# NON-COMMUTATIVE RANK AND SEMI-STABILITY OF QUIVER REPRESENTATIONS 

ALANA HUSZAR

#### Abstract

Fortin and Reutenauer defined the non-commutative rank for a matrix with entries that are linear functions. The non-commutative rank is related to stability in invariant theory, non-commutative arithmetic circuits, and Edmonds' problem. We will generalize the non-commutative rank to the representation theory of quivers and define non-commutative Hom and Ext spaces. We will relate these new notions to King's criterion for $\sigma$-stability of quiver representations, and the general Hom and Ext spaces studied by Schofield. We discuss polynomial time algorithms that compute the non-commutative Homs and Exts and find an optimal witness for the $\sigma$-semi-stability of a quiver representation.

## 1. Introduction

Given $A_{1}, A_{2}, \ldots, A_{m}, n \times n$ matrices over a field $\mathbb{F}$, and $x_{1}, x_{2}, \ldots, x_{m}$, variables in the free skew-field defined by Cohn in [Coh95], Fortin and Reutenauer [FR04] defined the noncommutative rank $\operatorname{ncrk}(A(\underline{x}))$ as the rank of the matrix of linear functions $A(\underline{x})=x_{1} A_{1}+$ $x_{2} A_{2}+\cdots+x_{m} A_{m}$ over the free skew field. The non-commutative $\operatorname{rank} \operatorname{ncrk}(A(\underline{x}))$ is also equal to the maximal value of

$$
\frac{\operatorname{rk}\left(X_{1} \otimes A_{1}+X_{2} \otimes A_{2}+\cdots+X_{n} \otimes A_{n}\right)}{d}
$$

where $d$ is a positive integer and $X_{1}, X_{2}, \ldots, X_{n}$ are $d \times d$ matrices. A third characterization of non-commutative rank is in terms of shrunk subspaces. Non-commutative rank is related to the notion of stability in geometric invariant theory. Consider the action of $\mathrm{SL}_{n} \times \mathrm{SL}_{n}$ on the space Mat ${ }_{n, n}^{m}$ of $m$-tuples of $n \times n$ matrices by left-right multiplication. Then $\underline{A}=$ $\left(A_{1}, A_{2}, \ldots, A_{m}\right)$ is semi-stable with respect to this action if and only if $A(\underline{x})$ has full noncommutative rank, i.e., $\operatorname{ncrk}(A(\underline{x}))$ is equal to the maximal value $n$.

The example of $m$-tuples of $n \times n$ matrices fits in the broader framework of representation theory of quivers. A quiver $Q$ is just a directed graph, with vertex set $Q_{0}$ and arrow set $Q_{1}$. If we consider the generalized Kronecker quiver $Q$ with two vertices, say $x$ and $y$, and $m$ arrows from $x$ to $y$ and we choose the dimension vector $\alpha=(n, n)$, then the representation space $\operatorname{Rep}_{\alpha}(Q)$ of $\alpha$-dimensional representations of $Q$ is equal to Mat ${ }_{n, n}^{m}$. To construct a moduli space of $\alpha$-dimensional representations one needs to quotient out the $\mathrm{SL}_{n} \times \mathrm{SL}_{n}$ action. The goal of this paper is to generalize the notion of non-commutative rank and its properties to arbitrary quivers and dimension vectors. Geometric invariant theory for quiver representations was studied by King in [Kin94]. For every quiver $Q$, dimension vector $\alpha \in \mathbb{Z}_{\geq 0}^{Q_{0}}$ and weight $\sigma \in \mathbb{Z}^{Q_{0}}$ King constructed a quotient for $\alpha$-dimensional representations
of $Q$ with respect to the weight $\sigma$. So for every weight $\sigma$ there is a notion of semi-stability for quiver representations and King gave a criterion $\sigma$-semi-stability of a representation of $Q$.

In this paper, we connect non-commutative rank to $\sigma$-semi-stability of quiver representations. Through King's Criterion [Kin94], we discuss the importance of special subrepresentations that are optimal in witnessing the $\sigma$-semi-stability. We provide a framework to use existing algorithms to find these optimal $\sigma$-witnesses, as well as provide an algorithm using a sequence of subrepresentations. We then generalize work of Schofield on pairs of general representations, general ext, and general hom to pairs with one representation fixed, non-commutative ext, and non-commutative hom. We conclude by using non-commutative rank methods to demonstrate useful inequalities for the non-commutative ext.

The Edmonds' problem, posed in 1967, asks to determine the rank of the $n \times n$ matrix $A(\underline{x})$, with homogeneous linear polynomials in $\mathbb{Z}\left[x_{1}, \ldots, x_{m}\right]$ over $\mathbb{Q}\left(x_{1}, \ldots, x_{m}\right)$ [Edm67]. The decision version of this question, asking whether $A(\underline{x})$ has full rank or not, is known as the symbolic determinant identity testing problem (SDIT). We are considering instead the rank of $A(\underline{x})$ over the free skew field, and so the question of finding $\operatorname{ncrk}(A)$ is the noncommutative Edmonds' problem, and the relaxation in simply deciding whether $A(\underline{x})$ has full non-commutative rank is the non-commutative full rank problem (NCFullRank). Letting $\mathcal{A}=\operatorname{span}\left\{A_{1}, A_{2}, \ldots, A_{n}\right\}$, we alternatively denote the non-commutative rank of $A(\underline{x})$ by $\operatorname{ncrk}(\mathcal{A})$. Ivanyos, Qiao, and Subrahmanyam give equivalent formulations and history of NCFullRank in [IQS17]. We are interested in the $c$-shrunk subspace, tensor blow-up, and particularly the nullcone formulations, which are discussed in Section 2.

Lots of work from different angles has been done on this non-commutative rank. Cohn and Reutenauer proved NCFullRank was in PSPACE (can be solved using polynomial space) [CR99]. Fortin and Reutenauer connected non-commutative rank explicitly to $c$-shrunk subspaces [FR04]. Coming from studying non-commutative arithmetic circuits with divisions, Hrubes and Wigderson proved that non-commutative rank was equivalent to rank for large enough tensor blow-ups [HW14]. Garg, Gurvitz, Oliveira, and Wigderson provide a polynomial time algorithm of non-commutative rank for fields of characteristic zero. In [IKQS15], for certain matrix spaces, Karpinski, Ivanyos, Subrahmanyam, and Qiao use Wong sequences to calculate the non-commutative rank. Building on this using blow-ups, the latter three authors provide an algorithm for finding the non-commutative rank of any matrix space [IQS17]. Utilizing results on bounds from [DM18b], in [IQS18], they give a deterministic polynomial time algorithm.

This problem can be expanded to that of finding a subrepresentation of a quiver representation $W$ that demonstrates the representation's semi-stability. This optimal $\sigma$-witness, $W^{\prime}$, can be found using algorithms finding a $c$-shrunk subsapce of a certain matrix space. Work by Chindris and Kline connect this problem to that of simultaneous robust subspace recovery (SRSR) [CK20], and provide an algorithm for certifying the semi-stability of $W$ [CK21].

In [Sch92], Schofield explored the dimension of $\operatorname{Hom}(V, W)$ and $\operatorname{Ext}(V, W)$ for a fixed quiver representation $V$, and generic quivers representation $W$ and $V$. This work was generalized by Crawley-Boevey, who described the asymptotic behavior of these dimensions when one of $W$ or $V$ is fixed (rather than both generic) [CB96]. We re-prove many of these results using insights from non-commutative rank methods, ultimately leading us to a bound on the asymptotic behavior.

## 2. Non-commutative Rank

We will be concerned with the free skew field, made up of non-commuting polynomials, $\mathbb{F}\left\langle x_{1}, \ldots, x_{m}\right\rangle$, their inverses, and then enlarged to contain all sums, products, and inverses. The free skew field was first defined by Amitsur, [Ami66]. In the free skew field, there is no standardized way to express elements, and elements may need to be defined with nested inverses. For example, $\left(x+y z^{-1} w\right)^{-1}$ can not be written without a nested inverse [HW14].

Given a matrix, $A(\underline{x})$, with homogeneous linear polynomials in $\mathbb{F}\left\langle x_{1}, \ldots, x_{m}\right\rangle$, the noncommutative analogue of the Edmonds' problem asks to determine the rank of $A(\underline{x})$ over the free skew field. We denote this rank by $\operatorname{ncrk}(A)$. Similarly, the NCFullRank problem asks whether $A(\underline{x})$ has full rank over the free skew field. For example, we row reduce the following skew symmetric matrix over the free skew field to get:

$$
T=\left[\begin{array}{ccc}
0 & x_{1} & x_{2}  \tag{1}\\
-x_{1} & 0 & x_{3} \\
-x_{2} & -x_{3} & 0
\end{array}\right] \sim\left[\begin{array}{ccc}
0 & x_{1} & x_{2} \\
-x_{1} & 0 & x_{3} \\
0 & 0 & x_{3} x_{1}^{-1} x_{2}-x_{2} x_{1}^{-1} x_{3}
\end{array}\right]
$$

Unfortunately, by the nature of the free skew field, it is hard to determine polynomial identities - so it is not immediately clear if this matrix has non-commutative rank 2 or 3. For this reason, we explore additional equivalent formulations of non-commutative rank. For sketches on their equivalence, see [IQS17].

We note here that many aspects of rank carry over to the non-commutative rank, for instance, the non-commutative row rank and column rank of $A(\underline{x})$ equal the $\operatorname{ncrk}(A)$ and we must have a minor with full rank equal to $\operatorname{ncrk}(A)$. We must still be careful, as other aspects do not: naively finding the "determinant" of $A(\underline{x})$, and comparing it to zero will not tell us whether the non-commutative rank is full (in fact, even how to define a single determinant in this context is unclear) [GR91].
2.1. Blow-ups. If $T=x_{1} A_{1}+\ldots x_{m} A_{m}$, let $\mathcal{A}=\operatorname{Span}\left\{A_{1}, \ldots, A_{m}\right\}$. The $d$ th tensor blow-up of $\mathcal{A}$ is

$$
\mathcal{A}^{\{d\}}:=M(d, \mathbb{F}) \otimes \mathcal{A} \subseteq M(d n, \mathbb{F})
$$

The rank of a matrix space, $\operatorname{rk} \mathcal{A}$, is the maximal $r$ so that there is a matrix with rank $r$ in $\mathcal{A}$. When $\mathbb{F}$ is large enough, $d$ divides the rank of $\mathcal{A}^{\{d\}}$ [IQS17]. We have

$$
\operatorname{ncrk}(A)=\lim _{\substack{d \rightarrow \infty \\ 3}} \frac{\operatorname{rk} \mathcal{A}^{\{d\}}}{d}
$$

We may also write $\operatorname{ncrk}(\mathcal{A})$ instead of $\operatorname{ncrk}(A)$. The value of $\left(\operatorname{rk} \mathcal{A}^{\{d\}}\right) / d$ is increasing as $d$ increases, and is bounded by $n$. Derksen and Makam proved that if $\mathcal{A}$ has maximal noncommutative rank, then taking $d \geq n-1$ ensures $\operatorname{rk} \mathcal{A}^{\{d\}}=n d$ [DM18a]. If ncrk $(A)=r<n$, then restricting to a full rank $r \times r$ submatrix of $A(\underline{x})$, we see that rk $\mathcal{A}^{\{d\}}=n d$ for $d \geq r-1$. So we always have $\operatorname{rk} \mathcal{A}^{\{d\}}=n d$ for $d \geq n-1$.

For our example (1), take $d=2$. We then look for $2 \times 2$ matrices $D_{1}, D_{2}, D_{3}$, so that $A_{1} \otimes D_{1}+A_{2} \otimes D_{2}+A_{3} \otimes D_{3}$ has max rank. Letting

$$
D_{1}=\left[\begin{array}{ll}
1 & 0 \\
0 & 0
\end{array}\right], D_{2}=\left[\begin{array}{ll}
0 & 0 \\
0 & 1
\end{array}\right], D_{3}=\left[\begin{array}{ll}
0 & 1 \\
1 & 0
\end{array}\right]
$$

We find

$$
\mathrm{rk}\left[\begin{array}{c|c|c}
0 & D_{1} & D_{2} \\
\hline-D_{1} & 0 & D_{3} \\
\hline-D_{2} & -D_{3} & 0
\end{array}\right]=6,
$$

which must be maximal, and so $\operatorname{ncrk}(T)=3$.
2.2. $c$-shrunk subspaces. A subspace $U \subseteq \mathbb{F}^{n}$ is a $c$-shrunk subspace of $\mathcal{A}$ if there exists a subspace $W \subseteq \mathbb{F}^{n}$ with $\operatorname{dim}(W) \leq \operatorname{dim}(U)-c$, and for every $A$ in $\mathcal{A}, A(U) \subseteq W$. The NCFullRank problem is equivalent to determining whether $\mathcal{A}$ has no $c$-shrunk subspace for $c>0$ [Coh95]. More generally [FR04],

$$
\operatorname{ncrk}(\mathcal{A})=n-\max \{c \mid \text { there is a } c \text {-shrunk subspace of } \mathcal{A}\} .
$$

Throughout the rest of this paper, we let $c=n-\operatorname{ncrk}(\mathcal{A})$, i.e. all $c$-shrunk subspaces discussed are so that $c$ is maximal.

Lemma 2.1. Let $c=n-\operatorname{ncrk}(\mathcal{A})$. If $U_{1}, U_{2}$ are $c$-shrunk subspaces of $\mathcal{A}$, then so are $U_{1} \cap U_{2}$ and $U_{1}+U_{2}$.

Proof. By assumption $\operatorname{dim} U_{i}-\operatorname{dim} \mathcal{A}\left(U_{i}\right)=c$. Let $U_{3}=U_{1} \cap U_{2}, U_{4}=U_{1}+U_{2}$. We then have:

$$
\begin{aligned}
& c+c \geq\left(\operatorname{dim} U_{3}-\operatorname{dim} \mathcal{A}\left(U_{3}\right)\right)+\left(\operatorname{dim} U_{4}-\operatorname{dim} \mathcal{A}\left(U_{4}\right)\right)= \\
& =\left(\operatorname{dim}\left(U_{1} \cap U_{2}\right)+\operatorname{dim}\left(U_{1}+U_{2}\right)\right)-\left(\operatorname{dim}\left(\mathcal{A}\left(U_{1}\right) \cap \mathcal{A}\left(U_{2}\right)\right)+\operatorname{dim}\left(\mathcal{A}\left(U_{1}\right)+\mathcal{A}\left(U_{2}\right)\right)\right) \geq \\
& \geq\left(\operatorname{dim} U_{1}+\operatorname{dim} U_{2}\right)-\left(\operatorname{dim} \mathcal{A}\left(U_{1}\right)+\operatorname{dim} \mathcal{A}\left(U_{2}\right)\right)= \\
& \quad=\left(\operatorname{dim} U_{1}-\operatorname{dim} \mathcal{A}\left(U_{1}\right)\right)+\left(\operatorname{dim} U_{2}-\operatorname{dim} \mathcal{A}\left(U_{2}\right)\right)=c+c
\end{aligned}
$$

We conclude that $\operatorname{dim} U_{3}-\operatorname{dim} \mathcal{A}\left(U_{3}\right)=\operatorname{dim} U_{4}-\operatorname{dim} \mathcal{A}\left(U_{4}\right)=c$, as $c$ is maximal. Therefore, $U_{3}$ and $U_{4}$ are $c$-shrunk subspaces.

In particular, there is a unique $c$-shrunk subspace of the lowest dimension, namely, the intersection of all $c$-shrunk subspaces. A recent similar discussion can be found in [IMQ21]. In our skew-symmetric example (1), although any matrix in $\mathcal{A}$ has rank 2 , the image of any subspace $U$ of $\mathbb{F}^{3}$ has the same dimension as $U$. In this case $c=n-\operatorname{ncrk}(\mathcal{A})=3-3=0$, and the minimal $c$-shrunk subspace is the zero subspace.
2.3. Semi-stability of Kronecker quiver. A quiver $Q$ is a directed graph, with vertex set denoted $Q_{0}$ and arrow set denoted $Q_{1}$. A representation $W$ of a quiver $Q$, is an assignment of finite dimensional $\mathbb{F}$ vector spaces $W(x)$ to each $x$ in $Q_{0}$, and an assignment of linear maps $W(a)$ to each $a$ in $Q_{1}$. We let $h a$ and $t a$ denote the head and tail vertices of the arrow $a$ respectively. A dimension vector is a function $\alpha: Q_{0} \rightarrow \mathbb{N}=\{0,1,2, \ldots\}$. The dimension vector $\underline{\operatorname{dim}} W$ of a representation $W$ is defined by $(\underline{\operatorname{dim}} W)(x)=\operatorname{dim} W(x)$. Fixing $Q$ and a dimension vector $\alpha$, there is an action on quiver representations by GL $(\alpha):=$ $\prod_{x \in Q_{0}} \mathrm{GL}(\alpha(x))$. The action of $\left(Y(x), x \in Q_{0}\right)$ takes $W(a)$ to $Y(h a) W(a) Y(t a)^{-1}$ for all $a \in Q_{1}$, and leaves each $W(x)$ with $x \in Q_{0}$ unchanged. For a path $p=a_{j} a_{j-1} \cdots a_{1}$, we denote by $W(p)$ the composition of linear maps $W\left(a_{j}\right) W\left(a_{j-1}\right) \cdots W\left(a_{1}\right)$. The empty path from vertex $x$ to itself is denoted by $e_{x}$ and $W\left(e_{x}\right)$ is defined as the identity map of $W(x)$.

The representations of $Q$ with dimension vector $\alpha$ (indexed by the vertices) is denoted $\operatorname{Rep}_{\alpha}(Q)$. A representation is semi-stable if its orbit closure does not contain the zero representation; representations that are not semi-stable define the nullcone. No acyclic quiver representations are semi-simple. Instead, for a weight $\sigma$ in $\mathbb{Z}^{Q_{0}}$, we additionally use the 1dimensional representation $\chi_{\sigma}$, a character with action of $\mathrm{GL}(\alpha)$ given by multiplication by

$$
\chi_{\sigma}\left(Y(x), x \in Q_{0}\right)=\prod_{x \in Q_{0}} \operatorname{det}(Y(x))^{\sigma(x)} .
$$

A representation $W$ is $\sigma$ semi-stable if $(W, 1)$ is semi-stable in $\operatorname{Rep}_{\alpha}(Q) \oplus \chi_{\sigma}$.
The NCFullRank problem for $T=x_{1} A_{1}+\ldots, x_{m} A_{m}$ is equivalent to determining whether the quiver representation $W$,

$$
\mathbb{F}^{n} \xrightarrow[A_{m}]{\stackrel{A_{1}}{\vdots}} \mathbb{F}^{n}
$$

is $\sigma$-semistable, for $\sigma=(1,-1)$. In our skew-symmetric matrix example (1), we would like to determine whether the above quiver with

$$
A_{1}=\left[\begin{array}{ccc}
0 & 1 & 0 \\
-1 & 0 & 0 \\
0 & 0 & 0
\end{array}\right], A_{2}=\left[\begin{array}{ccc}
0 & 0 & 1 \\
0 & 0 & 0 \\
-1 & 0 & 0
\end{array}\right], A_{3}=\left[\begin{array}{ccc}
0 & 0 & 0 \\
0 & 0 & 1 \\
0 & -1 & 0
\end{array}\right]
$$

is $(1,-1)$-semi-stable.
We would like to be able to relate quiver representations to the non-commutative rank, rather than just to NCFullRank. To do this, we need a way of measuring how far a representation $V$, is from being $\sigma$-semistable. For this, we use King's Criterion [Kin94]. For a representation $W$, let $\sigma(\underline{\operatorname{dim}}(W))=\sum \operatorname{dim}(W(x)) \sigma(x)$.

Proposition 2.2 (King's Criterion, [Kin94]). A representation $W$ in $\operatorname{Rep}_{\alpha}(Q)$ is $\sigma$-semistable if and only if $\sigma(\alpha)=0$ and $\sigma(\underline{\operatorname{dim}}(W)) \leq 0$ for all subrepresentations $W^{\prime}$ of $W$.

Proposition 2.3. Given $\mathcal{A}=\operatorname{Span}\left\{A_{1}, \ldots, A_{m}\right\}$, and $c$ the maximum $\sigma\left(\underline{\operatorname{dim}}\left(W^{\prime}\right)\right)$ over all subrepresentations $W^{\prime}$ of the Kronecker quiver with maps $\left\{A_{i}\right\}$, the $\operatorname{ncrk}(\mathcal{A})=n-c$.

Proof. If $W$ is a Kronecker quiver, and $\sigma=(1,-1)$, let $W^{\prime}$ be a subrepresentation with $c:=\sigma\left(\underline{\operatorname{dim}}\left(W^{\prime}\right)\right)$ maximal. Then, since $\mathcal{A}\left(W^{\prime}(x)\right)$ is contained in $W^{\prime}(y), W^{\prime}(x)$ is a $c$-shrunk subspace. On the other hand, if instead we start with a $c$-shrunk subspace $U, W^{\prime}(x):=U$, and $W^{\prime}(y):=\sum_{i=1}^{m} A_{i} U$. This defines a subrepresentation $W^{\prime}$, where $\sigma\left(\underline{\operatorname{dim}}\left(W^{\prime}\right)\right)=c$. So for Kronecker quivers, $c$-shrunk subspaces give us subrepresentations $W^{\prime}$ with $\sigma\left(\underline{\operatorname{dim}}\left(W^{\prime}\right)\right)$ maximal, and vice-versa.

So, the non-commutative rank of $\mathcal{A}$ is equal to the maximum of $\sigma\left(\underline{\operatorname{dim}}\left(W^{\prime}\right)\right)$ over all subrepresentations $W^{\prime}$ of the Kronecker quiver with maps $A_{1}, \ldots, A_{n}$.

## 3. Reduction to Kronecker Quiver

Through Proposition 2.3, if a representation $W$ is not $\sigma$-semi-stable, we can still measure its closeness to $\sigma$-semi-stability by finding a subrepresentation $W^{\prime}$ with $\sigma\left(\underline{\operatorname{dim}}\left(W^{\prime}\right)\right)$ maximal. In [CK21], this is called the discrepancy of $(W, \sigma)$. Note that we are now no longer limited to the Kronecker quiver - we can now ask this question for any acyclic quiver $W$, for any $\sigma$. We call a subrepresentation $W^{\prime}$ which maximizes $c=\sigma\left(\underline{\operatorname{dim}}\left(W^{\prime}\right)\right)$ an optimal $\sigma$-witness. When $\sigma$ is understood, we call this $W^{\prime}$ an optimal witness. We can generalize Lemma 2.1 for subrepresentations.

Proposition 3.1. If $W_{1}, W_{2}$ are optimal $\sigma$-witnesses of $W$, then so are $W_{1} \cap W_{2}$ and $W_{1}+W_{2}$. In particular, there is a minimal and maximal optimal $\sigma$-witness.

Proof. Let $c$ be the discrepancy of $(W, \sigma)$. Let $\sigma_{+}(x)=\max \{0, \sigma(x)\}$, and similarly, $\sigma_{-}(x)=$ $-\min \{0, \sigma(x)\}$. For $i=1,2$, by assumption

$$
\sigma\left(\underline{\operatorname{dim}}\left(W_{i}\right)\right)=\sum_{x \in Q_{0}}\left(\sigma_{+}(x)-\sigma_{-}(x)\right) \operatorname{dim} W_{i}(x)=c .
$$

Let $W_{3}=W_{1} \cap W_{2}, W_{4}=W_{1}+W_{2}$. We then have:

$$
\begin{aligned}
& c+c \geq \sum\left(\sigma_{+}(x)-\sigma_{-}(x)\right) \operatorname{dim} W_{3}(x)+\left(\sigma_{+}(x)-\sigma_{-}(x)\right) \operatorname{dim} W_{4}(x)= \\
& =\sum \sigma_{+}(x) \operatorname{dim} W_{3}(x)-\sigma_{-}(x) \operatorname{dim} W_{3}(x)+\sigma_{+}(x) \operatorname{dim} W_{4}(x)-\sigma_{-}(x) \operatorname{dim} W_{4}(x)= \\
& \quad=\sigma_{+}(x)\left(\operatorname{dim} W_{1}(x)+\operatorname{dim} W_{2}(x)\right)-\sigma_{-}(x)\left(\operatorname{dim} W_{1}(x)+\operatorname{dim} W_{2}(x)\right)=c+c .
\end{aligned}
$$

We conclude that $\sigma\left(\underline{\operatorname{dim}}\left(W_{3}\right)\right)=\sigma\left(\underline{\operatorname{dim}}\left(W_{4}\right)\right)=c$, as $c$ is maximal. Therefore, $W_{3}$ and $W_{4}$ are optimal $\sigma$-witnesses. We can find a minimal optimal $\sigma$-witness by taking the intersection of all optimal $\sigma$-witnesses, and similarly find a maximal optimal $\sigma$-witness by taking the sum of all optimal $\sigma$-witnesses.

We would like to extend the techniques in [IQS17] in order to find an optimal $\sigma$-witness. To do this, we reduce any acyclic quiver to the Kronecker quiver. We use the construction described in [DM18a], but provide an altered set up, using presentations as in [DF15]. Let $P_{x}$ be the indecomposable representation of $Q$ with basis given by all paths starting at vertex $x$.

Let $P_{x}$ be the indecomposable projective representation corresponding to vertex $x$. So, $P_{x}(y)=e_{y} \mathbb{F} Q e_{x}$, with basis given by paths from $x$ to $y$. Let $\mathbf{P}_{1}:=\bigoplus_{x \in Q_{0}} P_{x}^{\sigma_{-}(x)}$, and $\mathbf{P}_{\mathbf{0}}:=\bigoplus_{x \in Q_{0}} P_{x}{ }^{\sigma_{+}(x)}$. Consider all possible morphisms $\varphi$ between the quiver representations

$$
\varphi: \mathbf{P}_{\mathbf{1}} \rightarrow \mathbf{P}_{\mathbf{0}}
$$

To our above set of morphisms, apply $\operatorname{Hom}(\cdot, W)$ to get

$$
A(\varphi): \operatorname{Hom}\left(\mathbf{P}_{\mathbf{0}}, W\right) \rightarrow \operatorname{Hom}\left(\mathbf{P}_{\mathbf{1}}, W\right)
$$

where $A(\varphi):=\operatorname{Hom}(\varphi, W)$. We can consider a subspace $\operatorname{Hom}\left(P_{x}{ }^{\sigma_{+}(x)}, W^{\prime}\right)$ as $Z_{+}(x) \otimes W^{\prime}(x)$ for some $Z_{+}(x)=\mathbb{F}^{\sigma_{+}(x)}$. Notice $\operatorname{Hom}\left(\mathbf{P}_{\mathbf{0}}, W\right)$ is a right $\operatorname{End}\left(\mathbf{P}_{\mathbf{0}}\right)$-module by precomposition. Let $x, y$ be so that both $\sigma_{+}(x)$ and $\sigma_{+}(y)$ are positive. Note $\operatorname{End}\left(\mathbf{P}_{\mathbf{0}}\right)$ contains $H=\prod_{x \in Q_{0}} \mathrm{GL}\left(\sigma_{+}(x)\right)$, a reductive group, which acts on the $Z_{+}(x)$, leaving the $W(x)$ alone. So, an $H$-subrepresentation of $\bigoplus_{x \in Q_{0}} Z_{+}(x) \otimes W(x)$ must be of the form $\bigoplus_{x \in Q_{0}} Z_{+}(x) \otimes W^{\prime}(x)$ for some subspaces $W^{\prime}(x)$ of each $W(x)$. Our set of maps can also be considered between the spaces

$$
A(\varphi): \bigoplus_{x \in Q_{0}} W(x)^{\sigma_{+}(x)} \rightarrow \bigoplus_{x \in Q_{0}} W(x)^{\sigma_{-}(x)}
$$

Now, we have a matrix space $\mathcal{A}$ consisting of all $A(\varphi)$. This is the space of block matrices with blocks mapping $W(x)$ to $W(y)$ given by a linear combination of $W(p)$, where $p$ is a path from $x$ to $y$. For this new Kronecker Quiver, we may run the algorithm in [IQS17] to get the minimal $c$-shrunk subspace of $\bigoplus_{x \in Q_{0}} W(x)^{\sigma_{+}(x)}, U$.

Lemma 3.2. The minimal c-shrunk subspace, $U \subseteq \operatorname{Hom}\left(\mathbf{P}_{\mathbf{0}}, W\right)$, is a left $\operatorname{End}\left(\mathbf{P}_{\mathbf{0}}\right)$ module, and $\sum_{\varphi} A(\varphi) U$ is a left $\operatorname{End}\left(\mathbf{P}_{\mathbf{1}}\right)$ module.

Proof. First, we prove that given any $c$-shrunk subspace, $U$, and invertible $T$ in $\operatorname{End}\left(\mathbf{P}_{\mathbf{0}}\right)$, $T \cdot U$ is also $c$-shrunk. We have the image of $T \cdot U$ :

$$
\sum_{\varphi} A(\varphi)(T \cdot U)=\sum_{\varphi} A(\varphi \cdot T) U=\sum_{\varphi} A(\varphi) U
$$

Here the sum is taken over all morphisms $\varphi$ as above. It follows that

$$
\operatorname{dim} \sum_{\varphi} A(\varphi)(T \cdot U)=\operatorname{dim} \sum_{\varphi} A(\varphi) U
$$

As $T$ is an automorphism, we also have $\operatorname{dim} T \cdot U=\operatorname{dim} U$, so $T \cdot U$ is $c$-shrunk. If $U$ is the minimal $c$-shrunk subspace, $T \cdot U$ is also $c$-shrunk and of the same dimension, so $T \cdot U=U$. As $\operatorname{End}\left(\mathbf{P}_{\mathbf{0}}\right)$ is spanned by invertible elements, this shows that the minimal $c$-shrunk subspace $U$ is a left $\operatorname{End}\left(\mathbf{P}_{\mathbf{0}}\right)$ module. Similarly, given $S$ in $\operatorname{End}\left(\mathbf{P}_{\mathbf{1}}\right)$, we see that

$$
S \cdot \sum_{\varphi} A(\varphi)(U)=\sum_{\varphi} A(S \cdot \varphi) U=\sum_{\varphi} A(\varphi) U
$$

Theorem 3.3. Given the minimal c-shrunk subspace for the set of linear maps

$$
A(\varphi): \bigoplus_{x \in Q_{0}} W(x)^{\sigma_{+}(x)} \rightarrow \bigoplus_{x \in Q_{0}} W(x)^{\sigma_{-}(x)}
$$

we can construct a subrepresentation of $W, W^{\prime}$, so that $\sigma\left(\underline{\operatorname{dim}}\left(W^{\prime}\right)\right)$ is maximal. Furthermore, $\sigma\left(\underline{\operatorname{dim}}\left(W^{\prime}\right)\right)=c$.

Proof. Considered as a subspace of $\bigoplus Z(x) \otimes W(x)$, the minimal $c$-shrunk $U$ is of the form $\bigoplus Z(x) \otimes W^{\prime}(x)$, for some subspaces $W^{\prime}(x)$ of $W(x)$. For $y$ so that $\sigma_{+}(y)=0$, define $W^{\prime}(y)=\sum_{a: x \rightarrow y} W(a) W^{\prime}(x)$. This ensures we have a subrepresentation. Note that $c \leq \sum \operatorname{dim}\left(W^{\prime}(x)^{\sigma_{+}(x)}\right)-\sum \operatorname{dim}\left(W^{\prime}(x)^{\sigma_{-}(x)}\right)$, but $c$ is maximal, so $\sigma\left(\underline{\operatorname{dim}}\left(W^{\prime}\right)\right)=c$. We note that the $W^{\prime}(y)$ are similarly closed under the action of $\operatorname{End}\left(\mathbf{P}_{\mathbf{1}}\right)$.

If there were a subrepresentation $W^{\prime \prime}$ with $\sigma\left(\underline{\operatorname{dim}}\left(W^{\prime \prime}\right)\right)$ less than $c$, Note that $U^{\prime}=$ $\bigoplus W^{\prime \prime}(x)^{\sigma_{+}(x)}$ is a shrunk subspace, with $\operatorname{dim}\left(U^{\prime}\right)-\operatorname{dim}\left(\mathcal{A}\left(U^{\prime}\right)\right)>c$, so $c$ would not be $x \in Q_{0}$.
maximal.
3.1. Algorithms. After using this reduction of a quiver representation to a Kronecker quiver, we can employ any previous algorithms or other techniques for finding a $c$-shrunk subspace. If we successfully find a $c$-shrunk subspace, $U$, that is not minimal, we can construct a $c$-shrunk subspace that is fixed under the action of $\operatorname{End}\left(P_{1}\right)$ by taking instead

Such a subspace will give a optimal $\sigma$ witness. We may use a basis of $\operatorname{End}\left(\mathbf{P}_{\mathbf{1}}\right)$ to get this subspace in polynomial time.

In [IKQS15], Wong sequences, originally defined by Kai-Tek Wong [Won74], are used in certain cases to find a $c$-shrunk subspace. In [IQS17], blow-ups are used to extend the original algorithm to find a $c$-shrunk subspace for any collection of matrices. The algorithm takes a matrix $A$ in $\mathcal{A}$, constructing a sequence starting with $W_{0}=0$, and letting $W_{i+1}=\mathcal{A} A^{-1}\left(W_{i}\right)$. This sequence stabilizes to some subspace, $W^{*}$. In the case that $W^{*}$ is contained in $\operatorname{Im} A, A^{-1}\left(W^{*}\right)$ is a $c$-shrunk subspace with $c$ maximal and equal to $n-\operatorname{rk} A$. In this case, where the algorithm returns a $c$-shrunk subspace, we claim the subspace is minimal.

The minimal shrunk subspace, $U$, is the intersection of all $c$-shrunk subspaces, so $U \subseteq$ $A^{-1}\left(W^{*}\right)$. The limit of the sequence $W^{*}$ is the smallest subspace $Z$ so that $\bigcup_{i=1}^{m} A_{i}^{-1}(Z)$ contains $A^{-1}(Z)$. So by minimality, $U$ is returned when this sequence terminates with $W^{*}$ contained in $\operatorname{Im}(A)$. In the case where blow-ups are invoked to find a $c$-shrunk subspace, the same sequence is used in the larger space, finding a $c d$-shrunk subspace. This by the same reasoning must be minimal, so when pulled back to a $c$-shrunk subspace in the original space, it must remain minimal.

Let $n=\min \left\{\sum \sigma_{+}(x) \operatorname{dim} W(x), \sum \sigma_{-}(y) \operatorname{dim} W(y)\right\}$. For sufficiently large fields, $(|\mathbb{F}|>$ $2 n)$ there is a randomized algorithm to find a $c$-shrunk subspace [IQS17, Corollary 1.5]. This randomized algorithm is much simpler and typically must faster than the deterministic algorithm. In the context of representations, this algorithm immediately after reduction, blow up by a sufficiently large [IQS18, DM18a] factor, $d \geq n-1$. In this blow-up, randomly choose a matrix

$$
A: \bigoplus_{x \in Q_{0}} W(x)^{d \sigma_{+}(x)} \rightarrow \bigoplus_{x \in Q_{0}} W(y)^{d \sigma_{-}(y)}
$$

where $A$ is in $\mathcal{A}^{\{d\}}:=M(d, \mathbb{F}) \otimes \mathcal{A}$. Through the Schwarz-Zippel-DeMillo-Lipton lemma [Sch80, Zip79, DL78], if a field is large enough, evaluating a non-zero polynomial over that field at a randomly chosen point is likely to give a non-zero result. Taking the determinant of minors of a matrix in the blow-up, we are likely to have rk $A=\operatorname{ncrk} \mathcal{A}^{\{d\}}$. Thus, running the Wong sequence on this $A$ will result in the return of a $c d$-shrunk subspace [IKQS15, Lemma 9]. From this $c d$-shrunk subspace in the blow-up, we can find a $c$-shrunk subspace of $\bigoplus_{x \in Q_{0}} W(x)^{\sigma_{+}(x)}$, constructing a subrepresentation as above.

The deterministic Wong sequence algorithm for finding non-commutative rank, introduced in [IKQS15], uses a sequence of subspaces, testing its limit, $W^{*}$ for evidence of a $c$-shrunk subspace. In the quiver representation context, we would like to instead use a sequence of subrepresentations. In this deterministic setting, we only need $|\mathbb{F}|>n$.

To do this, we again start with a random matrix $A$ in the blow-up, as above. Next, find a pseudo-inverse of $A$, a matrix $B$ so that $B$ 's restriction to $\operatorname{Im}(A)$ is the inverse to $A$ 's restriction to a direct complement of $\operatorname{ker}(A)$. Note that $B$ is a block matrix as well, with blocks mapping each $W(y)$ for $\sigma(y)<0$ to each $W(x)$ with $\sigma(x)>0$. Let $I_{x}$ index the $|d \sigma(x)|$ copies of $W(x)$. Let $\pi_{x, i}: \bigoplus_{x \in Q_{0}} W(x)^{d \sigma_{+}(x)} \rightarrow W(x)$ be the projection to the $i$ th copy of $W(x)$. Each projection can be thought of as coming from the action of $\operatorname{End}\left(\mathbf{P}_{\mathbf{0}}\right)$. Similarly, define this for vertices $y$ with $\sigma_{-}(y)>0$.

For each block, take the projection $\pi_{y, i} B \pi_{x, j}$. This gives a linear map from $W(x)$ to $W(y)$. Construct a new quiver representation, $W^{+}$, on a new quiver $Q^{+}$by adding arrows $p: y \rightarrow x$ for each block in the pseudo-inverse, with each $W^{+}(p)$ defined as $\pi_{y, i} B \pi_{x, j}$.

Define a subspace at vertices $x$ with $\sigma(x)>0$ of $W^{+}$:

$$
K(x):=\sum_{i \in I_{x}} \pi_{x, i} \operatorname{ker}(A)
$$

For all other vertices, define $K(y)=0$. Let $W^{\prime}$ be the smallest subrepresentation of $W^{+}$ containing each $K(x)$. Note that $W^{\prime}$ must also be a subrepresentation of our original $W$.

Proposition 3.4. For $W^{\prime}$ as defined above, $\bigoplus_{x \in Q_{0}} W^{\prime}(x)^{d \sigma_{+}(x)}$ is cd-shrunk, with image (under $\left.\mathcal{A}^{[d]}\right) \bigoplus_{x \in Q_{0}} W^{\prime}(x)^{d \sigma_{-}(x)}$. Thus, $W^{\prime}$ is an optimal $\sigma$ witness.

First, we claim that $\bigoplus_{x \in Q_{0}} W^{\prime}(x)^{d \sigma_{+}(x)}$ is the minimal $c d$-shrunk subspace of $\mathcal{A}^{\{d\}}$. By construction, the Wong sequence algorithm returns the smallest subspace containing $\operatorname{ker}(A)$, and closed under $\mathcal{A}^{\{d\}}$ and our pseudo-inverse $B$. The $K(x)$ must remain inside the minimal shrunk subspace, as the projections come from $\operatorname{End}\left(\mathbf{P}_{\mathbf{0}}\right)$. Similarly, the new maps in $W^{+}$
come from the action of $\operatorname{End}\left(\mathbf{P}_{\mathbf{0}}\right) \bigoplus \operatorname{End}\left(\mathbf{P}_{\mathbf{1}}\right)$, so in finding the smallest subrepresentation, we must still remain in the minimal shrunk subspace (at positive vertices). So in finding the minimal representation of $W^{+}$that contains each $K(x), W^{\prime}$, we get the smallest subspace $\bigoplus_{x \in Q_{0}} W^{\prime}(x)^{d \sigma_{+}(x)}$ containing $\operatorname{ker}(A)$ and closed under $\mathcal{A}^{\{d\}}$ and $B$, i.e. the minimal $c d-$ shrunk subspace.

Proposition 3.5. Given a quiver representation $W$, a weight vector $\sigma$, $|\mathbb{F}|>n$, letting $n_{x}:=\operatorname{dim}(W(x))$, and $N=\sum_{x \in Q_{0}} n_{x}$, there is an algorithm polynomial time in the $n_{x}$ to find an optimal $\sigma$ witness.

Recalling the above discussion, we first construct $Q^{+}$and $W^{+}$. To do this, we chose a random matrix in the $d=N-1$ blowup, $A$, and find its pseudo-inverse, $B$, which takes polynomial time $\left(\leq(d N)^{3}\right)$. We then construct new linear maps for each of the $d^{2} \sigma_{+} \sigma_{-}$blocks in $B$ by composing $B$ with projection maps. This composition is matrix multiplication, which can be done in polynomial time. Next we contruct $K(x)$ at each vertex $x$, which is the sum over the $d \sigma(x)$ projections of $\operatorname{ker}(A)$. We can find a basis for $\operatorname{ker}(A)$ itself in polynomial time using row reduction. Last, we use Algorithm 3.6 to loop through all our arrows $N$ times, to find the optimal $\sigma$ witness, $W^{\prime}$ from the $K(x)$. This algorithm will stabilize at the $N$ th loop or shorter, as each iteration of the outside loop will either raise the dimension of the current $W^{\prime}$, or will not (in which case, we are done, we have found the final $W^{\prime}$ ). We can increase the dimension at most $N$ times, so this must be a correct bound for the number of times to run the outer loop.

## Algorithm 3.6. Algorithm for finding $W^{\prime}$.

Input: Quiver $Q$, Representation $W$ of $Q$, subspaces $K(x) \subseteq W(x)$ for all vertices $x$.
Output: Smallest subrepresentation $W^{\prime}$ so that $K(x) \subseteq W^{\prime}(x)$ for all vertices $x$.

```
\(W^{\prime}(x)=K(x)\) for all \(x\);
for \(i=1\) to \(N\) do
        for \(a \in Q_{1}\) do
            \(W^{\prime}(h a)=W^{\prime}(h a)+W(a) W^{\prime}(t a) ;\)
        end for
end for
```

## 4. Non-commutative General Ext and Hom

In [Sch92], Schofield studied the minimal dimension of $\operatorname{Ext}(V, W)$ for representations $V$ and $W$ of dimension vectors $\alpha$ and $\beta$. Define

$$
Z^{t}(\alpha, \beta):=\left\{(V, W) \in \operatorname{Rep}_{\alpha}(Q) \times \operatorname{Rep}_{\beta}(Q) \mid \operatorname{dim} \operatorname{Hom}_{Q}(V, W) \geq t\right\}
$$

Each of these subsets of $\operatorname{Rep}_{\alpha}(Q) \times \operatorname{Rep}_{\beta}(Q)$ are closed. Take $t$ the minimal positive value of $\operatorname{dim} \operatorname{Hom}_{Q}(V, W)$. Then, $Z^{t+1}(\alpha, \beta)$ is a proper closed subset. We call the pair $(V, W)(\alpha, \beta)-$ general if they are in the (open and dense) complement of $Z^{t+1}(\alpha, \beta)$. On this complement, $\operatorname{dim} \operatorname{Hom}_{Q}(V, W)$ is constant, as is $\operatorname{dim}_{\operatorname{Ext}_{Q}}(V, W)$. Schofield calls these generic hom and
ext respectively:

$$
\begin{aligned}
\operatorname{hom}(\alpha, \beta) & =\operatorname{dim}\left(\operatorname{Hom}_{Q}(V, W)\right), \text { and } \\
\operatorname{ext}(\alpha, \beta) & =\operatorname{dim}\left(\operatorname{Ext}_{Q}(V, W)\right)
\end{aligned}
$$

Crawley-Boevey generalized the generic hom in [CB96], which we show along with the generalization of generic ext. To do this, fix a representation $W$ of $Q$, with dimension vector $\beta$. Define now

$$
Z^{t}(\alpha, W):=\left\{V \in \operatorname{Rep}_{\alpha}(Q) \mid \operatorname{dim} \operatorname{Hom}_{Q}(V, W) \geq t\right\}
$$

Again, each of these subsets are closed, and we take $t$ minimal so that $\operatorname{dim} \operatorname{Hom}_{Q}(V, W)$ is positive. We call $V(\alpha, W)$-general if it is in the complement of $Z^{t+1}(\alpha, W)$.

Definition 4.1. Let $V$ be an $(\alpha, W)$-general representation. We define the ( $\alpha, W$ )-general hom and ext as

$$
\begin{aligned}
\operatorname{hom}(\alpha, W) & =\operatorname{dim}\left(\operatorname{Hom}_{Q}(V, W)\right), \text { and } \\
\operatorname{ext}(\alpha, W) & =\operatorname{dim}\left(\operatorname{Ext}_{Q}(V, W)\right)
\end{aligned}
$$

Lemma 4.2. We have

$$
\operatorname{ext}(\alpha, W) \geq \max \left\{-\left\langle\alpha, \underline{\operatorname{dim}} W^{\prime}\right\rangle \mid W^{\prime} \text { factor representation of } W\right\} .
$$

Proof. If $V$ is a general representation of dimension $\alpha$, then applying $\operatorname{Hom}_{Q}(V, \cdot)$ to

$$
0 \rightarrow W^{\prime \prime} \rightarrow W \rightarrow W^{\prime} \rightarrow 0
$$

gives an exact sequence

$$
\cdots \rightarrow \operatorname{Ext}_{Q}(V, W) \rightarrow \operatorname{Ext}_{Q}\left(V, W^{\prime}\right) \rightarrow 0
$$

so $\operatorname{dim} \operatorname{Ext}_{Q}\left(V, W^{\prime}\right) \leq \operatorname{dim} \operatorname{Ext}_{Q}(V, W)$ and $\operatorname{ext}\left(\alpha, W^{\prime}\right) \leq \operatorname{ext}(\alpha, W)$. We get

$$
-\left\langle\alpha, \underline{\operatorname{dim}} W^{\prime}\right\rangle=\operatorname{ext}\left(\alpha, W^{\prime}\right)-\operatorname{hom}\left(\alpha, W^{\prime}\right) \leq \operatorname{ext}\left(\alpha, W^{\prime}\right) \leq \operatorname{ext}(\alpha, W)
$$

Definition 4.3. The non-commutative ext and hom are defined by the following limits of ext and hom:

$$
\begin{aligned}
\operatorname{ncext}(\alpha, W) & =\lim _{d \rightarrow \infty} \frac{\operatorname{ext}(d \alpha, W)}{d} \\
\operatorname{nchom}(\alpha, W) & =\lim _{d \rightarrow \infty} \frac{\operatorname{hom}(d \alpha, W)}{d}
\end{aligned}
$$

Note that for every representation $W$ of dimension $\beta$, we have $\operatorname{nchom}(\alpha, W)-\operatorname{ncext}(\alpha, W)$ equal to $\langle\alpha, \beta\rangle$. These limits were originally studied in [CB96], though we give them a name to highlight their connection to non-commutative rank, as seen in the next discussion and proposition.

We have a map

$$
f_{W}^{\alpha}: \operatorname{Rep}_{\alpha} \longrightarrow \operatorname{Hom}\left(\bigoplus_{x \in Q_{0}} \operatorname{Hom}\left(\mathbb{F}^{\alpha(x)}, W(x)\right) \rightarrow \bigoplus_{a \in Q_{1}} \operatorname{Hom}\left(\mathbb{F}^{\alpha(t a)}, W(h a)\right)\right)
$$

given by sending a representation $V$ to the map $f_{W}^{\alpha}(V)$, which takes the set of $\varphi(x)$ from $\operatorname{Hom}\left(\mathbb{F}^{\alpha(x)}, W(x)\right)$ over all vertices $x$ to the set of maps $\varphi(h a) V(a)-W(a) \varphi(t a)$ over all arrows $a$. Note that the kernel of each $f_{W}^{\alpha}(V)$ is $\operatorname{Hom}_{Q}(V, W)$, and and the cokernel is $\operatorname{Ext}_{Q}(V, W)$. From this point forward, we will refer to the image of $f_{W}^{\alpha}$ (the set of $f_{W}^{\alpha}(V)$ over all $V$ ), as simply $f_{W}^{\alpha}$ itself.

Next, we note that we can consider $\operatorname{Rep}_{d \alpha}$ as the blow-up of $\operatorname{Rep}_{\alpha}$ as follows. Each $Z$ in $\operatorname{Rep}_{d \alpha}$ is so that $Z(x) \cong \mathbb{F}^{\alpha(x)} \otimes U(x)$ for $U(x) \cong \mathbb{F}^{d}$. At the arrows, we have $Z(a) \cong$ $\sum V_{i}(a) \otimes U_{i}(a)$, a finite sum where each $U_{i}(a)$ is a $d \times d$ matrix over $\mathbb{F}$, and each $V_{i}$ is from $\operatorname{Rep}_{\alpha}$. Now, given a $\bar{V}$ in $\operatorname{Rep}_{d \alpha}$, we get a map:

$$
\operatorname{Hom}\left(\bigoplus_{x \in Q_{0}} \operatorname{Hom}\left(\mathbb{F}^{d \alpha(x)}, W(x)\right) \xrightarrow{f_{W}^{d \alpha}(\bar{V})} \bigoplus_{a \in Q_{1}} \operatorname{Hom}\left(\mathbb{F}^{d \alpha(t a)}, W(h a)\right)\right) .
$$

Notice that we can find $\operatorname{ncrk}\left(f_{W}^{\alpha}\right)$ using $\operatorname{ncrk}\left(f_{W}^{d \alpha}\right)$ and dividing by $d$ since $f_{W}^{d \alpha}$ is the $d$ th blow-up of $f_{W}^{\alpha}$.

Proposition 4.4. The rank and non-commutative rank of $f_{W}^{d \alpha}$ are equal if and only if $\operatorname{nchom}(\alpha, W)=\frac{\operatorname{hom}(d \alpha, W)}{d}$.

For a $(d \alpha, W)$-general $\bar{V}$ in $\operatorname{Rep}_{d \alpha}$, the kernel of $f_{W}^{d \alpha}(\bar{V})$ is of minimal dimension. So, $\operatorname{rk}\left(f_{W}^{d \alpha}\right)=\sum d \alpha(x) \beta(x)-\operatorname{hom}(d \alpha, W)$. We get

$$
\frac{\operatorname{rk} f_{W}^{d \alpha}}{d}=\sum \alpha(x) \beta(x)-\frac{\operatorname{hom}(d \alpha, W)}{d}
$$

showing that $d$ which maximizes the left-side (giving us the non-commutative rank), maximizes the right side (minimizing $\frac{\operatorname{hom}(d \alpha, W)}{d}$, giving us the non-commutative hom).

Corollary 4.5. Given dimension vector $\alpha$, and a representation $W$ of dimension $\beta$, the $d$ in the limit of definition 4.3 can be chosen to be

$$
\min \left\{\sum_{x \in Q_{0}} \alpha(x) \beta(x)-1, \sum_{a \in Q_{1}} \alpha(t a) \beta(h a)-1\right\}
$$

Recall the bound for non-commutative rank blow-ups from [DM18a] is $n-1$, where $n$ is the dimension of both the domain and co-domain. We may not have a space of square matrices, so a large enough $d$ will be found when we first reach either $\sum_{x \in Q_{0}} \alpha(x) \beta(x)-1$ or $\sum_{a \in Q_{1}} \alpha(t a) \beta(h a)-1$.

Theorem 4.6. We have

$$
\operatorname{ncext}(\alpha, W)=\max \left\{-\left\langle\alpha, \underline{\operatorname{dim}} W^{\prime \prime}\right\rangle \mid W^{\prime \prime} \text { factor representation of } W\right\}
$$

Proof. Choose $d$ so that $\operatorname{ncext}(d \alpha, W)$ equals $\frac{\operatorname{ext}(d \alpha, W)}{d}$. Look at the set of maps:

$$
\operatorname{Hom}\left(\bigoplus_{x \in Q_{0}} \operatorname{Hom}\left(\mathbb{F}^{\alpha(x)}, W(x)\right) \xrightarrow{f_{W}^{d \alpha}(\bar{V})} \bigoplus_{a \in Q_{1}} \operatorname{Hom}\left(\mathbb{F}^{\alpha(t a)}, W(h a)\right)\right),
$$

for all representations $\bar{V}$ in $\operatorname{Rep}_{d \alpha}$. By Proposition 4.4, this set of maps has non-commutative rank equal to its rank. So we can find the minimal $c$-shrunk subspace, which:
(1) has the form $\bigoplus_{x \in Q_{0}} \operatorname{Hom}\left(\mathbb{F}^{d \alpha(x)}, W^{\prime}(x)\right.$ ), for some subrepresentation $W^{\prime}$ of $W$ (from discussion in section 3), and
(2) has image of the form $\bigoplus_{a \in Q_{1}} \operatorname{Hom}\left(\mathbb{F}^{d \alpha(t a)}, W^{\prime}(h a)\right)$.

So we get $c=d \sum \alpha(x) \operatorname{dim}\left(W^{\prime}(x)\right)-d \sum \alpha(t a) \operatorname{dim}\left(W^{\prime}(h a)\right)=\left\langle d \alpha, \underline{\operatorname{dim}}\left(W^{\prime}\right)\right\rangle$, but $c$ is the non-commutative rank, so also can be found by $\sum d \alpha(x) \beta(x)-\operatorname{rk}\left(f_{W}^{d \alpha}\right)=\operatorname{hom}(d \alpha, W)$. This leaves us with $\frac{\operatorname{hom}(d \alpha, W)}{d}=\left\langle\alpha, \underline{\operatorname{dim}}\left(W^{\prime}\right)\right\rangle$ after dividing by $d$. As for non-commutative ext, we then get $\operatorname{ncext}(\alpha, W)=\operatorname{nchom}(\alpha, W)-\langle\alpha, \beta\rangle$, finally leaving us with ncext $(\alpha, W)=$ $-\left\langle\alpha, \underline{\operatorname{dim}} W^{\prime \prime}\right\rangle$, for $W^{\prime \prime}=W / W^{\prime}$.

We note that we can dually fix a representation $V$, and look at $\operatorname{hom}(V, \beta)$ and $\operatorname{ext}(V, \beta)$ to define $\operatorname{nchom}(V, \beta)$ and $\operatorname{ncext}(V, \beta)$.

Definition 4.7. The non-commutative ext and hom are defined by the following limits of ext and hom:

$$
\begin{aligned}
\operatorname{ncext}(V, \beta) & =\lim _{d \rightarrow \infty} \frac{\operatorname{ext}(V, d \beta)}{d} \\
\operatorname{nchom}(V, \beta) & =\lim _{d \rightarrow \infty} \frac{\operatorname{hom}(V, d \beta)}{d}
\end{aligned}
$$

Theorem 4.8. We have

$$
\operatorname{ncext}(V, \beta)=\max \left\{-\left\langle\underline{\operatorname{dim}} V^{\prime}, \beta\right\rangle \mid V^{\prime} \text { subrepresentation of } V\right\}
$$

Proof. The proof follows from duality of theorem 4.6. We note that this can also be seen by using Corollary 1 from [CB96], by subtracting $\langle\underline{\operatorname{dim} V, ~} \beta\rangle$.

Corollary 4.9. For large enough $|\mathbb{F}|$, there are both deterministic and randomized algorithms for calculating $\operatorname{ncext}(\alpha, W)$, $\operatorname{nchom}(\alpha, W), \operatorname{ncext}(V, \beta)$, and $\operatorname{nchom}(V, \beta)$.

Proof. We can apply any of the algorithms used to find $c$-shrunk subspaces to the set of maps $f_{W}^{\alpha}(V)$ or $f_{\beta}^{V}(W)$ respectively, and use the dimension of $c$ to calculate the non-commutative ext and hom.
