem 3.1** For sufficiently large \( L > 0 \), we take sufficiently small \( \varepsilon > 0 \) such that Proposition 3.3 is established. Let \( \Psi \) be an interaction on \( \Omega \) which is symmetric, zero on non-path-connected sets and \( \|\Psi\| < \varepsilon \) and we write \( \Phi = \Phi^L + \Psi \). By Proposition 3.3 the Gibbs state \( \mu^+ \) for \( \Phi \) satisfies, for some \( a > 0 \),

\[
\int_{\Omega} f_x \, d\mu^+ > a
\tag{3.5}
\]

for any \( x \in \mathbb{Z}^d \). Since \( \Phi \) is translation invariant, \( \tau_x^+ \mu^+ \) is also a Gibbs state for \( \Phi \) (where \( \tau_x^+ \mu^+ \in \mathcal{M}(\Omega) \) is defined by \( \tau_x^+ \mu^+(B) = \mu^+(\tau_x^2 B) \)). Then, by the convexity of \( K_\Phi \),

\[
\nu_n^+ = \frac{1}{|\Lambda_n|} \sum_{x \in \Lambda_n} \tau_x^+ \mu^+
\]

is also a Gibbs state for \( \Phi \) for each positive integer \( n \). Moreover, form (3.5),

\[
\int_{\Omega} f_0 \, d\nu_n^+ = \frac{1}{|\Lambda_n|} \sum_{x \in \Lambda_n} \int_{\Omega} f_0 \circ \tau_x \, d\mu^+
= \frac{1}{|\Lambda_n|} \sum_{x \in \Lambda_n} \int_{\Omega} f_x \, d\mu^+
> a.
\tag{3.6}
\]

Since \( K_\Phi \subset \mathcal{M}(\Omega) \) is compact, there exist a subsequence \( \{\nu_{n_k}^+\}_{k=1}^{\infty} \) of \( \{\nu_n^+\}_{n=1}^{\infty} \) and \( \nu^+ \in K_\Phi \) such that \( \nu_{n_k}^+ \rightarrow \nu^+ \) in \( \mathcal{M}(\Omega) \) as \( k \rightarrow \infty \). It is easily seen that \( \nu^+ \) is translation invariant and hence, by Proposition 1.2, \( \nu^+ \) is an equilibrium state for \( \Phi \). Furthermore, by letting \( n = n_k \) in (3.6) and \( k \rightarrow \infty \),

\[
\int_{\Omega} f_0 \, d\nu^+ \geq a > 0.
\tag{3.7}
\]

We define \( T : \Omega \rightarrow \Omega \) as the inversion of the sign on \( \Omega \), that is,

\[(T\xi)(x) = -\xi(x)\]

for any \( \xi \in \Omega \). We write \( \nu^- = T_\ast \nu^+ \in \mathcal{M}(\Omega) \). By the symmetricity of \( \Phi \), it is easily seen
that $\nu^-$ is also an equilibrium state for $\Phi$. Furthermore, by (3.7),
\[
\int_{\Omega} f_0 \, d\nu^- = \int_{\Omega} f_0 \circ T \, d\nu^+ \\
= -\int_{\Omega} f_0 \, d\nu^+ < 0.
\]
Then $\nu^+$ and $\nu^-$ are distinct equilibrium states for $\Phi$, and hence we complete the proof.

At the end of this section, we give an example which shows that Theorem 1.3 (2) is not true if the symmetricity of an interaction drops.

Example 3.1. Let $h \in \mathbb{R} \setminus \{0\}$ and define an interaction $\Psi^h$ as
\[
\Psi^h_{\Lambda}(\xi) = \begin{cases} 
 h\xi(x), & \text{if } \Lambda = \{x\} \text{ for some } x \in \mathbb{Z}^d \\
 0, & \text{otherwise}
\end{cases}
\]
for any finite $\Lambda \subset \mathbb{Z}^d$. $\Psi^h$ is a translation invariant and $d$-th order decreasing interaction on $\Omega$ with $\|\Psi^h\| = |h|$, which is not symmetric. It is known that, for any $L > 0$ and any $h \in \mathbb{R} \setminus \{0\}$, $\Phi^L + \Psi^h$ has a unique Gibbs state and a unique equilibrium state (for example, see [4, Theorem 5-28] or [5]).

Acknowledgements

The author is grateful to Masayuki Asaoka and Mitsuhiro Shishikura for their valuable guidance. He also thanks Takehiko Morita, Masaki Tsukamoto and Tom Meyerovitch for their instructive comments. In particular, Tom Meyerovitch told me Example 3.1 and the fact that Theorem 1.3 (1) follows from Theorem 2.2.
