# Hybrid models for homological projective duals and noncommutative resolutions 

Jirui Guo ${ }_{-}^{1}$ and Mauricio Romo ${ }_{-}^{2}$<br>Yau Mathematical Sciences Center, Tsinghua University, Beijing, 100084, China

#### Abstract

We study hybrid models arising as homological projective duals (HPD) of certain projective embeddings $f: X \rightarrow \mathbb{P}(V)$ of Fano manifolds $X$. More precisely, the category of B-branes of such hybrid models corresponds to the HPD category of the embedding $f$. B-branes on these hybrid models can be seen as global matrix factorizations over some compact space $B$ or, equivalently, as the derived category of the sheaf of $\mathcal{A}$-modules on $B$, where $\mathcal{A}$ is a sheaf of $A_{\infty}$-algebras. This latter interpretation corresponds to a noncommutative resolution of $B$. We compute explicitly the algebra $\mathcal{A}$ by several methods, for some specific class of hybrid models. If the target space of the hybrid model is a global orbifold, $\mathcal{A}$ takes the form of a smash product of an $A_{\infty}$-algebra with a finite group. However, this is not the case in general because the orbifold group can only be defined locally. One needs to treat the target space as an algebraic stack in such cases. We apply our results to the HPD of $f$ corresponding to a Veronese embedding of projective space and the projective embedding of Fano complete intersections in $\mathbb{P}^{n}$.

## 1 Introduction

It is known that hybrid models provide realizations of a series of two-dimensional superconformal field theories which can be obtained from certain phases of gauged linear sigma models (GLSM) [1]. Roughly speaking, a hybrid model is a two-dimensional $\mathcal{N}=(2,2)$ supersymmetric field theory whose target space is of the form $Y=\operatorname{Tot}(\mathcal{E} \rightarrow B)$ for some holomorphic vector bundle (or an orbibundle, in general) $\mathcal{E}$ over the base space $B$ where the fields interact via a superpotential $W \in H^{0}\left(\mathcal{O}_{Y}\right)$ which is a holomorphic function on the total space. The hybrid model can be viewed as a family of Landau-Ginzburg (LG) models fibred over the base space. Further sufficient conditions (but not necessary) in $Y$ and $W$ guarantee that these models RG flows to SCFTs and also makes them tractable as quantum field theories (QFT), see for instance $[2,3]$.

Recently, it is found that homological projective dual (HPD) [4] of certain projective embeddings can be described by hybrid models. This was found in mathematics [ $[\underline{6}, \underline{6}]$ and a physics formulation is presented in ${ }_{-}^{1}$ [8]: if a GLSM $\mathcal{T}_{X}$ for a projective morphism $f: X \rightarrow$ $\mathbb{P}(V)$ is known, one can build up an extended GLSM $\mathcal{T}_{\mathcal{X}}$ such that the Higgs branch of one

[^1]of its phases gives rise to the HPD of $f: X \rightarrow \mathbb{P}(V)$. In the abelian cases, this construction provides a very explicit characterization of the HPD of $f: X \rightarrow \mathbb{P}(V)$. Indeed, the Higgs branch of the phase of $\mathcal{T}_{\mathcal{X}}$, relevant to the question, is a hybrid model.

These hybrid models, with target space $Y=\operatorname{Tot}(\mathcal{E} \rightarrow B)$ can be view as (orbifold) LG models over affine charts of $B$ in the cases that $B$ is smooth, or if it has the structure of a global orbifold. This gives rise to the global structure of a noncommutative resolution or more generally, the B-brane category becomes the derived category of sheaves of $\mathcal{A}$-modules for some sheaf of algebras $\mathcal{A}$. Let us illustrate this in a well known example.

For a LG model with quadratic superpotential $W_{L G}$, it was shown in [9] that the category of B-branes (homotopy category of matrix factorizations) $M F\left(W_{L G}\right)$ is equivalent to the derived category of finite dimensional Clifford modules, where the Clifford algebra is defined by the Hessian of the superpotential $W_{L G}$. In addition, if a $\mathbb{Z}_{2}$ orbifold is present that leaves $W_{L G}$ invariant, then the category of B-branes of this LG orbifold $M F\left(W_{L G}, \mathbb{Z}_{2}\right)$ is equivalent to the derived category of finite dimensional modules of the even subalgebra of the corresponding Clifford algebra. Consequently, the category of matrix factorizations of a $\mathbb{Z}_{2^{-}}$ orbifold hybrid model with superpotential quadratic along the fiber coordinates is equivalent to the derived category of the sheaf of modules of the sheaf of even parts of a Clifford algebra over the base $B$. This is the case of the HPD category of the degree 2 Veronese embedding $\mathbb{P}(V) \hookrightarrow \mathbb{P}\left(\mathrm{Sym}^{2} V\right)[10]$. Thus, the hybrid model orbifold can be viewed as a noncommutative resolution of $B$.

In this work, we generalize the idea and construct an explicit correspondence between hybrid models and noncommutative spaces. Consider first the case where $B$ can be described locally by affine charts and $Y$ is a global orbifold such that the orbifold group $G$ acts trivially on $B$. Then, at a generic point in the base $p \in B$ of the hybrid model, we can model its dynamics by a LG orbifold. Denote the category of B-branes of this LG orbifold as $M F(W, G)$, where $G$ is the orbifold group. We first study the $A_{\infty}$-algebra $\mathcal{A}_{D 0}=\operatorname{End}\left(\mathcal{B}_{D 0}\right)$ associated with the endomorphism algebra of a $D 0$-brane $\mathcal{B}_{D 0} \in M F(W)$ of the LG model. The algebra $\mathcal{A}_{D 0}$ takes the form of an $A_{\infty}$ algebra with a finite number of generators (as an algebra) $\psi_{i}$ that satisfy the higher products relations given in (4.65) and (4.66) (for a homogeneous $W)$ and for general elements (4.69) and (4.70 $)^{2}$. It then sets up the equivalence between matrix factorizations and $A_{\infty}$-modules of $\mathcal{A}_{D 0} \sharp G$, where $\sharp$ denotes the smash product (the mathematical approach toward this equivalence can be found in [11]), more precisely

$$
\begin{equation*}
M F(W, G) \cong D\left(\operatorname{Mod}-\mathcal{A}_{D 0} \sharp G\right), \tag{1.1}
\end{equation*}
$$

where the appeareance of the derived category is a consequence that $M F(W, G)$ is taken to be the homotopy category. We then use this equivalence to relate a hybrid model to a noncommutative resolution

$$
\begin{equation*}
D(Y, W) \cong D\left(B, \mathcal{A}_{D 0 \sharp} \sharp G\right), \tag{1.2}
\end{equation*}
$$

i.e. the derived category of sheaf of $\mathcal{A}_{D 0} \sharp G$-modules over $B$.

The more general case, for example when $G$ acts on $B$, or more precisely, when $B$ has orbifold singularities and/or it cannot be written as a global orbifold still has a similar structure. In such a case we have that $D(Y, W)$ is equivalent to the derived category of $\mathcal{A}$-modules for some sheaf of $A_{\infty}$-algebras $\mathcal{A}$, defined over the algebraic stack $Y$. We studied this case in detail in section 4.5 .

[^2]These results can be used to study HPD of several spaces. As mentioned above, the GLSM construction realizes the HPDs as hybrid orbifold models, which can be identified with noncommutative resolutions, or derived categories of sheaves of $A_{\infty}$-modules, as the equivalence suggests. Therefore, given a projective embedding engineered by an abelian GLSM, the hybrid model describing the HPD can be read off following [ 8$]$. One can then use the correspondence discussed in this paper to give a noncommutative geometric decription of the HPD. More precisle we apply these results to the follwoing families of examples

1. HPD of degree $d$ Veronese embedding of $\mathbb{P}^{n}$ : The HPD of the degree $d$ Veronese embedding $\mathbb{P}(V) \hookrightarrow \mathbb{P}\left(\mathrm{Sym}^{2} V\right), V \cong \mathbb{C}^{n+1}$ was studied in $[8,12]$ and is found to be given by a hybrid LG orbifold i.e. its target space $Y$ can be written as a global orbifold, specifically

$$
Y=\operatorname{Tot}\left(\mathcal{O}\left(-\frac{1}{d}\right)^{\oplus(n+1)} \rightarrow \mathbb{P}^{\binom{n+d}{d}-1}\right) / \mathbb{Z}_{d}
$$

where $\mathcal{O}\left(-\frac{1}{d}\right)$ denotes an orbibundle (see appendix C ) and a superpotential of degree $d$ in the fiber coordinates. In section 5.1 we show that the B-brane category of this hybrid model can be written as

$$
\begin{equation*}
D\left(\mathbb{P}^{\binom{n+d}{d}-1}, \mathcal{A}_{0} \sharp \mathbb{Z}_{d}\right)=\left\langle\mathcal{A}^{\left(1-C_{d, n}\right)}, \cdots, \mathcal{A}^{(-1)}, \mathcal{A}^{(0)} \cong \mathcal{A}_{0}\right\rangle, \tag{1.3}
\end{equation*}
$$

where $\mathcal{A}_{0} \cong \mathcal{A}_{D 0}$ is the $A_{\infty}$-algebra described above. We also describe explicitly the components of the semiorthogonal decomposition (predicted in [8]), in (1.3), in terms of $\mathcal{A}_{0} \not \mathbb{Z}_{d}$-modules.
2. HPD of Fano hypersurfaces: The HPD of the degree $d$ Fano hypersurface inside $\mathbb{P}^{n}$, embedded naturally, is analyzed in section 5.2. This case, analyzed in [8,12], is similar to the HPD of the degree $d$ Veronese embedding, since the target space of the HPD is also a hybrid LG orbifold with target space given by a global orbifold, namely

$$
Y=\operatorname{Tot}\left(\mathcal{O}_{\mathbb{P}^{n}}^{\oplus(n+1)} \oplus \mathcal{O}_{\stackrel{\mathbb{P}}{ }^{n}}(-1) \rightarrow \check{\mathbb{P}}^{n}\right) / \mathbb{Z}_{d}
$$

and superpotential

$$
\begin{equation*}
W=F_{d}(x)+p \sum_{i=0}^{n} x_{i} y_{i} \tag{1.4}
\end{equation*}
$$

(see section $\underline{5.2}$ for a detailed description of the variables). The B-brane category of this hybrid model has a (dual) Lefschetz decomposition proposed in [8]:

$$
\begin{equation*}
D(Y, W)=\left\langle\mathcal{B}_{n-1}(1-n), \mathcal{B}_{n-2}(2-n), \cdots, \mathcal{B}_{2}(-2), \mathcal{B}_{1}(-1), \mathcal{B}_{0}\right\rangle, \tag{1.5}
\end{equation*}
$$

in section 5.2 we describe this decomposition explicitly using the Lefschetz decomposition of the Fano hypersurface, induced by the natural embedding. In addition we describe $D(Y, W)$ as a noncommutative resolution

$$
\begin{equation*}
D(Y, W) \cong D\left(\check{\mathbb{P}}^{n}, \mathcal{A}_{0} \not \mathbb{Z}_{d}\right), \tag{1.6}
\end{equation*}
$$

giving very explicit constructions for the cases of degrees $d=2,3$.
3. HPD of Fano complete intersections: The HPD of Fano complete intersections was studied in [8]. For an intersection of hypersurfaces of degree $d_{i}, i=1, \ldots, k$ on $\mathbb{P}^{n}$, the HPD was found to be given by a hybrid model with target space

$$
Y=\operatorname{Tot}\left(\mathcal{O}(-1,0)^{\oplus(n+1)} \oplus \mathcal{O}(1,-1) \rightarrow \mathrm{WP}\left(d_{1}, \cdots, d_{k}\right) \times \check{\mathbb{P}}^{n}\right)
$$

and superpotential

$$
W=\sum_{\alpha=1}^{k} p_{\alpha} F_{d_{\alpha}}(x)+p \sum_{i=0}^{n} x_{i} y_{i},
$$

details of the notation can be found in section 5.3. In this case, the main difficulty lays on the fact that, in general, $Y$ cannot be written as a global orbifold, but as a local one. In special cases such as $d_{i}=d$ for all $i$, we can write it as a global orbifold. As far as we are aware this is the less studied case in the literature. In section 4.5 we describe the sheaf of algebra $\mathcal{A}$ in this case, as a sheaf of algebras over the algebraic stack $Y$ and we apply it, in section 5.3, to the HPD of Fano complete intersections.

This paper is organized as follows. We review the basic facts about GLSMs for HPD and $A_{\infty}$-algebras in sections $\underline{2}$ and $\underline{3}$ respectively. In section $\underline{4}$, we set up the relationship between matrix factorizations and $A_{\infty}$-modules. We first find the structure of the $A_{\infty}$-algebra $\mathcal{A}_{D 0}$ by various means (deformation theory of $\mathcal{B}_{D 0}$ and effective superpotential, $A_{\infty}$-homomorphism), then we propose a functor realizing the equivalence between the category of matrix factorizations and the derived category of $A_{\infty}$-modules of $\mathcal{A}_{D 0}$ and sketch its generalization to the orbifold case $\mathcal{A}_{D 0} \sharp G$. We provide checks of this proposal in appendix $\mathbb{A}$. We then apply this correspondence in section $\underline{5}$ to describe the HPD of degree $d$ Veronese embedding of projective space, Fano hypersurfaces and complete intersections in projective spaces as noncommutative spaces with the structure sheaf given by the corresponding sheaf of $A_{\infty}$-algebras. The same result was obtained for Veronese embeddings by summing over the ribbon trees in [12], we review this method in appendix B. Finally, in section $\underline{6}$ we give some details of the functor $D(B, \mathcal{A}-M o d) \rightarrow D(\mathcal{X})$, i.e. of the embedding of the noncommutative resolution category into the derived category of the universal hyperplane section of $X$.

## 2 Lightning review of GLSMs for HPD

In this section, we review the construction of homological projective duals (HPD) of projective morphisms $f: X \rightarrow \mathbb{P}(S)$ (where $S \cong \mathbb{C}^{n+1}$ ) proposed in [8]. We refer the reader to [8] for the details of definitions and notations. The construction of [8] assumes that we have a gauged linear sigma model (GLSM) construction for $f: X \rightarrow \mathbb{P}(S)$, i.e. a GLSM having a geometric phase corresponding to a Higgs branch ${ }_{-}^{3}$ that RG flows to a nonlinear sigma model (NLSM) whose target space is the image of $f$ in $\mathbb{P}(S)$. Denote that GLSM by

$$
\begin{equation*}
\mathcal{T}_{X}=\left(G, \rho_{m}: G \rightarrow G L(V), W, t_{\text {ren }}, R\right) . \tag{2.1}
\end{equation*}
$$

We make some remarks about the tuple $\mathcal{T}_{X}$ :

- The gauge group $G$ is taken to be a compact Lie group and $W \in \operatorname{Sym}\left(V^{\vee}\right)^{G}$ denotes the superpotential.

[^3]- The FI-theta parameter $t_{\text {ren }}$ is renormalized and depends on the energy scale for the case of anomalous GLSMs. In the following, to avoid cluttering we will simply denote $t:=t_{\text {ren }}$ having in mind that $t$ may depend on the energy scale.
- The (vector) R-charge assignment $R$ will not play an important role in our discussions below. Moreover, it is only well defined in the IR and depends on the phase. Hence we will leave it unspecified.
- For simplicity, in the discussion below, we will assume that the gauge group $G$ gets classically broken to a finite subgroup in every phase. This is always true if $G$ is abelian and $\rho_{m}$ is faithful. In the case that $G$ is nonabelian this is usually not true (see for example [13]) however, the GLSM phases are still well defined theories and we expect that our analysis can be carried out. All the examples we will cover in this work corresponds to $G$ abelian. Some comments and conjectures for nonabelian $G$ can be found in [8].

The morphism $f$ must be base point free, hence $f$ defines a line bundle $\mathcal{L}$ over $X$ given by

$$
\begin{equation*}
\mathcal{L}=f^{*} \mathcal{O}_{\mathbb{P}(S)}(1) . \tag{2.2}
\end{equation*}
$$

Then, since there is a corresponding character $\chi \in \operatorname{Hom}\left(G, \mathbb{C}^{*}\right)$ to $\mathcal{L}$ be there exist a distinguished $U(1)_{\mathcal{L}} \subset G$ (with associated FI-theta parameter $t_{\mathcal{L}}=\zeta_{\mathcal{L}}-i \theta_{\mathcal{L}}$ ) associated to $\mathcal{L}$ (see [8] for more details). The components of $f$ transforms under $g \in G$ by multiplication by $\chi(g)$ i.e. they have homogeneous weight under $U(1)_{\mathcal{L}}$ and corresponds to sections of $\mathcal{L}$. In the following we assume that the aforementioned geometric phase is a pure Higgs phase ${ }_{-}^{4}$ and its category of B-branes will be denoted by $D\left(X_{\zeta_{c} \gg 1}\right):=D^{b} \operatorname{Coh}\left(X_{\zeta c \gg 1}\right)$, if this phase is located at $\zeta_{\mathcal{L}} \gg 1$. As we vary the parameter $\zeta_{\mathcal{L}}$ we find, in general that the phase at $\zeta_{\mathcal{L}} \ll-1$ has a Higgs branch whose category of B-branes we denote ${ }^{5} D\left(Y_{\zeta_{\mathcal{L} \ll-1}}, W_{\zeta_{\mathcal{L} \ll-1}}\right)$ and a mixed Coulomb-higgs branch that splits into several isolated vacua, whose categories of B-branes we denote as $E_{1}, \ldots, E_{k}$. Both categories of B-branes at the different values of $\zeta_{\mathcal{L}}$ are expected to be related by [14-17]

$$
\begin{equation*}
\left\langle D\left(Y_{\zeta \mathcal{L}<-1}, W_{\zeta_{\mathcal{L}}<-1}\right), E_{1}, \ldots, E_{k}\right\rangle \cong D\left(X_{\zeta \mathcal{L} \gg 1}\right) \tag{2.3}
\end{equation*}
$$

The equivalence (2.3) is realized at the level of the GLSM via the so called window categories. They are defined entirely via the UV datum (or GLSM datum) i.e. the tuple $\mathcal{T}_{X}$. Defining a B-brane $\mathcal{B}$ in the GLSM requires to specify a representation $\rho_{M}: G \rightarrow G L(M)$. If we denote $q^{\mathcal{L}}$ the weight of $\rho_{M}$ restricted to $U(1)_{\mathcal{L}}$, then we define two conditions on the weights $q^{\mathcal{L}}$ :

$$
\begin{array}{lr}
\text { Small window : } & \left|\theta_{\mathcal{L}}+2 \pi q^{\mathcal{L}}\right|<\pi \min \left(N_{\mathcal{L}, \pm}\right), \\
\text { Big window : } & \left|\theta_{\mathcal{L}}+2 \pi q^{\mathcal{L}}\right|<\pi \max \left(N_{\mathcal{L}, \pm}\right), \tag{2.4}
\end{array}
$$

where $N_{\mathcal{L}, \pm}:=\sum_{a}\left(Q_{a}^{\mathcal{L}}\right)^{ \pm},(x)^{ \pm}:=(|x| \pm x) / 2$ and $Q_{a}^{\mathcal{L}}$ are the weights of $\rho_{m}$ restricted to $U(1)_{\mathcal{L}}$. Therefore we have the definition of the window subcategories by the constraints (2.4):

[^4]$\mathcal{W}_{+, b}^{\mathcal{L}}$ (resp. $\mathcal{W}_{-, b}^{\mathcal{L}}$ ) corresponds to the objects $\mathcal{B}$ such that the weights $q^{\mathcal{L}}$ of $\rho_{M}$ satisfy the $\operatorname{big}$ (resp. small) window constraint for $b=\left\lfloor\frac{\theta_{\mathcal{L}}}{2 \pi}\right\rfloor$. The we have
\[

$$
\begin{equation*}
D\left(Y_{\zeta_{\mathcal{L}} \ll-1}, W_{\zeta_{\mathcal{L}} \ll-1}\right) \cong \mathcal{W}_{-, b}^{\mathcal{L}} \hookrightarrow D\left(X_{\zeta_{\mathcal{L}} \gg 1}\right) \cong \mathcal{W}_{+, b}^{\mathcal{L}} \tag{2.5}
\end{equation*}
$$

\]

for any $b \in \mathbb{Z}$. It is straightforward to see that in the nonanomalous case, $N_{\mathcal{L},+}=N_{\mathcal{L},-}$ and small and big window categories become equivalent giving an equivalence of categories

$$
\begin{equation*}
D\left(Y_{\zeta_{\mathcal{L}} \ll-1}, W_{\zeta_{\mathcal{L}} \ll-1}\right) \cong \mathcal{W}_{b}^{\mathcal{L}} \cong D\left(X_{\zeta_{\mathcal{L}} \gg 1}\right) \tag{2.6}
\end{equation*}
$$

where we dropped the $\pm$ index. This equivalence, via window categories is known as the grade restriction rule and was originally proposed for $G$ abelian and nonanomalous GLSMs in [18] and later rigurously generalized to anomalous GLSMs and nonabelian $G$ in [14, 19], the physical aspects of these generalizations where first studied in $[15,16]$ for nonanomalous and nonabelian GLSMs (plus some aspects of the anomalous case only for $G=U(1)$ ) and for anomalous and abelian GLSMs in [17]. Our presentation of the window categories (2.4) is based on [17]. Before moving on to the construction of the GLSM containing the HPD of $f: X \rightarrow \mathbb{P}(S)$ we illutrate this construction with a few examples:

- Consider the case $\mathcal{T}_{X}=\left(U(1), \rho_{m}: U(1) \rightarrow G L\left(\mathbb{C}^{n+2}\right), W=p_{0} F_{d}(x), t, R\right)$ where $\left(p_{0}, x_{0}, \ldots, x_{n}\right) \in \mathbb{C}^{n+2}, \rho_{m}$ is defined as

$$
\begin{equation*}
\rho_{m}(\lambda) \cdot\left(p_{0}, x_{0}, \ldots, x_{n}\right)=\left(\lambda^{-d} p_{0}, \lambda x_{0}, \ldots, \lambda x_{n}\right), \quad \lambda \in U(1) \tag{2.7}
\end{equation*}
$$

and $F_{d}(x) \in \mathbb{C}\left[x_{0}, \ldots, x_{n}\right]$ is homogeneous of degree $d \leq n+1$ satisfying $d F_{d}^{-1}(0)=\{0\}$. Then

$$
\begin{equation*}
X_{\zeta \gg 1}=\left\{F_{d}=0, p_{0}=0\right\} \cap Y_{\zeta \gg 1}, \quad Y_{\zeta \gg 1}=\mathcal{O}(-d) \rightarrow \mathbb{P}^{n} \tag{2.8}
\end{equation*}
$$

then, the function $f$ corresponds to the natural embedding of $X_{\zeta \gg 1}$ in $\mathbb{P}^{n}$ and $\mathcal{L}=$ $\mathcal{O}_{X}(1)$. The analysis of the window categories gives [14-17]

$$
\begin{equation*}
D\left(\mathbb{C}^{n+1} / \mathbb{Z}_{d}, F_{d}\right) \cong \mathcal{W}_{-, b}^{\mathcal{L}} \hookrightarrow D\left(X_{\zeta \gg 1}\right) \cong \mathcal{W}_{+, b}^{\mathcal{L}} \tag{2.9}
\end{equation*}
$$

and the equivalence (2.3) becomes

$$
\begin{equation*}
\left\langle D\left(\mathbb{C}^{n+1} / \mathbb{Z}_{d}, F_{d}\right), E_{1}, \ldots, E_{n+1-d}\right\rangle \cong D\left(X_{\zeta \gg 1}\right) \tag{2.10}
\end{equation*}
$$

- Consider the case $\mathcal{T}_{X}=\left(U(1), \rho_{m}: U(1) \rightarrow G L(V), W, t, R\right)$ where

$$
\begin{equation*}
V=\operatorname{Sym}^{d} \mathbb{C}^{n+1} \oplus \operatorname{Sym}^{d} \mathbb{C}^{n+1} \oplus \mathbb{C}^{n+1} \tag{2.11}
\end{equation*}
$$

denote $\left(p_{1}, \ldots, p_{\binom{n+d}{d}}, y_{1}, \ldots, y_{\binom{n+d}{d}}, x_{0}, \ldots, x_{n}\right) \in V$, the representation $\rho_{m}$ is defined by

$$
\begin{align*}
\rho_{m}(\lambda) \cdot(p, y, x) & =\left(\lambda^{-d} p, \lambda^{d} y, \lambda x\right), \quad \lambda \in U(1)  \tag{2.12}\\
W & =\sum_{j=1}^{\binom{n+d}{d}} p_{j}\left(y_{j}-f_{j}(x)\right) \tag{2.13}
\end{align*}
$$

where $f_{j}(x) \in \mathbb{C}\left[x_{0}, \ldots, x_{n}\right]$ are the monomials of degree $d$ in $x$. In this case $X_{\zeta \gg 1} \cong \mathbb{P}^{n}$, but the function $f: \mathbb{P}^{n} \rightarrow \mathbb{P}\left(\operatorname{Sym}^{d} \mathbb{C}^{n+1}\right)$ becomes the degree $d$ Veronese embedding. However, an analysis of this GLSM shows that the small window is empty and the equivalence (2.3) becomes

$$
\begin{equation*}
\left\langle E_{1}, \ldots, E_{n+1}\right\rangle \cong D\left(\mathbb{P}^{n}\right) \cong \mathcal{W}_{+, b}^{\mathcal{L}} \tag{2.14}
\end{equation*}
$$

Ondeed, this GLSM is equivalent to the GLSM $\mathcal{T}_{\mathbb{P} n}=\left(U(1), \rho_{m}: U(1) \rightarrow G L\left(\mathbb{C}^{n+1}\right), W \equiv\right.$ $0, t, R)$, where $\rho_{m}(\lambda)$ acts with weight 1 on every variable [20], i.e., to the usual GLSM for $\mathbb{P}^{n}$. However, the HPD is expected to depend on $f$ [4]. This is reflected in the following construction of the extended GLSM $\mathcal{T}_{\mathcal{X}}$, which is the GLSM containing the HPD. The extended GLSM $\mathcal{T}_{\mathcal{X}}$ depends on whether it is induced from $\mathcal{T}_{X}$ or $\mathcal{T}_{\mathbb{P}^{n}}$.

Starting from $\mathcal{T}_{X}$, we define an extension $\mathcal{T}_{\mathcal{X}}$ of $\mathcal{T}_{X}$ given by

$$
\begin{equation*}
\mathcal{T}_{\mathcal{X}}=\left(\widehat{G}=G \times U^{\prime}(1), \hat{\rho}_{m}: \widehat{G} \rightarrow G L\left(V \oplus V^{\prime}\right), \widehat{W}, \widehat{R}\right), \tag{2.15}
\end{equation*}
$$

where $V^{\prime}$ is a representation of $U^{\prime}(1) \times U(1)_{\mathcal{L}} \subseteq \widehat{G}$ with weights $(-1,-Q) \oplus(1,0)^{\oplus(n+1)}$, where $Q \in \mathbb{Z}$ is the weight of the character $\chi$ defined above. Denoting the coordinates of $V^{\prime}$ as $\left(p, s_{0}, \ldots, s_{n}\right)$, the superpotential $\widehat{W}$ is given by

$$
\begin{equation*}
\widehat{W}=W+p \sum_{j=0}^{n} s_{j} f_{j}(x), \tag{2.16}
\end{equation*}
$$

where $f_{j}(x)$ are the components of the image of the map $f$. The GLSM $\mathcal{T}$ is identified with the GLSM of the universal hyperplane section ${ }^{6} \mathcal{X}$ of $X$ : Its Higgs branch deep in the first quadrant of the FI parameter of $U^{\prime}(1) \times U(1)_{\mathcal{L}}$ corresponds to a NLSM with target space $\mathcal{X}$. The phase space of $\left(\zeta^{\prime}, \zeta_{\mathcal{L}}\right)$ takes generically the form specified in Figure 1, as analyzed in [8]. In Figure 1 we have specified the B-brane categories on the Higgs branches in every phase, which are the relevant branches for determining the HPD of $f: X \rightarrow \mathbb{P}(S)$.

Keeping $\zeta^{\prime} \gg 1$ and varying $\zeta_{\mathcal{L}}$ leads to the following equivalence of categories

$$
\begin{equation*}
\mathcal{C}=D\left(\widehat{Y}_{\zeta_{\mathcal{L}}<-1}, \widehat{W}_{\zeta_{\mathcal{L}} \ll-1}\right) \cong \widehat{\mathcal{W}}_{-, b}^{\mathcal{L}} \hookrightarrow D\left(\mathcal{X}_{\zeta \mathcal{L} \gg 1}\right) \cong \widehat{\mathcal{W}}_{+, b}^{\mathcal{L}}, \tag{2.17}
\end{equation*}
$$

where the categories $\widehat{\mathcal{W}}_{ \pm, b}^{\mathcal{L}}$ are defined analogously to $\mathcal{W}_{ \pm, b}^{\mathcal{L}}$, but in the GLSM $\mathcal{T}_{\mathcal{X}}$. The category $\mathcal{C}$ is identified with the HPD category of $f: X \rightarrow \mathbb{P}(S)$ i.e. the proposal of $[5, \underline{6}, \underline{8}]$ is that the subcategory of $D(\mathcal{X})$ corresponding to the small window category is equivalent to $\mathcal{C}$. We proceed to illustrate $\mathcal{T}_{\mathcal{X}}$ and $\mathcal{C}$ in the example of a degree $d$ Veronese embedding (the example of a Fano hypersurface is reviewed in detail in section 5.2.

- Consider the GLSM $\mathcal{T}_{\mathcal{X}}$ corresponding the the degree $d$ Veronese embedding. Then, $\widehat{G}=U^{\prime}(1) \times U(1)_{\mathcal{L}}$. The weights of the representation $\hat{\rho}_{m}: \widehat{G} \rightarrow G L\left(V \oplus V^{\prime}\right)$ are given in the following table

[^5]

Figure 1: Higgs branches of the GLSM $\mathcal{T}_{\mathcal{X}}$
The theory $\mathcal{T}_{\mathcal{X}}$ has a geometric phase realizing the universal hyperplane section $\mathcal{X}$ and a LG phase realizing the HPD category $\mathcal{C}$. When $D\left(Y_{\zeta_{l} \ll-1}, W_{\zeta_{l} \ll-1}\right)$ is empty, $\mathcal{C}^{\prime} \cong \mathcal{C}$, otherwise $\mathcal{C}^{\prime}$ is a subcategory of $\mathcal{C}$. The dashed arrow shows the direction of RG flow.

We remark that here, the fields $\left(p, s_{j}\right)$ span the representation $V^{\prime}$ and the fields $x_{i}$ span the representation $V$, where we simplified the model by integrating out the massive fields $(y, p)$ of the original representation. The superpotential $\widehat{W}$ then becomes

$$
\begin{equation*}
\widehat{W}=p \sum_{j=1}^{\binom{n+d}{d}} s_{j} f_{j}(x) . \tag{2.18}
\end{equation*}
$$

Then, the Higgs branch in the region $\zeta_{\mathcal{L}} \ll-1$ and $\zeta^{\prime} \gg 1$ becomes the hybrid model with target space

$$
\begin{equation*}
Y_{L G}=\operatorname{Tot}\left(\mathcal{O}\left(-\frac{1}{d}\right)^{\oplus(n+1)} \rightarrow \mathbb{P}^{\binom{n+d}{d}-1}\right) / \mathbb{Z}_{d} \tag{2.19}
\end{equation*}
$$

and superpotential

$$
\begin{equation*}
W_{L G}=\sum_{j=1}^{\binom{n+d}{d}} s_{j} f_{j}(x) \tag{2.20}
\end{equation*}
$$

then, the category $\mathcal{C}$, corresponding to the HPD of the degree $d$ Veronese embedding of $\mathbb{P}^{n}$, is given by $\mathcal{C}=D\left(Y_{L G}, W_{L G}\right)$. In this particular family of examples one can show $\mathcal{C} \cong \mathcal{C}^{\prime}[8]$. We will revisit the category $\mathcal{C}=D\left(Y_{L G}, W_{L G}\right)$ in section 5.1

Everything can be carried over when taking linear sections of $X$, but in this work we will be mainly interested in the HPD of $X$.

Using this proposal, we can express $\mathcal{C}$ as the category of B-branes on a Higgs branch that can be described as a fibered LG model i.e. a hybrid model, which usually will have the characteristics of a good hybrid in the sense of $[2,3]$, making it very tractable.

## 3 Lightning review of $A_{\infty}$ algebras and their relation to open topological strings

In this section we present the useful definitions and results that relate $A_{\infty}$ to the relevant physical systems we are going to need in the subsequent sections. Let us start with the definition of $A_{\infty}$ algebra (our main reference is [21] but other useful sources are [22-24]).

Definition. An $A_{\infty}$ algebra over a field $\mathbb{K}$ Consist of a $\mathbb{Z}$-graded $\mathbb{K}$-vector space $A$

$$
\begin{equation*}
A=\bigoplus_{p \in \mathbb{Z}} A^{p} \tag{3.1}
\end{equation*}
$$

endowed with homogeneous $\mathbb{K}$-linear maps ${ }_{-}^{7}$

$$
\begin{equation*}
m_{n}: A^{\otimes n} \rightarrow A, \quad n \geq 1 \tag{3.2}
\end{equation*}
$$

of degree $2-n$ satisfying the relations

$$
\begin{equation*}
\sum_{r+s+t=n}(-1)^{r+s t} m_{u}\left(\mathbf{1}^{\otimes r} \otimes m_{s} \otimes \mathbf{1}^{\otimes t}\right)=0, \quad n \geq 1 \tag{3.3}
\end{equation*}
$$

where $u=r+t+1$ and $s \geq 1, r, t \geq 0$.
Let us make a few important remarks. First, note that (3.3) implies $m_{1} \circ m_{1}=0$ hence, $m_{1}$ is a differential. Second, the maps in the tensor products, such as in (3.3) are subject to the Koszul sign rule:

$$
\begin{equation*}
(f \otimes g)(a \otimes b)=(-1)^{|g||a|} f(a) \otimes g(b) \tag{3.4}
\end{equation*}
$$

where we assume $a$ is a homogeneous element of degree $|a|$, and $|g|$ denotes the degree of the map $g$. We define next a morphism of $A_{\infty}$ algebras.

Definition. A morphism $f: A \rightarrow B$ between $A_{\infty}$ algebras consists of a family of maps

$$
\begin{equation*}
f_{n}: A^{\otimes n} \rightarrow B \tag{3.5}
\end{equation*}
$$

of degree $1-n$ satisfying

$$
\begin{equation*}
\sum_{r+s+t=n}(-1)^{r+s t} f_{u}\left(\mathbf{1}^{\otimes r} \otimes m_{s}^{A} \otimes \mathbf{1}^{\otimes t}\right)=\sum_{l=1}^{n} \sum_{I=n}(-1)^{\epsilon(l)} m_{l}^{B}\left(f_{i_{1}} \otimes \cdots \otimes f_{i_{l}}\right), \quad n \geq 1 \tag{3.6}
\end{equation*}
$$

where $u=r+t+1, s \geq 1, r, t \geq 0$ and the second sum over $I=n$ means sum over all decompositions $i_{1}+\ldots+i_{l}=n$ (with $i_{k} \geq 1$ ). The $\operatorname{sign} \epsilon(l)$ is given by

$$
\begin{equation*}
\epsilon(l)=(l-1)\left(i_{1}-1\right)+(l-2)\left(i_{2}-1\right)+\ldots+2\left(i_{l-2}-1\right)+\left(i_{l-1}-1\right) \tag{3.7}
\end{equation*}
$$

Finally, we denote $m_{n}^{A, B}$ the maps of $A$ and $B$, respectively.
Note that the map $f_{1}$ induces a map $f_{1, *}$ between the cohomologies

$$
\begin{equation*}
f_{1, *}: H(A) \rightarrow H(B) \tag{3.8}
\end{equation*}
$$

[^6]where $H(A)(H(B))$ denotes the cohomology of the differential $m_{1}^{A}\left(m_{1}^{B}\right)$. Then, a morphism is called quasi-isomorphism if $f_{1, *}$ is an isomorphism and is called strict if $f_{i}=0$ for all $i \neq 1$.

Definition. An $A_{\infty}$-module over $A$ is given by a $\mathbb{Z}$-graded vector space $M$ endowed with maps

$$
\begin{equation*}
m_{n}^{M}: M \otimes A^{\otimes n-1} \rightarrow M, \quad n \geq 1 \tag{3.9}
\end{equation*}
$$

of degree $2-n$ satisfying

$$
\begin{equation*}
\sum_{r+s+t=n}(-1)^{r+s t} m_{u}^{M}\left(\mathbf{1}^{\otimes r} \otimes \tilde{m}_{s} \otimes \mathbf{1}^{\otimes t}\right)=0 \quad, n \geq 1 \tag{3.10}
\end{equation*}
$$

where $u=r+t+1, s \geq 1, r, t \geq 0$ and

$$
m_{u}^{M}\left(\mathbf{1}^{\otimes r} \otimes \tilde{m}_{s} \otimes \mathbf{1}^{\otimes t}\right)= \begin{cases}m_{u}^{M}\left(\mathbf{1}^{\otimes r} \otimes m_{s} \otimes \mathbf{1}^{\otimes t}\right), & \text { if } r>0  \tag{3.11}\\ m_{u}^{M}\left(m_{s}^{M} \otimes \mathbf{1}^{\otimes t}\right) . & \text { if } r=0\end{cases}
$$

There is an alternative construction of the $A_{\infty}$-algebra known as the bar construction. Consider a $\mathbb{Z}$-graded $\mathbb{K}$-vector space $V$ and the tensor algebra

$$
\begin{equation*}
T^{\bullet} V:=\bigoplus_{n \geq 1} V^{\otimes n} \tag{3.12}
\end{equation*}
$$

Then, any coderivation $b: T^{\bullet} V \rightarrow T^{\bullet} V$ can be written in terms of degree 1 maps $b_{n}: V^{\otimes} \rightarrow V$. Explicitly, by denoting $b_{n, u}$ the component of $b$ mapping $V^{\otimes n}$ to $V^{\otimes u}$, we can write

$$
\begin{equation*}
b_{n, u}=\sum_{r+s+t=n, r+t+1=u} \mathbf{1}^{\otimes r} \otimes b_{s} \otimes \mathbf{1}^{\otimes t}, \quad r, t \geq 1, s \geq 1 \tag{3.13}
\end{equation*}
$$

Imposing $b^{2}=0$ is equivalent to the conditions

$$
\begin{equation*}
\sum_{r+s+t=n} b_{u}\left(\mathbf{1}^{\otimes r} \otimes b_{s} \otimes \mathbf{1}^{\otimes t}\right)=0, \quad n \geq 1 \tag{3.14}
\end{equation*}
$$

where $u=r+t+1$ and $s \geq 1, r, t \geq 0$. Then, if we identify $V=A[1]$, where $A[1]$ is the grading shift $(A[1])^{p}=A^{p+1}$ and we denote the natural degree -1 map $h: A \rightarrow A[1]$, then if we write

$$
\begin{equation*}
m_{n}=h^{-1} \circ b_{n} \circ h^{\otimes n} \tag{3.15}
\end{equation*}
$$

or equivalently ${ }_{-}^{8}$

$$
\begin{equation*}
b_{n}=(-1)^{\frac{n(n-1)}{2}} h \circ m_{n} \circ\left(h^{-1}\right)^{\otimes n} \tag{3.16}
\end{equation*}
$$

[^7]The relations (3.14) are equivalent to (3.3). An $A_{\infty}$-algebra $A$ is called minimal if $m_{1} \equiv 0$ and is called strictly unital if there exists a degree 0 element $1_{A} \in A^{0}$ satisfying

$$
\begin{align*}
& m_{1}\left(1_{A}\right)=0 \\
& m_{2}\left(1_{A} \otimes a\right)=m_{2}\left(a \otimes 1_{A}\right)=a \\
& m_{i}\left(a_{1} \otimes \cdots \otimes a_{i}\right)=0, \quad \text { if any } a_{k}=1_{A} \quad i>2 \tag{3.17}
\end{align*}
$$

for all $a, a_{1}, \ldots, a_{i} \in A$. Moreover, if $A$ is equipped with a bilinear form $\langle\cdot, \cdot\rangle: A \otimes A \rightarrow \mathbb{C}$, then $A$ is called cyclic (w.r.t. $\langle\cdot, \cdot\rangle$ ) if it satisfies

$$
\begin{equation*}
\left.\left.\left\langle a_{0}, b_{n}\left(a_{1} \otimes \cdots \otimes a_{n}\right)\right)\right\rangle=(-1)^{\left(\left|a_{0}\right|+1\right)\left(\left|a_{1}\right|+\ldots+\left|a_{n}\right|+n\right)}\left\langle a_{1}, b_{n}\left(a_{2} \otimes \cdots \otimes a_{0}\right)\right)\right\rangle \tag{3.18}
\end{equation*}
$$

where $a_{i} \in A$ are homogeneous elements.
We have the following important theorem [25, 26]:
Theorem. Any $A_{\infty}$-algebra $\left(A, m_{n}\right)$ is $A_{\infty}$-quasi-isomorphic to a minimal $A_{\infty}$-algebra called a minimal model for $A$. Moreover this minimal model can be taken to be $\left(H(A), m_{n}^{H}\right)$ which is unique up to $A_{\infty}$-isomorphism and satisfies

1. The map $f_{1}: H(A) \rightarrow A$ is given by the inclusion map.
2. The map $m_{2}^{H}$ is given by the map induced by $m_{2}$.

Then, this theorem plus the conditions (3.6) for $A_{\infty}$ morphisms applied to the inclusion map $\iota: H(A) \rightarrow A$ give us a way to recursively determine the products $m_{n}^{H}$ from the knowledge of $\left(A, m_{n}\right)$. Let us write some of these relations to ilustrate this point (recall that $m_{1}^{H} \equiv 0$ ):

$$
\begin{align*}
\iota \circ m_{2}^{H} & =m_{2}(\iota \otimes \iota)+m_{1} \circ f_{2} \\
\iota \circ m_{3}^{H} & =f_{2}\left(m_{2}^{H} \otimes \mathbf{1}\right)-f_{2}\left(\mathbf{1} \otimes m_{2}^{H}\right)+m_{2}\left(\iota \otimes f_{2}\right)-m_{2}\left(f_{2} \otimes \iota\right)+m_{1} \circ f_{3} \tag{3.19}
\end{align*}
$$

so, the maps $f_{n}: H(A)^{\otimes n} \rightarrow A$ and the higher products $m_{n}^{H}$ can be determined recursively (see for example [27]).

In the case of topological strings we will be interested in $A_{\infty}$-categories, which are defined as follows

Definition. A $A_{\infty}$-category $\mathcal{A}$ with objects $\operatorname{Ob}(\mathcal{A})$ consists of the data

1. For all $A, B \in \operatorname{Ob}(\mathcal{A})$ the space $\operatorname{Hom}_{\mathcal{A}}(A, B)$ is a $\mathbb{Z}$-graded vector space.
2. For all $n \geq 1$ and any set of objects $A_{0}, \ldots, A_{n} \in \operatorname{Ob}(\mathcal{A})$ there exists a degree $2-n$ map

$$
m_{n}: \operatorname{Hom}_{\mathcal{A}}\left(A_{n-1}, A_{n}\right) \otimes \operatorname{Hom}_{\mathcal{A}}\left(A_{n-2}, A_{n-1}\right) \otimes \cdots \operatorname{Hom}_{\mathcal{A}}\left(A_{0}, A_{1}\right) \rightarrow \operatorname{Hom}_{\mathcal{A}}\left(A_{0}, A_{n}\right)
$$

satisfying

$$
\begin{equation*}
\sum_{r+s+t=n}(-1)^{r+s t} m_{u}\left(\mathbf{1}^{\otimes r} \otimes m_{s} \otimes \mathbf{1}^{\otimes t}\right)=0 \tag{3.20}
\end{equation*}
$$

We also define
Definition. An $A_{\infty}$-functor between $A_{\infty}$-categories $\mathcal{A}_{1}$ and $\mathcal{A}_{2}$ consists of the data

1. A map $\mathcal{F}: \mathrm{Ob}\left(\mathcal{A}_{1}\right) \rightarrow \mathrm{Ob}\left(\mathcal{A}_{2}\right)$.
2. For all $n \geq 1$ and any set of objects $A_{0}, \ldots, A_{n} \in \operatorname{Ob}\left(\mathcal{A}_{1}\right)$ there exists a degree $1-n$ map
$\mathcal{F}_{n}: \operatorname{Hom}_{\mathcal{A}_{1}}\left(A_{n-1}, A_{n}\right) \otimes \operatorname{Hom}_{\mathcal{A}_{1}}\left(A_{n-2}, A_{n-1}\right) \otimes \cdots \operatorname{Hom}_{\mathcal{A}_{1}}\left(A_{0}, A_{1}\right) \rightarrow \operatorname{Hom}_{\mathcal{A}_{2}}\left(\mathcal{F}\left(A_{0}\right), \mathcal{F}\left(A_{n}\right)\right)$ satisfying conditions analogous to (3.6).

More precisely, in topological string theory we encounter cyclic, unital and minimal $A_{\infty^{-}}$ categories ${ }_{-}^{9}$ and we take the field $\mathbb{K}=\mathbb{C}$ from now on. It is easy to see that the $A_{\infty}$-category of a single object is equivalent to an $A_{\infty}$-algebra. Next we move on to explain how these structures arise in topological strings. For simplicty we consider a worldsheet with disk topology and boundary conditions characterized by a single D-brane $\mathcal{D}$. Upon topological twist, this configuration has a single scalar nilpotent supercharge $\mathbf{Q}$. The 'off-shell' space of open strings stretching from $\mathcal{D}$ to itself is given by a graded vector space, which we denote $V_{\mathcal{D}}$ and there is an action of $\mathbf{Q}$ in this vector space, hence we can take the cohomology

$$
\begin{equation*}
\operatorname{End}(\mathcal{D}):=H_{\mathbf{Q}}\left(V_{\mathcal{D}}\right), \tag{3.21}
\end{equation*}
$$

which is the space of physical states of the topological strings stretching between $\mathcal{D}$ and itself. If we denote $\psi_{a}$ the elements of $\operatorname{End}(\mathcal{D})$, their disc correlators encode the Stasheff conditions (3.3). More precisely, the disk correlator of two elements (the boundary topological metric), denoted $\left\langle\psi_{a}, \psi_{b}\right\rangle$, equips $\operatorname{End}(\mathcal{D})$ with an (nondegenerate) inner product. In $[28,29]$ it is found that the relation between the disk correlators with more than two insertions and the maps $b_{k}$

$$
\begin{equation*}
B_{i_{0} i_{1} \cdots i_{k}}:=(-1)^{\left|a_{1}\right|+\ldots+\left|a_{k-1}\right|+k-1}\left\langle\psi_{i_{0}} \psi_{i_{1}} P \int \psi_{i_{2}}^{(1)} \cdots \int \psi_{i_{k-1}}^{(1)} \psi_{i_{k}}\right\rangle=\left\langle\psi_{i_{0}}, b_{k}\left(\psi_{i_{1}}, \cdots, \psi_{i_{k}}\right)\right\rangle, \tag{3.22}
\end{equation*}
$$

where $\psi_{a}^{(1)}$ denotes the 1-form descendants of $\psi_{a}$. The correlators (3.22) are defined using an appropriate regulator [29] and they satisfy a cyclicity condition:

$$
\begin{equation*}
B_{i_{0} i_{1} \cdots i_{k}}=(-1)^{\left(\left|a_{m}\right|+1\right)\left(\left|a_{0}\right|+\ldots+\left|a_{k-1}\right|+k\right)} B_{i_{k} i_{0} \cdots i_{k-1}} . \tag{3.23}
\end{equation*}
$$

It is important to remark that on the right hand side of (3.22), the operators $\psi_{a}$ should be considered in the space $\operatorname{End}(\mathcal{D})[1]$. In other words, the graded space $A$ is identified with $\operatorname{End}(\mathcal{D})$. Hence, up to a sign that, in general depends on the degree of the insertions, we can identify

$$
\begin{equation*}
B_{i_{0} i_{1} \cdots i_{k}} \sim\left\langle m_{k}\left(\psi_{i_{0}}, \cdots, \psi_{i_{k-1}}\right), \psi_{i_{k}}\right\rangle . \tag{3.24}
\end{equation*}
$$

In general, for a SCFT we can define a trace function $\underline{\underline{10}}$

$$
\begin{equation*}
\gamma: A \rightarrow \mathbb{C} \tag{3.25}
\end{equation*}
$$

[^8]of degree $-\hat{c}=-\frac{c}{3}$, where $c$ is the central charge of the SCFT. Then the inner product can be written as
\[

$$
\begin{equation*}
\langle\cdot, \cdot\rangle: A \otimes A \rightarrow \mathbb{C}, \quad\left(\psi_{a}, \psi_{b}\right) \mapsto\left\langle\psi_{a}, \psi_{b}\right\rangle=\gamma\left(m_{2}\left(\psi_{a}, \psi_{b}\right)\right) \tag{3.26}
\end{equation*}
$$

\]

Then, we simply write the relation:

$$
\begin{equation*}
B_{i_{0} i_{1} \cdots i_{k}}=\gamma\left(m_{2}\left(m_{k}\left(\psi_{i_{0}}, \cdots, \psi_{i_{k-1}}\right), \psi_{i_{k}}\right)\right) \tag{3.27}
\end{equation*}
$$

where the sign is hidden in $\gamma$. When considering multiple branes, this structure becomes an $A_{\infty}$-category. For instance, in the case of a SCFT defined by the NLSM with a CY target space $X$, the category of B-branes (topological open strings in the B-model) is equivalent to $\operatorname{DCoh}(X)$, the derived category of coherent sheaves on $X[31-34]$ and an $A_{\infty}$ structure on this category has been derived from physics and mathematical point of view [35-38]. Analogous results also exist in the case of $G$-equivariant categories of matrix factorizations $M F_{G}(W)$, when $G$ is a finite abelian group and $W$ is a quasi-homogeneous polynomial [29, 39, 40].

## $4 \quad A_{\infty}$-algebras associated with Landau-Ginzburg models

In this section we will apply the results reviewed in section $\underline{3}$ to the specific case of LG orbifolds. We begin by reviewing the physics approach of categories of matrix factorizations, arising as B-branes on LG orbifolds. Fix a vector space $\mathbb{V}$ of rank $N$ with coordinates denoted by $x_{i}, i=1, \ldots, N$. We specify a left R-symmetry given by a $\mathbb{C}_{L}^{*}$ action on $\mathbb{V}$ with weights $q_{i} \in \mathbb{Q} \cap(0,1)$. The orbifold group will be specified by a finite abelian group $G$ and a representation $\rho_{\text {orb }}: G \rightarrow G L(\mathbb{V})$. We specify a superpotential, that is a holomorphic, $G$ invariant function $W: \mathbb{C}^{N} \rightarrow \mathbb{C}, W \in \mathbb{C}\left[x_{1}, \ldots, x_{N}\right]$. As an $\mathcal{N}=(2,2)$ theory, the LG orbifold is specified by the data

$$
\begin{equation*}
\left(W, G, \rho_{\text {orb }}, \mathbb{C}_{L}^{*}\right) \tag{4.1}
\end{equation*}
$$

but we impose some extra requirement on (4.1). In order for the vector R-symmetry to be nonanomalous, we require $W$ to be quasi-homogeneous, of weight 1 under the $\mathbb{C}_{L}^{*}$ action i.e. $W\left(\lambda^{q_{i}} \phi_{i}\right)=\lambda W\left(\phi_{i}\right)$ [41] (this implies that $W$ has charge 2 under the vector R-symmetry). Moreover, $W$ being quasi-homogeneous implies $d W^{-1}(0)=\{0\}$, i.e. $W$ is compact, in the sense that it defines a compact SCFT in the IR. Quasi-homogeneity of $W$ guarantees that we always have the symmetry $x_{j} \rightarrow e^{2 i \pi q_{i}} x_{j}$. If $d$ denotes the lowest nonzero integer such that $d q_{i} \in \mathbb{Z}$ for all $i$, then this specifies a $\mathbb{Z}_{d}$ action generated by $J=\operatorname{diag}\left(e^{2 i \pi q_{1}}, \ldots, e^{2 i \pi q_{N}}\right)$. Denote by $\operatorname{Aut}(W)$ the group of diagonal automorphisms of $W$, i.e.

$$
\begin{equation*}
\operatorname{Aut}(W)=\left\{\operatorname{diag}\left(e^{2 \pi i \lambda_{1}}, \ldots, e^{2 \pi i \lambda_{N}}\right) \in U(1)^{N}: W\left(e^{2 \pi i \lambda_{i}} x_{i}\right)=W\left(x_{i}\right)\right\} \tag{4.2}
\end{equation*}
$$

we then say an orbifold group $G$ is admissible if it satisfies

$$
\begin{equation*}
\langle J\rangle \subseteq G \subseteq \operatorname{Aut}(W) \tag{4.3}
\end{equation*}
$$

and we will require this condition. B-type D-branes $\mathcal{B}$ in LG orbifolds are characterized in terms of matrix factorizations of $W[9,42]$. More precisely, $\mathcal{B}$ consists of the data

$$
\begin{equation*}
\mathcal{B}=\left(M, \sigma, Q, R_{M}, \rho_{M}\right) \tag{4.4}
\end{equation*}
$$

where $M$ (the Chan-Paton space) is a free $\mathbb{C}\left[x_{1}, \ldots, x_{N}\right]$-module, $\sigma$ is an involution on $M$, inducing a $\mathbb{Z}_{2}$-grading (so we can write $M=M_{0} \oplus M_{1}$, with $\sigma M_{i}=(-1)^{i} M_{i}$ ) and $Q(x)$ is a $\mathbb{Z}_{2}$-odd endomorphism on $M$ satisfying

$$
\begin{equation*}
Q^{2}=W \cdot \mathrm{id}_{M} \tag{4.5}
\end{equation*}
$$

Under the vector R-charge, $W$ has charge 2 : $W\left(\lambda^{2 q_{i}} x_{i}\right)=\lambda^{2} W\left(x_{i}\right)$ with the charges $q_{i}$ of the left R-symmetry. Therefore, by (4.5), $Q$ must have vector R-charge 1 . This defines a compatible representation $R_{M}: U(1)_{V} \rightarrow G L(M)$ of the vector R-symmetry, satisfying:

$$
\begin{equation*}
R_{M}(\lambda) Q\left(\lambda^{2 q_{i}} x_{i}\right) R_{M}^{-1}(\lambda)=\lambda Q\left(x_{i}\right) \tag{4.6}
\end{equation*}
$$

as well as another compatible representation of $G, \rho_{M}: G \rightarrow G L(M)$ satisfying

$$
\begin{equation*}
\rho_{M}(g)^{-1} Q\left(\rho_{\text {orb }}(g) \cdot x_{j}\right) \rho_{M}(g)=Q\left(x_{j}\right) \tag{4.7}
\end{equation*}
$$

Given a pair of B-branes $\mathcal{B}_{i}=\left(M^{(i)}, \sigma_{i}, Q_{i}, R_{M}^{(i)}, \rho_{M}^{(i)}\right), i=1,2$, we can define the space of morphisms betwen them, $\operatorname{Hom}\left(\mathcal{B}_{1}, \mathcal{B}_{2}\right)$ as graded morphisms

$$
\begin{equation*}
\Psi: M^{(1)} \rightarrow M^{(2)} \tag{4.8}
\end{equation*}
$$

i.e. $\Psi \in V_{r_{1}, r_{2}}:=M a t_{r_{1}, r_{2}}\left(\mathbb{C}\left[x_{1}, \ldots, x_{N}\right]\right)$, the space of $r_{1} \times r_{2}$ matrices with coefficients in $\mathbb{C}\left[x_{1}, \ldots, x_{N}\right]$, where $r_{i}=\operatorname{rk}\left(M^{(i)}\right)$ satisfying

$$
\begin{equation*}
D_{12} \circ \Psi:=Q_{2} \Psi-\sigma_{2} \Psi \sigma_{1} Q_{1}=0 \tag{4.9}
\end{equation*}
$$

modulo $D_{12}$-exact morphisms. The differential $D_{12}$ can be identified with the conserved supercharge $\mathbf{Q}$ of the worldsheet theory on the open string stretching between $\mathcal{B}_{1}$ and $\mathcal{B}_{2}$. Therefore we can denote

$$
\begin{equation*}
\operatorname{Hom}\left(\mathcal{B}_{1}, \mathcal{B}_{2}\right)=H_{D_{12}}\left(V_{r_{1}, r_{2}}\right) \tag{4.10}
\end{equation*}
$$

The space $\operatorname{Hom}\left(\mathcal{B}_{1}, \mathcal{B}_{2}\right)$ is $\mathbb{Z}_{2}$-graded and we denote its homogeneous components, and elements, as

$$
\begin{equation*}
\operatorname{Hom}\left(\mathcal{B}_{1}, \mathcal{B}_{2}\right)=H^{0}\left(\mathcal{B}_{1}, \mathcal{B}_{2}\right) \oplus H^{1}\left(\mathcal{B}_{1}, \mathcal{B}_{2}\right), \quad \phi_{i} \in H^{0}\left(\mathcal{B}_{1}, \mathcal{B}_{2}\right), \quad \psi_{i} \in H^{1}\left(\mathcal{B}_{1}, \mathcal{B}_{2}\right) \tag{4.11}
\end{equation*}
$$

The category $M F(W, G)$ of objects $\mathcal{B}$ with morphisms defined as

$$
\begin{equation*}
\operatorname{Hom}_{M F(W, G)}\left(\mathcal{B}_{1}, \mathcal{B}_{2}\right):=\operatorname{Hom}\left(\mathcal{B}_{1}, \mathcal{B}_{2}\right)^{G} \tag{4.12}
\end{equation*}
$$

i.e., $\Psi \in \operatorname{Hom}_{M F(W, G)}\left(\mathcal{B}_{1}, \mathcal{B}_{2}\right)$ satisfies

$$
\begin{equation*}
\rho_{M^{(2)}}(g)^{-1} \Psi\left(\rho_{\text {orb }}(g) \cdot x_{i}\right) \rho_{M^{(1)}}(g)=\Psi\left(x_{i}\right) \tag{4.13}
\end{equation*}
$$

will be referred as the category of B-branes on the LG orbifold. This category also has a grading that we will review next.

## Gradings

The category $\operatorname{MF}(W, G)$ defined above has a natural $\mathbb{Q}$-grading given by the R -charge. More precisely, it is the fact that the superpotential $W$ is quasi-homogeneous that guarantees the existence of this $\mathbb{Q}$-grading (because then the vector R -charge is conserved) [43]. The orbifold by $G$ satisfying (4.3) guarantees that the physical states will have integer R-charges [44] and hence, we can put an integer grading on open string states. For a reduced and irreducible matrix factorization $\mathcal{B} \in M F(W, G)$, the map $\rho_{M}$ satisfies [43]

$$
\begin{equation*}
\rho_{M}(J)=\sigma \circ R_{M}\left(e^{i \pi}\right) e^{-i \pi \varphi} \tag{4.14}
\end{equation*}
$$

for some $\varphi \in \frac{2}{d} \mathbb{Z}$. The morphism $\Psi \in \operatorname{Hom}_{M F(W, G)}\left(\mathcal{B}_{1}, \mathcal{B}_{2}\right)$ has R-charge $q_{\Psi} \in \mathbb{Q}$ defined by

$$
\begin{equation*}
R_{M^{(2)}}(\lambda) \Psi\left(\lambda^{2 q_{i}} x_{i}\right) R_{M^{(1)}}(\lambda)^{-1}=\lambda^{q_{\Psi}} \Psi\left(x_{i}\right) . \tag{4.15}
\end{equation*}
$$

Then, a $\mathbb{Z}$-grading on $\Psi$ is defined by

$$
\begin{equation*}
\operatorname{deg}(\Psi)=\varphi_{2}-\varphi_{1}+q_{\Psi} \tag{4.16}
\end{equation*}
$$

The category $\operatorname{MF}(W, G)$ with this additional grading is known in the mathematics literature as the category of graded, $G$-equivariant matrix factorizations [45].

### 4.1 Effective superpotential, deformations and $A_{\infty}$ structures

The category $M F(W, G)$ can be given an $A_{\infty}$ structure [46], and the higher order products can be read off from the computation of the unobstructed deformations of the objects $\mathcal{B} \in$ $M F(W, G)$, as we will explain in this section, and will become useful later. However, it is very convenient to use a description of $M F(W, G)$ that follows very closely [9]. Consider first the case of a trivial orbifold

$$
\begin{equation*}
G=\mathbf{1}, \tag{4.17}
\end{equation*}
$$

then we denote the category just as $M F(W)$. Then, in the case $d W^{-1}(0)=\{0\}$, this category has a single generator [47] given by the matrix factorization $\mathcal{B}_{D 0}=\left(M, \sigma, Q_{D 0}, R_{M}\right)$ with

$$
\begin{equation*}
Q_{D 0}=\sum_{i=1}^{N}\left(x_{i} \bar{\eta}_{i}+q_{i} \frac{\partial W}{\partial x_{i}} \eta_{i}\right), \tag{4.18}
\end{equation*}
$$

where the subscript $D 0$ is because this matrix factorization is reminiscent to the $D 0$-brane in [9]. The objects $\bar{\eta}_{i}, \eta_{i}, i=1, \ldots, N$ are generators of a Clifford algebra of rank $2 N$, namely they satisfy the relations

$$
\begin{equation*}
\left\{\bar{\eta}_{i}, \eta_{j}\right\}=\delta_{i, j} \mathbf{1} \quad\left\{\bar{\eta}_{i}, \bar{\eta}_{j}\right\}=\left\{\eta_{i}, \eta_{j}\right\}=0 \tag{4.19}
\end{equation*}
$$

Then, we can consider

$$
\begin{equation*}
\mathcal{A}_{D 0}:=\operatorname{Hom}_{M F(W)}\left(\mathcal{B}_{D 0}, \mathcal{B}_{D 0}\right), \tag{4.20}
\end{equation*}
$$

which has the structure of an $A_{\infty}$-algebra $\stackrel{11}{\text { [47] }}$ and moreover we have the equivalence

$$
\begin{equation*}
M F(W) \cong D\left(\operatorname{Mod}-\mathcal{A}_{D 0}\right) \tag{4.21}
\end{equation*}
$$

[^9]where $D\left(\operatorname{Mod}-\mathcal{A}_{D 0}\right)$ stands for the derived category of $A_{\infty}$-modules over $\mathcal{A}_{D 0}$. Given an object $\mathcal{B} \in M F(W)$, the module associated to $\mathcal{B}$ is given by $M_{\mathcal{B}}:=\operatorname{Hom}_{M F(W)}\left(\mathcal{B}_{D 0}, \mathcal{B}\right)$ where the maps
\[

$$
\begin{equation*}
m_{n}^{\mathcal{B}}: M_{\mathcal{B}} \otimes \mathcal{A}_{D 0}^{\otimes n-1} \rightarrow M_{\mathcal{B}} \tag{4.22}
\end{equation*}
$$

\]

come from the $A_{\infty}$ structure of the category $M F(W)$, in particular

$$
\begin{equation*}
m_{2}^{\mathcal{B}}: M_{\mathcal{B}} \otimes \mathcal{A}_{D 0} \rightarrow M_{\mathcal{B}}, \quad m_{2}^{\mathcal{B}}\left(\Psi^{\mathcal{B}}, \Psi\right)=\Psi^{\mathcal{B}} \circ \Psi \tag{4.23}
\end{equation*}
$$

When we add an orbifold, we expect the following equivalence

$$
\begin{equation*}
M F(W, G) \cong D\left(\operatorname{Mod}-\mathcal{A}_{D 0} \sharp G\right), \tag{4.24}
\end{equation*}
$$

where $\mathcal{A}_{D 0} \sharp G$ is the smash product between $\mathcal{A}_{D 0}$ and the group algebra $\mathbb{C}[G]$, the product in $\mathcal{A}_{D 0} \sharp G$ is given by [11]

$$
\begin{equation*}
\left(a \sharp g_{1}\right) \cdot\left(b \sharp g_{2}\right)=\left(a \cdot g_{1} b g_{1}^{-1}\right) \sharp g_{1} g_{2}, \tag{4.25}
\end{equation*}
$$

hence, studying the algebra $\mathcal{A}_{D 0}$ is crucial. The higher order products $m_{n}: \mathcal{A}_{D 0}^{\otimes n} \rightarrow \mathcal{A}_{D 0}$ can be read off from the effective superpotential $\mathcal{W}_{\text {eff }}$ defined by

$$
\begin{equation*}
\mathcal{W}_{\mathrm{eff}}=\operatorname{Tr}\left(\sum_{k=2}^{\infty} \sum_{i_{0}, i_{1}, \cdots, i_{k}} \frac{B_{i_{0} \cdots i_{k}}}{k+1} Z_{i_{0}} Z_{i_{1}} \cdots Z_{i_{k}}\right) \tag{4.26}
\end{equation*}
$$

the function $\mathcal{W}_{\text {eff }}$ encodes obstructions to the boundary deformations of the SCFT, and can be computed as follows. Consider the matrix factorization $Q_{D 0}$, then our objective is to find a deformed matrix factorization

$$
\begin{equation*}
Q_{D 0}^{\mathrm{def}}=Q_{D 0}+\sum_{\vec{m} \in B} \alpha_{\vec{m}} u^{\vec{m}}, \quad u^{\vec{m}}:=\prod_{i=1}^{n} u_{i}^{m_{i}} \tag{4.27}
\end{equation*}
$$

where $B \subset \mathbb{N}^{n}, n=\operatorname{dim} H^{1}\left(\mathcal{B}_{D 0}, \mathcal{B}_{D 0}\right), \alpha_{\vec{m}}$ are fermionic operators and $u_{i}, i=1, \ldots, n$ are commutative parameters. The matrix factorization satisfies

$$
\begin{equation*}
\left(Q_{D 0}^{\mathrm{def}}\right)^{2}=W \cdot \operatorname{id}_{M}+\sum_{i=1}^{n} f_{i}(u) \phi_{i} \tag{4.28}
\end{equation*}
$$

where, using the same notation as (4.11), $\phi_{i} \in H^{0}\left(\mathcal{B}_{D 0}, \mathcal{B}_{D 0}\right)$. Then, the critical locus of $\mathcal{W}_{\text {eff }}$ coincides, as a set, with $f_{1}=f_{2}=\cdots=f_{n}=0$. More precisely, if we identify the variables $Z_{i}$ with the parameters $u_{i}, Z_{i} \equiv u_{i}$ in $\mathcal{W}_{\text {eff }}$, then $d \mathcal{W}_{\text {eff }}^{-1}(0)$ coincides with the solutions to the equations $f_{1}=f_{2}=\cdots=f_{n}=0$ i.e. we can integrate the equations

$$
\begin{equation*}
\frac{\partial \widetilde{\mathcal{W}}_{\mathrm{eff}}}{\partial u_{i}}=f_{i}(u) \tag{4.29}
\end{equation*}
$$

and $\widetilde{\mathcal{W}}_{\text {eff }}$ coincides with $\mathcal{W}_{\text {eff }}$ up to a nonlinear redefinition of the parameters $u_{i}$. The operators $\alpha_{\vec{m}}$ are computed iteratively. We can summarize this process as follows. Define $|\vec{m}|:=\sum_{i} m_{i}$. We start by defining

$$
\begin{equation*}
\alpha_{e_{i}}:=\psi_{i} \quad i=1, \ldots, n \tag{4.30}
\end{equation*}
$$

with $e_{i}, i=1, \ldots, n$ the cannonical basis of $\mathbb{N}^{n}$. Then, in the first step we write

$$
\begin{equation*}
Q_{D 0}^{\mathrm{def},(1)}=Q_{D 0}+\sum_{i=1}^{n} u_{i} \alpha_{e_{i}} \tag{4.31}
\end{equation*}
$$

and we look at the terms of order $|\vec{m}|=2$ in $\left(Q_{D 0}^{\text {def,(1) }}\right)^{2}$, denote them $\sum_{|\vec{m}|=2} y_{\vec{m}} u^{\vec{m}}$. Then, if $y_{\vec{m}}$ is $Q_{D 0}$-exact, then we can define an operator $\alpha_{\vec{m}}$ (with $|\vec{m}|=2$ ) such that

$$
\begin{equation*}
\beta_{\vec{m}}:=-y_{\vec{m}}=\left[Q_{D 0}, \alpha_{\vec{m}}\right] . \tag{4.32}
\end{equation*}
$$

Then, if we denote $B_{2}$ the set of all vectors $\vec{m}$ with $|\vec{m}|=2$ such that $y_{\vec{m}}$ is exact, we can write

$$
\begin{equation*}
Q_{D 0}^{\mathrm{def},(2)}=Q_{D 0}+\sum_{i=1}^{n} u_{i} \alpha_{e_{i}}+\sum_{\vec{m} \in B_{2}} \alpha_{\vec{m}} u^{\vec{m}} \tag{4.33}
\end{equation*}
$$

and repeat the process to find the operators $\alpha_{\vec{m}}$ with $|m|>2$. The process ends when none of the $y_{\vec{m}}$ are $Q_{D 0}$-exact.

### 4.2 LG model with homogeneous superpotential

In this section we consider the case of a LG model with chiral superfields $x_{i}, i=1, \cdots, n$. The superpotential $W$ is a homogeneous polynomial in $x_{i}$ with degree $d \geq 2$. We will set the orbifold $G$ to be trivial in this section, hence the relevant category of B-branes will be $\operatorname{MF}(W)$. The $D 0$-brane of this model is the matrix factorization $\mathcal{B}_{D 0}$ described in the previous subsection (4.18), therefore

$$
\begin{equation*}
Q_{D 0}=\sum_{i=1}^{n}\left(x_{i} \bar{\eta}_{i}+\frac{1}{d} \frac{\partial W}{\partial x_{i}} \eta_{i}\right) . \tag{4.34}
\end{equation*}
$$

We want to deduce the multiplication rule of the $A_{\infty}$-algebra

$$
\begin{equation*}
\mathcal{A}_{D 0}=\operatorname{End}\left(\mathcal{B}_{D 0}\right) . \tag{4.35}
\end{equation*}
$$

The generators of the ring $H^{1}\left(\mathcal{B}_{D 0}, \mathcal{B}_{D 0}\right)$ are straightforward to compute and given by $\underline{\underline{12}}$

$$
\begin{equation*}
\psi_{i}=i \sqrt{\frac{d(d-1)}{2}} \bar{\eta}_{i}-\frac{i}{\sqrt{2 d(d-1)}} \sum_{j=1}^{n} \frac{\partial^{2} W}{\partial x_{i} \partial x_{j}} \eta_{j}, 1 \leq i \leq n \tag{4.36}
\end{equation*}
$$

which satisfy $\left\{Q_{D 0}, \psi_{i}\right\}=0$. Note that

$$
\begin{equation*}
\left\{\psi_{i}, \psi_{j}\right\}=\frac{\partial^{2} W}{\partial x_{i} \partial x_{j}} \mathbf{1} \tag{4.37}
\end{equation*}
$$

where $\mathbf{1} \in H^{0}\left(\mathcal{B}_{D 0}, \mathcal{B}_{D 0}\right)$ is the identity operator and $\left\{\psi_{i}, \psi_{j}\right\} \simeq 0$, for $d>2$, i.e. (4.37) says that $\left\{\psi_{i}, \psi_{j}\right\}$ is $Q_{D 0}$-exact, because $\left\{Q_{D 0}, \eta_{i}\right\}=x_{i}$. Hence, any monomial in $x_{i}$ with positive degree is $Q_{D 0}$-exact. We remark that the operators (4.36) generate the whole $H^{1}\left(\mathcal{B}_{D 0}, \mathcal{B}_{D 0}\right)$ as a ring (not necessarily as a vector space). Indeed they generate the whole space $\operatorname{End}\left(\mathcal{B}_{D 0}\right)$.

[^10]This can be shown, for instance, using the explicit form of $Q_{D 0}$ and the fact that the Dirac matrices $\eta_{i}, \bar{\eta}_{i}, i=1 \ldots, n$ plus the identify $\mathbf{1}$ generate the off-shell dg algebra.

Next we propose an explicit expression for the functor from $M F(W)$ to the category of modules of $\mathcal{A}_{D 0}$, for the case at hand. For any matrix factorization $\mathcal{B}=\left(M, \sigma_{M}, Q_{M}, R_{M}\right)$, the corresponding $A_{\infty}$-module is given by $\operatorname{Hom}\left(\mathcal{B}_{D 0}, \mathcal{B}\right)$. The $A_{\infty}$-module structure is given by the $A_{\infty}$-multiplications of the $A_{\infty}$-category $M F(W)$ as described in (4.22). Conversely, given any $\mathbb{Z}_{2}$-graded $A_{\infty}$-module $\mathbf{N}$ of $\mathcal{A}_{D 0}$, we propose that the corresponding matrix factorization is given by $M=\mathbf{N} \otimes \mathbb{C}\left[x_{1}, \cdots, x_{n}\right]$ and

$$
\begin{equation*}
Q_{M}(\phi)=\sum_{k=1}^{d-1} \sum_{i_{1}, i_{2}, \cdots, i_{k}} m_{k+1}^{\mathbf{N}}\left(\phi, \psi_{i_{1}}, \cdots, \psi_{i_{k}}\right) x_{i_{1}} x_{i_{2}} \cdots x_{i_{k}} \tag{4.38}
\end{equation*}
$$

for $\phi \in M$. We provide several consistency checks for (4.38) in Appendix A.
The $A_{\infty}$ structure of $\mathcal{A}_{D 0}$ was constructed explicitly in [12], in the case $W$ homogeneous of degree $d$. The $A_{\infty}$-algebra relations were found to be given by (A.1) when $d=2$ or (A.2) and (A.3) when $d>2$. In [12], this $A_{\infty}$ structure was proved by summing over the ribbon trees. In the remainder of this subsection, we give some alternative derivation of (A.1), (A.2) and (A.3) and we give explicit expressions for the higher order products $m_{d}$, when acting on arbitrary elements of $\mathcal{A}_{D 0}$. For this purpose we analyze separately the case $d=2$ and $d>2$. In the following we write the map

$$
\begin{equation*}
\iota: \mathcal{A}_{D 0}=\operatorname{End}\left(\mathcal{B}_{D 0}\right) \rightarrow V_{M_{D 0}} \tag{4.39}
\end{equation*}
$$

where $V_{M_{D 0}}$ is the space of $\operatorname{rk}(M)$-square matrices with values in $\mathbb{C}\left[x_{1}, \ldots, x_{n}\right]$, i.e. the space of endomorphisms of $\mathcal{B}_{D 0}$ without taking the homology. We can always give to the algebra $V_{M_{D 0}}$ a dg algebra structure and will not spoil the $A_{\infty}$-relations of $\mathcal{A}_{D 0}$. In other words, $V_{M_{D 0}}$ is the off-shell algebra of open strings and we can always find a dg algebra that is $A_{\infty}$-quasiisomprphic to it (this fact is true for any $A_{\infty}$-algebra [24]). We will denote the image under $\iota$ of $\psi_{i}$ in $V_{M_{D 0}}$ by $v_{i}$ :

$$
\begin{equation*}
\iota\left(\psi_{i}\right)=v_{i} . \tag{4.40}
\end{equation*}
$$

In the following we will also make use of the open disk one-point function correlators on the disk, for LG models. This was computed in [49] (see [50,51] for a mathematical treatment) and is given by

$$
\begin{equation*}
\langle\Phi\rangle=\frac{1}{(2 \pi i)^{n}} \oint_{x_{i}=0} \frac{\operatorname{Str}\left(\frac{\partial Q_{D 0}}{\partial x_{1}} \wedge \cdots \wedge \frac{\partial Q_{D 0}}{\partial x_{n}} \Phi\right)}{\frac{\partial W}{\partial x_{1}} \cdots \frac{\partial W}{\partial x_{n}}} d x_{1} \cdots d x_{n} . \tag{4.41}
\end{equation*}
$$

This corresponds to the (B-model) correlator in $D^{2}$ with a single boundary insertion $\Phi \in \mathcal{A}_{D 0}$ and boundary conditions defined by the brane $\mathcal{B}_{D 0}$.

### 4.2.1 $\quad \mathcal{A}_{D 0}$ for $d=2$

From the relations (3.6) and (3.19) (i.e. $f_{2}: \mathcal{A}_{D 0}^{\otimes 2} \rightarrow V_{M_{D 0}}$ ):

$$
\begin{equation*}
\iota\left(m_{2}\left(\psi_{i}, \psi_{j}\right)\right)=v_{i} v_{j}+\left\{Q_{D 0}, f_{2}\left(\psi_{i}, \psi_{j}\right)\right\} . \tag{4.42}
\end{equation*}
$$

When $d=2, v_{i} v_{j}$ has no $Q_{D 0}$-exact terms, therefore we can choose $f_{2}\left(\psi_{i}, \psi_{j}\right)=0$. Consequently,

$$
\begin{equation*}
m_{2}\left(\psi_{i}, \psi_{j}\right)+m_{2}\left(\psi_{j}, \psi_{i}\right)=\frac{\partial^{2} W}{\partial x_{i} \partial x_{j}} \tag{4.43}
\end{equation*}
$$

i.e. under the multiplication $m_{2}, \mathcal{A}_{D 0}$ is the same as the Clifford algebra $C l(n, \mathbb{C})$ with the quadratic form given by the Hessian of $W$. (4.43) can also be obtained by computing the correlation functions, using (4.41). We illustrate this case with a simple example:

Example: $W=x_{1} x_{2}$
The D0-brane is

$$
\begin{equation*}
Q=x_{1} \bar{\eta}_{1}+x_{2} \bar{\eta}_{2}+\frac{x_{2}}{2} \eta_{1}+\frac{x_{1}}{2} \eta_{2} . \tag{4.44}
\end{equation*}
$$

The fermionic open string states are

$$
\begin{equation*}
\psi_{1}=\bar{\eta}_{1}-\frac{1}{2} \eta_{2}, \quad \psi_{2}=\bar{\eta}_{2}-\frac{1}{2} \eta_{1} . \tag{4.45}
\end{equation*}
$$

The bosonic open string states can be taken to be ${ }^{13} e=1$ and $\phi$ such that $\langle e, \phi\rangle=1$ and $\langle e, e\rangle=\langle\phi, \phi\rangle=0$. One can compute

$$
\begin{equation*}
\gamma\left(m_{2}\left(\psi_{1}, \psi_{2}\right)\right)=\left\langle\psi_{1} \psi_{2}\right\rangle=\frac{1}{(2 \pi i)^{2}} \oint_{x_{1}=x_{2}=0} \frac{\operatorname{Str}\left(\frac{\partial Q}{\partial x_{1}} \frac{\partial Q}{\partial x_{2}} \psi_{1} \psi_{2}\right)}{\frac{\partial W}{\partial x_{1}} \frac{\partial W}{\partial x_{2}}}=1, \tag{4.46}
\end{equation*}
$$

from which we also deduce

$$
\gamma\left(m_{2}\left(m_{2}\left(\psi_{1}, \psi_{2}\right), e\right)\right)=1
$$

Furthermore,

$$
\gamma\left(m_{2}\left(m_{2}\left(\psi_{1}, \psi_{2}\right), \psi_{1} \psi_{2}\right)\right)=\left\langle\psi_{1} \psi_{2} \psi_{1} \psi_{2}\right\rangle=\frac{1}{(2 \pi i)^{2}} \oint_{x_{1}=x_{2}=0} \frac{\operatorname{Str}\left(\frac{\partial Q}{\partial x_{1}} \frac{\partial Q}{\partial x_{2}} \psi_{1} \psi_{2} \psi_{1} \psi_{2}\right)}{\frac{\partial W}{\partial x_{1}} \frac{\partial W}{\partial x_{2}}}=1,
$$

thus

$$
m_{2}\left(\psi_{1}, \psi_{2}\right)=e+\phi .
$$

The same computation shows

$$
m_{2}\left(\psi_{1}, \psi_{1}\right)=m_{2}\left(\psi_{2}, \psi_{2}\right)=0 .
$$

### 4.2.2 $d>2$

Now assume the degree of $W$ is greater than 2. Because $\left\{v_{i}, v_{j}\right\}=\frac{\partial^{2} W}{\partial x_{i} \partial x_{j}}$ is $Q_{D 0}$-exact, we can take $f_{2}$ such that

$$
\iota\left(m_{2}\left(\psi_{i}, \psi_{j}\right)+m_{2}\left(\psi_{j}, \psi_{i}\right)\right)=\left\{v_{i}, v_{j}\right\}+\left\{Q_{D 0}, f_{2}\left(\psi_{i}, \psi_{j}\right)+f_{2}\left(\psi_{j}, \psi_{i}\right)\right\}=0,
$$

and therefore

$$
\begin{equation*}
m_{2}\left(\psi_{i}, \psi_{j}\right)+m_{2}\left(\psi_{j}, \psi_{i}\right)=0, \tag{4.47}
\end{equation*}
$$

[^11]which means that $\mathcal{A}_{D 0}$ is the exterior algebra $\wedge^{\bullet} \mathbb{C}^{n}$ under the multiplication $m_{2}$.
Alternatively, $m_{2}\left(\psi_{i}, \psi_{j}\right)$ can be determined by the correlation functions (4.41). First note that the one-point correlator
\[

$$
\begin{equation*}
\left\langle\psi_{i_{1}} \cdots \psi_{i_{m}}\right\rangle=0 \quad \text { if } i_{s}=i_{t} \tag{4.48}
\end{equation*}
$$

\]

for any pair of indices $i_{s}$ and $i_{t}$. This is simply because $\left\{\psi_{i}, \psi_{j}\right\}$ and $\psi_{i}^{2}$ are $Q_{D 0}$-exact and as a consequence the correlation function can be rewritten as a sum of correlation functions, each involving a $Q_{D 0}$-exact operator. A corollary of this observation is that

$$
\begin{equation*}
\left\langle\psi_{i_{1}} \cdots \psi_{i_{m}}\right\rangle=0 \quad \text { if } m>n . \tag{4.49}
\end{equation*}
$$

Now assume that $m \leq n$. The formula (4.41) implies

$$
\begin{equation*}
\left\langle\psi_{i_{1}} \cdots \psi_{i_{m}}\right\rangle=\frac{1}{(2 \pi i)^{n}} \oint_{x_{i}=0} \frac{\operatorname{Str}\left(\frac{\partial Q_{D 0}}{\partial x_{1}} \wedge \cdots \wedge \frac{\partial Q_{D 0}}{\partial x_{n}} \psi_{i_{1}} \cdots \psi_{i_{m}}\right)}{\frac{\partial W}{\partial x_{1}} \cdots \frac{\partial W}{\partial x_{n}}} d x_{1} \cdots d x_{n} \tag{4.50}
\end{equation*}
$$

The degree of the denominator of the integrand is $n d-n$. In order to have a nonzero result, the numerator of the integrand must have degree $n d-2 n$, which can only result from the term in $\frac{\partial Q_{D 0}}{\partial x_{1}} \wedge \cdots \wedge \frac{\partial Q_{D 0}}{\partial x_{n}} \psi_{i_{1}} \cdots \psi_{i_{m}}$ proportional to $\eta_{1} \cdots \eta_{n}$. But in order to make nonzero contribution to the supertrace, there should also be $n \bar{\eta}$ 's to contract with the $\eta^{\prime} s$, this is possible only when $m=n$. In conclusion,

$$
\begin{equation*}
\left\langle\psi_{i_{1}} \cdots \psi_{i_{m}}\right\rangle=0 \quad \text { if } m<n, \tag{4.51}
\end{equation*}
$$

and it is straightforward to compute from (4.41) that

$$
\begin{equation*}
\left\langle\psi_{1} \psi_{2} \cdots \psi_{n}\right\rangle=1 \tag{4.52}
\end{equation*}
$$

up to a normalization factor, which implies $\psi_{i_{1}} \cdots \psi_{i_{m}}$ is dual to $\pm \prod_{j \neq i_{s}, 1 \leq s \leq m} \psi_{j}$. Combining (4.48), (4.49) and (4.51), we see that for a monomial $f$ in $\psi_{i}$,

$$
\begin{equation*}
\gamma\left(m_{2}\left(m_{2}\left(\psi_{i}, \psi_{j}\right), f\left(\psi_{1}, \cdots, \psi_{n}\right)\right)\right)= \pm\left\langle\psi_{i} \psi_{j} f\left(\psi_{1}, \cdots, \psi_{n}\right)\right\rangle \tag{4.53}
\end{equation*}
$$

vanishes unless $f\left(\psi_{1}, \cdots, \psi_{n}\right)= \pm \prod_{k \neq i, j} \psi_{k}$. This allows us to conclude that $\iota\left(m_{2}\left(\psi_{i}, \psi_{j}\right)\right)$ only contains the term dual to $\prod_{k \neq i, j} v_{k}$, i.e.

$$
\begin{equation*}
m_{2}\left(\psi_{i}, \psi_{j}\right)=\frac{1}{2} \pi\left(\left[v_{i}, v_{j}\right]\right) . \tag{4.54}
\end{equation*}
$$

where $\pi: V_{M_{D 0}} \rightarrow \mathcal{A}_{D 0}$ is the projection onto $Q_{D 0}$-classes.
Now we compute the higher order multiplications $m_{k}, k>2$. In principle, this can be done by performing the algorithm described in section $\underline{3}$ using (3.6). Here we take the physical perspective and determine the multiplications by studying the deformations of $Q_{D 0}$ as reviewed in section 4.1.

Assume that we deform $Q_{D 0}$ using the fermionic generators $\psi_{i}$ :

$$
\begin{equation*}
Q_{D 0}^{\mathrm{def}}=Q_{D 0}+\sum_{\vec{m}:|\vec{m}|>0} \alpha_{\vec{m}} u^{\vec{m}}, \tag{4.55}
\end{equation*}
$$

where $\alpha_{e_{i}}=\psi_{i} /(\sqrt{d(d-1)})$. In principle, we can consider further deformations by other elements of $H^{1}\left(\mathcal{B}_{D 0}, \mathcal{B}_{D 0}\right)$ (and even elements of $H^{0}\left(\mathcal{B}_{D 0}, \mathcal{B}_{D 0}\right)$ ), but if we are interested in extracting the higher order products involving only $\psi_{i}$ operators, this suffices. Indeed, if the most general first order deformation (i.e. $|m|=1$ ) has the form

$$
\begin{equation*}
\sum_{i} u_{i} \psi_{i}+\sum_{\mu} u_{\mu} \Lambda_{\mu} \tag{4.56}
\end{equation*}
$$

where $\Lambda_{\mu}$ denote the operators in $H^{1}\left(\mathcal{B}_{D 0}, \mathcal{B}_{D 0}\right)$ that are not $\psi_{i}$ 's, then if we set $u_{\mu}=0$, after running the algorithm outlined in section 4.1 we will get that $\left(Q_{D 0}^{\text {def }}\right)^{2}$ has the form

$$
\begin{equation*}
\left(Q_{D 0}^{\mathrm{def}}\right)^{2}=W \cdot \mathbf{1}+\sum_{a} f_{a}\left(u_{i}\right) \phi_{a} \tag{4.57}
\end{equation*}
$$

where $f_{a}$ 's will have the following interpretation

$$
\begin{equation*}
f_{a}\left(u_{i}\right)=\left.\frac{\partial \widetilde{W}_{\text {eff }}}{\partial u_{a}}\right|_{u_{\mu}=0}=\sum_{k \geq 2} \sum_{i_{1}, \ldots, i_{k}}\left\langle m_{k}\left(\psi_{i_{1}}, \ldots, \psi_{i_{k}}\right), \Lambda_{a}^{D}\right\rangle u_{i_{1}} \cdots u_{i_{k}} \tag{4.58}
\end{equation*}
$$

where $a$ runs over all operators in $\mathcal{A}_{D 0}$ and $\Lambda_{a}^{D}$ denotes the operator dual to $\Lambda_{a} \in\left\{\psi_{i}, \Lambda_{\mu}\right\}$. Hence, (4.57) will contain all the information we need about the higher products $m_{k}\left(\psi_{i_{1}}, \ldots, \psi_{i_{k}}\right)$, when we set $u_{\mu}=0$.

Define $\alpha_{i_{1} \cdots i_{s}}:=\alpha_{e_{i_{1}}+\cdots+e_{i_{s}}}, \beta_{i_{1} \cdots i_{s}}:=\beta_{e_{i_{1}}+\cdots+e_{i_{s}}}$ and $W_{i_{1} \cdots i_{s}}:=\partial_{i_{1}} \cdots \partial_{i_{s}} W$. Then we have

$$
\beta_{i j}=\left\{\alpha_{i}, \alpha_{j}\right\}=\frac{1}{d(d-1)} W_{i j}
$$

As $d>2, \beta_{i j}$ is $Q_{D 0}$-exact: $d(d-1) \beta_{i j}=W_{i j}=\left\{Q_{D 0}, \sum_{k} W_{i j k} \eta_{k}\right\} /(d-2)$. Then we can take $\alpha_{i j}=-1 \sum_{k} W_{i j k} \eta_{k} /(d(d-1)(d-2))$ to cancel $\beta_{i j}$ in $\left(Q_{D 0}^{\text {def }}\right)^{2}$. Then at degree 3 , one computes $\beta_{i j k}=-W_{i j k} /(d(d-1)(d-2))$ and $\alpha_{i j k}=\sum_{l} W_{i j k l} \eta_{l} /(d(d-1)(d-2))$. This process continues and at degree $m$ we have

$$
\begin{equation*}
\beta_{i_{1} \cdots i_{m}}=(-1)^{m} \frac{W_{i_{1} \cdots i_{m}}}{d(d-1) \cdots(d-m+1)} \tag{4.59}
\end{equation*}
$$

and

$$
\begin{equation*}
\alpha_{i_{1} \cdots i_{m}}=(-1)^{m-1} \frac{\sum_{j} W_{i_{1} \cdots i_{m j}} \eta_{j}}{d(d-1) \cdots(d-m+1)} \tag{4.60}
\end{equation*}
$$

for $2 \leq m \leq d$. In particular, $\beta_{i_{1} \cdots i_{d}}$ is not $Q_{D 0 \text {-exact and cannot be cancelled by a choice of }}$ $\alpha_{i_{1} \cdots i_{d}}$. As a result,

$$
\begin{equation*}
\left(Q_{D 0}^{\mathrm{def}}\right)^{2}=Q_{D 0}^{2}+\frac{(-1)^{d}}{d!} \sum_{r_{1}+\cdots+r_{n}=d} \frac{\partial^{d} W}{\partial x_{1}^{r_{1}} \cdots \partial x_{n}^{r_{n}}} u_{1}^{r_{1}} u_{2}^{r_{2}} \cdots u_{n}^{r_{n}} \mathbf{1} \tag{4.61}
\end{equation*}
$$

This means the obstruction to the deformation is given by the identity operator. Therefore $\widetilde{\mathcal{W}}_{\text {eff }}$ takes the form

$$
\begin{equation*}
\widetilde{\mathcal{W}}_{\mathrm{eff}}=\sum_{i_{1}, \ldots, i_{d}}\left\langle m_{d}\left(\psi_{i_{1}}, \ldots, \psi_{i_{d}}\right), \Lambda\right\rangle u_{i_{1}} \cdots u_{i_{d}} u_{0}+\mathcal{O}\left(u_{0}^{2}\right), \quad \Lambda=\psi_{1} \cdots \psi_{n} \tag{4.62}
\end{equation*}
$$

where $\Lambda$ is the dual to the identity operator. Due to the correlation function (4.52) and (4.61) together with (4.62) we conclude that

$$
\begin{equation*}
m_{d}\left(\psi_{i_{1}}, \psi_{i_{2}}, \cdots, \psi_{i_{d}}\right)+\text { cyclic permutations }=\frac{(-1)^{d}}{d!} W_{i_{1} \cdots i_{d}} \tag{4.63}
\end{equation*}
$$

and

$$
\begin{equation*}
m_{k}\left(\psi_{i_{1}}, \psi_{i_{2}}, \cdots, \psi_{i_{k}}\right)+\text { cyclic permutations }=0 \quad k \neq d \tag{4.64}
\end{equation*}
$$

where the $i_{l}$ 's are not necessarily distinct. Using directly the algorithm outlined in $\underline{3}$, and $(3.6){ }^{14}$ we can further determine exactly all the higher order products $m_{k}$. This computation ends up determining the $A_{\infty}$ relations as

- If $d=2, \mathcal{A}_{D 0}$ is a family of Clifford algebras:

$$
\begin{equation*}
m_{2}\left(\psi_{i}, \psi_{j}\right)+m_{2}\left(\psi_{j}, \psi_{i}\right)=\frac{\partial^{2} W}{\partial x_{i} \partial x_{j}} \tag{4.65}
\end{equation*}
$$

- If $d>2, \mathcal{A}_{D 0}$ is an $A_{\infty}$-algebra, where $m_{2}$ is the wedge product, $m_{k}=0$ for $k=$ $1,3,4, \cdots, d-1$ and

$$
\begin{equation*}
m_{d}\left(\psi_{i_{1}}, \psi_{i_{2}}, \cdots, \psi_{i_{d}}\right)=\frac{1}{d!} \frac{\partial^{d} W}{\partial x_{i_{1}} \cdots \partial x_{i_{d}}} \tag{4.66}
\end{equation*}
$$

We illustrate with an example the computation of $m_{k}$, exactly, for $d=3$ (using the relations (3.6) and (3.19)):

$$
\left\{v_{i}, v_{j}\right\}=W_{i j}=\left\{Q, \sum_{k} W_{i j k} \eta_{k}\right\}
$$

Because

$$
v_{i} v_{j}=\frac{1}{2}\left\{v_{i}, v_{j}\right\}+\frac{1}{2}\left[v_{i}, v_{j}\right]=\frac{1}{2} W_{i j}+\frac{1}{2}\left[v_{i}, v_{j}\right],
$$

we have

$$
m_{2}\left(\psi_{i}, \psi_{j}\right)=\frac{1}{2} \pi\left(\left[v_{i}, v_{j}\right]\right), \quad f_{2}\left(\psi_{i}, \psi_{j}\right)=-\frac{1}{2} \sum_{k} W_{i j k} \eta_{k}
$$

Thus $m_{2}\left(\psi_{i}, \psi_{j}\right)+m_{2}\left(\psi_{j}, \psi_{i}\right)=0$.

$$
v_{j} v_{i} v_{k}=\left\{v_{i}, v_{j}\right\} v_{k}-v_{i} v_{j} v_{k}=W_{i j} v_{k}-W_{j k} v_{i}+v_{i} v_{k} v_{j}
$$

yields

$$
v_{i}\left[v_{j}, v_{k}\right]-\left[v_{i}, v_{j}\right] v_{k}=\left\{Q,-\sum_{l} W_{j k l} \eta_{l} v_{i}-\sum_{l} W_{i j l} v_{k} \eta_{l}\right\}
$$

Therefore

$$
\begin{gathered}
f_{2}\left(\psi_{i}, m_{2}\left(\psi_{j}, \psi_{k}\right)\right)-f_{2}\left(m_{2}\left(\psi_{i}, \psi_{j}\right), \psi_{k}\right)=\frac{1}{2}\left(\sum_{l} W_{i j l} v_{k} \eta_{l}+\sum_{l} W_{j k l} \eta_{l} v_{i}\right) \\
\iota\left(m_{3}\left(\psi_{i}, \psi_{j}, \psi_{k}\right)\right)=f_{2}\left(\psi_{i}, m_{2}\left(\psi_{j}, \psi_{k}\right)\right)-f_{2}\left(m_{2}\left(\psi_{i}, \psi_{j}\right), \psi_{k}\right)-v_{i} f_{2}\left(\psi_{j}, \psi_{k}\right)-f_{2}\left(\psi_{i}, \psi_{j}\right) v_{k} \\
=\frac{1}{2} \sum_{l}\left(W_{i j l} v_{k} \eta_{l}+W_{j k l} \eta_{l} v_{i}+W_{j k l} v_{i} \eta_{l}+W_{i j l} \eta_{l} v_{k}\right)=\frac{1}{2}\left(W_{i j l} \delta_{l k}+W_{j k l} \delta_{l i}\right)=W_{i j k}
\end{gathered}
$$

[^12]In conclusion, $m_{3}\left(\psi_{i}, \psi_{j}, \psi_{k}\right)=W_{i j k}$.
Therefore, in general, we can say that all the elements of $\mathcal{A}_{D 0}$ can be written as linear combinations of the form $(d>2)$

$$
\begin{equation*}
\Lambda_{i}=\psi_{1} \wedge \cdots \wedge \psi_{i_{r}}, \quad \operatorname{deg}\left(\Lambda_{i}\right):=r \tag{4.67}
\end{equation*}
$$

where we $\operatorname{defined} \operatorname{deg}\left(\Lambda_{i}\right)$ for later convenience and $\wedge$ denotes the usual skew-symmetric wedge product. The fact that all the elements can be write as in the formula (4.67) is just a consequence of (4.47). Now, we can determine $m_{d}\left(\Lambda_{1}, \Lambda_{2}, \cdots, \Lambda_{d}\right)$ for $\Lambda_{i}=\psi_{i_{1}} \wedge \cdots \wedge \psi_{i_{\operatorname{deg}\left(\Lambda_{i}\right)}}$. Since $m_{k}=0$ for $k \neq 2, d$, the relation (3.3) can be solved by the rule $-\underline{15}$

$$
\begin{align*}
& m_{k}\left(\Lambda_{1}, \Lambda_{2}, \cdots, m_{2}\left(\Lambda_{i}, \Lambda_{i+1}\right), \cdots, \Lambda_{k+1}\right) \\
= & (-1)^{\operatorname{deg}\left(\Lambda_{i}\right)\left(\operatorname{deg}\left(\Lambda_{i+1}\right)+\cdots+\operatorname{deg}\left(\Lambda_{k+1}\right)\right)} m_{2}\left(m_{k}\left(\Lambda_{1}, \cdots, \Lambda_{i-1}, \Lambda_{i+1}, \cdots, \Lambda_{k+1}\right), \Lambda_{i}\right)  \tag{4.68}\\
& +(-1)^{\operatorname{deg}\left(\Lambda_{i+1}\right)\left(\operatorname{deg}\left(\Lambda_{i+2}\right)+\cdots+\operatorname{deg}\left(\Lambda_{k+1}\right)\right)} m_{2}\left(m_{k}\left(\Lambda_{1}, \cdots, \Lambda_{i}, \Lambda_{i+2}, \cdots, \Lambda_{k+1}\right), \Lambda_{i+1}\right) .
\end{align*}
$$

By repeated use of (4.68), we are lead to the conclusion that

$$
\begin{equation*}
m_{d}\left(\psi_{i_{0}} \wedge \cdots \wedge \psi_{i_{t_{1}}}, \psi_{j_{0}} \wedge \cdots \wedge \psi_{j_{t_{2}}}, \cdots, \psi_{k_{0}} \wedge \cdots \wedge \psi_{k_{t_{d}}}\right) \tag{4.69}
\end{equation*}
$$

is equal to the sum

$$
\begin{align*}
& \sum_{a_{1}=0}^{t_{1}} \sum_{a_{2}=0}^{t_{2}} \cdots \sum_{a_{d}=0}^{t_{d}} m_{d}\left(\psi_{i_{a_{1}}}, \psi_{j_{a_{2}}}, \cdots, \psi_{k_{a_{d}}}\right)(-1)^{a_{1}+\cdots+a_{d}}  \tag{4.70}\\
& \psi_{i_{0}} \wedge \cdots \hat{\psi}_{i_{a_{1}}} \cdots \wedge \psi_{i_{t_{1}}} \wedge \psi_{j_{0}} \wedge \cdots \hat{\psi}_{j_{a_{2}}} \cdots \wedge \psi_{j_{t_{2}}} \wedge \cdots \wedge \psi_{k_{0}} \wedge \cdots \hat{\psi}_{k_{a_{d}}} \cdots \wedge \psi_{k_{t_{d}}}
\end{align*}
$$

up to an overall sign.
We finish this section with a very simple example to illustrate the consistency between the $\widetilde{\mathcal{W}}_{\text {eff }}$ computation and the relations (4.65) and (4.66):

Example: $W=x^{d}$
Let's consider the LG model with a single chiral superfield $x$ and a superpotential $W=x^{d}$, $d \geq 2$. The D0-brane is given by

$$
\begin{equation*}
Q=x \bar{\eta}+x^{d-1} \eta . \tag{4.71}
\end{equation*}
$$

The bosonic open string state is $e=1$ and the fermionic open string state is $\psi=\bar{\eta}-\eta$. One can use the Kapustin-Li formula [49] to compute the three-point correlation function

$$
\langle\psi \psi \psi\rangle=\frac{1}{2 \pi i} \oint_{x=0} \frac{\operatorname{Str}\left(\frac{d Q}{d x} \psi \psi \psi\right)}{\frac{d W}{d x}}= \begin{cases}1, & d=2, \\ 0, & d>2 .\end{cases}
$$

From the relation

$$
\langle\psi \psi \psi\rangle=\gamma\left(m_{2}\left(m_{2}(\psi, \psi), \psi\right)\right)
$$

and

$$
\gamma(e)=0, \quad \gamma(\psi)=1,
$$

[^13]we see
\[

m_{2}(\psi, \psi)= $$
\begin{cases}e, & d=2 \\ 0, & d>2\end{cases}
$$
\]

It was shown in [52] that the effective superpotential, or disk partition function, of the LG model with Dirichlet boundary condition, which is equivalent to (4.71), is

$$
\mathcal{W}_{\mathrm{eff}}=\operatorname{Tr}\left(\frac{Z^{d+1}}{d+1}\right)
$$

up to a rescaling, where $Z$ is the world volume field dual to $\psi$. From this effective superpotential we conclude

$$
\gamma\left(m_{2}\left(m_{s}\left(\psi^{\otimes s}\right), \psi\right)\right)= \begin{cases}1, & s=d, \\ 0, & s \neq d .\end{cases}
$$

or equivalently

$$
m_{s}\left(\psi^{\otimes s}\right)= \begin{cases}e, & s=d, \\ 0, & s \neq d .\end{cases}
$$

Finally, we remark that in principle we can study the correspondence between $M F(W)$ and $D\left(\operatorname{Mod}-\mathcal{A}_{D 0}\right)$ from the point of view of tensor products of minimal models. A homogeneous superpotential $W \in \mathbb{C}\left[x_{1}, \ldots, x_{n}\right]$ of degree $d$ at a special point in complex structure moduli can be seen as the tensor product of $n A_{d-1}$ minimal models. This relates to the well known structure of tensor products in matrix factorization categories. It will be interesting to study further how this tensor product structure translates to the category $D\left(\operatorname{Mod}-\mathcal{A}_{D 0}\right)$ as it is well known that tensor products of $A_{\infty}$-algebras is rather nontrivial [53-55].

### 4.3 Inhomogeneous superpotential

Consider now a quasi-homogeneous superpotential $W \in \mathbb{C}\left[x_{1}, \ldots, x_{N}\right]$. Then, we write the superpotential as a sum of homogeneous polynomial-degree terms:

$$
\begin{equation*}
W(x)=\sum_{l=2}^{d} W^{(l)}(x), \tag{4.72}
\end{equation*}
$$

where each term $W^{(l)}(x)$ has polynomial-degree $l$, i.e. where we assign degree 1 to each variable $x_{i}$. The brane $\mathcal{B}_{D 0}$ and the fermionic generators of the open string states are still given by (4.34) and (4.36) respectively. If we turn on deformations as in (4.55), we can use the same argument ${ }^{16}$ to deduce that the obstruction is given by

$$
\begin{equation*}
\frac{(-1)^{l}}{l!} \sum_{i_{1}+\cdots+i_{n}=l} \frac{\partial^{l} W^{(l)}}{\partial x_{1}^{i_{1}} \cdots \partial x_{n}^{i_{n}}} u_{1}^{i_{1}} u_{2}^{i_{2}} \cdots u_{n}^{i_{n}} \tag{4.73}
\end{equation*}
$$

at degree $l$. Therefore we have the following multiplications

$$
\begin{equation*}
m_{2}\left(\psi_{i}, \psi_{j}\right)+m_{2}\left(\psi_{j}, \psi_{i}\right)=\frac{\partial^{2} W^{(2)}}{\partial x_{i} \partial x_{j}} \tag{4.74}
\end{equation*}
$$

and

$$
\begin{equation*}
m_{l}\left(\psi_{i_{1}}, \psi_{i_{2}}, \cdots, \psi_{i_{l}}\right)=\frac{1}{l!} \frac{\partial^{l} W^{(l)}}{\partial x_{i_{1}} \partial x_{i_{2}} \cdots \partial x_{i_{l}}} \tag{4.75}
\end{equation*}
$$

for $3 \leq l \leq d$ and $m_{k}=0$ for $k>d$.

[^14]
### 4.4 Landau-Ginzburg Orbifold

So far we have considered LG models with trivial orbifold group. For a LG orbifold, there is a finite abelian group $G$ acting on the field space, and $W \in \mathbb{C}\left[x_{1}, \ldots, x_{n}\right]^{G}$. As such, the open string states are those invariant under the action of $G$. Let $\psi_{1}, \cdots, \psi_{n}$ be the degree-one fermionic generators (4.36) in $\operatorname{End}_{M F(W)}\left(\mathcal{B}_{D 0}\right)$ of the LG model without orbifolding. Note that each $\psi_{1}$ transforms in a definite representation, when we take the $G$ action into account. When we incorporate the orbifold the brane defined by the matrix factorization $Q_{D 0}$ in (4.34) requires the specification of a representation $\rho_{M}$, compatible with $\rho_{\text {orb }}$. It is easy to see that $\rho_{M}: G \rightarrow G L(M)$ is almost completely fixed by its action, via conjugation, over $\eta_{j}, \bar{\eta}_{j}$, in the definition of $Q_{D 0}$. Then $\rho_{M}$ is fixed up to its action on the Clifford vacuum $|0\rangle$ (defined by $\eta_{j}|0\rangle=0$ for all $j$ ). Hence, we can label $\mathcal{B}_{D 0}^{(a)}$ in the category $M F(W, G)$ by a single (one-dimensional) irreducible representation ${ }^{17}$ : the representation of $|0\rangle$. Then, if $G=\mathbb{Z}_{d}$, we have $a=0, \ldots, d-1$ and we denote

$$
\begin{equation*}
\mathcal{B}_{\text {orb }}:=\bigoplus_{a=0}^{d-1} \mathcal{B}_{D 0}^{(a)} \in M F(W, G), \tag{4.76}
\end{equation*}
$$

where the set of branes $\mathcal{B}_{D 0}^{(a)}, a=0, \ldots, d-1$ form a set of generators of $M F(G, W)$ [11] and the algebra $\mathcal{A}_{D 0}$ must be replaced by

$$
\begin{equation*}
\mathcal{A}_{\text {orb }}=\operatorname{End}_{M F(W, G)}\left(\mathcal{B}_{\text {orb }}\right) . \tag{4.77}
\end{equation*}
$$

The correspondence $\operatorname{MF}(W, G) \cong D\left(\operatorname{Mod}-\mathcal{A}_{\text {orb }}\right)$ was studied in [56,58], for homogeneous potentials. Moreover, the results in [11] implies the following isomorphism of $A_{\infty}$ algebras:

$$
\begin{equation*}
\mathcal{A}_{\text {orb }} \cong \mathcal{A}_{D 0} \sharp G, \tag{4.78}
\end{equation*}
$$

where $\mathcal{A}_{D 0} \sharp G$, the smash product of $\mathcal{A}_{D 0}$ and $\mathbb{C}[G]$, is regarded as an $A_{\infty}$-algebra with $m_{2}\left(g_{1}, g_{2}\right)=g_{1} \cdot g_{2}$ and $m_{k} \equiv 0$ for $k \neq 2\left(g_{1}, g_{2} \in G\right)$. Then $\mathcal{A}_{\text {orb }}$ can be regarded as the product of two $A_{\infty}$-algebras. We can still use the construction introduced in section 4.2 to set up the correspondence between objects of $M F(W, G)$ and the $A_{\infty}$-modules over $\mathcal{A}_{D 0} \sharp G$. The difference is that the module is not only an $A_{\infty}$-module of $\mathcal{A}_{D 0}$, but also a $\mathbb{C}[G]$-module, this corresponds to the fact that the Chan-Paton spaces of the matrix factorizations of LG orbifold all carries a $G$-representation.

Specifically for the case $G=\mathbb{Z}_{d}$. Because the multiplication $m_{2}^{\mathcal{A}_{D 0} \not \mathbb{Z}_{d}}$ of $\mathcal{A}_{D 0} \sharp \mathbb{Z}_{d}$ satisfies

$$
\begin{equation*}
m_{2}^{\mathcal{A}_{D 0} \sharp \mathbb{Z}_{d}}\left(a \sharp g_{1}, b \sharp g_{2}\right)=m_{2}^{\mathcal{A}_{D 0}}\left(a, g_{1} b g_{1}^{-1}\right) \sharp\left(g_{1} \cdot g_{2}\right), \tag{4.79}
\end{equation*}
$$

an $\mathcal{A}_{D 0} \not \mathbb{Z}_{d}$-module is of the form $\oplus_{i=0}^{d-1} M_{i} \otimes \rho_{\lambda+i}$, where $\oplus_{i=0}^{d-1} M_{i}$ is a $\mathbb{Z}_{d}$-graded $\mathcal{A}_{D 0}$-module and $\rho_{l}$ denotes the one-dimensional representation of $\mathbb{Z}_{d}$ with weight $\exp (2 \pi i l / d)$.

For example, when $d=2, \mathcal{A}_{D 0}$ is a Clifford algebra $C l(n, \mathbb{C})$, hence if $G=\mathbb{Z}_{2}$ we have

$$
\begin{equation*}
M F\left(W, \mathbb{Z}_{2}\right) \cong D\left(\operatorname{Mod}-\mathcal{A}_{D 0 \sharp} \not \mathbb{Z}_{2}\right) . \tag{4.80}
\end{equation*}
$$

The category $M F\left(W, \mathbb{Z}_{2}\right)$ is very similar to the graded category $M F(W)$ but its morphisms are diferent. Because of the $\mathbb{Z}_{2}$ orbifold all the morphisms between irreducible objects are

[^15]either even or odd, but not both. This is exactly the category studied in [59] and so, we can use the results in [59] to conclude
\[

$$
\begin{equation*}
M F\left(W, \mathbb{Z}_{2}\right) \cong D\left(M o d_{\mathbb{Z}_{2}}-C l(n, \mathbb{C})\right) \tag{4.81}
\end{equation*}
$$

\]

where $D\left(M o d_{\mathbb{Z}_{2}}-C l(n, \mathbb{C})\right)$ denotes the derived category of graded modules over $C l(n, \mathbb{C})$. A classical result of Atiyah-Bott-Shapiro [60] (see also [59]) establish

$$
\begin{equation*}
M F\left(W, \mathbb{Z}_{2}\right) \cong D\left(\operatorname{Mod}_{\mathbb{Z}_{2}}-C l(n, \mathbb{C})\right) \cong D\left(M o d-C l_{0}(n, \mathbb{C})\right) \tag{4.82}
\end{equation*}
$$

where $C l_{0}(n, \mathbb{C})$ denotes the even part of the Clifford algebra $C l(n, \mathbb{C})$. We remark that the category considered in [9] is the category $\operatorname{MF}(W)$ where the morphisms are odd and even, and hence is equivalent to $D(\operatorname{Mod}-C l(n, \mathbb{C}))$, where the modules are not graded. Finally, we illustrate the correspondence (4.80) with an example. Set $W=\sum_{i=1}^{2 m} x_{i}^{2}$ and each $x_{i}$ is $\mathbb{Z}_{2}$-odd. Let $S_{+}$and $S_{-}$be the spinor representation with left and right chirality respectively. The $\mathcal{A}_{D 0} \not \mathbb{Z}_{2}$ module $M:=S_{+} \otimes \rho_{0} \oplus S_{-} \otimes \rho_{1}$ corresponds to the matrix factorization with $Q_{M}=\sum_{i=1}^{m}\left(x_{2 i-1}+i x_{2 i}\right) \bar{\eta}_{i}+\sum_{i=1}^{m}\left(x_{2 i-1}-i x_{2 i}\right) \eta_{i}$ and the vacuum being $\mathbb{Z}_{2}$-even. The $\mathcal{A}_{D 0} \sharp \mathbb{Z}_{2}$ module $S_{+} \otimes \rho_{1} \oplus S_{-} \otimes \rho_{0}$ corresponds to the matrix factorization with the same $Q_{M}$ but the vacuum being $\mathbb{Z}_{2}$-odd ( $\bar{\eta}_{i}$ and $\eta_{i}$ are $\mathbb{Z}_{2}$-odd in both cases).

### 4.5 Hybrid Model

Finally, let us consider the $A_{\infty}$ structure of the matrix factorizations of hybrid models.
Start with the trivial fibration. In this case, the theory under consideration is defined on the target space

$$
\begin{equation*}
\left(V_{f} \times V_{b}\right) / G \tag{4.83}
\end{equation*}
$$

where $V_{b}=\mathbb{C}^{m}$ and $V_{f}=\mathbb{C}^{n}$ are regarded as the base space and the fiber respectively, and $G$ is the orbifold group acting on $V_{b}$ and $V_{f}$. Suppose that the base coordinates are $z_{i}, i=1, \cdots, m$ and the fiber coordinates are $x_{j}, j=1, \cdots, n$. The superpotential $W(x, z)$ is a $G$-invariant holomorphic function in $x_{j}$ and $z_{i}$.

The analogue of the $D 0$-brane for the LG models we discussed in previous sections is point-like along each fiber, i.e. it localizes to the base space. We call this brane the reference brane and denote it by $\mathcal{B}_{0}$. The superpotential can be written as

$$
W=\sum_{l} W^{(l)}(x, z)
$$

where $W(l)$ is homogeneous in $x_{i}$ with degree $l$, therefore the endomorphism $Q_{0} \in \mathcal{B}_{0}$ (see (4.4)) is

$$
Q_{0}=\sum_{i=1}^{n} x_{i} \bar{\eta}_{i}+\sum_{i=1}^{n} \sum_{l} \frac{1}{l} \frac{\partial W^{(l)}(x, z)}{\partial x_{i}} \eta_{i} .
$$

Then, as discussed in section $\underline{4.4}$, the $A_{\infty}$-algebra of the hybrid model on (4.83) is

$$
\mathcal{A}_{0} \sharp G,
$$

where $\mathcal{A}_{0}$ is generated by $\psi_{i}(z) \in \operatorname{End}_{M F(W)}\left(\mathcal{B}_{0}\right)$ satisfying

$$
m_{2}\left(\psi_{i}(z), \psi_{j}(z)\right)+m_{2}\left(\psi_{j}(z), \psi_{i}(z)\right)=\frac{\partial^{2} W^{(2)}(x, z)}{\partial x_{i} \partial x_{j}}
$$

$$
m_{l}\left(\psi_{i_{1}}(z), \psi_{i_{2}}(z), \cdots, \psi_{i_{l}}(z)\right)=\frac{1}{l!} \frac{\partial^{l} W^{(l)}(x, z)}{\partial x_{i_{1}} \partial x_{i_{2}} \cdots \partial x_{i_{l}}}, l>2 .
$$

For a hybrid model (for details on the precise definition of hybrid models see [3]), defined on a space of the form

$$
\begin{equation*}
Y:=\operatorname{Tot}(\mathcal{V} \xrightarrow{\pi} B) \tag{4.84}
\end{equation*}
$$

with superpotential $W \in H^{0}\left(\mathcal{O}_{Y}\right)$, where $\mathcal{V}$ is a vector bundle over the base space $B$, we can decompose $Y$ into a set of coordinate patches

$$
Y=\bigcup_{i} U_{i},
$$

such that every patch has the form

$$
U_{i}=\left(V_{f} \times V_{b}\right) / G_{i}=\widetilde{U}_{i} / G_{i}
$$

and $\operatorname{dim} V_{f}=\operatorname{rank} \mathcal{V}, \operatorname{dim} V_{b}=\operatorname{dim} B$. We use the notation $\widetilde{U}_{i}$ to denote the affine space $V_{f} \times V_{b}$. The reference brane $\mathcal{B}_{0}$ is of the form

$$
\mathcal{O} \underset{f(X, P)}{\xrightarrow{X}} \pi^{*} \mathcal{V} \underset{f(X, P)}{\xrightarrow{X}} \pi^{*} \wedge^{2} \mathcal{V} \underset{f(X, P)}{\xrightarrow{X}} \cdots \underset{f(X, P)}{\xrightarrow{X}} \pi^{*} \wedge^{n-1} \mathcal{V} \underset{f(X, P)}{\xrightarrow{X}} \pi^{*} \wedge^{n} \mathcal{V},
$$

where $X$ denotes collectively the coordinates along the fiber of $\mathcal{V}$ and $f(X, P)$ is a map that depends also on the base coordinate $P$ such that $f(X, P) \cdot X=X \cdot f(X, P)=W(X, P)$. Then from the discussion above, the reference brane $\mathcal{B}_{0}$ that is point-like along each fiber gives rise to an $A_{\infty}$-algebra $\mathcal{A}_{0 i} \sharp G_{i}$ within each coordinate patch, we can define a sheaf of $A_{\infty}$-algebra $\mathcal{A}$ by

$$
\mathcal{A}\left(U_{i}\right)=\mathcal{A}_{0}\left(U_{i}\right) \sharp G_{i} .
$$

If we denote by $x^{(i)}$ and $z^{(i)}$ the local fiber and base coordinates in $U_{i}$, then $\mathcal{A}_{0}\left(U_{i}\right)$ is generated by $\psi_{s}^{(i)}, s=1, \cdots, n$, which satisfy

$$
\begin{aligned}
& m_{2}\left(\psi_{s}^{(i)}, \psi_{t}^{(i)}\right)+m_{2}\left(\psi_{t}^{(i)}, \psi_{s}^{(i)}\right)=\frac{\partial^{2} W^{(2)}\left(x^{(i)}, z^{(i)}\right)}{\partial x_{s}^{(i)} \partial x_{t}^{(i)}} \\
& m_{l}\left(\psi_{s_{1}}^{(i)}, \psi_{s_{2}}^{(i)}, \cdots, \psi_{s_{l}}^{(i)}\right)=\frac{1}{l!} \frac{\partial^{l} W^{(l)}\left(x^{(i)}, z^{(i)}\right)}{\partial x_{s_{1}}^{(i)} \partial x_{s_{2}}^{(i)} \cdots \partial x_{s_{l}}^{(i)}}, l>2
\end{aligned}
$$

In other words, the algebra $\mathcal{A}_{0}\left(U_{i}\right)=\mathcal{A}_{0}\left(\widetilde{U}_{i}\right)$ i.e. it is constructed by ignoring the orbifold structure. In order to understand how these algebras are glued together as we change charts, we have to be careful with the treatment of the orbifold singularities of $B$. It has been proposed that the correct mathematical framework to study this problem is to view the GLSM as an algebraic stack $\underline{\underline{18}}$. In this context the intersection of two patches $U_{i} \cap U_{j}$ is given by the fibered product over $Y$

$$
\begin{equation*}
U_{i} \cap U_{j}=U_{i} \times_{Y} U_{j} \cong\left(V_{f} \times \mathcal{V}_{i j}\right) / G_{i j} \tag{4.85}
\end{equation*}
$$

[^16]where $G_{i j}$ is a subgroup of $G_{i} \times G_{j}$ and $\mathcal{V}_{i j}$ is a quasiprojective variety. Therefore, in order to define $\mathcal{A}\left(U_{i} \cap U_{j}\right)$ we have to be more careful, because $V_{f} \times \mathcal{V}_{i j}$ is not necessarily an affine space. The main difference with the usual LG orbifold case, is that in this case the branes $\mathcal{B}_{0}^{(g)} \in M F\left(W, G_{i j}\right), g \in G_{i j}$ are not necessarily all inequivalent objects. There can be a subgroup $H_{i j} \subseteq G_{i j}$ such that
\[

$$
\begin{equation*}
\mathcal{B}_{0}^{(0)} \cong \mathcal{B}_{0}^{(h)} \quad \text { for all } h \in H_{i j} \tag{4.86}
\end{equation*}
$$

\]

then the algebra $\mathcal{A}\left(U_{i} \cap U_{j}\right)$ is defined by

$$
\begin{equation*}
\mathcal{A}\left(U_{i} \cap U_{j}\right)=\operatorname{End}_{M F\left(W, G_{i j}\right)}\left(\bigoplus_{g \in G_{i j} / H_{i j}} \mathcal{B}_{0}^{(g)}\right) . \tag{4.87}
\end{equation*}
$$

The subgroup $H_{i j}$ depends on the specific model we study. We illustrate it in an example below. However, we expect that $\mathcal{A}$ has the structure of a sheaf of algebras over $Y$ hence we must have the isomorphism

$$
\begin{equation*}
\left.\left.\mathcal{A}\left(U_{i}\right)\right|_{U_{i} \cap U_{j}} \cong \mathcal{A}\left(U_{j}\right)\right|_{U_{i} \cap U_{j}} \tag{4.88}
\end{equation*}
$$

and the inclusions

$$
\begin{equation*}
\left.\left.\mathcal{A}\left(U_{i}\right)\right|_{U_{i} \cap U_{j}} \hookrightarrow \mathcal{A}\left(U_{i} \cap U_{j}\right) \hookleftarrow \mathcal{A}\left(U_{j}\right)\right|_{U_{i} \cap U_{j}} . \tag{4.89}
\end{equation*}
$$

The category of matrix factorizations of the hybrid model defined on $Y$ is thus equivalent to the derived category of sheaves of $\mathcal{A}$-modules. In the next section, we apply these results to homological projective duality.

## Example: Hybrid model on $\operatorname{Tot}(\mathcal{O}(-1) \rightarrow \mathrm{WP}(2,3))$

As an illustrative example, we derive the sheaf of $A_{\infty}$-algebra associated with a hybrid model on $Y=\operatorname{Tot}(\mathcal{O}(-1) \rightarrow \mathrm{WP}(2,3))$. This is a simple example where we cannot write $Y$ as a global orbifold. Let $p_{1}$ and $p_{2}$ be the homogeneous coordinates of the weighted projective space, i.e. $\left(p_{1}, p_{2}\right) \sim\left(\lambda^{2} p_{1}, \lambda^{3} p_{2}\right)$. Assume that the hybrid model is defined by the superpotential $W=P_{1} X^{2}+P_{2} X^{3}$, where $x$ is the fiber coordinate. The reference brane $\mathcal{B}_{0}$ is given by the following matrix factorization

$$
\begin{equation*}
\mathcal{O} \underset{P_{1} X+P_{2} X^{2}}{\stackrel{X}{\rightleftarrows}} \mathcal{O}(-1) \tag{4.90}
\end{equation*}
$$

Let $U_{i}$ be the open set defined by $p_{i} \neq 0$, then $U_{1} \cong \mathbb{C}^{2} / \mathbb{Z}_{2}$ and $U_{2} \cong \mathbb{C}^{2} / \mathbb{Z}_{3}$. The local coordinates are $\left(x_{1}, z_{1}\right)$ in $U_{1}$ and $\left(x_{2}, z_{2}\right)$ in $U_{2}$, where $x_{1}$ and $x_{2}$ denote the fiber coordinates. Then $z_{1}$ and $z_{2}$ satisfy $z_{1}^{2} z_{2}^{3}=1$ on $U_{1} \cap U_{2}$. In $U_{1}$, the superpotential reads $W=x_{1}^{2}+z_{1} x_{1}^{3}$ and the generator of $\mathbb{Z}_{2}$ acts as $\left(x_{1}, z_{1}\right) \mapsto\left(-x_{1},-z_{1}\right)$. In $U_{2}$, the superpotential reads $W=z_{2} x_{2}^{2}+x_{2}^{3}$ and the generator of $\mathbb{Z}_{3}$ acts as $\left(x_{2}, z_{2}\right) \mapsto\left(\exp (-2 \pi i / 3) x_{2}, \exp (-2 \pi i / 3) z_{2}\right)$. In $U_{1}$, the reference brane (4.90) can be written as $\mathcal{B}_{01}$ :

$$
\mathbb{C}_{+} \underset{x_{1}+z_{1} x_{1}^{2}}{\stackrel{x_{1}}{\rightleftarrows}} \mathbb{C}_{-},
$$

where the subscript $\pm$ indicates whether the complex plane is $\mathbb{Z}_{2}$-even or $\mathbb{Z}_{2}$-odd. As discussed before, the $A_{\infty}$-algebra $\mathcal{A}\left(U_{1}\right)$ is the $\mathbb{Z}_{2}$-invariant subspace of $\operatorname{End}\left(\mathcal{B}_{01}^{(0)} \oplus \mathcal{B}_{01}^{(1)}\right)$, where $\mathcal{B}_{01}^{(0)}=$ $\mathcal{B}_{01}$ and $\mathcal{B}_{01}^{(1)}$ is obtained from $\mathcal{B}_{01}$ by a $\mathbb{Z}_{2}$-twist, i.e. $\mathcal{B}_{01}^{(1)}$ is the matrix factorization

$$
\mathbb{C}_{-} \underset{x_{1}+z_{1} x_{1}^{2}}{\stackrel{x_{1}}{\rightleftarrows}} \mathbb{C}_{+}
$$

Therefore we have four independent $\mathbb{Z}_{2}$-invariant endomorphisms in $\operatorname{End}\left(\mathcal{B}_{01}^{(0)} \oplus \mathcal{B}_{01}^{(1)}\right)$, namely $\operatorname{id} \sharp \pm 1$ and $\psi_{1} \sharp \pm 1$, where id $\sharp+1(\mathrm{id} \sharp-1)$ is the identity map on $\mathcal{B}_{01}^{(0)}\left(\mathcal{B}_{01}^{(1)}\right)$ and $\psi_{1} \sharp+1\left(\psi_{1} \sharp-1\right)$ is the homomorphism in $\operatorname{Hom}\left(\mathcal{B}_{01}^{(0)}, \mathcal{B}_{01}^{(1)}\right)\left(\operatorname{Hom}\left(\mathcal{B}_{01}^{(1)}, \mathcal{B}_{01}^{(0)}\right)\right)$ given by the matrix

$$
\left(\begin{array}{cc}
0 & -i\left(1+z_{1} x_{1}\right) \\
i & 0
\end{array}\right) .
$$

The structure of the $A_{\infty}$-algebra is given by

$$
m_{2}\left(\psi_{1}, \psi_{1}\right)=2, \quad m_{3}\left(\psi_{1}, \psi_{1}, \psi_{1}\right)=z_{1} .
$$

Similarly, in $U_{2}$, the reference brane (4.90) can be written as $\mathcal{B}_{02}$ :

$$
\mathbb{C}_{0} \underset{z_{2} x_{2}+x_{2}^{2}}{\stackrel{x_{2}}{\rightleftarrows}} \mathbb{C}_{2},
$$

where the subscript $a$ indicates that the complex plane has $\mathbb{Z}_{3}$-weight $\exp (2 \pi i a / 3)$ for $a=$ $0,1,2 \bmod 3$. The $A_{\infty}$-algebra $\mathcal{A}\left(U_{2}\right)$ is the $\mathbb{Z}_{3}$-invariant subspace of $\operatorname{End}\left(\oplus_{a=0,1,2} \mathcal{B}_{02}^{(a)}\right)$, where $\mathcal{B}_{02}^{(0)}=\mathcal{B}_{02}$ and $\mathcal{B}_{02}^{(a)}$ is obtained from $\mathcal{B}_{02}$ by a $\mathbb{Z}_{3}$-twist, i.e. $\mathcal{B}_{01}^{(a)}$ is the matrix factorization

$$
\mathbb{C}_{a} \underset{z_{2} x_{2}+x_{2}^{2}}{x_{2}} \mathbb{C}_{a+2}
$$

We have six independent $\mathbb{Z}_{3}$-invariant endomorphisms in $\operatorname{End}\left(\oplus_{a=0,1,2} \mathcal{B}_{02}^{(a)}\right)$, namely id $\sharp \exp (2 \pi i a / 3)$ and $\psi_{2} \sharp \exp (2 \pi i a / 3)$ for $a=0,1,2 \bmod 3$, where $\operatorname{id} \sharp \exp (2 \pi i a / 3)$ is the identity map on $\mathcal{B}_{01}^{(a)}$ and $\psi_{2} \sharp \exp (2 \pi i a / 3)$ is the homomorphism in $\operatorname{Hom}\left(\mathcal{B}_{02}^{(a)}, \mathcal{B}_{02}^{(a+2)}\right)$ given by the matrix

$$
\left(\begin{array}{cc}
0 & -i\left(z_{2}+x_{2}\right) \\
i & 0
\end{array}\right) .
$$

The structure of the $A_{\infty}$-algebra is given by

$$
m_{2}\left(\psi_{2}, \psi_{2}\right)=2 z_{2}, \quad m_{3}\left(\psi_{2}, \psi_{2}, \psi_{2}\right)=1 .
$$

It is easy to check that $\psi_{1}$ and $\psi_{2}$ constitute a section of $\mathcal{O} \oplus \mathcal{O}(2)$. We see that $\mathcal{A}\left(U_{1}\right)=$ $\mathcal{A}_{0}\left(U_{1}\right) \not \mathbb{Z}_{2}$ and $\mathcal{A}\left(U_{2}\right)=\mathcal{A}_{0}\left(U_{2}\right) \not \mathbb{Z}_{3}$, where $\mathcal{A}_{0}\left(U_{i}\right)$ is generated by $\psi_{i}$.

The intersection $U_{1} \cap U_{2}$ is given by the fibered product, as indicated above, then we find

$$
U_{1} \cap U_{2}=U_{1} \times{ }_{Y} U_{2} \cong\left(\mathbb{C} \times \mathbb{C}^{*}\right) / \mathbb{Z}_{2} \times \mathbb{Z}_{3}
$$

We denote the coordinates of $U_{1} \cap U_{2}$ as $\left(x_{12}, z_{12}\right) \in \mathbb{C} \times \mathbb{C}^{*}$. The generator of $\mathbb{Z}_{2}$ acts as $\left(x_{12}, z_{12}\right) \rightarrow\left(-x_{12},-z_{12}\right)$ and the generator of $\mathbb{Z}_{3}$ acts as $\left(x_{12}, z_{12}\right) \rightarrow\left(x_{12}, \exp (-2 \pi i / 3) z_{12}\right)$. The relation between $\left(-x_{12},-z_{12}\right)$ and the coordinates in the charts $U_{i}$ is given by

$$
z_{1}=z_{12}^{3}, \quad z_{2}=z_{12}^{-2}, \quad x_{12}=x_{1}=x_{2} z_{12}^{-1} .
$$

The superpotential in the intersection can be written as $W=x_{12}^{2}+z_{12}^{3} x_{12}^{3}$. Given any matrix factorization of $W$ in the intersection $U_{1} \cap U_{2}$, i.e. an object of $M F\left(W, \mathbb{Z}_{2} \times \mathbb{Z}_{3}\right)$, defined over $\mathbb{C} \times \mathbb{C}^{*}$, we can define a similarity transformation [43] $z_{12}^{s} \mathbf{1}$, where $\mathbf{1}$ is the identity on the Chan-Paton space and $s \in \mathbb{Z}$. In $U_{1} \cap U_{2}$ clearly $z_{12}^{s} \mathbf{1}$ is invertible for any $s$ and it leaves invariant the endomorphism $Q$ but it changes $\rho_{M}$, shifting all its weights simultaneously by $(-1)^{s} \exp (-2 \pi i s / 3)$. So, it is clear from the argument above, the matrix factorization $\left.\mathcal{B}_{01}^{(0)}\right|_{U_{1} \cap U_{2}}$, given by:

$$
\mathbb{C}_{(+, 0)} \underset{x_{12}+z_{12}^{3} x_{12}^{2}}{x_{12}} \mathbb{C}_{(-, 0)}
$$

where the subscript $\mathbb{C}_{(a, b)}$ labels the weights of the $\mathbb{Z}_{2} \times \mathbb{Z}_{3}$ representation, is equivalent to $\left.\mathcal{B}_{01}^{(1)}\right|_{U_{1} \cap U_{2}}$, given by:

$$
\mathbb{C}_{(-, 0)} \underset{x_{12}+z_{12}^{3} x_{12}^{2}}{\stackrel{x_{12}}{\rightleftarrows}} \mathbb{C}_{(+, 0)}
$$

Moreover, we can also show $\left.\left.\mathcal{B}_{01}^{(0)}\right|_{U_{1} \cap U_{2}} \cong \mathcal{B}_{02}^{(a)}\right|_{U_{1} \cap U_{2}}$, for any $a$ using the similarity transformation

$$
\left(\begin{array}{cc}
0 & x_{12}+z_{12}^{3} x_{12}^{2} \\
x_{12} & 0
\end{array}\right)=\left(\begin{array}{cc}
z_{12} & 0 \\
0 & 1
\end{array}\right)\left(\begin{array}{cc}
0 & z_{12}^{-1} x_{12}+z_{12}^{2} x_{12}^{2} \\
z_{12} x_{12} & 0
\end{array}\right)\left(\begin{array}{cc}
z_{12}^{-1} & 0 \\
0 & 1
\end{array}\right)
$$

composed with the transformation $z_{12}^{s} \mathbf{1}$ for appropriately chosen $s$. The induced transformation on the open string morphism, namely

$$
\left(\begin{array}{cc}
0 & -i\left(1+z_{1} x_{1}\right) \\
i & 0
\end{array}\right)=\left(\begin{array}{cc}
z_{2}^{-\frac{1}{2}} & 0 \\
0 & 1
\end{array}\right)\left(\begin{array}{cc}
0 & -i\left(z_{2}+x_{2}\right) \\
i & 0
\end{array}\right)\left(\begin{array}{cc}
1 & 0 \\
0 & z_{2}^{-\frac{1}{2}}
\end{array}\right)
$$

let us conclude that

$$
\left.\left.\mathcal{A}\left(U_{1}\right)\right|_{U_{1} \cap U_{2}} \cong \mathcal{A}\left(U_{1}\right)\right|_{U_{1} \cap U_{2}}
$$

as expected. We also conclude that $\mathcal{A}\left(U_{1} \cap U_{2}\right)$ is thus generated by a single element $\psi_{12}$ and the restriction map of the sheaf $\mathcal{A}$ is given by

$$
\begin{array}{rlrl}
\mathcal{A}\left(U_{1}\right) \rightarrow \mathcal{A}\left(U_{1} \cap U_{2}\right) & \mathcal{A}\left(U_{2}\right) \rightarrow \mathcal{A}\left(U_{1} \cap U_{2}\right) \\
\text { id } \sharp \pm \mapsto \text { id } & & \text { id } \sharp e^{2 \pi i a / 3} & \mapsto \text { id } \\
\psi_{1} \sharp \pm \mapsto \psi_{12} & & \psi_{2} \sharp e^{2 \pi i a / 3} & \mapsto \psi_{12}
\end{array}
$$

## 5 Examples of categories of B-branes on HPD phases

In this section we apply the results from the previous section to HPD constructed from GLSMs introduced in [8]. The Higgs branch category $\mathcal{C}$ defined in (2.17) takes the form

$$
\begin{equation*}
\mathcal{C}=D\left(\widehat{Y}_{\zeta_{\mathcal{L}} \ll-1}, \widehat{W}_{\zeta_{\mathcal{L}} \ll-1}\right), \tag{5.1}
\end{equation*}
$$

which generically corresponds to a hybrid model as the ones reviewed in section 4.5. We analyze the following examples in detail:

- Degree $d$ Veronese embeddings.
- Fano complete intersections in $\mathbb{P}^{n}$.

### 5.1 HPD of Veronese embedding

As reviewed in section $\underline{2}$, the HPD category (2.17) of degree- $d$ Veronese embedding of $\mathbb{P}^{n}=$ $\mathbb{P}(V)(\operatorname{dim} V=n+1)$, can be described by the category of B-branes on hybrid model with target space ${ }^{19}$ [8]

$$
\begin{equation*}
\operatorname{Tot}\left(\mathcal{O}\left(-\frac{1}{d}\right)^{\oplus(n+1)} \rightarrow \mathbb{P}^{\binom{n+d}{d}-1}\right) / \mathbb{Z}_{d} \tag{5.2}
\end{equation*}
$$

with superpotential

$$
\begin{equation*}
W=\sum_{a=1}^{\binom{n+d}{d}} s_{a} f_{a}(x), \tag{5.3}
\end{equation*}
$$

where $f_{a}$ 's are the degree $d$ monomials in $x_{i}, i=0, \cdots, n$ and $s_{a}$ are homogeneous coordinates in $\mathbb{P}^{\binom{n+d}{d}-1}$. One can interpret the category of matrix factorizations of this LG model as the derived category of a noncommutative space $\left.D\left(\mathbb{P}^{(n+d}{ }_{d}\right)-1, \mathcal{A}_{0} \sharp \mathbb{Z}_{d}\right)$, i.e. the category of sheaves of modules over the sheaf of $A_{\infty}$-algebras $\mathcal{A}_{0} \sharp \mathbb{Z}_{d}$. Here, when restricted to a single fiber, the sheaf of $A_{\infty}$-algebra $\mathcal{A}_{0}$ is the algebra of endomorphisms of the $D 0$-brane we defined previously, so $\mathcal{A}_{0}$ localizes to the base projective space. Let us denote by $Q_{0}$ the matrix factorization corresponding to the reference brane $\mathcal{B}_{0}^{(0)}$ given by

$$
\begin{equation*}
Q_{0}=\sum_{i}\left(x_{i} \bar{\eta}_{i}+\frac{1}{d} \frac{\partial W}{\partial x_{i}} \eta_{i}\right), \tag{5.4}
\end{equation*}
$$

where we have chosen the trivial $\mathbb{Z}_{d}$ representation for the Clifford vaccum. Then, at a generic point $p \in \mathbb{P}^{\binom{n+d}{d}-1}, \mathcal{A}_{0, p}$ is given by the $A_{\infty}$-algebra with relations (4.65) and (4.66).

For completeness, let us write the generators of $D\left(\mathbb{P}^{\left(n^{n+d}\right)-1}, \mathcal{A}_{0} \not \mathbb{Z}_{d}\right)$ as $\mathcal{A}_{0} \sharp \mathbb{Z}_{d}$-modules. The B-brane $\mathcal{B}_{0}^{(0)}$ can be represented as the curved complex

$$
\begin{equation*}
\mathcal{O} \underset{\frac{\partial W}{\partial x} \eta}{\underset{\sim}{\eta}} \mathcal{O}\left(-\frac{1}{d}\right) \otimes V \underset{\frac{\partial W}{\partial x} \eta}{\stackrel{x \bar{\eta}}{\leftrightarrows}} \mathcal{O}\left(-\frac{2}{d}\right) \otimes \wedge^{2} V \underset{\frac{\partial W}{\partial x} \eta}{\stackrel{x \bar{\eta}}{\rightleftarrows}} \cdots \underset{\frac{\partial W}{\partial x} \eta}{\stackrel{x \bar{\eta}}{\leftrightarrows}} \mathcal{O}\left(-\frac{n}{d}\right) \otimes \wedge^{n} V \underset{\frac{\partial W}{\partial X} \eta}{\stackrel{x \bar{\eta}}{\leftrightarrows}} \mathcal{O}\left(-\frac{n+1}{d}\right) \otimes \wedge^{n+1} V, \tag{5.5}
\end{equation*}
$$

where $\mathcal{O}(m)$ denotes orbibundles over $\mathbb{P}^{\binom{n+d}{d}-1}$. Define $\mathcal{B}_{0}^{(l)}$ to be the matrix factorization (5.5) twisted by $\mathcal{O}(l / d)$ for $l \in \mathbb{Z}$ and therefore the sheaf of $A_{\infty}$ modules corresponding to $\mathcal{B}_{0}^{(l)}$ is given by ${ }^{20}$

$$
\begin{equation*}
\mathcal{A}^{(l)}:=\operatorname{Hom}\left(\bigoplus_{a=0}^{d-1} \mathcal{B}_{0}^{(a)}, \mathcal{B}_{0}^{(l)}\right)=\bigoplus_{a=0}^{d-1} \bigoplus_{k \geq 0} \mathcal{O}\left(\frac{l-a}{d}-k\right) \otimes \wedge^{k d+a} V, \tag{5.6}
\end{equation*}
$$

[^17]where the sum over $k$ is such that $k d+a \leq n+1$ then, we can simplify (5.6) to
\[

$$
\begin{equation*}
\mathcal{A}^{(l)}=\bigoplus_{i=0}^{n+1} \mathcal{O}\left(\frac{l-i}{d}\right) \otimes \wedge^{i} V \tag{5.7}
\end{equation*}
$$

\]

We can therefore write

$$
\begin{equation*}
D\left(\mathbb{P}^{\binom{n+d}{d}-1}, \mathcal{A}_{0} \sharp \mathbb{Z}_{d}\right)=\left\langle\mathcal{A}^{\left(1-C_{d, n}\right)}, \cdots, \mathcal{A}^{(-1)}, \mathcal{A}^{(0)} \cong \mathcal{A}_{0}\right\rangle, \tag{5.8}
\end{equation*}
$$

where $C_{d, n}=d\binom{n+d}{d}-(n+1)$ is the expected number of factors obtained from the analysis of the Coulomb vacua in [8].

### 5.2 HPD of Fano hypersurface in projective space

A degree $d \leq n$ Fano hypersurface in $\mathbb{P}^{n}$, denoted $\mathbb{P}^{n}[d]$, can be described by a GLSM with $U(1)$ gauge group, $n+1$ chiral multiplets $x_{i}$ with gauge charge 1 , one chiral multiplet $p$ with gauge charge $-d$ and a superpotential

$$
\begin{equation*}
W_{\text {Fano }}=p_{0} F_{d}(x) \tag{5.9}
\end{equation*}
$$

where the polynomial $F_{d}(x)$, of degree $d$, is the defining equation of the hypersurface (which we assume to be smooth). We consider $x_{i}$ to be the coordinates on a complex vector space $V(\operatorname{dim} V=n+1)$, hence $\mathbb{P}^{n}=\mathbb{P}(V)$. In this case, the equivalence (2.3) takes the form

$$
\begin{equation*}
D^{b} \operatorname{Coh}\left(\mathbb{P}^{n}[d]\right)=\left\langle M F\left(F_{d}, \mathbb{Z}_{d}\right), \mathcal{O}_{\mathbb{P}^{n}[d]}, \mathcal{O}_{\mathbb{P}^{n}[d]}(1), \cdots, \mathcal{O}_{\mathbb{P}^{n}[d]}(n-d)\right\rangle \tag{5.10}
\end{equation*}
$$

The associated Lefschetz decomposition is

$$
\begin{equation*}
D^{b}\left(\mathbb{P}^{n}[d]\right)=\left\langle\mathcal{A}_{0}, \mathcal{A}_{1}, \cdots, \mathcal{A}_{n-d}\right\rangle \tag{5.11}
\end{equation*}
$$

where $\mathcal{A}_{0}:=\left\langle M F\left(F_{d}, \mathbb{Z}_{d}\right), \mathcal{O}_{\mathbb{P}^{n}[d]}\right\rangle, \mathcal{A}_{i}:=\left\langle\mathcal{O}_{\mathbb{P}^{n}[d]}\right\rangle, i>0$. The small window category $\mathcal{W}_{-, b}^{\mathcal{L}}$ of this GLSM, defined in (2.4) consists of B-branes with charges $q$ satifying

$$
\begin{equation*}
\left|q+\frac{\theta}{2 \pi}\right|<\frac{d}{2} \tag{5.12}
\end{equation*}
$$

We choose the theta angle (i.e. the integer $b$ ) as $\theta=\pi d-\varepsilon$, with $0<\varepsilon \ll 1$, so $q$ takes values $-(d-1),-(d-2), \cdots,-2,-1,0$.

As shown in [8], the universal hyperplane section can be described by the geometric phase (with FI parameters lying in the first quadrant) of the GLSM $\mathcal{T}_{\mathcal{X}}$, this corresponds to a GLSM with gauge group $U(1)_{\mathcal{L}} \times U(1)$ and with matter content

$$
\begin{array}{ccccccccccc} 
& x_{0} & x_{1} & \cdots & x_{n} & p_{0} & p & \cdots & y_{0} & \cdots & y_{n} \\
U(1)_{\mathcal{L}} & 1 & 1 & \cdots & 1 & -d & -1 & \cdots & 0 & \cdots & 0 \\
U(1)_{1} & 0 & 0 & \cdots & 0 & 0 & -1 & \cdots & 1 & \cdots & 1
\end{array}
$$

and superpotential

$$
\widehat{W}=p_{0} F_{d}(x)+p \sum_{i=0}^{n} x_{i} y_{i}
$$

The HPD of $\mathbb{P}^{n}[d]$ with Lefschetz decomposition given by (5.11) can be described by the Higgs branch of the phase of $\mathcal{T}_{\mathcal{X}}$ corresponding to the FI parameters lying in the second quadrant: $\left(\zeta_{\mathcal{L}} \ll-1, \zeta_{1} \gg 1\right)$. This is a hybrid model with target space

$$
Y:=\operatorname{Tot}\left(\mathcal{O}_{\mathbb{\mathbb { P }}^{n}}^{\oplus(n+1)} \oplus \mathcal{O}_{\mathbb{P}^{n}}(-1) \rightarrow \check{\mathbb{P}}^{n}\right) / \mathbb{Z}_{d}
$$

and superpotential

$$
\begin{equation*}
W=F_{d}(x)+p \sum_{i=0}^{n} x_{i} y_{i} \tag{5.13}
\end{equation*}
$$

where $\check{\mathbb{P}}^{n}:=\mathbb{P}\left(V^{\vee}\right), x_{i}$ 's are fiber coordinates of $\mathcal{O}_{\mathbb{P}^{n}}^{\oplus(n+1)}, p$ is the fiber coordinate of $\mathcal{O}_{\mathbb{P}^{n}}(-1)$ and the $y_{i}$ 's are homogeneous coordinates on the base $\check{\mathbb{P}}^{n}$. The $\mathbb{Z}_{d}$ orbifold acts with weight 1 on the $x_{i}$ 's and -1 on $p$. Denote the category of B-branes of this hybrid model as $D(Y, W)$. Then $D(Y, W)$ has a (dual) Lefschetz decomposition that takes the form (as proposed in [8]):

$$
\begin{equation*}
D(Y, W)=\left\langle\mathcal{B}_{n-1}(1-n), \mathcal{B}_{n-2}(2-n), \cdots, \mathcal{B}_{2}(-2), \mathcal{B}_{1}(-1), \mathcal{B}_{0}\right\rangle, \tag{5.14}
\end{equation*}
$$

where we have the equivalence of categories $\mathcal{B}_{0} \cong \mathcal{A}_{0}$. Denote the functor implementing this equivalence by $\mathcal{F}$ :

$$
\mathcal{F}: \mathcal{A}_{0} \rightarrow \mathcal{B}_{0} .
$$

Then $\mathcal{B}_{i}=\left\langle\mathcal{F}\left(M F\left(F_{d}, \mathbb{Z}_{d}\right)\right), \mathcal{F}(\mathcal{O})\right\rangle$ for $0 \leq i \leq d, \mathcal{B}_{j}=\left\langle\mathcal{F}\left(M F\left(F_{d}, \mathbb{Z}_{d}\right)\right)\right\rangle$ for $d+1 \leq j \leq n-1$. The relationship between the Lefschetz decomposition and its dual decomposition is illustrated by figure 2 . Next we describe the functor $\mathcal{F}$ explicitly. Define the matrix factorization $Q^{\prime}$ of

Figure 2: Lefschetz decomposition of the hypersurface $\mathbb{P}^{n}[d]$ and the dual Lefschetz decomposition of the HPD.
$p \sum_{i=0}^{n} x_{i} y_{i}$ as

$$
\mathcal{O}_{\tilde{\mathbb{P}}^{n}}(1) \underset{\sum_{i=0}^{n} x_{i} y_{i}}{\underset{ }{\rightleftarrows}} \mathcal{O}_{\tilde{\mathbb{P}}^{n}} .
$$

Any matrix factorization $\mathcal{M} \in M F\left(F_{d}, \mathbb{Z}_{d}\right)$ can be lifted to a GLSM B-brane with $U(1)_{\mathcal{L}}$ charges in the small window (5.12). On the other hand the category $\widehat{\mathcal{W}}_{-, b}^{\mathcal{L}} \cong D(Y, W)$ in (2.17) can be chosen (by adjusting $b$ ) such that the $U(1)_{\mathcal{L}}$ charges $q^{\prime}$ in the $\mathcal{T}_{\mathcal{X}}$ model satisfy $q^{\prime} \in\{-(d-1),-(d-2), \cdots,-1,0,1\}$. Then, the tensor product $\mathcal{M} \otimes Q^{\prime}$ has $U(1)_{\mathcal{L}}$ charges belonging to $\widehat{\mathcal{W}}_{-, b}^{\mathcal{L}}$. The same is true for the B-brane $\underline{-}^{21} \mathcal{O}_{\mathbb{P}^{n}[d]} \otimes Q^{\prime}$. We conclude that the

[^18]functor is given by
$$
\mathcal{F}(\mathcal{M})=\mathcal{M} \otimes Q^{\prime}
$$

For every fixed point on the base, the superpotential along the fiber is given by (5.13) with fixed $y_{i}$. The reference brane $\mathcal{B}_{0}^{(0)}$ can be written as

$$
Q_{0}=\sum_{i=0}^{n}\left(x_{i} \bar{\eta}_{i}\right)+p \bar{\eta}_{n+1}+\sum_{i=0}^{n}\left(\frac{1}{d} \frac{\partial F_{d}}{\partial x_{i}}+\frac{1}{2} p y_{i}\right) \eta_{i}+\frac{1}{2}\left(\sum_{i=0}^{n} x_{i} y_{i}\right) \eta_{n+1}
$$

where the trivial represenation of $\mathbb{Z}_{d}$ is chosen for the Clifford vacuum. Because the superpotential (5.13) has a quadratic term $p \sum_{i=0}^{n} x_{i} y_{i}$ and a degree- $d$ term $F_{d}(x)$, the structure of the $\mathcal{A}_{0}$ factor in the sheaf of $A_{\infty}$-algebras $\mathcal{A}_{0} \sharp \mathbb{Z}_{d}$ is determined by the relations ${ }^{22}$

$$
\begin{align*}
& m_{2}\left(\psi_{i}, \psi_{j}\right)+m_{2}\left(\psi_{j}, \psi_{i}\right)=\left.\frac{\partial^{2} W}{\partial x_{i} \partial x_{j}}\right|_{x_{i}=0}  \tag{5.15}\\
& m_{d}\left(\psi_{i_{1}}, \psi_{i_{2}}, \cdots, \psi_{i_{d}}\right)=\left.\frac{\partial^{d} W}{\partial x_{i_{1}} \cdots \partial x_{i_{d}}}\right|_{x_{i}=0} \tag{5.16}
\end{align*}
$$

at each point of the base, where we have identified $p$ with $x_{n+1}$.
As in the case of Veronese embedding, the global sheaf structure of $\mathcal{A}_{0} \sharp \mathbb{Z}_{d}$ can also be read off from the global behavior of $x_{i}$ and $p$, we present two examples for illustration.

## Example: Quadrics

In the case $d=2$, at each point of the base, the superpotential is quadratic in the fiber coordinates. Therefore, the sheaf of algebra is the Clifford algebra associated with the quadratic form given by $\frac{\partial^{2} W}{\partial x_{i} \partial x_{i}}, i=0, \ldots, n+1, x_{n+1}:=p$ at fixed $y_{i}$. We can take the reference brane $\mathcal{B}_{0}^{(0)}$ to be given by the matrix factorization

$$
Q_{0}=\sum_{i=0}^{n}\left(x_{i} \bar{\eta}_{i}\right)+p \bar{\eta}_{n+1}+\sum_{i=0}^{n}\left(\frac{1}{2} \frac{\partial F_{2}}{\partial x_{i}}+\frac{1}{2} p y_{i}\right) \eta_{i}+\frac{1}{2}\left(\sum_{i=0}^{n} y_{i} x_{i}\right) \eta_{n+1}
$$

hence, the curved complex associated to $\mathcal{B}_{0}^{(0)}$ is given by
where all the sheaves $\mathcal{O}_{(-)^{i}}(a)$ in (5.17) denote sheaves over $\mathbb{P}^{n}$ and the subindex $\pm$ indicates the $\mathbb{Z}_{2}$-weight of the sheaf. A similar computation as the one in section 5.1 let us conclude that

$$
\begin{equation*}
\mathcal{A}_{0} \cong\left(\bigoplus_{i=0}^{n+1} \mathcal{O}_{(-)^{i}} \otimes \wedge^{i} V\right) \oplus\left(\bigoplus_{i=0}^{n+1} \mathcal{O}_{(-)^{i+1}}(-1) \otimes \wedge^{i} V\right) \tag{5.18}
\end{equation*}
$$

globally. So, we can write

$$
\begin{equation*}
D(Y, W) \cong D\left(\mathbb{P}^{n}, \mathcal{A}_{0} \sharp \mathbb{Z}_{2}\right) \tag{5.19}
\end{equation*}
$$

i.e., the hybrid model B-brane category $D(Y, W)$ is equivalent to the derived category of sheaves of $A_{\infty} \mathcal{A}_{0} \sharp \mathbb{Z}_{2}$-modules.

[^19]
## Example: Cubic hypersurfaces

The $\mathcal{B}_{0}^{(0)}$-brane is given by

$$
Q_{0}=\sum_{i=0}^{n}\left(x_{i} \bar{\eta}_{i}\right)+p \bar{\eta}_{n+1}+\sum_{i=0}^{n}\left(\frac{1}{3} \frac{\partial F_{3}}{\partial x_{i}}+\frac{1}{2} p y_{i}\right) \eta_{i}+\frac{1}{2}\left(\sum_{i=0}^{n} x_{i} y_{i}\right) \eta_{n+1}
$$

and its associated curved complex is

$$
\mathcal{O}_{0} \rightleftarrows \begin{gather*}
\mathcal{O}_{1} \otimes V  \tag{5.20}\\
\rightleftarrows \\
\mathcal{O}_{-1}(-1)
\end{gather*} \rightleftarrows \cdots \rightleftarrows \mathcal{O}_{n} \otimes \wedge^{n+1} V
$$

where the subscripts of the line bundles are the $\mathbb{Z}_{3}$-weights. At each point of the base, the $A_{\infty}$-algebra is given by

$$
\begin{gathered}
m_{2}\left(\psi_{i}, \psi_{n+1}\right)+m_{2}\left(\psi_{n+1}, \psi_{i}\right)=y_{i} \\
m_{3}\left(\psi_{i}, \psi_{j}, \psi_{k}\right)=\frac{\partial^{3} F_{3}}{\partial x_{i} \partial x_{j} \partial x_{k}}
\end{gathered}
$$

Globally, the sheaf of $A_{\infty}$-algebra $\mathcal{A}_{D 0}$ is

$$
\mathcal{A}_{D 0}=\left(\bigoplus_{i=0}^{n+1} \mathcal{O}_{i} \otimes \wedge^{i} V\right) \oplus\left(\bigoplus_{i=-1}^{n-1} \mathcal{O}_{i}(-1) \otimes \wedge^{i+1} V\right) \oplus\left(\mathcal{O}_{n} \otimes \wedge^{n+1} V\right)
$$

Therefore, the HPD of $\mathbb{P}^{n}[3]$ is the noncommutative space $\left(\mathscr{P}^{n}, \mathcal{A}_{0} \sharp \mathbb{Z}_{3}\right)$.

### 5.3 HPD of complete intersections

The method can also be applied to the HPD of Fano complete intersections of the form $\mathbb{P}^{n}\left[d_{1}, d_{2}, \cdots, d_{k}\right], \sum_{\alpha=1}^{k} d_{\alpha}<n+1$. From the GLSM construction, it is straightforward to see that the HPD can be described by the hybrid model on the space

$$
\begin{equation*}
Y=\operatorname{Tot}\left(\mathcal{O}(-1,0)^{\oplus(n+1)} \oplus \mathcal{O}(1,-1) \rightarrow \mathrm{WP}\left(d_{1}, \cdots, d_{k}\right) \times \check{\mathbb{P}}^{n}\right) \tag{5.21}
\end{equation*}
$$

with superpotential

$$
\begin{equation*}
W=\sum_{\alpha=1}^{k} p_{\alpha} F_{d_{\alpha}}(x)+p \sum_{i=0}^{n} x_{i} y_{i} \tag{5.22}
\end{equation*}
$$

where $p_{\alpha}$ are homogeneous coordinates of the weighted projective space $\mathrm{WP}\left(d_{1}, \cdots, d_{k}\right), y_{i}$ are homogeneous coordinates of $\check{\mathbb{P}}^{n}, x_{i}$ and $p$ are coordinates along the fibers of $\mathcal{O}(-1,0)^{\oplus(n+1)}$ and $\mathcal{O}(1,-1)$ respectively.

As in the case of hypersurfaces, $\mathcal{A}_{0}$ is spanned by $\psi_{0}, \ldots, \psi_{n+1}$ and the $A_{\infty}$-products of $\mathcal{A}_{0}$ are determined by

$$
\begin{aligned}
& m_{2}\left(\psi_{i}, \psi_{j}\right)+m_{2}\left(\psi_{j}, \psi_{i}\right)=\left.\frac{\partial^{2} W}{\partial x_{i} \partial x_{j}}\right|_{x_{i}=0} \\
& m_{d_{\alpha}}\left(\psi_{i_{1}}, \psi_{i_{2}}, \cdots, \psi_{i_{d}}\right)=\left.\frac{\partial^{d} W}{\partial x_{i_{1}} \cdots \partial x_{i_{d}}}\right|_{x_{i}=0}
\end{aligned}
$$

at each point of the base $\mathrm{WP}\left[d_{1}, \cdots, d_{k}\right] \times \check{\mathbb{P}}^{n}$, where we have identified $x_{n+1}:=p$. However, $\mathcal{A}_{0}$ is not the sheaf of algebra corresponding to the hybrid model under consideration, because we cannot ignore the orbifold singularity coming from the affine patches of $\mathrm{WP}\left[d_{1}, \cdots, d_{k}\right]$ and, for generic $d_{\alpha}$, we cannot write the space $Y$ as a global orbifold. Exceptions are, for instance if $d_{\alpha}=d$ for all $\alpha$, then we have a noncommutative resolution of $\mathbb{P}^{k-1} \times \mathbb{P}^{n}$. Otherwise we have to deal with a sheaf of algebras over a singular space. Therefore we must resort to the general framework outlined in section 4.5. Here we just illustrate the idea by a case study, which can be easily genearalized.

Example: $\mathbb{P}^{n}[2,3]$
We study the HPD of the complete intersection of a quadric hypersurface and a cubic hypersurface in $\mathbb{P}^{n}$, denoted by $X$. The GLSM for this complete intersection is a $U(1)$ gauge theory with the following matter content and gauge charges:

$$
\begin{array}{cccccc}
X_{0} & X_{1} & \cdots & X_{n} & P_{1} & P_{2} \\
1 & 1 & \cdots & 1 & -2 & -3
\end{array}
$$

and the superpotential is

$$
\begin{equation*}
W_{0}=P_{1} G_{2}(X)+P_{2} G_{3}(X), \tag{5.23}
\end{equation*}
$$

where $G_{2}$ and $G_{3}$ are quadric and cubic polynomials in $X_{i}$ respectively. We assume $n \geq 4$. Suppose that $\zeta$ is the FI parameter of this model. Then the geometric phase $(\zeta \gg 1)$ is a nonlinear sigma model with target space the complete intersection defined by $G_{2}=G_{3}=0$ in $\mathbb{P}^{n}$.

For $\zeta \ll-1$ and generic $G_{2}, G_{3}$, the Higgs branch of the GLSM above is a hybrid model on

$$
\begin{equation*}
Y_{0} \equiv \operatorname{Tot}\left(\mathcal{O}(-1)^{\oplus(n+1)} \rightarrow \mathrm{WP}(2,3)\right) \tag{5.24}
\end{equation*}
$$

with the superpotential given by (5.23), where $P_{1}, P_{2}$ are homogeneous coordinates on the weighted projective space $\mathrm{WP}(2,3)$ and $X_{i}$ 's are the fiber coordinates. This hybrid model can be viewed as two LG orbifold theories, each defined on a coordinate patch of $\mathrm{WP}(2,3)$, glued together in a consistent way. Let's denote by $U_{i}$ the coordinate patch where $P_{i} \neq 0$. Then we have

$$
U_{1} \cong \mathbb{C} / \mathbb{Z}_{2}, \quad U_{2} \cong \mathbb{C} / \mathbb{Z}_{3} .
$$

Assume that $Z_{1}$ and $Z_{2}$ are local coordinates of $U_{1}$ and $U_{2}$ respectively. It is easy to see that when $P_{1} \neq 0$, the hybrid model reduces to a LG model with $\mathbb{Z}_{2}$ orbifold on $\mathbb{C}^{\oplus(n+2)}$, with the $\mathbb{Z}_{2}$-action:

$$
e^{\pi i} \cdot\left(Z_{1}, X_{i}\right)=\left(e^{3 \pi i} Z_{1}, e^{-\pi i} X_{i}\right)=\left(-Z_{1},-X_{i}\right)
$$

and superpotential

$$
W_{01}=G_{2}(X)+Z_{1} G_{3}(X) .
$$

Similarly, when $P_{2} \neq 0$, the hybrid model reduces to a LG model with $\mathbb{Z}_{3}$ orbifold on $\mathbb{C}^{\oplus(n+2)}$, with the $\mathbb{Z}_{3}$-action:

$$
e^{\frac{2 \pi i}{3}} \cdot\left(Z_{2}, X_{i}\right)=\left(e^{\frac{4 \pi i}{3}} Z_{2}, e^{-\frac{2 \pi i}{3}} X_{i}\right)=\left(e^{-\frac{2 \pi i}{3}} Z_{2}, e^{-\frac{2 \pi i}{3}} X_{i}\right)
$$

and superpotential

$$
W_{02}=Z_{2} G_{2}(X)+G_{3}(X) .
$$

Matrix factorizations of the hybrid model are of the form $(\mathcal{E}, Q)$, where $\mathcal{E}$ is a coherent sheave with $\mathbb{Z}_{2}$-grading on $Y_{0}$ defined in (5.24), and $Q$ is an odd endomorphism of $\mathcal{E}$ that squres to $W_{0} \cdot \mathrm{id}$. When restricted to a coordinate patch, the orbifold action on $\mathcal{E}$ can be read off from the sheaf structure. For example, sections of $\mathcal{O}(a)$ transform as $\exp (\pi i) \cdot \lambda=\exp (a \pi i) \lambda$ under $\mathbb{Z}_{2}$ in $U_{1}$ while they transform as $\exp (2 \pi i / 3) \cdot \lambda=\exp (a 2 \pi i / 3) \lambda$ under $\mathbb{Z}_{3}$ in $U_{2}$. Also, $Q\left(X, P_{1}, P_{2}\right)$ is replaced by $Q\left(X, 1, Z_{1}\right)$ in $U_{1}$ and is replaced by $Q\left(X, Z_{2}, 1\right)$ in $U_{2}$.

There is a semiorthogonal decomposition of the derived category of coherent sheaves of the complete intersection $X$ :

$$
D(X)=\left\langle M F\left(Y_{0}, W_{0}\right), \mathcal{O}_{X}, \mathcal{O}_{X}(1), \cdots, \mathcal{O}_{X}(n-4)\right\rangle
$$

therefore the Lefschetz decomposition associated with the embedding $X \hookrightarrow \mathbb{P}^{n}$ is ${ }^{23}$

$$
\begin{equation*}
D(X)=\left\langle\mathcal{A}_{0}, \mathcal{A}(1), \cdots, \mathcal{A}(n-5)\right\rangle \tag{5.25}
\end{equation*}
$$

where $\mathcal{A}_{0}=\left\langle M F\left(Y_{0}, W_{0}\right), \mathcal{O}_{X}\right\rangle$ if $n \geq 5, \mathcal{A}_{0}=M F\left(Y_{0}, W_{0}\right)$ if $n=4$, and $\mathcal{A}_{i}=\left\langle\mathcal{O}_{X}\right\rangle$ for $i>0$.

From our general construction, the GLSM for the universal hyperplane section $\mathcal{X}$ of the embedding $X \hookrightarrow \mathbb{P}^{n}$ is a $U(1) \times U(1)$ GLSM with the following matter content and gauge charges:

$$
\begin{array}{ccccccccccc} 
& X_{0} & X_{1} & \cdots & X_{n} & P_{1} & P_{2} & P & Y_{0} & \cdots & Y_{n} \\
U(1)_{1} & 1 & 1 & \cdots & 1 & -2 & -3 & -1 & 0 & \cdots & 0 \\
U(1)_{2} & 0 & 0 & \cdots & 0 & 0 & 0 & -1 & 1 & \cdots & 1
\end{array}
$$

together with the superpotential

$$
\begin{equation*}
W=P_{1} G_{2}(X)+P_{2} G_{3}(X)+P \sum_{i=0}^{n} X_{i} Y_{i} \tag{5.26}
\end{equation*}
$$

The geometric phase $\left(\zeta_{1} \gg 1, \zeta_{2} \gg 1\right)$ realizes the universal hyperplane section $\mathcal{X}$. The semiorthogonal decomposition of $D(\mathcal{X})$ corresponding to (5.25) is

$$
D(\mathcal{X})=\left\langle\mathcal{C}, \mathcal{A}_{1}(1) \boxtimes D\left(\check{\mathbb{P}}^{n}\right), \cdots \mathcal{A}_{n-5}(n-5) \boxtimes D\left(\check{\mathbb{P}}^{n}\right)\right\rangle,
$$

where $\mathcal{C}$ is the HPD category.
From the general argument, $\mathcal{C}$ consists of the B-branes of the Higgs branch on the phase with $\zeta_{1} \ll-1, \zeta_{2} \gg 1$. This Higgs branch is described by a hybrid model on

$$
Y \equiv \operatorname{Tot}\left(\mathcal{O}(-1,0)^{\oplus(n+1)} \oplus \mathcal{O}(1,-1) \rightarrow \mathrm{WP}(2,3) \times \check{\mathbb{P}}^{n}\right)
$$

with superpotential (5.26), where $P_{1}, P_{2}$ are homogeneous coordinates of the weighted projective space $\mathrm{W} \mathbb{P}(2,3), Y_{i}$ are homogeneous coordinates of $\check{\mathbb{P}}^{n}, X_{i}$ and $P$ are coordinates along the fibers of $\mathcal{O}(-1,0)^{\oplus(n+1)}$ and $\mathcal{O}(1,-1)$ respectively. Again, we can think of this hybrid model as a family of LG orbifolds defined on coordinate patches of $\mathrm{WP}(2,3) \times \check{\mathbb{P}}^{n}$ glued together consistently. The reference brane $\mathcal{B}_{0}$ has the tachyon profile

$$
Q_{0}=\sum_{i=0}^{n} X_{i} \bar{\eta}_{i}+P \bar{\eta}_{n+1}+\sum_{i=0}^{n}\left(\frac{1}{2} P_{1} \frac{\partial G_{2}}{\partial X_{i}}+\frac{1}{3} P_{2} \frac{\partial G_{3}}{\partial X_{i}}\right) \eta_{i}+\left(\sum_{i=0}^{n} X_{i} Y_{i}\right) \eta_{n+1}
$$

[^20]where the vacuum state of the Clifford algebra is identified with $\mathcal{O}$ on $\operatorname{WP}(2,3) \times \check{\mathbb{P}}^{n}$. Notice that $X_{i}$ 's are sections of $\mathcal{O}(-1,0)$ and $P$ is a section of $\mathcal{O}(1,-1)$, we see that the sheaf of algebras $\mathcal{A}=\operatorname{End}_{M F(Y, W)}\left(\mathcal{B}_{0}\right)$ can be written globally as
$$
\mathcal{A}=\bigoplus_{m=0}^{n+1}(\mathcal{O}(-m, 0) \oplus \mathcal{O}(1-m,-1)) \otimes \wedge^{m} V
$$
where $V=\mathbb{C}^{n+1}$. The $A_{\infty}$ structure of $\mathcal{A}$ can be analyzed in the same way as the example shown in section 4.5 .

## 6 The functor $D(B, \operatorname{Mod}-\mathcal{A}) \rightarrow D(\mathcal{X})$

In this section we give a description of the functor from the category $D(B, \operatorname{Mod}-\mathcal{A}):=$ $D(Y, W)$ used to describe the B-brane category of the hybrid models on $Y=\operatorname{Tot}(\mathcal{V} \rightarrow B)$ that arises as HPD of Fano embeddings. Given a projective embedding, the HPD category $\mathcal{C}$ is a subcategory of $D(\mathcal{X})$ by definition, where $\mathcal{X}$ is the universal hyperplane section. Therefore there exists a fully faithful functor from the proposed HPD category $D(B, \operatorname{Mod}-\mathcal{A})$ to $D(\mathcal{X})$, realizing the equivalence $D(B, \operatorname{Mod}-\mathcal{A}) \cong \mathcal{C}$, where $D(B, \operatorname{Mod}-\mathcal{A})$ is the derived category of $A_{\infty} \mathcal{A}$-modules. The GLSM construction gives a simple description of this functor.

First, we have a functor $\mathcal{F}: D(B, \operatorname{Mod}-\mathcal{A}) \rightarrow M F(\operatorname{Tot}(\mathcal{V} \rightarrow B), W)$. This functor can be defined by generalizing the functor from $D\left(\operatorname{Mod}-\mathcal{A}_{D 0}\right)$ to the category of matrix factorizations of LG models described in section 4.2 (cf. eq. (4.38)). Suppose we have an object $\mathcal{N}$ in $D(B, \operatorname{Mod}-\mathcal{A})$, i.e. $\mathcal{N}$ is a sheaf of $A_{\infty}$ module of $\mathcal{A}$ with $\mathcal{A}_{\infty}$ actions given by $m_{i}^{\mathcal{N}}, i \geq 1$. The matrix factorization $\mathcal{F}(\mathcal{N})$ can be defined as follows. The Chan-Paton sheaf of $\mathcal{F}(\mathcal{N})$ is

$$
\mathcal{M}=\mathcal{N} \otimes \operatorname{Sym}^{\vee}
$$

Let $x_{i}, i=1, \cdots, \operatorname{rank}(\mathcal{V})$ be a set of linearly independent sectionśㅗㄴ is a section of $\operatorname{Sym}^{\vee}$ for any set of indices $i_{1}, \cdots, i_{k}$. Consequently, the Tachyon profile $Q_{\mathcal{M}}$ of $\mathcal{F}(\mathcal{N})$ can be defined by

$$
Q_{\mathcal{M}}(\phi)=\sum_{k} \sum_{i_{1}, \cdots, i_{k}} m_{k+1}^{\mathcal{N}}\left(\phi, \psi_{i_{1}}, \cdots, \psi_{i_{k}}\right) x_{i_{1}} x_{i_{2}} \cdots x_{i_{k}},
$$

where $\phi$ is a section of $\mathcal{N}$. This functor is an equivalence with the inverse functor given by $\mathcal{B} \rightarrow \operatorname{Hom}_{M F(\operatorname{Tot}(\mathcal{V} \rightarrow B), W)}\left(\mathcal{B}_{0}, \mathcal{B}\right)$, where $\mathcal{B}_{0}$ is the reference brane that is point-like along each fiber of $\mathcal{V}$. In particular, $\mathcal{A}=\operatorname{End}_{M F(\operatorname{Tot}(\mathcal{V} \rightarrow B), W)}\left(\mathcal{B}_{0}\right)$.

Now we can use the GLSM $\mathcal{T}_{\mathcal{X}}$ defined in eq.(2.15) to construct a fully faithful functor $\mathcal{G}$ :

$$
\mathcal{G}: M F(\operatorname{Tot}(\mathcal{V} \rightarrow B), W) \rightarrow D(\mathcal{X})
$$

Recall that the hybrid model on $\operatorname{Tot}(\mathcal{V} \rightarrow B)$ with superpotential $W$ is the Higgs branch of the GLSM $\mathcal{T}_{\mathcal{X}}$ in the phase with $\zeta_{\mathcal{L}} \ll-1, \zeta^{\prime} \gg 1$ (LG phase), while the Higgs branch of the phase with $\zeta_{\mathcal{L}} \gg 1, \zeta^{\prime} \gg 1$ (geometric phase) is the nonlinear sigma model with target space $\mathcal{X}$. Consequently, the functor $\mathcal{G}$ can be implemented by the brane transport across the

[^21]classical phase boundary at $\zeta_{\mathcal{L}}=0, \zeta^{\prime} \gg 1$. More precisely, for each matrix factorization in the category $M F(\operatorname{Tot}(\mathcal{V} \rightarrow B), W)$, we first lift it to a matrix factorization of the GLSM $\mathcal{T}_{\mathcal{X}}$. Then, after possibly combining this matrix factorization with several branes that are empty in the LG phase, we can transport it to the geometric phase and project it to an object in $D(\mathcal{X})$. Here the grade restriction rule states that the combined brane must be in the small window category of the local model associated with the phase boundary. Thus we see the brane transport realizes the functor $\mathcal{G}$. There are examples in [8] demonstrating how this procedure works.

In conclusion, the fully faithful functor from $D(B, \operatorname{Mod}-\mathcal{A})$ to $D(\mathcal{X})$ is given by $\mathcal{G} \circ \mathcal{F}$, which is an equivalence between $D(B, \operatorname{Mod}-\mathcal{A})$ and the HPD category $\mathcal{C}$.

MR acknowledges support from the National Key Research and Development Program of China, grant No. 2020YFA0713000, and the Research Fund for International Young Scientists, NSFC grant No. 11950410500 .

## A Checkings on the $\left(\operatorname{Mod}-\mathcal{A}_{D 0}\right) \rightarrow M F(W)$ functor

Here we provide several checks for the proposed functor (4.38).
Check 1. $d=2$ Case. When $d=2$, we have $\mathcal{A}_{D 0}=C l(n, \mathbb{C})$, the Clifford algebra defined by the quadratic form $\frac{\partial^{2} W}{\partial x_{i} \partial x_{j}}$. The correspondence between the matrix factorization for quadratic superpotentials and Clifford modules is given in $[9,59]$, which matches (4.38).

Check 2. $\mathbf{N}=\mathcal{A}_{D 0}$. It is straightforward to check (4.38) for the case the module is $\mathcal{A}_{D 0}$ itself. Then (4.38) corresponds to $Q_{D 0}$. In fact, as shown in [12], the fermionic generators $\psi_{i}, i=1, \cdots, n$, satisfy

- If $d=2, \mathcal{A}_{D 0}$ is the Clifford algebra:

$$
\begin{equation*}
m_{2}\left(\psi_{i}, \psi_{j}\right)+m_{2}\left(\psi_{j}, \psi_{i}\right)=\frac{\partial^{2} W}{\partial x_{i} \partial x_{j}} \tag{A.1}
\end{equation*}
$$

- If $d>2, \mathcal{A}_{D 0}$ is an $A_{\infty}$-algebra, where $m_{2}$ satisfies

$$
\begin{equation*}
m_{2}\left(\psi_{i}, \psi_{j}\right)+m_{2}\left(\psi_{j}, \psi_{i}\right)=0, \tag{A.2}
\end{equation*}
$$

$m_{k}=0$ for $k=1, \cdots, d-1$ and

$$
\begin{equation*}
m_{d}\left(\psi_{i_{1}}, \psi_{i_{2}}, \cdots, \psi_{i_{d}}\right)=\frac{1}{d!} \frac{\partial^{d} W}{\partial x_{i_{1}} \cdots \partial x_{i_{d}}} \tag{A.3}
\end{equation*}
$$

Thus when $d>2$, if we identify $m_{2}\left(\cdot, v_{i}\right)$ with $\left\{\bar{\eta}_{i}, \cdot\right\}$ according to (A.2), then (A.3) tells us that $m_{d}\left(\cdot, \psi_{i_{1}}, \psi_{i_{2}}, \cdots, \psi_{i_{d-1}}\right)$ should be identified with

$$
\frac{1}{d!} \sum_{i=1}^{n} \frac{\partial^{d} W}{\partial x_{i} \partial x_{i_{1}} \cdots \partial x_{i_{d-1}}}\left\{\eta_{i}, \cdot\right\} .
$$

Because $W$ is homogeneous with degree $d$, we see that $Q_{M}$ defined by (4.38) is exactly $Q_{D 0}$ defined by (4.34) in this case.

Check 3. $Q_{M}^{2}=W \cdot$ id.. Here we will show that the object $Q_{M}^{2}$ is indeed a matrix factorization of $W$. We will make the assumption that $m_{s}^{\mathbf{N}}=0$ for $s>d$ (which can be shown below to be true for the case $n=1$ ), it can be shown that $Q_{M}^{2}=W \cdot$ id. For example, when $d=3$

$$
Q_{M}(\phi)=\sum_{i j} m_{3}^{\mathbf{N}}\left(\phi, \psi_{i}, \psi_{j}\right) x_{i} x_{j}+\sum_{i} m_{2}^{\mathbf{N}}\left(\phi, \psi_{i}\right) x_{i} .
$$

Therefore

$$
\begin{align*}
Q_{M}^{2}(\phi) & =\sum_{i j k l} m_{3}^{\mathbf{N}}\left(m_{3}^{\mathbf{N}}\left(\phi, \psi_{i}, \psi_{j}\right), \psi_{k}, \psi_{l}\right) x_{i} x_{j} x_{k} x_{l}+\sum_{i j k} m_{3}^{\mathbf{N}}\left(m_{2}^{\mathbf{N}}\left(\phi, \psi_{i}\right), \psi_{j}, \psi_{k}\right) x_{i} x_{j} x_{k} \\
& -\sum_{i j k} m_{2}^{\mathbf{N}}\left(m_{3}^{\mathbf{N}}\left(\phi, \psi_{i}, \psi_{j}\right), \psi_{k}\right) x_{i} x_{j} x_{k}+\sum_{i j} m_{2}^{\mathbf{N}}\left(m_{2}^{\mathbf{N}}\left(\phi, \psi_{i}\right), \psi_{j}\right) x_{i} x_{j} . \tag{A.4}
\end{align*}
$$

From (3.3), we get

$$
m_{2}^{\mathbf{N}}\left(m_{2}^{\mathbf{N}}\left(\phi, \psi_{i}\right), \psi_{j}\right)=m_{2}^{\mathbf{N}}\left(\phi, m_{2}\left(\psi_{i}, \psi_{j}\right)\right),
$$

then the last term of (A.4) vanishes due to (A.2). The first term of (A.4) also vanishes because of (3.3), (A.3) and $m_{k}(\cdots, 1, \cdots)=0$ for $k>2$. Also from (3.3) and (A.3), the second and third terms of (A.4) yield

$$
\begin{aligned}
& \sum_{i j k}\left(m _ { 3 } ^ { \mathbf { N } } \left(\left(m_{2}^{\mathbf{N}}\left(\left(\phi, \psi_{i}\right), \psi_{j}, \psi_{k}\right)-m_{2}^{\mathbf{N}}\left(\left(m^{\mathbf{N}}\left(3\left(\phi, \psi_{i}, \psi_{j}\right), v_{k}\right)\right) x_{i} x_{j} x_{k}\right.\right.\right.\right. \\
& =\sum_{i j k} m_{2}^{\mathbf{N}}\left(\left(\phi, m_{3}\left(\psi_{i}, \psi_{j}, \psi_{k}\right)\right) x_{i} x_{j} x_{k}=\frac{1}{3!} \phi \sum_{i j k} \frac{\partial^{3} W}{\partial x_{i} \partial x_{j} \partial x_{k}} x_{i} x_{j} x_{k}=W \cdot \phi,\right.
\end{aligned}
$$

which shows $Q_{M}^{2}=W \cdot$ id.
Check 4. $n=1$ case. Finally, we show that the functor reproduces the matrix factorizations for the case $n=1$, i.e. $W=x^{d}$. In this case, the $D 0$-brane is given by the matrix factorization

$$
\begin{equation*}
Q_{D 0}=x \bar{\eta}+x^{d-1} \eta . \tag{A.5}
\end{equation*}
$$

The fermionic generator of $\mathcal{A}_{D 0}=\operatorname{Hom}\left(\mathcal{B}_{D 0}, \mathcal{B}_{D 0}\right)$ is $\psi=\bar{\eta}-x^{d-2} \eta$. Let $\mathcal{B}_{l}$ be the matrix factorization with

$$
\begin{equation*}
Q_{M}=x^{l} \bar{\pi}+x^{d-l} \pi \tag{A.6}
\end{equation*}
$$

where $1<l<d$ and $\{\pi, \pi\}=\{\bar{\pi}, \bar{\pi}\}=0$. Next, we will show that (4.38) recovers $Q_{M}$. Start by considering the bosonic state $\phi_{0} \in \operatorname{Hom}_{0}\left(\mathcal{B}_{D 0}, \mathcal{B}_{l}\right)$ and the fermionic state $\phi_{1} \in$ $\operatorname{Hom}_{1}\left(\mathcal{B}_{D 0}, \mathcal{B}_{l}\right)$. If the vacuum state of $M$ is denoted as $|\Omega\rangle$, then

$$
\phi_{0}|0\rangle=|\Omega\rangle, \quad \phi_{0} \bar{\eta}|0\rangle=x^{l-1} \bar{\pi}|\Omega\rangle,
$$

and

$$
\phi_{1}|0\rangle=\bar{\eta}|\Omega\rangle, \quad \phi_{1} \bar{\eta}|0\rangle=-x^{d-l-1}|\Omega\rangle .
$$

In matrix form,

$$
\psi=\left(\begin{array}{cc}
0 & -x^{d-2} \\
1 & 0
\end{array}\right), \quad \phi_{0}=\left(\begin{array}{cc}
1 & 0 \\
0 & x^{l-1}
\end{array}\right), \quad \phi_{1}=\left(\begin{array}{cc}
0 & -x^{d-l-1} \\
1 & 0
\end{array}\right) .
$$

Using the algorithm reviewed in section $\underline{3}$, one can compute $(\iota \psi=v)^{25}$

$$
m_{k}\left(\psi^{\otimes k}\right)=0, \quad f_{k}\left(\psi^{\otimes k}\right)=(-1)^{k} x^{d-k-1} \eta, \quad 1<k<d
$$

and

$$
m_{d}\left(\psi^{\otimes d}\right)=1, \quad f_{d}\left(\psi^{\otimes d}\right)=0 .
$$

By composing the homomorphisms, one gets

$$
\phi_{0} \circ \psi=x^{l-1} \phi_{1}, \quad \phi_{1} \circ \psi=-x^{d-l-1} \phi_{0} .
$$

Therefore,

$$
\phi_{0} \circ \psi=\mathrm{d} \tilde{\phi}_{0}^{(1)}=\tilde{\phi}_{0}^{(1)} Q_{D 0}-Q_{M} \tilde{\phi}_{0}^{(1)}, \quad \phi_{1} \circ \psi=-\mathrm{d} \tilde{\phi}_{1}^{(d-l-1)}=-\tilde{\phi}_{1}^{(d-l-1)} Q_{D 0}-Q_{M} \tilde{\phi}_{1}^{(d-l-1)},
$$

where

$$
\tilde{\phi}_{0}^{(1)}=\left(\begin{array}{cc}
0 & 0 \\
0 & x^{l-2}
\end{array}\right), \quad \tilde{\phi}_{1}^{(d-l-1)}=\left(\begin{array}{cc}
0 & x^{d-l-2} \\
0 & 0
\end{array}\right)
$$

from which one can deduce that $\underline{\sim}^{26}$

$$
m_{2}^{\mathbf{N}}\left(\phi_{0}, v\right)=0, \quad f_{2}^{\mathbf{N}}\left(\phi_{0}, v\right)=-\tilde{\phi}_{0}^{(1)}
$$

and

$$
m_{2}^{\mathbf{N}}\left(\phi_{1}, \psi\right)=0, \quad f_{2}^{\mathbf{N}}\left(\phi_{1}, \psi\right)=\tilde{\phi}_{1}^{(d-l-1)}
$$

It can be shown by induction that

$$
m_{k+1}^{\mathbf{N}}\left(\phi_{0}, \psi^{\otimes k}\right)=0, \quad f_{k+1}^{\mathbf{N}}\left(\phi_{0}, \psi^{\otimes k}\right)=-\tilde{\phi}_{0}^{(k)}, \quad 1<k<l,
$$

where

$$
\tilde{\phi}_{0}^{(k)}=\left(\begin{array}{cc}
0 & 0 \\
0 & x^{l-k-1}
\end{array}\right) .
$$

Similarly,

$$
m_{k+1}^{\mathbf{N}}\left(\phi_{1}, \psi^{\otimes k}\right)=0, \quad f_{k+1}^{\mathbf{N}}\left(\phi_{1}, \psi^{\otimes k}\right)=\tilde{\phi}_{1}^{(d-l-k)}, \quad 1<k<d-l,
$$

where

$$
\tilde{\phi}_{1}^{(k)}=\left(\begin{array}{cc}
0 & x^{k-1} \\
0 & 0
\end{array}\right) .
$$

Now, one can compute

$$
\iota m_{l+1}^{\mathbf{N}}\left(\phi_{0}, \psi^{\otimes l}\right)=-f_{l}^{\mathbf{N}}\left(\phi_{0}, \psi^{\otimes(l-1)}\right) \circ \psi-\phi_{0} \circ f_{l}\left(\psi^{\otimes l}\right)=\phi_{1},
$$

[^22]similarly $\iota m_{d-l+1}^{N}\left(\phi_{1}, \psi^{\otimes(d-l)}\right)=\phi_{0}$, and all the higher order multiplications vanish. Therefore, in the basis $\left\{\phi_{0}, \phi_{1}\right\}$, (4.38) yields
\[

Q_{M}=\left($$
\begin{array}{ll}
0 & 0 \\
1 & 0
\end{array}
$$\right) x^{l}+\left($$
\begin{array}{ll}
0 & 1 \\
0 & 0
\end{array}
$$\right) x^{d-l}=\left($$
\begin{array}{cc}
0 & x^{d-l} \\
x^{l} & 0
\end{array}
$$\right)
\]

which is exactly the matrix factorization (A.6) we started with.

## B $\quad A_{\infty}$-algebras defined by ribbon trees

The structure of the $A_{\infty}$-algebra $\mathcal{A}=\operatorname{End}\left(\mathcal{B}_{D 0}\right)$ corresponding to a Landau-Ginzburg model with homogeneous superpotential was derived in [12] using the method of summing over ribbon trees. In this appendix, we review the idea of [12] and generalize it to LG models with inhomogeneous superpotentials.

Let $\iota$ be an embedding of $H(\mathcal{A}):=H_{m_{1}^{\mathcal{A}}}(\mathcal{A})$ into $\mathcal{A}$. If we define the projection $\pi$ : $\mathcal{A} \rightarrow H(\mathcal{A})$ such that $\pi \circ \iota=1$ and there is a map $h: \mathcal{A} \rightarrow \mathcal{A}$ of degree -1 such that $1-\iota \circ=m_{1}^{\mathcal{A}} \circ h+h \circ m_{1}^{\mathcal{A}}$ and $h^{2}=\pi h=h \iota=0$, then the $A_{\infty}$ products $m_{k}: H(\mathcal{A})^{\otimes k} \rightarrow H(\mathcal{A})$, $k \geq 2$ can be defined by summing over the contributions from ribbon trees [65]:

$$
\begin{equation*}
m_{k}=\sum_{T} m_{k, T} . \tag{B.1}
\end{equation*}
$$

For a LG model with degree- $d$ superpotential, the ribbon trees contributing to the sum have one root and $d$ leaves such that the valency of any vertex is 2 or 3 [12]. (B.1) is a solution to the defining relations (3.3).

In our convention, $\iota\left(\psi_{i}\right)=v_{i}$ defined by (4.36), consequently $h$ can be defined to be $h=\sum_{i} \eta_{i} \frac{\partial}{\partial x_{i}}$ where $\eta_{i}$ acts by multiplication in the Clifford algebra.

By definition, a ribbon tree is a tree $T$ with a collection of vertices, external edges and internal edges such that: (a) Each external edge is incident to a single vertex. (b) Each internal edge is incident to exactly two vertices. (c) One of the external edge is the root, the other external edges are the leaves. Every ribbon tree $T$ with one root and $k$ leaves determines a term $m_{k, T}$ in (B.1).

Given a tree $T$, to compute $m_{k, T}\left(\psi_{i_{1}}, \psi_{i_{2}}, \cdots, \psi_{i_{k}}\right)$ we put $\psi_{i_{1}}, \psi_{i_{2}}, \cdots, \psi_{i_{k}}$ on the leaves from left to right and then act on them a series of maps as follows:

- Each leaf gives a map $\iota$;
- Each bivalent vertex gives a map $f$;
- Each internal edge gives a map $h$;
- Each trivalent vertex corresponds to the multiplication in $\mathcal{A}$;
- The root gives the map $\pi$
while reading from the top to the bottom. Here $f$ is defined by

$$
\left\{\sum_{i} \frac{\partial W}{\partial x_{i}} \eta_{i}, \cdot\right]-\sum_{i} \frac{\partial W}{\partial x_{i}} \eta_{i},
$$

Figure 3: (a) Ribbon tree contributing to $m_{2}$. (b) Another contribution to $m_{2}$ when $d=2$.
where \{] denotes commutator/anticommutator depending on whether the second argument is of even/odd degree and the second term is the usual multiplication of the Clifford algebra.

It is shown in [12] that there is always a tree given by Figure.3a making a nontrivial contribution to $m_{2}$. For $d>2$, this is the only contribution and it makes $m_{2}$ to satisfy $m_{2}\left(\psi_{i}, \psi_{j}\right)+m_{2}\left(\psi_{j}, \psi_{i}\right)=0$. When $d=2$, there is another nontrivial contribution from the tree given by Figure.3b. The effect of Figure.3b is to modify $m_{2}$ such that $m_{2}\left(\psi_{i}, \psi_{j}\right)+$ $m_{2}\left(\psi_{j}, \psi_{i}\right)=\frac{\partial^{2} W}{\partial x_{i} \partial x_{j}}$. In general, other than the tree in Figure.3a, the only ribbon tree that can make a nonzero contribution is the one in Figure.4. If the input of the tree is $\psi_{i_{1}}, \psi_{i_{2}}, \cdots, \psi_{i_{k}}$, then before hitting the root, the image of the set of maps encoded in the tree is $\frac{1}{k!} \frac{\partial^{k} W}{\partial x_{i_{1}} \partial x_{2} \cdots \partial x_{i_{k}}}$ plus some $Q$-exact terms. When $k \neq d$, this image is $Q$-exact and annihilated by the projection $\pi$, so the output of the tree is zero. When $k=d$, the output is $\frac{1}{k!} \frac{\partial^{k} W}{\partial x_{i_{1}} \partial x_{i_{2}} \cdots \partial x_{i_{k}}}$ because it is not $Q$-exact. In summary, we have

- If $d=2, \mathcal{A}$ is a Clifford algebra given by:

$$
m_{2}\left(\psi_{i}, \psi_{j}\right)+m_{2}\left(\psi_{j}, \psi_{i}\right)=\frac{\partial^{2} W}{\partial x_{i} \partial x_{j}}
$$

- If $d>2, m_{2}$ is the wedge product, $m_{k}=0$ for $k \neq 2$ and $k \neq d$.

$$
m_{d}\left(\psi_{i_{1}}, \psi_{i_{2}}, \cdots, \psi_{i_{d}}\right)=\frac{\partial^{d} W}{\partial x_{i_{1}} \cdots \partial x_{i_{d}}}
$$

Now assume we have a inhomogeneous superpotential of the form

$$
W=\sum_{l=2}^{d} W^{(l)}
$$

where deg $W^{(l)}=l$. Because now every nonvanishing derivative $\frac{\partial^{l} W^{(l)}}{\partial x_{i_{1}} \partial x_{i_{2}} \cdots \partial x_{i_{l}}}$ is not $Q$-exact, we can use the same argument to deduce that

$$
\begin{equation*}
m_{2}\left(\psi_{i}, \psi_{j}\right)+m_{2}\left(\psi_{j}, \psi_{i}\right)=\frac{\partial^{2} W^{(2)}}{\partial x_{i} \partial x_{j}} \tag{B.2}
\end{equation*}
$$

Figure 4: Ribbon tree contributing to $m_{k}$.
and

$$
\begin{equation*}
m_{l}\left(\psi_{i_{1}}, \psi_{i_{2}}, \cdots, \psi_{i_{l}}\right)=\frac{1}{l!} \frac{\partial^{l} W^{(l)}}{\partial x_{i_{1}} \partial x_{i_{2}} \cdots \partial x_{i_{l}}} \tag{B.3}
\end{equation*}
$$

for $3 \leq l \leq d$.

## C Orbibundle

Let $X$ be a smooth manifold admitting a $G$-action, where $G$ is a group. An orbibundle on the quotient stack $[X / G]$ is a fiber bundle $E \xrightarrow{\pi} X / G$ with each fiber an orbifold. Explicitly, let $V$ be a vector space admitting a representation of $G$ :

$$
\rho: \quad G \rightarrow G L(V) .
$$

The fibre of $E$ is $V / \rho(G)$. If $\left\{U_{\alpha}: \alpha \in I\right\}$ is an open cover of $X / G$ and

$$
\phi_{\alpha}: U_{\alpha} \times V / \rho(G) \rightarrow \pi^{-1}\left(U_{\alpha}\right)
$$

are the corresponding local trivializations. Then the transition functions $g_{\alpha \beta}=\phi_{\alpha}^{-1} \circ \phi_{\beta}$ take values in $G L(V) / \rho(G)$. A local section of $E$ is given by a $\rho(G)$-invariant function $s_{\alpha}: U_{\alpha} \rightarrow V$ so the relation

$$
s_{\alpha}=g_{\alpha \beta} \cdot s_{\beta}
$$

is well defined on $U_{\alpha} \cap U_{\beta}$. Given a representation of $G$ as above, the orbibundles on $[X / G]$ are classified by $H^{1}(X, G L(V) / \rho(G))$. When the representation is trivial, the orbibundle is just an ordinary vector bundle. When $\operatorname{dim}_{\mathbb{C}} V=1$, we call it a line bundle.

A morphism between two orbibundles $E_{1} \xrightarrow{\pi_{子}} X / G$ and $E_{2} \xrightarrow{\pi_{2}} X / G$ is a bundle map $f: E_{1} \rightarrow E_{2}$, i.e. $\pi_{2} \circ f=\pi_{1}$. Given local trivializations of $E_{1}$ and $E_{2}$ in an open set $U$ :

$$
\begin{aligned}
& \phi_{1}: U \times V_{1} / \rho_{1}(G) \rightarrow \pi_{1}^{-1}(U), \\
& \phi_{2}: U \times V_{2} / \rho_{2}(G) \rightarrow \pi_{2}^{-1}(U),
\end{aligned}
$$

and for each $x \in U, f_{U}(x):=\left.\phi_{2}^{-1} \circ f \circ \phi_{1}\right|_{x}$ is a linear map from $V_{1}$ to $V_{2}$ satisfying

$$
f_{U}(x) \circ \rho_{1}(g)=\rho_{2}(g) \circ f_{U}(x)
$$

for all $g \in G$.

## Conflict of interest statement

On behalf of all authors, the corresponding author states that there is no conflict of interest.

[^0]:    ${ }^{1}$ jrguo@tsinghua.edu.cn
    ${ }^{2}$ mromoj@tsinghua.edu.cn

[^1]:    ${ }^{1}$ The first appeareance of HPD in the context of dynamics of GLSMs can be found in [7].

[^2]:    ${ }^{2}$ We also consider the case of inhomogenous $W$. The $A_{\infty}$ multiplication rules are given in (B.2) and (B.3).

[^3]:    ${ }^{3}$ We do not need to assume the GLSM is nonanomalous.

[^4]:    ${ }^{4}$ It is always possible in the cases $X$ is Fano or Calabi-Yau (CY) to set this phase being located at $\zeta_{\mathcal{L}} \gg 1$. These are the cases we will cover in this work. The generalization is straightforward.
    ${ }^{5}$ The space $D\left(Y_{\zeta_{\mathcal{L}} \ll-1}, W_{\zeta_{\mathcal{L}} \ll-1}\right)$ denotes the category of B-branes of a hybrid Landau-Ginzburg (LG) model with target space $Y_{\zeta_{\mathcal{L}} \ll-1}$ and superpotential $W_{\zeta_{\mathcal{L}} \ll-1}:=\left.W\right|_{Y_{\zeta_{\mathcal{L}} \ll-1}}$. The details on how such category arises in the current context can be found in [8].

[^5]:    ${ }^{6}$ We recall the reader that $\mathcal{X}$ is defined as the fiber product $X \times_{\mathbb{P}(S)} \mathcal{H} \subset X \times \mathbb{P}\left(S^{\vee}\right)$ where $\mathcal{H}=\{(u, v) \in$ $\left.\mathbb{P}(S) \times \mathbb{P}\left(S^{\vee}\right) \mid v(u)=0\right\} \subset \mathbb{P}(S) \times \mathbb{P}\left(S^{\vee}\right)$ is the incidence divisor.

[^6]:    ${ }^{7}$ The grading of $A^{\otimes n}$ is given by $\left(A^{\otimes n}\right)^{p}=\bigoplus_{i_{1}+\ldots+i_{n}=p} A^{i_{1}} \otimes \cdots \otimes A^{i_{n}}$.

[^7]:    ${ }^{8}$ Here we used that the inverse of $h^{\otimes n}$ is $(-1)^{\frac{n(n-1)}{2}}\left(h^{-1}\right)^{\otimes n}$. We remak that there are different ways to define $b_{n}$ in terms of $m_{n}$, leading to different sign conventions.

[^8]:    ${ }^{9}$ We say an $A_{\infty}$-category has strict identities if, for every $A \in \operatorname{Ob}(\mathcal{A})$ there is a degree 0 element $1_{A} \in$ $\operatorname{Hom}_{\mathcal{A}}(A, A)$ satisfying the conditions (3.17), whenever a map $m_{n}$ can be consistently inserted as defined in (3.20).
    ${ }^{10}$ This is just the (twisted) correlator on the sphere. See for example the review [30].

[^9]:    ${ }^{11}$ In the particular case that $W$ is homogeneous of degree 2 , then $\mathcal{A}_{D 0}$ becomes simply the (complex) Clifford algebra $C l(q)$ associated with the quadratic form $q_{i j}:=\partial_{i} \partial_{j} W[9,48]$.

[^10]:    ${ }^{12}$ Equation (4.36) denotes a particular representative of the $Q_{D 0}$-class of $\psi_{i}$. All the computations where the explicit matrix form of $\psi_{i}$ is used do not depend on the choice of representative.

[^11]:    ${ }^{13} \mathrm{~A}$ representative for $\phi$ can be taken to be, for instance, $\bar{\eta}_{1} \bar{\eta}_{2}-\frac{1}{2} \bar{\eta}_{1} \eta_{1}-\frac{1}{2} \bar{\eta}_{2} \eta_{2}+\frac{1}{4} \eta_{1} \eta_{2}$.

[^12]:    ${ }^{14}$ [12] used a different approach, namely summing the ribbon trees. We review this idea in the appendix B.

[^13]:    ${ }^{15}$ Notice that $\Lambda_{1} m_{k}\left(\Lambda_{2}, \cdots, \Lambda_{k+1}\right)=(-1)^{\operatorname{deg}\left(\Lambda_{1}\right)\left(\operatorname{deg}\left(\Lambda_{2}\right)+\cdots+\operatorname{deg}\left(\Lambda_{k+1}\right)+k\right)} m_{k}\left(\Lambda_{2}, \cdots, \Lambda_{k+1}\right) \Lambda_{1}$.

[^14]:    ${ }^{16}$ Also one can apply an argument based on ribbon trees as reviewed in Appendix B.

[^15]:    ${ }^{17}$ These are sometimes called the orbit branes related to $\mathcal{B}_{D 0}[56,57]$.

[^16]:    ${ }^{18}$ For an introduction to algebraic stacks see for example [61] and for the specific case of smooth toric Deligne-Mumnford stacks, relevant for the examples in this work, see [62]. A relation between GLSMs and stacks can be found in [63].

[^17]:    ${ }^{19}$ The notation $\mathcal{O}(m)$ with $m \in \mathbb{Q}$ denotes an orbibundle over $\mathbb{P}^{\binom{n+d}{d}-1}$. See [8] or appendix $\underline{C}$ a short review or [64] for details.
    ${ }^{20}$ Note that the Hom's are taken over the orbifold category of the hybrid model defined by (5.2), (5.3).

[^18]:    ${ }^{21}$ Here we should think of $\mathcal{O}_{\mathbb{P}^{n}[d]}$ as its lift to a matrix factorization for the GLSM $\mathcal{T}_{X}$, with theta angle $\theta=\pi d-\varepsilon$ and $U(1)_{\mathcal{L}}$ charges $q \in\{-d, 0\}$. So, it does not belong to $\mathcal{W}_{-, b}^{\mathcal{L}}$, but it does belong to $\widehat{\mathcal{W}}_{-, b}^{\mathcal{L}}$ upon tensoring with $Q^{\prime}$.

[^19]:    ${ }^{22}$ At a generic point $y \in \mathbb{P}^{n}$ the superpotential $\left.W\right|_{y}$ satisfies $\left.d W\right|_{y} ^{-1}(0)=\{0\}$, hence the assumed condition on the potential of LG orbifold is fulfilled.

[^20]:    ${ }^{23}$ Note that $n \geq 5$ in the Fano case. In the Calabi-Yau case, $n=4$, and $D(X) \cong M F\left(Y_{0}, W_{0}\right)$.

[^21]:    ${ }^{24}$ If $B=\cup_{i} U_{i}$ is an open cover, one can choose a basis $\left\{e_{1}^{(i)}, \cdots, e_{\operatorname{rank} \mathcal{V}}^{(i)}\right\}$ of $\left.\mathcal{V}\right|_{U_{i}}$ for every open patch $U_{i}$, then $x_{j}$ can be defined in $U_{i}$ as the linear function such that $x_{j}^{(i)}\left(e_{k}^{(i)}\right)=\delta_{j k}$.

[^22]:    ${ }^{25}$ Another computation for this result can be found in the example at the end of section 4.2.
    ${ }^{26}$ We use $\phi_{i}$ to denote the cohomology class and the representative, the meaning should be clear from the context.
